Adapter address	Selecting this option button forces the link service to use the default IP address associated with the network adapter specified in the adjacent list. (The alternative is to associate with a static IP address.) The list displays all available network adapters currently configured. Physical adapters are listed first, followed by virtual adapters (that is, WAN Mini-ports).
Static IP address	Selecting this option button forces the link service to use the IP address specified in the adjacent list. The list displays all static IP addresses defined to the local computer. Enter the IP address, host name, or fully qualified name for the IP-DLC link service.
Local APPN node	This set of parameters configures the network identification of the APPN branch network node implemented by the IP-DLC link service. Note: No other IP-DLC link service within the APPN network can use both the same network name and control point name as this one. Individual names may be reused, but the pair may not.
Network name	Enter the APPN network name for the IP-DLC link service operating as a local APPN node across which the IP-DLC link service will communicate. This value must be text with a maximum of eight characters and comply with the APPN naming convention. There is no default value.
Control point name	Enter the APPN control point name for the IP-DLC link service operating as a local APPN node. This value must be text with a maximum of eight characters and comply with the APPN naming convention. There is no default value. The control point name must be unique for this computer on the APPN network.

Use Dynamic PU Definition	Selecting this option allows the IP-DLC link service to attempt to use the dynamically defined PU definitions on the host.
Node ID	In the first box, enter any valid 3-digit hexadecimal number except the reserved numbers of 000 and FFF. In the second box, enter any valid hexadecimal number except the reserved number 00000. There is no default value.
Associated LEN node	Select an SNA service operating as an APPN LEN node to associate with this IP-DLC link service. Default value is the first SNA service on the local computer.

Downstream Pool

Enter a **Name** and **Comment** for the pool.

LUA pool

Enter a **Name** and **Comment** for the pool.

Messaging Help

Microsoft MSMQ-MQSeries Bridge is an adaptable system that can be customized. You can set up MSMQ-MQSeries Bridge to operate on almost any Message Queuing (also known as MSMQ) or IBM MQSeries network configuration.

For additional information on the MSMQ-MQSeries Bridge user interface, see the following sections:

In This Section

General Tab

This tab displays the following information:

Path Name	**Network name of the MSMQ-MQSeries Bridge computer.**
Service	Name of the Microsoft MSMQ-MQSeries Bridge Service.
Version	Version of the Microsoft MSMQ-MQSeries Bridge Service.
Status	Status of the Microsoft MSMQ-MQSeries Bridge Service (running, paused, or stopped).

Advanced Tab

By default, MSMQ-MQSeries Bridge allocates one thread for each type of message pipe.

If the MSMQ-MQSeries Bridge is connected to more than one MQSeries Queue Manager (QM), you should allocate a larger number of threads. This improves performance, and if a pipe to one QM fails, it lets the other pipes continue running.

For each type of message pipe, specify the following:

Parameter	**Description**
Max Threads	The maximum number of threads (recommended one per MQSeries QM).
Refresh Queue Cache	The interval (in minutes) at which the message pipes check for Cache Timeout (see Setting Message pipe properties).
Support MSMQ to Bridge Encryption	Check this option to enable the Encryption feature from MSMQ to MSMQ-MQSeries Bridge.
Replace '.' with '-' in Queue Manager	Enables the MQSeries QM to address an Message Queuing computer that has a '-' in its name. This is necessary because MQSeries does not support the '-' character. When this box is checked, MSMQ-MQSeries Bridge replaces '.' from the remote QM name on MQSeries with '-'. You should only enable this option if there is a '-' in the Message Queuing computer name.

MQI Channels Tab

MSMQ-MQSeries Bridge accesses MQSeries through MQI channels defined in both MQSeries and MSMQ-MQSeries Bridge.

Note
Each MQI channel connects an MSMQ-MQSeries Bridge to an MQSeries Queue Manager. Ordinarily, you should define one MQI channel for each connected network or foreign site.

First, define the channels in the MSMQ-MQSeries Bridge properties. Later, you can export the definitions to MQSeries (see Exporting MQSeries definitions).

The currently defined channels are listed in the dialog box. Click **Add** for a new MQI channel, **Properties** to edit the settings for an existing channel, or **Remove** to delete a channel.

On the **General** tab of the Channel Properties window, specify the following options:

Parameter	Description
Channel Name	A legal MQSeries name for the MQI channel. For convenience, you can assign the same name as you assigned to the connected network representing MQSeries in Message Queuing, for example IBMNT_CN.
MQSeries Queue Manager	The MQSeries Queue Manager to which the channel connects.
Transport Type	TCP/IP or SNA LU 6.2 communication.

On the **Address** tab of the Channel Propertieswindow, specify the following parameters for TCP/IP:

Parameter	Description
IP Address, Port	Of the MQSeries listener.

For SNA LU 6.2, specify:

Parameter	Description
Side Information Record	The CPI-C Symbolic Name defined in Host Integration Server.

For more information on the TCP/IP or SNA LU 6.2 configuration, see the IBM MQSeries documentation.

On the **Security** tab of the Channel Properties window, you may specify:

Parameter	Description
MCA User	An existing or new MQSeries user name, for example FMQUSER1, under which the server side of the MQI channel runs.

In MQSeries, you should set the permissions of the MCA User, that is, the queues that MSMQ-MQSeries Bridge can address. If you do not specify an MCA User, the server side of the channel runs under the default user name, which is the value of the MQSeries SYSTEM.DEF.SVRCONN parameter.

General Tab - CN

On the **General** tab of the CN properties window, specify the following options:

Parameter	Description
MQSeries QM Name	Select from the list of MQSeries Queue Managers to which you have defined MQI channels.

Note
If the same MSMQ-MQSeries Bridge is on two connected networks, do not connect them both to the same QM.

Parameter	Description
Reply to QM Name	The default MSMQ QM to which MQSeries should return report or acknowledgment messages. Ordinarily, you would enter the name of the MSMQ-MQSeries Bridge computer, for example **MSBridge1**.

The MSMQ-MQSeries Bridge Manager exports your entry to MQSeries as a queue manager alias (see Exporting MQSeries definitions). If the Microsoft® Windows® computer name contains an invalid MQSeries character such as a hyphen (-), replace it with another character such as an underscore (_) in the Reply to QM Name box. If you want to receive acknowledgments by nontransactional instead of transactional message pipe, add a % sign to the name (for example, MSBridge1%).

MQSeries uses the alias to identify the transmission queue where it should send acknowledgments. You can redirect the acknowledgments by specifying a different alias. For example, if you want to receive acknowledgments on another computer where MSMQ-MQSeries Bridge is installed, enter the name of the computer and define the name as an alias in MQSeries. For additional information, refer to your IBM MQSeries documentation.

Parameter	Description
Startup	Enabled or disabled at MSMQ-MQSeries Bridge startup (to change the status afterwards see Starting, Stopping, or Pausing an Object).

General Tab - Message Pipe

The **General** tab of the **Message Pipe Properties** window displays the following:

Parameter	Description
Status	**Running**, **Paused**, **Pending**, **Recovering**, **Stopped**,or **Error** (This is read-only; to change the status see **Starting, Stopping, or Pausing an Object)**.
Startup	Enabled or disabled at MSMQ-MQSeries Bridge startup.

For the MQSeries>MSMQ Transactional and Nontransactional message pipes:

Parameter	Description
Transmission Queue Name	A unique MQSeries transmission queue name for the pipe. The default names are <CN name>.XMITQ for the transactional message pipe and <CN name>.XMITQ.HIGH for the nontransactional message pipe. You can specify different names if you want.

For example, if the MSMQ-MQSeries Bridge computer name is MSBridge1, the default transmission queue names are MSBridge1.XMITQ and MSBridge1.XMITQ.HIGH.

Batch Tab

To optimize performance, MSMQ-MQSeries Bridge batches messages together. Increasing the batch size may improve performance. For transactional message pipes, this may increase the quantity of retransmitted data after a communication failure.

To change the batch size, specify any combination of:

Parameter	Description
Max. Number of Messages	The maximum number of messages in a batch.
Max. Accumulated Size	The maximum size (in bytes) of a batch.
Max. Accumulated Time	The maximum time (in milliseconds) during which messages are batched.

Transmission begins as soon as there are messages to be sent. When any of the above limits is reached the message pipe checks that the batch was fully received on the destination side.

Cache Tab

To reduce the overhead of opening and closing a queue for each message, MSMQ-MQSeries Bridge caches queue handles and reuses them when several messages are sent to the same queue. Specify the following option:

Parameter	Description
Cache Expiry	The time (in minutes) after which MSMQ-MQSeries Bridge closes an unused queue handle.

The system checks for Cache Timeout only at the Cache Refresh Time (see "Setting MSMQ-MQSeries Bridge Properties"). Thus the maximum time that an unused queue handle remains open is the Cache Timeout + Cache Refresh Time.

To refresh the cache immediately (for example to release a queue that is needed by another application), see "Refreshing the cache."

Retry Tab

If a message pipe fails, MSMQ-MQSeries Bridge tries to restart it automatically. For both the Short and Long retry cycles, specify:

Parameter	Description
Count	Maximum number of retries.
Delay	Interval between retries.

For example, you might specify a Short cycle of 3 retries at 30-second intervals. If the connection is still not successful, the system continues in a Long cycle of, for example, 10 retries at 300-second intervals.

Note

If you connect by TCP/IP, set the Delay to at least twice the keep-alive time of the destination MQSeries computer. This enables the MQSeries listener to release the resources of a broken connection before MSMQ-MQSeries Bridge tries to reconnect.

Trace Utility Help

If you are working to improve performance or solve a problem in Host Integration Server , you can use trace tools to determine the source of the problem.

A trace file contains a record of internal activities. When you enable the Trace utility, the Trace files are stored in the TRACES folder of the Host Integration Server folder. Trace files have the extension .ATF.

When gathering information about system difficulties, it is best to start with event log information. Event log information is generally more straightforward to interpret than tracing information. However, if you call product support, the technician may ask for some or all of the following information:

- Tracing. Trace files record activity between or within components of Host Integration Server. Trace files provide detailed information about the exact sequence of events occurring within Host Integration Server or between Host Integration Server and another system on the network. Tracing is turned on in Host Integration Server using the SNA Trace tool, which is located in the Applications and Tools program group of Host Integration Server. Trace files are created in the TRACES folder of the root folder with the filename extension .ATF.

- Windows Server event logs. When gathering information about system difficulties, it is generally best to start with the event logs, which record system and application events, including errors. Event logs are more straightforward to interpret than tracing information. Use tracing information if the event logs do not provide enough detail.

The Trace utility is started from SNA Manager, or the Trace icon in the Host Integration Server Applications and Tools program group. You can run the Trace utility on each server in the subdomain. For specific instructions on running traces, see the Host Integration Server online Help.

After you start the Trace utility in Host Integration Server or on a Host Integration Server client, you can enable or disable trace options.

Use the topics in this section to navigate through the Trace Utility User Interface. Click a topic below for more information.

In This Section

Trace Items Tab

The **Trace Items** tab has several items that must be selected and configured for the Trace application to operate properly.

List of Trace Items

The following components can be configured for tracing.

- SNA applications
- SNA Manager Client
- SNA Manager Agent (MngAgent)
- DB2 Network Library

Trace Items - Properties

Properties displays the **Trace Properties Sheet** that contains an **Internal Trace**, **Message Trace**, **API Trace** or the **TN3270 Internal Trace** tab depending on the Trace Item that was selected.

From the **Internal Trace**, **Message Trace**, **API Trace** and **TN3270 Internal Trace** tabs, you can either select a single item or click **Set All**.

To set Server trace properties

1. On the **Tools** menu, click **Trace Initiator**.
2. Click a component to trace from the list of Trace items.
3. Click **Properties**.
4. Click the appropriate trace tab.
5. Click the appropriate options for the trace, and then click **Apply**.

Trace Items - Clear All Traces

Clear All Traces will clear all trace settings and stop any running traces. If you only want to clear a specific trace item, double-click the item or select the item and click **Properties**. Then click **Clear All**.

When you select **Clear all Traces**, you will be presented with a dialog box to verify that you want to clear all trace setting.

Trace Items - Purge All Trace Files

Purge All Trace Files will delete all trace files from the Traces folder that is designated in the **Trace File Directory** tab.

When you select **Purge All Trace Files**, you will be presented with a dialog box to verify that you want to delete all trace files. If you purge all trace files, the trace settings are not deleted.

Tracing Global Properties Tab

The **Tracing Global Properties** tab has several items that can be modified to adjust how Trace runs. These items include:

Trace File Flip Length

The default size is 20,000,000 bytes.

You can change the maximum length by highlighting the number and typing a new value.

Tracing Global Properties tab to set the length of the trace file

1. In the **Trace Settings** dialog box, click the **Tracing Global Properties** tab.
2. Enter a value for the **Trace File Flip Length** box, and then click **OK**.

Write Traces on a Background Thread

Check this box to run tracing in the background. If the box is cleared (blank), tracing runs in the foreground.

To reduce performance impacts caused by tracing Host Integration Server 2006 components, traces can be queued and written by a background thread when this box is checked. Otherwise, trace files will be written immediately.

Background Thread Priority

If you select **Write Traces on a Background Thread**, check only one item to set the level of priority for tracing to run within the Microsoft Windows operating system. Highest gives tracing the highest level of priority, which means that tracing takes precedence over other jobs. Idle means that tracing runs when the CPU is idle.

Trace File Directory Tab

The following information details the **Trace File Directory** tab.

The **Trace File Directory** tab allows you to change where the Trace Initiator files will be stored.

Use **Browse** or enter a new location.

3270 Client Help

The Microsoft Host Integration Server 3270 Client enables your personal computer (PC) to access IBM hosts on the Systems Network Architecture (SNA) network. With the Host Integration Server 3270 Client, you can establish a single logical unit (LU) for your SNA session. You can connect to the following host application environments:

- Virtual Machine/Conversational Monitor System (VM/CMS)
- Time-Sharing Options (TSO)
- Customer Information Control System (CICS)

Once connected to a host application, you can transfer information between the host system and your computer without using an intermediate storage medium. This gives you the ability to:

- Transfer a file back and forth between your computer and the host. You can then continue working with the file even if the host is unavailable or slow.
- Edit a file and return it to the host, where it can be shared by other users.
- Print the information in the active window of a host application file.
- Extract information from the host for further analysis on your computer.

In This Section

Defining Session Settings

Before you can connect to a host, you must define the settings you will need for your session. These settings include the LU or Pool Name and the Host Code Page.

To define session settings for a Host Integration Server connection

1. On the **Session** menu, click **Session Configuration**. The **3270 Settings** dialog box appears.
2. In the **LU or Pool Name** box, select the correct LU or pool name.
3. In the **Host Code Page** box, select the correct host code page. The default is United States.
4. Optionally, use a **Script File** to record and playback an automatic logon procedure. For more information, see Recording and Playing Logon Scripts.
5. Click **OK**.

To define session settings for a TN3270E connection

1. On the **Session** menu, click **Session Configuration**. The **3270 Settings** dialog box appears.
2. Enter the **Server Name or Address**. This should be the IP address of the Host Integration Server running the TN3270 service.
3. Select the **Model** to use for the connection from the drop down list.
4. Leave **Device** blank if you want to allow the TN3270 service to select an LU. Optionally, you can enter the name of a specific LU or LU pool.
5. Enter the **Port** number to use when connecting to the TN3270 service. The default is 23.
6. In the **Host Code Page** box, select the correct host code page. The default is United States.
7. Optionally, use a **Script File** to record and playback an automatic logon procedure. For more information, see Recording and Playing Logon Scripts.
8. Click **OK**.

Connecting to a Host Application

After defining session settings, you can automatically connect to the host every time you start the 3270 Client.

To connect to the host application

1. On the **Session** menu, click **Connect**. The **logon** dialog box appears, ready for you to enter your user ID and password.

To disconnect from the host application

1. On the **Session** menu, click **Disconnect**. The host disconnects.

To turn on the Autoconnect option

1. On the **Session** menu, click **Autoconnect**. A check mark will appear next to the option. When you start the Client, connection will be automatic.

To turn off the Autoconnect option

1. 1. On the **Session** menu, click **Autoconnect** to clear the check mark.

Numeric Override Facility

The numeric override facility allows a user to enter non-numeric characters in numeric-only fields.

To toggle numeric override on and off, press CTRL+N (the CTRL key and the N key simultaneously). When numeric override is on, the number 9 appears in the operator information area at the bottom of the terminal, indicating that non-numeric characters can be entered in numeric-only fields.

Note
Make sure that the host computer will accept non-numeric characters in numeric-only fields before using this facility.

How to Record and Play Logon Scripts

The 3270 logon scripts make it easy for users and administrators to automate the logon procedure. You can use a script provided by your system administrator, or create your own. You can run the logon script at any time. The logon script feature enables Single Sign-On to host applications for the 3270 Host Integration Server clients and 3270 weblets, provided your host security administrator has enabled account password synchronization.

To use a logon script provided by your system administrator

1. Start the 3270 Client.
2. On the **Session** menu, click **Connect**. The **logon** dialog box appears, ready for you to enter your user ID and password.
3. On the **Script** menu, click **Play**. The script runs, and you are logged on.

To create your own logon script

1. Start the 3270 Client.
2. On the **Session** menu, click **Connect**. The **logon** dialog box appears, ready for you to enter your user ID and password.
3. On the **Script** menu, click **Record**.
4. Logon to the host using the 3270 screens and keyboard. The **Record** facility converts these actions into a logon script. (Click here to see a Sample Logon Script.)

When you are finished recording your logon script, on the **Script** menu, click **Stop**.

1. To run your logon script, on the **Script** menu, click **Play**.

The scripts can be modified using any text editor, such as Notepad.

To run the logon script automatically each time you connect

1. On the **Script** menu, select **Auto Run**. When you establish a connection to the host, the logon script runs automatically.
2. Optionally, on the **Session** menu, select **Autoconnect**. Every time you start the 3270 Client, the connection to the host will be made and you will be logged on automatically.

To choose different script files

1. On the **Session** menu, select Session Configuration. The **3270 Settings** dialog box appears.
2. On the **Script File** box, click **Browse** and select another script file.
3. Double-click the script file you want to use.
4. Click **OK**.

Defining File Transfer Settings

Using the 3270 Client, you can transfer a file between your computer and a host application. However, before you can send a file to the host or receive a file from the host, you must define the transfer settings that you need. These settings tell the 3270 Client which host environment you will be using (VM/CMS, TSO, or CICS) as well as the parameters for the connection between your computer and the host.

Before starting this procedure, review the configuration parameters under step 3 below to ensure that you have the necessary information at hand.

To define file transfer settings

1. On the **Transfer** menu, click **Settings**. The File Transfer Settings dialog box appears.

2. Under **Host Operating System**, select the option for the correct host environment. The host environment option that you select determines the rest of the settings you enter in the File Transfer Settings dialog box. Settings that you do not need for your host environment are unavailable.

3. Find the items that apply to your configuration, and supply the information as follows:

   Host Program Name Specify the host program name by typing the host name for the program used by the 3270 Client.

   Timeout Specify the amount of time, in seconds, that the 3270 Client will wait for a host response to the file transfer request.

   Packet Size Specify the packet size transferred at one time. The larger the size, the faster the file is transferred.

   Block Size (TSO) Select the Block Size check box, and specify the size of the data blocks, in bytes, in the new data set on your TSO volume.

   Issue Clear (VM/CMS and CICS) Select this check box to request the host to clear the terminal screen before transferring files.

   Host Code Page Select the correct EBCDIC code page translation table used by the host.

   PC Code Page Select the correct ASCII code page translation table used by your computer.

   Record (VM/CMS and TSO) Specify the type for the logical record length by selecting the correct option button for your configuration. This parameter controls whether the logical record length—the number of characters in each record of a file transferred to the host—is fixed, variable, undefined, or default; that is, controlled by host defaults (TSO only). A transferred file that replaces or appends to an existing file automatically takes the logical record length of the existing file.

   To update an existing host file, select Default.

   To create a new host file, select the record length type: Fixed, Variable, or Undefined.

   If you select Fixed, specify the logical record length in the Fixed box.

   Space (TSO) Select this check box to specify the space for a new data set, then select the option that corresponds to the unit of measurement (Blocks, Tracks, or Cylinders) and type the number of units to allocate. To allocate additional space, in the second box, type the number of additional blocks, tracks, or cylinders to allocate. To find out the correct amount of space to specify, contact the host administrator.

4. Click OK.

Specifying a File

Once you have defined the settings for transferring files, you can send a file to the host or receive a file from the host. You can select a file to transfer in one of two ways: by typing the name of the specific file to send or receive, or by browsing through a list of available files.

To type the name of a specific file

1. On the **Transfer** menu, click **Send File** or **Receive File**. Either the Send File dialog box or Receive File dialog box appears.

2. In the **PC File Name** box, type the name of the file to send or receive. Note that when receiving a file from the host application, if you type the name of an existing PC file, it will be overwritten by the host file.

3. To review your settings, click **Settings**.

To browse through a list of available files

1. On the **Transfer** menu, click **Send File** or **Receive File**. Either the Send File dialog box or Receive File dialog box appears.

2. Click **Browse**. The **Open** dialog box appears.

3. In the **File Name** list, select the file you want to send or receive. To see files of another type, select the type from the **List Files of Type** box.

4. Click **OK**. The Send File or Receive File dialog box reappears with your selection in the PC File Name box.

5. To review your settings, click **Settings**; to continue.

Sending or Receiving a File

Once you have defined the settings you need to transfer files, and selected the file to transfer, you can send a file to or receive a file from the host. To send or receive a file, you must supply certain configuration information. This information includes the host filename, host file type, host file mode, data set name, carriage return, whether you are appending to an existing file, EBCDIC conversion, and carriage return line feed.

To send a file to the host or receive a file from the host

1. After specifying the file, find the items that apply to your configuration, and supply the information as follows:

   Specify the host file type. For CICS, select either ASCII File or Binary File.

   Host File Mode (VM/CMS) Specify the host file mode, the specific minidisk where the user data resides. To find out the mode for a specific file, from an Client session, type the following command, substituting the name of the file for filename: list filename * *.

   In the resulting display, the third column contains the file mode. The default host file mode is A1.

   Data Set Name (TSO) Specify the host data set name. Be sure to include the Member name, in parentheses, if you are sending to a host partitioned data set (PDS). The following is an example of a data set name for a PDSDEF_009:

   PROJECT.GROUP.TYPE(MEMBER)

   Carriage Return (CICS) Select the carriage return option for the file you are sending or receiving. Delete CR/LF removes all carriage return/line feed characters from the file sent to the host. No CR/LF leaves the carriage return/line feed characters in the file when transferring to the host. None of the Above uses the default implied by the type of file (ASCII or binary) being transferred. The default for ASCII (being converted to EBCDIC) is CR/LF. The default for binary is No CR/LF, and CRLFs will not be interpreted.

   Append to Existing File (send) Select this check box to add new data to the end of an existing host file.

   Convert to EBCDIC (send) Select this check box to convert from ASCII to EBCDIC.

   Convert from EBCDIC (receive) Select this check box to convert from EBCDIC to ASCII. Use this option for text files rather than binary files.

   Delete Carriage Return/Line Feed CR/LF (send) Select this check box to replace all CR/LF characters with end of record marks.

   Insert Carriage Return/Line Feed CR/LF (receive) Select this check box to replace all end-of-record marks with CR/LF characters. Use this option for text files rather than binary files.

2. Click **OK**. The 3270 Client begins the transfer.

Using Macros

The 3270 Client provides macros for ease in using host function keys.

To use a macro, select the correct macro from the Macro menu. The appropriate function key is sent to the host.

The following table shows the macros for the 3270 Client:

Macro	Description
Attention	Sends an Attention key to the host. The Attention key is used to temporarily stop the present display station activity.
Clear	Sends a Clear key to the host. This macro clears the display screen.
Reset	Sends a Reset key to the host. Reset unlocks the keyboard and clears operator errors.
Sys Request	Sends a Sys Req key to the host. With most systems, use this macro to notify the host system that the display station is ready to select a new program or activity.

Printing the Screen

After you have established a connection to the host, you can print the information in the active window.

To print the screen

- On the **File** menu, click **Print**.

To change printer options

1. On the **File** menu, click **Printer Setup**.

   The Print Setup dialog box appears.

2. To change the printer, from the **Printer** list, select the correct printer.

   To view **Advanced Document Properties**, click **More**.

   To view printers on the network, click **Network**.

3. Change any other printer options as necessary.

4. Click **OK**.

Copying and Pasting Displayed Information

The 3270 Client allows you to make a copy of the information in the display, so that you can use that information in other applications. To do this, you select a portion of the displayed information, and then copy it to the Windows Clipboard. After copying information to the Clipboard, you can change to a different application and transfer the information into that application.

In reverse fashion, you can copy information from an application other than the Client, then paste the information into the Client. If the emulation session is in a state in which information can be received (indicated by the status line), the pasted information will be entered as a series of keystrokes.

To copy and paste displayed information

1. Select the portion of the displayed information that you want to copy

   -or-

   on the **Edit** menu, click **Select All**.

2. On the **Edit** menu, click **Copy**. The selection is copied to the Clipboard.

3. Change to the program in which you will insert the contents of the Clipboard.

4. Position the cursor at the location where you want to insert the contents of the Clipboard.

5. On the **Edit** menu, click **Paste**.

To copy information from an application and paste it into the Client window

1. From the application, copy information to the Clipboard by using the application's standard copy command(s).

2. Change to an active Client session, or start the Client and begin a session.

3. Check to see that the session is in a state in which keystrokes can be received.

4. On the **Edit** menu, click **Paste**. The copied information is entered as a series of keystrokes.

Saving a Configuration

After you have configured a connection to the host, you can save it. While you are connected to the host application, you cannot open a new or existing configuration.

To save a configuration

1. On the **File** menu, click **Save**.The Save As dialog box appears.
2. In the **Directories** box, select the appropriate directory.
3. In the **File Name** box, type a name for the configuration file or select a file from the list.
4. Click **OK**. Now, when you click **Open** on the **File** menu, the configuration appears as an available configuration.

To open a configuration

1. On the **File** menu, click **Open**. The Open dialog box appears.
2. In the **Directories** box, select the appropriate directory. To open a file from a directory on the network, click **Network**.
3. In the **File Name** box, type a name for the configuration file or select a file from the list.
4. Click **OK**.

To create a new configuration

- On the **File** menu, click **New**. The configuration settings are reset to their default values.

To rename a configuration

1. On the **File** menu, click **Save As**. The Save As dialog box appears.
2. In the **Directories** box, select the appropriate directory. To save a file to a directory on the network, click **Network**.
3. In the **File Name** box, type a new name for the configuration file or select a file from the list.
4. Click **OK**. Now, when you click Open on the File menu, the configuration is renamed and appears as an available configuration.

3270 Client Standard Keyboard Map

The following table maps values from the 3270 keyboard to the Enhanced 101 keyboard.

3270 Keyboard	**Enhanced 101 Keyboard**
DUP	CTRL ALT INSERT
FIELD MARK	SHIFT HOME

OIA Inidcators

The Operator Information Area (OIA) is used to display the status of a 3270 screen session. The OIA is the last (bottom) line display in the terminal window of the 3270 session. Except for the initial three positions (system connection indicators), status line indicators only appear when they apply.

The following tables describe the OIA and explain each indicator. In the table, position refers to the column(s) that a specific indicator occupies on the OIA, where the left-most column of the OIA is position 1. Note that the "female" symbol used for certain system connection and input-inhibited indicators cannot be displayed in this table. In its place is the "^" symbol.

Following is a list of symbols found on each system connection and their respective meanings.

System Connection (position 1)

Does not apply to Host Integration Server 3270 Client.

System Connection (position 2)

B Connection uses an SNA protocol.

A Connection uses a non-SNA protocol.

System Connection (position 3)

b Connected to a host application (LU-LU session).

^ Connected to host system services (SSCP-LU session).

? Session is established, but is not connected to any host program (unknown).

Session ID (positions 4-7)

aaaa First four characters of your configured long name session ID.

Input-Inhibited messages (keyboard locked) (positions 9-17)

X COMMnnn Communications error. See Communications Status (positions 19-26).

X MACHnnn Machine check error.

X PROGnnn Program check error. See Communications Status (positions 19-26).

X SYSTEM Keyboard input is being processed by the host. Wait for the message to clear or press RESET.

X[] The host requires more time to process your request. Wait for indicator to clear or press RESET.

X -f Function is not supported. Press RESET and select a valid function.

X^> More data was typed than the field allows or can accept. Press RESET and re-enter the data.

X <-^-> Protected field; you cannot type data. Press RESET and move the cursor to an unprotected field.

X -f^X Function is not authorized. Press RESET and select a valid function.

X^+? Invalid accent/character combination typed. The accent is displayed in position 12. Press RESET and type a valid combination.

Communications Status (positions 19-26)

COMM500 All the link services configured for use by the connection were inactive.

COMM504 Communications are not established with the host. This message disappears as soon as communication is established with the host. If this message does not disappear, check to ensure proper settings of the host network address, local node ID, or local SAP.

COMM505 The host terminated the connection used by your 3270 session.

COMM510 The host has deactivated the communications link. Report the message to your system administrator.

COMM518 A segment was out of sequence. Contact your system administrator.

COMM695 A communications error occurred.

COMM5nn The communications link is still being established; the keyboard is locked. Wait for the message to clear; also check

Input-Inhibited messages.

PROG703 A session control, data flow control or network control command is not supported. Press RESET, and try the operation again.

PROG705 A sequence number error has occurred. Press RESET, and try the operation again.

PROG706 A chaining error has occurred. Press RESET, and try the operation again.

PROG707 A bracket state error has occurred. Press RESET, and try the operation again.

PROG708 A data traffic reset state exists. Press RESET and try the operation again.

PROG717 The support level requested is not valid. Press RESET, and try the operation again.

PROG723 The LU type requested is not valid. Press RESET, and try the operation again.

PROG724 The screen size requested is not valid. Press RESET, and try the operation again.

Screen Session LU Address (positions 79-80)

Nn The LU address of the currently displayed 3270 screen session.

5250 Client Help

The Microsoft Host Integration Server 5250 Client is a powerful communications product that enables you to access AS/400 systems on the Systems Network Architecture (SNA) network from your computer. Once connected to a host application, you can print the screen, copy and paste displayed information via the Clipboard, and save a configuration.

This section contains:

Defining Session Settings

Before you can connect to an AS/400 system, you must define the settings you will need for your 5250 session such as the Local LU Alias, Remote APPC LU Alias, Host Code Page, and Display Size. You can also change the Device Name, although this is generally not necessary.

To define basic session settings for the 5250 Client for a Host Integration Server

1. On the **Session** menu, click **Session Configuration**. The 5250 Session Information dialog box appears.
2. Select the Server Type: **Host Integration Server**.
3. In the **Local APPC LU Alias** box, type the Local LU Alias provided by your system administrator. In some cases, the Local LU Alias provided by your system administrator may be the same as your user name. In other cases, your system administrator may instruct you to leave the box blank; this allows the Host Integration Server to use the default local LU configured for your user name.
4. In the **Remote APPC LU Alias** box, select the system name of the AS/400, as provided by your system administrator. Your system administrator may instruct you to leave the box blank; this allows the Host Integration Server to use the default system name (also called the remote LU) configured for your user name.
5. In the **Host Code Page** box, select the correct host code page. The default is English-US.
6. Under **Display Size**, select the option button for the correct display size. The default is 24 x 80.
7. To specify a device name other than the default, in the **Device Name** box, type the correct device name.
8. Select the **System 36 Compatibility** check box to connect to a System 36 computer.
9. Select the **Automatic Logon** check box to use the single sign-on feature. You must install the Host Security Integration feature to enable single sign-on.
10. Click **OK**.

To define basic session settings for the 5250 Client for a TN 5250 Server

1. On the **Session** menu, click **Session Configuration**. The 5250 Session Information dialog box appears.
2. Select the Server Type: **TN 5250**.
3. Enter the Server Name or IP Address for the server where Host Integration Server is installed. If you are unsure, see your system administrator.
4. Select a **Terminal Type** from the list box to allow the TN5250 Service to accept client requests from TN5250 clients emulating those types of terminals. Clear a name to cause TN5250 Service to reject requests from clients emulating that terminal type. All terminal names are selected by default.
5. Select **Use Default** to use the port number configured with the service (on the **Host Integration Server Service Properties** page).
6. You can override the default value for a given session by selecting Use and typing another port number.

   Note that TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers. See the Host Integration Server help for more information.

7. In the **Host Code Page** box, select the correct host code page. The default is English-US.

8. Click **OK**.

Using the Keypad Menu

Standard 5250 function keys can be selected from the Keypad menu. The direct keyboard mapping is displayed in the right-most column of the menu.

To send a 5250 keystroke to the host

- From the Keypad menu, choose the correct 5250 function. The appropriate function key is sent to the host.

Note
Limited keyboard remapping is provided for the standard IBM 101 keyboard.

Printing the Screen

After you have established a connection to the host, you can print the information in the active window.

To print the screen

- On the **File** menu, click **Print**.

To change printer options

1. On the **File** menu, click **Printer Setup**. The Print Setup dialog box appears.
2. To change the printer, in the **Printer** list, select the correct printer. To view Advanced Document Properties, click **More**. To view printers on the network, click **Network**.
3. Change any other printer options as necessary.
4. Click **OK**.

Copying and Pasting Displayed Information

The 5250 Client allows you to make a copy of the information in the display, so that you can use that information in other applications. To do this, select a portion of the displayed information, and then copy it to the Windows Clipboard. After copying information to the Clipboard, you can change to a different application and transfer the information into that application.

In reverse fashion, you can copy information from an application other than the Client, and then paste the information into the Client. If the emulation session is in a state in which information can be received (indicated by the status line), the pasted information will be entered as a series of keystrokes.

To copy and paste displayed information in the Client window

1. Select the portion of the displayed information that you want to copy

   -or-

   on the **Edit** menu, click **Select All**.

2. On the **Edit** menu, click **Copy**. The selection is copied to the Clipboard.

3. Change to the application in which you will insert the contents of the Clipboard.

4. Position the cursor where you want to insert the contents of the Clipboard.

5. On the **Edit** menu, click **Paste**.

To copy information from an application and paste it into the Client window

1. From the application, copy information to the Clipboard by using the applications standard copy command(s).

2. Change to an active Client session, or start the Client and begin a session.

3. Check to see that the session is in a state in which keystrokes can be received.

4. On the **Edit** menu, click **Paste**. The copied information is entered as a series of keystrokes.

Saving a Configuration

After you have configured a connection to the host, you can save it. While you are connected to the host application, you cannot open a new or existing configuration.

To save a new configuration

1. On the **File** menu, click **Save**. The Save As dialog box appears.
2. In the **Directories** box, select the appropriate directory.
3. In the **File Name** box, type a name for the configuration file or select a file from the list. To save the configuration to a directory on the network, click **Network**.
4. Click **OK**. Now, when you choose **Open** from the **File** menu, the configuration appears as an available configuration.

To open a configuration

1. On the **File** menu, click **Open**. The Open dialog box appears.
2. In the **Directories** box, select the appropriate directory. To open a file from a directory on the network, click **Network**.
3. In the **File Name** box, type a name for the configuration file or select a file from the list.
4. Click **OK**.

To create a new configuration

- On the **File** menu, click **New**. The configuration settings are reset to their default values.

To rename a configuration

1. On the **File** menu, click **Save As**. The Save As dialog box appears.
2. In the **Directories** box, select the appropriate directory. To save a file to a directory on the network, click **Network**.
3. In the **File Name** box, type a new name for the configuration file or select a file from the list.
4. Click **OK**. Now, when you choose **Open** from the **File** menu, the configuration is renamed and appears as an available configuration.

5250 Client Standard Keyboard Map

The following table maps values from the 5250 keyboard to the Enhanced 101 keyboard.

5250 Keyboard	Enhanced 101 Keyboard

Remapping for the Standard IBM 101 Keyboard Layout

When using the Host Integration Server 5250 Client, function keys located on the numeric keypad (such as PGUP, PGDN and ENTER) are not mapped to 5250 functions for PAGE UP, PAGE DOWN, and ENTER. The standard cursor control keys for PageUp and PageDown (located on the keypad positioned between the BACKSPACE and NUMLOCK keys) and the standard ENTER key do work.

The <Snaroot>\System\5250.kbd file can be edited to support limited keyboard remapping, for the standard IBM 101 keyboard layout. For example, the procedure below describes how to add support for the ENTER, PGUP and PGDN keys located on the numeric keypad:

To add support for the ENTER, PGUP and PGDN keys

1. Save the original copy of <Snaroot>\System\5250.kbd to 5250.old.

2. Add the following lines to the 5250.kbd file:

    - NumPgUp : PAGE_UP
    - NumPgDn : PAGE_DOWN
    - NumEnter: ENTER

Note
5250.kbd will already include default entries for the 5250 PAGE_UP, PAGE_DOWN, and ENTER functions, mapped to the PAGEUP, PAGEDOWN, and ENTER keys respectively.

1. Copy the 5250.kbd file to Keyboard.map, and place Keyboard.map in the same directory where the Win5250.exe program resides:

    - for Windows 3.x clients, the default is <sna.win>
    - for Windows 95 clients, the default is <sna95>\system
    - for Windows NT clients, the default is <sna>\system

2. . Restart the 5250 Client.

Note
The Host Integration Server 5250 Client does support limited keyboard remapping by following the instructions in the <Snaroot>\System\5250.kbd file. This keyboard mapping support is not available in SNA Server 2.x versions of the 5250 Client.

5250 Client Status Line

The following list describes the information displayed in the status line of the 5250 Client.

Connection Indicator The session is in the indicated state: connected or disconnected. When menu items are highlighted, an explanation of the menu item is displayed.

Status Indicators These indicators are only true when red.

SA (System Available) The AS/400 is operating and is available to the PC.

MW (Message Waiting) The AS/400 has one or more messages for you.

KS (Keyboard Shift) The keyboard is in shifted mode.

IM (Insert Mode) Characters inserted into an existing field will not type over the existing data.

II (Input Inhibited) Keyboard input is not being accepted by the AS/400. Try pressing the ERROR RESET key. If it is still highlighted, the system is processing your request.

KB (Keystroke Buffering) Keystrokes are being saved in a temporary buffer (storage space), because keyboard input is not being accepted by the AS/400 (as indicated by the II indicator). After the II indicator goes off, the keystrokes will be processed. To clear the keystroke buffering, press the ERROR RESET key.

System and Device Indicators These indicators appear only when the Client is connected to the AS/400.

Administrator's Reference

The Administrator's Reference section provides technical information about working with Microsoft Host Integration Server.

To use this reference section effectively, you should be familiar with the following:

- Host Integration Server
- Microsoft Windows
- IBM Systems Network Architecture (SNA) concepts

In This Section

Document Conventions explains the formatting conventions this documentation set uses to distinguish important elements of text.

Common Acronyms and Abbreviations lists common industry abbreviations and acronyms, along with their meanings.

Host Integration Server Support explains how Host Integration Server works within Systems Network Architecture (SNA) networks.

Network Management describes the support that Host Integration Server provides for centralized network management

Network Protocols and Client/Server Communication describes how clients using different local area network (LAN) protocols can communicate with Host Integration Server computers.

Error Messages describes the audit and error messages database and how to access it.

Command-Line Interface describes the command-line interface that can be used when you want to view a configuration setting quickly, or when you wnat to store configuration commands.

Sample Host Definitions presents samples for establishing Host Integration Server connections to an IBM host system.

CICS and VTAM Sample Definitions for LU 6.2 presents sample definitions for CICS and VTAM for Host Integration Server connections to an IBM host system.

Sense Codes lists sense codes used by Host Integration Server.

Character Tables provides tables of the ASCII, ANSI, and IBM Extended character sets. It also provides a character translation table that can be used by the custom code page option of Host Print service.

For more information about systems network architecture, see the latest version of the IBM publication, *Systems Network Architecture Technical Overview* (GC30-3073).

For frequently used terms, see the Glossary.

Document Conventions

This *Administrator's Reference* uses the following formatting conventions to distinguish important elements of text.

Convention	Purpose
bold	Indicates syntax items that must be typed exactly as shown.
italic	Indicates variables.
UPPERCASE	Represents file names, paths, volumes, array and structure names, values, and conversation states. Also represents return values and key names (such as ALT or CTRL).
[brackets]	Enclose optional items in square brackets.
{braces}	Enclose required items in curly brackets.
| (vertical bar)	Stands for OR and separates items in syntax statements.
... (ellipsis)	Indicates that the preceding syntax item can be repeated. If a punctuation mark precedes the ellipsis, you must include the punctuation when repeating the item.
X'*nnnn*'	Indicates hexadecimal digits.

Common Acronyms and Abbreviations

The following table contains a list of common abbreviations used in this reference. For definitions of these and other terms, see the Glossary.

Abbreviation	Description
ACTLU	Activate Logical Unit
ACTPU	Activate Physical Unit
ADO	ActiveX Data Objects
API	application programming interface
APPC	Advanced Program-to-Program Communications
APPN	Advanced Peer-to-Peer Networking
ASCII	American Standard Code for Information Interchange
BB RQE	Begin Bracket, Exception Response
BTU	basic transmission unit
CD	Change Direction
CEB	Conditional End Bracket
CICS	Customer Information Control System
CCSID	Coded Character Set ID
COM	Component Object Model
CPI-C	Common Programming Interface for Communications
CSV	Common Service Verb
CTS	clear-to-send
DACTLU	Deactivate Logical Unit
DAF	destination address field
DCA	Digital Communications Associates, Inc.
DCOM	Distributed Component Object Model
DDM	Distributed Data Management
DDS	Digital Data System
DFC	data flow control

DLC	data link control
DLL	dynamic-link library
DLS	Distributed Link Service
DM	disconnect mode
DMA	Direct Memory Access
DMOD	Dynamic Module
DRDA	Distributed Relational Database Architecture
DSC	data stream compatible
DSR	Data Set Ready
DTR	Data Terminal Ready
EB	End Bracket
EBCDIC	Extended Binary Coded Decimal Interchange Code
EN	End Node
ESCON	Enterprise System Connection
FDDI	Fiber Distributed Data Interface
FEP	front-end processor
FM	function management
FRMR	frame reject
FTP	File Transfer Protocol
IMS	Information Management System
KB	Kilobyte
LAN	local area network
LCS	link connection subsystem
LL	record length field
LLC	Logical Link Control
LU	logical unit
LUA	Logical Unit for Applications (programming interface)

MAC	media access control
MB	Megabyte
MMC	Microsoft Management Console
MVS	Multiple Virtual Storage
NAU	Network Addressable Unit
NCP	Network Control Panel
NMVT	network management vector transport
NN	Network Node
N(r)	number returned
NRM	Normal Response Mode
NRZ	non-return to zero
NRZI	non-return to zero inverted
N(s)	number sent
ODBC	Open Database Connectivity
OLE	object linking and embedding
OLE DB	Object Linking and Embedding Database
PCT	Program Control Table
PDSE	Partitioned Data Set Extended
PIP	program initialization parameter
PLU	primary logical unit
PPT	Program Processing Table
PU	physical unit
PVC	permanent virtual circuit
QLLC	Qualified Logical Link Control
RH	request/response header
RIM	ring indicator monitor

RSP	Response
RTM	Response Time Monitor
RU	request/response unit
RUI	Request Unit Interface
SAP	service access point
SDK	software development kit
SDLC	Synchronous Data Link Control
SID	Security ID
SLI	Session Level Interface
SLU	secondary logical unit
SNA	Systems Network Architecture
SNRM	Set Normal Response Mode
SP	Service Pack
SQL	Structured Query Language
SSCP	System Services Control Point
SVC	switched virtual circuit
TCP/IP	Transmission Control Protocol/Internet Protocol
TCT	Terminal Control Table
TH	transmission header
TN	Telnet
TP	transaction program
TS	transmission service
TSO	time sharing option
VSAM	Virtual Storage Access Method
VTAM	Virtual Telecommunications Access Method
WAN	wide area network
XID	Exchange Identification

Host Integration Server Support

This section explains how Host Integration Server works in Systems Network Architecture (SNA) networks. The following information is included:

- A summary of the types and number of SNA sessions supported by Host Integration Server.
- A list of the SNA commands supported by Host Integration Server. This section also shows the type of SNA sessions in which the commands flow.
- The transmission service (TS) and function management (FM) profiles supported by Host Integration Server.
- A list and explanation of the five categories of SNA sense codes generated by Host Integration Server. This section also describes logical unit (LU) type 6.2-specific sense data.

For specific information about an application programming interface (API) supported by Host Integration Server, see the programmer's guide for that API:

- APPC Programmer's Guide
- CPI-C Programmer's Guide
- LUA Programmer's Guide

In This Section

SNA Session Support

This section lists and explains the types and numbers of SNA sessions supported by Host Integration Server.

In This Section

LU Support

A Host Integration Server node can support as many as 15,000 sessions.

Logical unit 6.2 (LU 6.2) works in combination with node type 2.1 to provide Advanced Program-to-Program Communications (APPC). An LU 6.2 can be either a primary logical unit (PLU) or a secondary logical unit (SLU). The partner LU can reside in a type 2.1 node, within an upstream type 5 node, or within the Host Integration Server node itself.

LU types 0, 1, 2, or 3 are always SLUs, and the partner LU in an upstream type 5 node is always the PLU. LU 0 supports session-level cryptography, within certain limits, on the Request Unit Interface (RUI). You implement session-level cryptography through Cryptography Verification (CRV) requests; the RUI applications must perform all necessary processing. For details about the limits of session-level cryptography and about the processing carried out by the RUI application, see the LUA Programmer's Guide. For all interfaces other than RUI, CRV requests are handled with a negative response.

SNA Session Support

Session Support

Host Integration Server supports many types of SNA communications sessions:

- A System Services Control Point – physical unit (SSCP-PU)
- A Host Integration Server physical unit (PU) Services Manager which communicates with the System Services Control Point (SSCP) on the host
- An SSCP-LU
- A Host Integration Server logical unit (LU) which communicates with a host SSCP
- A Primary logical unit-secondary logical unit (PLU-SLU)
- A Host Integration Server LU which communicates with host or peer LUs

Host Integration Server Support

Command Request Support

The next three tables list the SNA command requests supported by Host Integration Server. Note that not all commands are supported for every LU-to-LU session type. For example, Bracket Initiation Stopped (BIS) is only supported for use by an APPC LU.

The following three tables categorize requests in the following order:

1. Session control requests
2. Function management data requests: network services (maintenance) and network services (session)
3. Data flow control requests

The three tables denote the category for each request by the setting of the request/response unit (RU) category bits in the request/response header (RH), and by the function of the request. Host Integration Server does not support commands that fall in the network control request category.

For more information about command requests, see your IBM documentation.

SNA Request Support for Session Control Requests

Session	Request	Direction
SSCP-PU	ACTPU	SSCP to PU
	DACTPU	SSCP to PU
SSCP-LU	ACTLU	SSCP to SLU
	DACTLU	SLU to SSCP
PLU-SLU	BIND	PLU to SLU
	UNBIND	PLU to/from SLU
	CLEAR	PLU to SLU
	SDT	PLU to SLU

SNA Request Support for Function Management Data Requests

Session	Request	Direction
SSCP-PU	NMVT (1)	SSCP to/from PU
	INIT-SELF (2)	SLU to SSCP
	TERM-SELF (2)	SLU to SSCP
	NOTIFY (2)	SLU to SSCP
	NSPE (2)	SSCP to SLU

1. Network services, maintenance services

2. Network services, session services

SNA Request Support for Data Flow Control Requests

Session	Request	Direction

PLU-SLU	BID	PLU to/from SLU
	BIS	PLU to/from SLU
	CANCEL	PLU to/from SLU
	CHASE	PLU to SLU
	LUSTAT	PLU to/from SLU
	RTR	PLU to/from SLU
	SHUTC	PLU from SLU
	SHUTD	PLU to SLU
	SIGNAL	PLU to/from SLU

Host Integration Server Support

Transmission Service and Function Management Profiles

Host Integration Server enforces the rules that govern active sessions between communicating partners on an SNA network.

The Host Integration Server computer can select some of these session protocols—such as request/response control modes, bracket usage, and pacing—when you activate a session. The term "profiles" refers to specific combinations of these selectable protocol options.

Transmission service (TS) profiles refer to transmission control options, while function management (FM) profiles refer to data flow control and function management data options.

When activated, TS and FM profiles of a session are specified by using parameters in the appropriate session activation request and response such as ACTPU, ACTLU, BIND.

The following table specifies the TS and FM profiles supported by each of the Host Integration Server session types.

Session type	TS profiles	FM profiles
SSCP-LU session	1	0
SSCP-PU session	1	0
3270 display and printer PLU-SLU session	3	3
LU 6.2 PLU-SLU session	7	19
LUA PLU-SLU session	2, 3, 4	2, 3, 4, 7, 18

In This Section

TS Profile 1

Transmission service (TS) Profile 1 is supported on System Services Control Point physical unit (SSCP-PU) and System Services Control Point secondary logical unit (SSCP-SLU) sessions; the profile does not require a TS usage field. This profile specifies the following session rules:

- Pacing is not supported.
- Identifiers, rather than sequence numbers, are used on the normal flows.
- ACTPU, DACTPU, ACTLU, and DACTLU are supported.
- Maximum outbound request/response (RU) size is 256 bytes.
- Maximum inbound RU size is 512 bytes.

See Also
Other Resources
Transmission Service and Function Management Profiles

TS Profile 2

Transmission service (TS) Profile 2 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 0. This profile specifies the following session rules:

- Primary logical unit-secondary logical unit (PLU-SLU) and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows whenever the transmission header (TH) format used includes a sequence number field.
- CLEAR is supported.
- SDT, RQR, STSN, and CRV are not supported.

The TS usage subfields defining the options for this profile are the following:

- Pacing window counts
- Maximum request/response (RU) sizes on the normal flows

See Also

Other Resources

Transmission Service and Function Management Profiles

TS Profile 3

Transmission service (TS) Profile 3 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU types 0, 1, 2, or 3. Selection is a BIND option. This profile specifies the following session rules:

- PLU-SLU and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows.
- BIND, UNBIND, CLEAR, and SDT are supported.

The TS usage subfields defining the options for this profile are the following:

- Pacing counts
- Maximum request/response (RU) sizes on the normal flows

Transmission Service and Function Management Profiles

TS Profile 4

Transmission service (TS) Profile 4 is supported on logical unit-logical unit (LU-LU) sessions using LU types 0 or 1. This profile specifies the following session rules:

- Primary logical unit-secondary logical unit (PLU-SLU) and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows whenever the transmission header (TH) format used includes a sequence number field.
- SDT, CLEAR, RQR, and STSN are supported.
- CRV is supported when session-level cryptography is selected via a BIND parameter.

The TS usage subfields defining the options for this profile are the following:

- Pacing window counts
- Maximum request/response (RU) sizes on the normal flows

Transmission Service and Function Management Profiles

TS Profile 7

Transmission service (TS) Profile 7 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 6.2. This profile specifies the following session rules:

- PLU-SLU and SLU-PLU normal flows are paced.
- Sequence numbers are used on the normal flows.
- BIND and UNBIND are supported.

The TS Usage subfields defining the options for this profile are the following:

- Pacing counts
- Maximum request/response (RU) sizes on the normal flows

Transmission Service and Function Management Profiles

FM Profile 0

Function management (FM) Profile 0 is supported on SSCP-PU and SSCP-SLU sessions. This profile specifies the following session rules:

- SSCP, PU, and SLU use immediate request mode and immediate response mode.
- Only single-RU chains are allowed.
- All chains require definite response.
- No compression.
- No data flow control (DFC) RUs.
- No function management (FM) headers.
- No brackets.
- No alternate code.
- Normal flow send/receive mode is half-duplex contention.
- Secondary wins contention.
- SSCP is responsible for recovery.

Other Resources

Transmission Service and Function Management Profiles

FM Profile 2

Function management (FM) Profile 2 is supported on primary logic unit-secondary logic unit (PLU-SLU) sessions using LU 0. This profile uses the following session rules:

- SLU uses delayed request mode.
- SLU uses immediate response mode.
- Only single-RU chains are allowed.
- SLU requests indicate no-response.
- No FMH-1 SCB compression.
- Length-checked compression allowed.
- No data flow control (DFC) RUs.
- No FM headers.
- SLU is the first speaker if brackets are used.
- Bracket termination rule 2 is used if brackets are used.
- PLU will send an end bracket (EB).
- SLU will not send an EB.
- Normal-flow send/receive mode is full duplex (FDX).
- PLU is responsible for recovery.

The following FM Usage fields define the options for Profile 2:

- Primary request control mode selection
- Primary chain response protocol (no-response cannot be used)
- Brackets usage and reset state
- Alternate code

Transmission Service and Function Management Profiles

FM Profile 3

Function management (FM) Profile 3 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU types 0, 1, 2, or 3. This profile specifies the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server):
    - **CANCEL**
    - **SIGNAL**
    - **LUSTAT** (SLU-PLU only)
    - **CHASE***
    - **SHUTD**
    - **SHUTC**
    - **RSHUTD***
    - **BID** and **RTR**

The following FM Usage fields define the options for Profile 3:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Bracket usage
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode

The next three tables list the FM Profile 3 options that Host Integration Server supports. Host Integration Server rejects any BIND option that specifies an option value not listed in these tables.

Supported options for BIND requests from primary LUs

Usage option	Value	Meaning
Chaining use element	0	Can send only single-element chains

	1	Can send single- or multiple-chains
Request control mode	0	Immediate request mode used
Chain response protocol	01	Can request only exception-only responses
	10	Can request only definite responses
	11	Can request definite or exception-only responses
Compression indicator	0	Cannot send compressed data
	1	Can send compressed data (LU 1 only)
Send EB indicator	1	Can send an end bracket

Supported options for BIND requests from secondary LUs

Usage option	Value	Meaning
Chaining use element	0	Can only send single-element chains (not LU 2)
	1	Can send single- or multiple-chains
Request control mode	0	Immediate request mode used
Chain response protocol	01	Can request only exception-only responses
	10	Can request only definite responses
	11	Can request definite or exception-only responses
Compression indicator	0	Cannot send compressed data
Send EB indicator	1	Cannot send end bracket

Supported common protocol values for BIND requests from any LU

Usage option	Value	Meaning
FM header usage	0	Cannot exchange FM headers
	1	Can exchange FM headers
Bracket usage	1	Bracket protocols must be used
Bracket termination rule	1	Bracket termination rule 1 is used
Alternate code set allowed	0	Must use Extended Binary Coded Decimal Interchange Code (EBCDIC)
Normal flow send/receive mode	10	Half-duplex flip-flop

Transmission Service and Function Management Profiles

FM Profile 4

Function management (FM) Profile 4 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU types 0 or 1. This profile uses the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server):
    - **CANCEL**
    - **SIGNAL**
    - **LUSTAT**
    - **QEC**
    - **QC**
    - **RELQ**
    - **CHASE***
    - **SHUTD**
    - **SHUTC**
    - **RSHUTD***
    - **BID** and **RTR** (allowed only if brackets are used)
- Length-checked compression allowed

The following FM Usage fields define the options for Profile 4:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- FMH-1 SCB (String Control Byte) Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Brackets usage and reset state
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode

- Recovery responsibility
- Contention winner/loser
- Half-duplex flip-flop reset states

Transmission Service and Function Management Profiles

FM Profile 7

Function management (FM) Profile 7 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 0. This profile uses the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server):
    - **CANCEL**
    - **SIGNAL**
    - **LUSTAT**
    - **RSHUTD***
- Length-checked compression is allowed on LU 0 only.

The following FM Usage fields define the options for Profile 7:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- FMH-1 SCB Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Brackets usage and reset state
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode
- Recovery responsibility
- Contention winner/loser
- Half-duplex flip-flop reset states

Transmission Service and Function Management Profiles

FM Profile 18

Function management (FM) Profile 18 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 0. This profile uses the following session rules:

- PLU and SLU use immediate response mode.
- PLU and SLU support the following data flow control (DFC) commands (an asterisk [*] indicates commands permitted by the FM profile that are never sent by Host Integration Server):
    - **CANCEL**
    - **SIGNAL**
    - **LUSTAT**
    - **BIS** and **SBI** (allowed only if brackets are used)
    - **CHASE***
    - **BID** and **RTR** (allowed only if brackets are used)
- Length-checked compression is allowed.

The following FM Usage fields define the options for Profile 18:

- Chaining use (PLU and SLU)
- Request control mode selection (PLU and SLU)
- Chain response protocol (PLU and SLU)
- FMH-1 SCB Compression indicator (PLU and SLU)
- Send EB indicator (PLU and SLU)
- FM header usage
- Brackets usage and reset state
- Bracket termination rule
- Alternate Code Set Allowed indicator
- Normal-flow send/receive mode
- Recovery responsibility
- Contention winner/loser
- Half-duplex flip-flop reset states

Other Resources

FM Profile 19

Function management (FM) Profile 19 is supported on primary logical unit-secondary logical unit (PLU-SLU) sessions using LU 6.2. This profile specifies the following session rules:

- PLU and SLU use immediate request mode.
- PLU and SLU use immediate response mode.
- Multiple RU chains are allowed.
- PLU and SLU requests indicate definite or exception response.
- No compression is used.
- Brackets are used.
- FM headers (types 5, 7, and 12 only) are allowed.
- Conditional termination for brackets, specified by conditional end bracket (CEB),is used.
- PLU and SLU may send CEB.
- Normal-flow send/receive mode is half-duplex flip-flop.
- Half-duplex flip-flop reset state is SEND for PLU.
- Symmetric error responsibility.
- Contention winner/loser is negotiated at BIND time.
- PLU and SLU support the following data flow control (DFC) commands:
    - **SIGNAL**
    - **LUSTAT**
    - **BIS**
    - **RTR**
- The following combinations of RQE, RQD, CEB, and CD are allowed on end-chain Russ

RQE	CD	CEB
RQD2	CD	CEB
RQD3	CD	CEB
RQE1	CD	CEB
RQD	CD	CEB

The only option for Profile 19 is contention winner/loser.

Option Set Support

The following table lists the option sets supported by Host Integration Server. The reference numbers are those specified in IBM documentation.

Ref No.	Option Set
101	Flush the send buffer of the LU
102	Get attributes
103	Post on receipt with test for posting (supported by asynchronous APPC verbs)
104	Post on receipt with wait (supported by asynchronous APPC verbs)
105	Prepare to receive
106	Receive immediate
109	Get TP name and instance identifier
110	Get conversation type
201	Queued allocation of a contention winner session
203	Immediate allocation of a session
204	Conversations between programs located at the same LU
205	Queued allocation for when session is free
211	Session-level LU-LU verification
212	User ID verification
213	Program-supplied user ID and password
214	User ID authorization
241	Send program initialization parameter (PIP) data
243	Accounting
244	Long locks
245	Test for request-to-send received
246	Data mapping
251	Extract transaction and conversation identification information
290	Logging of data in a system log
291	Mapped conversation LU services component

505	LU definition verbs (operator only)
601	MIN_CONWINNERS_TARGET parameter
602	RESPONSIBLE(TARGET) parameter
603	DRAIN_TARGET(NO) parameter
605	LU-LU session limit
606	Locally known LU names
607	Uninterpreted LU names
610	Maximum RU size bounds
612	Automatic activation limit for contention winner

Host Integration Server Support

SNA Sense Codes

If there is a communication problem during an SNA session, Host Integration Server can generate sense codes that notify the remote system of the type of problem. The sense codes fall into five distinct categories, corresponding to the type of problem that occurred.

Value	Category
X'08'	Request Reject
X'10'	Request Error
X'20'	State Error
X'40'	RH Usage Error
X'80'	Path Error

The following sections list the sense codes by category, and include two additional categories of sense codes:

- Sense codes sent by a 3270 emulator on LUSTAT requests
- Sense codes that can only flow on LU 6.2 sessions

In This Section

Request Reject (Category X'08')

This category indicates that the request was delivered to the intended half session, and was understood and supported, but not executed. The following codes are in this category.

Code	Meaning
0801	Resource not available
0802	Intervention required (LU 1/LU 3 printer soft error)
0805	Session limit exceeded
0809	Mode inconsistency
080A	Permission rejected, NOTIFY will not be sent
080B	Bracket race error
080C	Procedure not supported
0812	Insufficient resources
0814	Bracket bid reject-RTR forthcoming
0815	Function active
081B	Contention race condition
081C	Request not executable (hard error)
0821	Invalid session parameters
0829	Change direction required
082B	Presentation space integrity lost
082D	LU busy (usually local copy print in progress)
082E	Intervention required (local copy print soft error)
082F	Request not executable (local copy print hard error)
0831	LU component disconnected
0843	WCC print command not sent (RQD or RQE, CD, EB)
0845	Permission rejected, NOTIFY will be sent
0863	Referenced character set does not exist
0871	Read partition state error (SLU in retry state)

See Also
Other Resources
SNA Sense Codes

Request Errors (Category X'10')

Sense codes in this category represent an imbalance in half-session capabilities. They indicate that the RU (request/response unit) was delivered to the intended half-session but could not be processed. The following codes are in this category.

Code	Meaning
1003	Function not supported (also used instead of X'0826', which is not supported by Host Integration Server)
1005	Parameter modifying a control function is invalid
1007	Category not supported (SSCP data for host printer)

See Also
Other Resources
SNA Sense Codes

State Errors (Category X'20')

Sense codes in this category indicate a sequence number error, or a request/response header (RH) or request/response unit (RU) that is not allowed in the receiver's current state. This condition prevents delivery of the request to the intended half-session. The following codes are in this category.

Code	Meaning
2001	Sequence number error
2002	Chaining error
2003	Bracket error
2004	Direction error
2005	Data traffic reset
2006	Data traffic quiescent
2007	Data traffic not quiescent

See Also
Other Resources
SNA Sense Codes

RH Usage Errors (Category X'40')

These sense codes indicate that fields in the request/response header (RH) are contrary to SNA rules or previously selected BIND options and prevent the intended half-session from receiving the request.

The checks 400A and 4012 are also performed. These do not permit negative responses because they apply to no-response sessions and responses, respectively.

The following codes are in this category.

Code	Meaning
4006	Exception response not allowed
4007	Definite response not allowed
400F	Incorrect use of format indicator
4011	Incorrect specification of RU category
4014	Incorrect use of DR1, DR2, ER

See Also

Other Resources

SNA Sense Codes

Path Errors (Category X'80')

Sense codes in this category indicate that the request could not be delivered to the required half-session because of path errors. The following codes are in this category.

Code	Meaning
8004	Unrecognized destination field address (DAF)
8005	No session
8006	Invalid format identification (FID): Error detected and logged; negative response not sent
8007	Segmentation error request/response header (RH) not present or too short: negative response sent only for segmentation error
8008	Primary unit (PU) not active: SSCP-PU was not active and request was not ACTPU or DACTPU
8009	Logical unit (LU) not active: DAF specified an LU for which the SSCP-SLU session has not been activated, and request was not ACTLU or DACTLU
800F	Invalid address combination

Other Resources

SNA Sense Codes

LUSTAT Sense Codes

The following sense codes are sent by a 3270 emulator on LUSTAT requests.

Code	Meaning
0001 B000	Host initialized local copy soft error recovery
081C 0000	Soft error changed to hard error (LU 1/LU 3)
081C B000	Soft error changed to hard error (local copy)
082B 0000	SLU session changed from SSCP to PLU (SYSREQ)

SNA Sense Codes

Sense Data Specific to LU 6.2

The LU 6.2 sense codes are specified and interpreted by SNA components within Host Integration Server, and, in general, are presented as return codes and as parameters to specific verbs.

The following sense codes are carried on responses flowing on LU 6.2 sessions.

Code	Meaning
0814	Bracket bid reject RTR forthcoming
0819	RTR not required receiver of RTR request has nothing to send
0835	Invalid parameter request contained a fixed or variable field that is invalid. Bytes 2 and 3 contain a 2-byte binary count which indexes the field error (zero origin)
0846	ERP message forthcoming: The received request was rejected for a reason to be specified in a forthcoming FMH-7 request which itself carries SNA sense data (see the following table for a list of these codes)
088B	BB not accepted BIS reply requested
2010	BIS protocol error receiver detected a BIS error, for example, two BIS replies received

The following data is carried on an FMH-7 request, coming after the flow of a negative response X'0846'.

Code	Meaning
1008 600B	Resource failure no retry
1008 6021	Allocation error TPN not recognized
1008 6031	Allocation error PIP not allowed
1008 6032	Allocation error PIP not specified correctly
1008 6034	Allocation error conversation type mismatch
1008 6041	Allocation error sync level not supported by pgm
080F 6051	Allocation error security not valid
084B 6031	Allocation error trans pgm not available retry
084C 0000	Allocation error trans pgm not available no retry
0864 0000	Deallocate abend prog
0864 0001	Deallocate abend svc
0846 0002	Deallocate abend timer

0889 0000	Prog error no trunc or prog error purging
0889 0001	Prog error trunc
0889 0100	Svc error no trunc or svc error purging
0889 1001	Svc error trunc

SNA Sense Codes

Network Management

This section describes the support that Host Integration Server provides for centralized network management.

In This Section

Connections Used for NetView and RTM

Link Alerts for SDLC and Token Ring

Link Statistics

Alerts Used by Applications, NVAlert, and NVRunCmd

Local Logging of Network Management Data

For information about how to configure Host Integration Server to work with NetView, and information about configuring the NVAlert and NVRunCmd services, see Network Integration User's Guide.

Connections Used for NetView and RTM

Host Integration Server can make use of NetView, a reporting system that runs on an IBM host (mainframe). NetView sends alerts between the host and the PCs that connect to it. Host Integration Server can also receive information from Response Time Monitor (RTM), a 3270 and NetView facility that monitors the amount of time it takes for a host to respond during 3270 display sessions.

To send link alerts, link statistics, and application-generated alerts to the NetView program at the host, you must specify the connection on which the alerts will be sent. See the Host Integration Server online Help for information about specifying the connection.

RTM data and NetView alerts sent to the host by 3270 users are not necessarily sent via the NetView connection. RTM data is sent on the connection for the session to which it refers, while 3270 user alerts are sent on the connection for the currently selected 3270 session.

For information about configuring SNA Management to work with NetView and information about configuring the NVAlert and NVRunCmd services, see Network Integration User's Guide.

Network Management

Link Alerts for SDLC and Token Ring

When a Synchronous Data Link Control (SDLC) or Token Ring connection fails, Host Integration Server logs diagnostic information, called link alerts, about the connection failure. The alerts are logged in a log file that can be viewed using the Windows Event Log service. To find a Host Integration Server log, in the Event Log service, on the Log menu, make sure Application is selected. Under the "Source" heading, the application log file will have a name starting with "SNA."

The link alerts are also used to build a network management vector transport (NMVT) alert, which includes probable causes and suggested actions for the alert. If a connection on the server running Host Integration Server has been designated for NetView, and the connection is active, the NMVT alert will be sent on that connection.

This section includes information that includes an explanation of the general format of link alerts, common to both SDLC and Token Ring, descriptions of individual alerts produced by the SDLC link service, detailed information about the local logging of SDLC alerts, descriptions of individual alerts produced by the Token Ring link service, and details of the local logging of Token Ring alerts.

In This Section

For information about the NetView vectors supported by the NVAlert and NVRunCmd services, see Alerts Used by Applications, NVAlert, and NVRunCmd.

Link Alert Format and Common Subvectors

The general format of link alerts is as follows:

```
NMVT HEADER
41 03 8D 00 00 00 00 00     NMVT Header
Major Vector Header
LL LL     Length of Major Vector
00 00     Alert major vector
```

The specific alert is identified by the alert description and alert ID (part of the generic alert subvector). Common subvectors are listed later in this section. SDLC and Token Ring failure alerts are described in the SDLC Failure Alerts and Token Ring Failure Alerts.

Each subvector or subfield begins with a 1-byte length field and a 1-byte key identifying the subvector or subfield. The length field contains the length in bytes of the entire subvector or subfield, including the length and key bytes. Where the length byte is shown as LL (record length field), this indicates that the length is not fixed because different alerts require different data to be included.

The following table lists all the possible subvectors used in the alert, with their subvector keys (identifiers).

Link alert subvectors

Subvector key (identifier)	Subvector
05	Hierarchy/Resource List Subvector
03	Hierarchy Name List Subvector
01	Date/Time Subvector
10	Product Set ID Subvector (this appears twice, as Alert Sender PSID and Indicated Resource PSID).
51	LAN LCS Data Subvector
52	LCS Configuration Data Subvector
8C	Link Station Data Subvector
91	Basic Alert Subvector
92	Generic Alert Subvector
93	Probable Cause Subvector
94	User Causes Subvector
95	Install Causes Subvector
96	Failure Causes Subvector
A1	Detail Qualifier Subvector

The following tables describe the formats of link alert subvectors. Additional tables, in this section describe the individual link alerts.

Hierarchy/resource list subvector

Format and contents	Description
LL 05	Hierarchy/Resource List Subvector
LL 10	Hierarchy/Resource List Subfield
hh	Flags: 80 (1-User) 00 (Server)
LL	Name field length: name length plus this length byte.
hh...hh	Adapter name in EBCDIC, 8 bytes
00	Flags byte: always 0
3F	Resource type: port
Optional second name	Remote host name. For Token Ring, use the local ring name. See the individual alert descriptions found later in this section.
LL	Name field length: name length plus this length byte.
hh...hh	Name in EBCDIC, up to 8 bytes
00	Flags byte: always 0
F4 or 2E	Resource type: control point or Token Ring.

Hierarchy/name list subvector

Format and contents	Description
LL 03	Hierarchy Name List subvector
00 or 03	Reserved byte
hh	Number of names in the hierarchy name list.
LL	Length of each name, including this length byte.
hh...hh	Name of resource for each name.
D3 C3 D6 D5	Resource type identifier: LCON (logical link connection not known to SNA)

Date/time subvector alerts

Format and contents	Description
0A 01	Date/Time Subvector
08 10	Local Date/Time subfield
hh	Year two digits
hh	Month
hh	Date
hh	Hours

hh	Minutes
hh	Seconds (binary)

Product set ID subvector

Format and contents	Description
2A 10	Product Set ID subvector
00	(unused field)
27 11	Product ID subvector
0C	Product classification: non-IBM software
08 04	Software product common level subfield
F0 F2	Version identifier: 02
F0 F0	Release identifier: 00
F0 F0	Modification identifier: 00
13 06	Software product common name subfield
C4 C3 C1 61 D4 E2 40 C3 D6 D4 D4 40 E2 C5 D9 E5 D9	Product name: Microsoft Host Integration Server
09 08	Software product program number subfield
F0 F0 F0 F0 F0 F0 F0	Product program number: zeros

LAN link connection subsystem data subvector*

Format and contents	Description
LL 51	LAN LCS Data Subvector
04 02	Ring Identifier subfield
hh hh	Ring number
08 03	Local Individual MAC Address subfield
hh...hh	Local individual MAC address
08 04	Remote Individual MAC Address subfield
hh...hh	Remote individual MAC address
LL 05	LAN Routing Information subfield
hh...hh	LAN routing information

* Token ring only.

Link connection subsystem configuration data subvector

Format and contents	Description

LL 52	LCS Configuration Data Subvector
04 01	Port Address subfield
hh hh	Port address
03 02	Remote Device Address subfield
hh	Remote device address
03 04	Local Device Address subfield
hh	Local device address
04 06	Link Station Attributes subfield
01 or 02 or 03	Link station role: Primary, Secondary, or Negotiable
03 or 04	Remote node type: Type 4 or Type 2.1
06 07	Link Attributes subfield
01 or 02	Link connection type: nonswitched or switched
01 or 02	Half-duplex or full-duplex
01	Protocol: SDLC
01 or 02	Point-to-point or multipoint

Link station data subvector

Format and contents	Description
LL 8C	Link Station Data Subvector
04 01	N(s) and N(r) counts subfield
hh	N(s) count
hh	N(r) count
03 02	Outstanding frame count subfield
hh	Outstanding frame count
04 03	Last SDLC Control Field Received subfield
hh hh	Last control field received
04 04	Last SDLC Control Field Sent subfield
hh hh	Last control field sent

03 05	Sequence Number Modulus subfield
80	Sequence number modulus
03 06	Link Station State subfield
80 or 40	Link station state: local or remote station sending RNR
04 07	LLC Reply Timer Expiration Count subfield
hh hh	Reply timer expiration count
03 08	Last Received N(r) Count subfield
hh	Last received N(r) (binary)

Basic alert subvector

Format and contents	Description
0E 91	Basic Alert subvector
00	Not-operator initiated
01	Alert type: permanent
0E	General cause code: link-level protocol error
00 80 or 00 34	Specific component code: Token Ring LAN or SDLC data link control
00 00	Alert description code
00 00	User action code
00 00	Detail text reference code
00	Unused field

Generic alert subvector

Format and contents	Description
0B 92	Generic Alert subvector
00 00	Flags: not operator-initiated, not a held alert
01	Alert type: permanent
hh hh	Alert description: See alert descriptions.
hh hh hh hh	Alert ID number (unique to a particular alert)

Probable cause subvector

Format and contents	Description
LL 93	Probable cause subvector
hh hh	Probable cause: See individual alert descriptions. This alert may include more than one entry.

User causes subvector

Format and contents	Description
LL 94	User Causes Subvector
LL 01	User causes subfield
hh hh	User cause: See individual alert descriptions. More than one entry may appear here.
LL 81	Recommended actions subfield
hh hh	Recommended action: See individual alert descriptions. More than one entry may appear here.
03 83	Product set ID index subfield
99	Product Set ID index
LL 82	Detailed data subfield. This subfield may appear more than once.
99	Product Set ID code
hh	Data ID: See individual alert descriptions.
00	Data encoding: hexadecimal
hh...hh	Detailed data: See individual alert descriptions.

Install cause subvector

Format and contents	Description
LL 95	Install Causes Subvector
LL 01	Install causes subfield
hh hh	Install cause: See individual alert descriptions. More than one entry may appear here.
LL 81	Recommended actions subfield
hh hh	Recommended action: See individual alert descriptions. More than one entry may appear here.
03 83	Product set ID index subfield
99	Product Set ID index
LL 82	Detailed data subfield. This subfield may occur more than once.
99	Product Set ID code
Hh	Data ID: See individual alert descriptions.
00	Data encoding: hexadecimal
Hh...hh	Detailed data: See individual alert descriptions.

Failure cause subvector

Format and contents	Description

LL 96	Failure Causes Subvector
LL 01	Failure causes subfield
hh hh	Failure cause: See individual alert descriptions. More than one entry may appear here.
LL 81	Recommended actions subfield
hh hh	Recommended action: See individual alert descriptions. More than one entry may appear here.
03 83	Product set ID index subfield
99	Product Set ID index
LL 82	Detailed data subfield. This subfield may occur more than once.
99	Product Set ID code
hh	Data ID: See individual alert descriptions.
00	Data encoding: hexadecimal
hh...hh	Detailed data: See individual alert descriptions.

Detail qualifier (hexadecimal) subvector

Format and contents	Description
06 A1	Detail Qualifier subvector
hh hh hh hh	Detail Qualifier subfield four bytes as follows: Token ring: adapter number Alert number Two-byte error code SDLC: link ID Station address, outage

SDLC Failure Alerts

The tables in this section describe the alerts generated by the SDLC link service provided with Host Integration Server. The alerts are listed in numerical order by alert description and within each description in numerical order by alert ID.

Write timeout alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	61D0 2E7B	
Probable causes:	2031	Line
	3601	Local modem
	2200	Remote node
	3603	Remote modem
Failure causes:	3511	Line
	3601	Local modem
	2200	Remote node
	3603	Remote modem
	F034	CTS failed to rise
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	2E	Write timeout retry exceeded

Abnormal modem response alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	70A1 5CB0	
Probable causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
User causes:	3401	Cabling installed incorrectly
Recommended actions:	0301	Check cable and its connections

Failure causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
	F035	DSR dropped
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	2D	Abnormal response

DSR failure alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	83BB 6EC8	
Probable causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
User causes:	3400	Cable loose
	0205	Local modem power off
Failure causes:	3601	Local modem
	3401	Local cable
	3302	Communications adapter
	F035	DSR dropped
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	11	DSR failure

DCD failure alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1000	Equipment malfunction
Alert ID:	C3BB 504A	

Probable causes:	2031	Line
	3601	Local modem
Failure causes:	3511	Line
	3601	Local modem
	F038	Carrier detect lost
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	14	DCD failure

Invalid frame received: i-field not permitted alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	1103 D152	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F021	I-field received when not permitted
Recommended actions:	2011	Review hexadecimal display of alert report
	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	87	Invalid frame received

Invalid frame received: invalid/unsupported cmd/rsp alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	15C2 CCE5	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F020	Invalid/unsupported command or response received.
Recommended actions:	2011	Review hexadecimal display of alert

	32A0	Report the following detail qualifier: Outage qualifier
Detail qualifier:	87	Invalid frame received

Invalid frame received: invalid n(r) received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	1C40F78B	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F022	Invalid N(R) received
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	87	Invalid frame received

RIM/RD received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	29BF 0032	
Probable causes:	2104	SDLC communications/remote node
	1023	Communications program in remote node
Failure causes:	2104	SDLC communications/remote node
	3511	Line
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	88	RIM received
	89	RD received

Invalid frame received: max i-field length exceeded alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	5F76 24FD	
Probable causes:	2104	SDLC communications/remote node

	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F023	Received I-field exceeded maximum length
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	87	Invalid frame received

FRMR received: no reason given alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	A472 BC48	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F014	FRMR received: no reason specified
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: i-field received when not permitted

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	B3B7 D723	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F011	FRMR received: I-field sent when not permitted
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: invalid/unsupported command or response alert

Name of subvector	Hexadecimal value in subvector	Description

Alert description:	2100	Software program error
Alert ID:	B776 CA94	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F010	FRMR received: invalid/unsupported command or response sent
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: max i-field length exceeded alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	BA35 EC4D	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F013	FRMR received: maximum I-field length exceeded
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

FRMR received: invalid n(r) sent alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	BEF4 F1FA	
Probable causes:	2004	SDLC communications
	1000	Software program
Failure causes:	1000	Software program
	F012	FRMR received: invalid N(R) sent
Recommended actions:	2011	Review hexadecimal display of alert

	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	86	FRMR received

DISK/SNRM received: snrm received in nrm alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	D635 CA1E	
Probable causes:	2004	SDLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F015	SNRM received while in NRM
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	15	Connection terminated by host

CTS failure alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	0231 CF0A	
Probable causes:	2031	Line
	3601	Local modem
Failure causes:	3511	Line
	3601	Local modem
	F030	CTS dropped
Recommended actions:	0403	Run modem tests
	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	12	CTS failure

Connection problem: xid (exchange identification) retransmission alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	0AEC C2A6	

Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F018	XID poll count exhausted

Idle timeout alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	0E2D DF11	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F019	Inactivity timer expired
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	25	Idle timeout retry exceeded

Poll count exhausted alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	32A3 7F1B	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power

Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F017	Poll count exhausted
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	81	Disconnect retry limit
	82	Contact retry limit
	83	Poll retry limit
	84	No response retry limit

Remote busy retry alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	66D6 DA74	
Probable causes:	2104	SDLC communications/remote node
User causes:	0209	Remote device power off
Recommended actions:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F00F	RNR received threshold reached
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	85	Remote busy retry limit

DM Received in Information Transfer Alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	BD84 C4C9	
Probable causes:	2004	SDLC communications
Failure causes:	2004	SDLC communications
	F01A	DM received

Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	80	DM received

Nonproductive receive timeout alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	C458 E284	
Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F00E	NPR timeout retry limit reached
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	24	Nonproductive receive retry exceeded

DISK/SNRM received: disk received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	D9C4 172B	
Probable causes:	2004	SDLC communications
Failure causes:	2004	SDLC communications
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	15	Connection terminated by host

Connection problem: i-frame retransmission alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3300	Link error
Alert ID:	E3DA E42F	

Probable causes:	2104	SDLC communications/remote node
	2031	Line
User causes:	0209	Remote device power off
Recommended action:	0200	Check power
Failure causes:	2104	SDLC communications/remote node
	3511	Line
	F06A	Transmit retry limit reached
Recommended actions:	2011	Review hexadecimal display of alert
	32A0	Report the following detail qualifier: Outage qualifier.
Detail qualifier:	29	Connection problem

Link Alerts for SDLC and Token Ring

SDLC Alert Local Logging

Before Host Integration Server attempts to build and send an SDLC link alert, information about the outage that caused the alert is recorded in a log file that can be viewed using the Windows Event Log service. Message 182 is always logged, as follows:

```
182I:  Connection failure, code = (outagecode)
Cause Data                          = hh...hh
Link Role                           = hh
Remote Node Type                    = hh
```

The Outage Code (outagecode) is also reported on Message 23. For a complete list of these codes, the conditions they represent, and the specific link alerts on which they are used, see the next section.

Cause Data is a list of the failure causes from the Failure causes subvector in the alert. Link Role and Remote Node type are as described in the Link Connection Subsystem Configuration Data subvector in the alert.

A connection failure can be due to a station outage, rather than a link outage. If it is due to a station outage which can be recognized by outage code values of X'80' or higher then Message 183, formatted as follows, is also logged:

```
183I:
Detailed diagnostic data for station (stationaddress):
SBSY   CFTX   CFRX   V(S)   V(R)   N(R)   OSFC   T1CT
hh   hhhh   hhhh   hh     hh     hh     hh     hhhh
```

The value (stationaddress) is the station address as given in the Detail qualifier subvector in the alert.

The other fields are all data from the Link Station Data subvector, as follows:

Field	Description
SBSY	Link station state: 80 or 40
	(local or remote station sending RNR)
CFTX	Last SDLC control field sent
CRX	Last SDLC control field received
V(S)	N(S) count
V(R)	N(R) count
N(R)	Last received N(R)
OSFC	Outstanding frame count
T1CT	Reply timer expiration count

Link Alerts for SDLC and Token Ring

Identifying Alerts from Local Logs Only

When only the local log of an alert is available, you can still obtain the information that would have been supplied on the alert. To do this, check the outage code given on Message 182 against the following list. Find the alert that uses this outage code, and then check the alert data in SDLC Failure Alerts. Some Outage Codes are used for more than one alert. In these cases, you can find the appropriate alert by comparing the Failure causes codes given on Message 182 with those given in the alert data.

SDLC outage codes

Outage code	Condition	Alert description/ID
11	DSR failure	1000 : 83BB6EC8
12	CTS failure	3300 : 0231CF0A
14	DCD failure	1000 : C3BB504A
15	Connection terminated by host	2100 : D635CA1E 2100 : D9C4172B
24	Nonproductive receive retry exceeded	3300 : C458E284
25	Idle timeout retry exceeded	3300 : 0E2DDF11
29	Connection problem	3300 : 0AECC2A6 3300 : E3DAE42F
2D	Abnormal response	1000 : 70A15CB0
2E	Write timeout retry exceeded	1000 : 61D02E7B
80	DM received	3300 : BD84C4C9
81	Disconnect retry limit	3300 : 32A37F1B
82	Contact retry limit	3300 : 32A37F1B
83	Poll retry limit	3300 : 32A37F1B
84	No response retry limit	3300 : 32A37F1B
85	Remote busy retry limit	3300 : 66D6DA74
86	FRMR received	2100 : A472BC48
		2100 : B3B7D723
		2100 : B776CA94
		2100 : BA35EC4D
		2100 : BEF4F1FA
87	Invalid frame received	2100 : 1103D152
		2100 : 15C2CCE5
		2100 : 1C40F78B
		2100 : 5F7624FD
88, 89	RIM or RD received	2100 : 29BF0032

Link Alerts for SDLC and Token Ring

Token Ring Failure Alerts

The tables in this section describe the alerts generated by the Token Ring link service provided with Host Integration Server. The alerts are listed in numerical order by alert description and within each description in numerical order by alert ID.

Adapter check error: adapter error alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	1010	Adapter error
Alert ID:	3BA0 3B6D	
Probable causes:	3320	Local Token Ring adapter
Failure causes:	3320	Local Token Ring adapter
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 02):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	02	Data ID: adapter check status
	hh hh	Adapter check status
LAN LCS:		Ring identifier Local individual MAC address

DLC status error: frmr sentinvalid N(R) received

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name.
Alert description:	2100	Software program error
Alert ID:	216D 1033	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F012	Invalid N(r) received
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number

	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR sentreceived i-field exceeded maximum length alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	25AC 0D84	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F023	Received I-field exceeded maximum length
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR sentinvalid/unsupported command/response received alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	28EF 2B5D	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node

	F020	Invalid/unsupported command or response received
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR senti-field received when not permitted alert

Name of subvector	**Hexadecimal value in subvector**	**Description**
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	2C2E 36EA	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F021	I-field received when not permitted
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

Adapter command error: software alert

Name of subvector	**Hexadecimal value in subvector**	**Description**

Alert description:	2100	Software program error
Alert ID:	3EF7 89B7	
Probable causes:	1000	Software program
Failure causes:	1000	Software program
Recommended actions:	30E1	Contact service representative
	32C0	Report the following data:
		Product Set ID index subfield included
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	03	Data ID: adapter return code
	hh	Adapter return code

DLC status error: dm or disk received alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	4B74 26FB	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F01A	DM received
Recommended actions:	3301	If problem persists, do the following:
	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR receivedinvalid N(R) sent alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list		Second name is remote node CP name

Alert description:	2100	Software program error
Alert ID:	83D9 1642	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000 F012	Software program Frame reject received: Invalid N(r) sent
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR receivedmax I-field length

Name of subvector	**Hexadecimal value in subvector**	**Description**
Hierarchy/resource list:		Second name is remote node CP name.
Alert description:	2100	Software program error
Alert ID:	8718 0BF5	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000	Software program
	F013	Frame reject received: maximum I-field length exceeded
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number

LAN LCS:		Ring identifier Local individual MAC (Media Access Control) address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR receivedinvalid/unsupported commands/response sent alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	8A5B 2D2C	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000	Software program
	F010	Frame reject received: Invalid/unsupported command or response sent
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

DLC status error: FRMR received

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name
Alert description:	2100	Software program error
Alert ID:	8E9A 309B	
Probable causes:	2007	LAN LLC communications
	1000	Software program
Failure causes:	1000	Software program
	F011	Frame reject received: I-field sent when not permitted

Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

Software program error: adapter interface alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	2100	Software program error
Alert ID:	DA7B C09D	
Probable causes:	3220	Token ring adapter interface
Install causes:	1600	Mismatch between software and microcode
	1601	Incorrect customization image
Recommended actions:	1500	Correct installation problem
	1502	Correct customization parameters
Failure causes:	3220	Token ring adapter interface
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Ring identifier Local individual MAC address

DLC status error: SABME received for open link station alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is remote node CP name

Alert description:	2100	Software program error
Alert ID:	E65B 0B7F	
Probable causes:	2007	LAN LLC communications
	1023	Communications program in remote node
Failure causes:	1023	Communications program in remote node
	F016	SABME received while in ABME
Recommended actions:	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32A0):
	2010	Review link detailed data
	3103	Contact LAN administrator responsible for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
LAN LCS:		Ring identifier Local individual MAC address Remote individual MAC address LAN routing information
LCS configuration:		Remote device address Local device address
Link Station Data subvector included		

Bring-up error alert

Name of subvector	**Hexadecimal value in subvector**	**Description**
Alert description:	3210	Initialization failure
Alert ID:	AB86 8B0B	
Probable causes:	3320	Local Token Ring adapter
Install causes:	1200	Incorrect hardware configuration
	1402	Mismatch between hardware and software configurations
Recommended actions:	1503	Correct configuration
Failure causes:	3320	Local Token Ring adapter
Recommended actions:	30E1	Contact service representative
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code

LAN LCS:		Local individual MAC address

Adapter open error: open failure alert

Name of subvector	Hexadecimal value in subvector	Description
Hierarchy/resource list:		Second name is ring name
Alert description:	3211	Open failure
Alert ID:	016E 5F4E	
Probable causes:	3702	Token ring lobe
	3701	Token ring LAN component
Failure causes:	3712	Local Token Ring lobe
	3701	Token ring LAN component
	2600	Interference
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: remove command received alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	44D1 AD86	
Probable causes:	3705	Token ring remove command received
User causes:	3320	Token ring remove adapter command received
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code

	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: problem on local lobe alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	55BF 3E1C	
Probable causes:	3702	Token ring lobe
Failure causes:	3320	Local Token Ring adapter
	3711	Local Token Ring lobe
	3434	Local lobe cables
Recommended actions:	1009	Try reopening adapter after 30 seconds
	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3103, or 32C0):
	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

Adapter open error: beaconing detected alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	CAF3 C58A	
Hierarchy/resource list:		Second name is ring name
Probable causes:	3703	Token ring fault domain
Failure causes:	3703	Token ring fault domain
Recommended actions:	1009	Try reopening adapter after 30 seconds
	3301	If problem persists, do the following (available messages correspond to subvectors 2010, 3101, or 32C0):
	2010	Review link detailed data

	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code

Adapter open error: duplicate address alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	D615 A61E	
Probable causes:	3704	Token ring duplicate station address
Install causes:	3704	Token ring duplicate station address assigned
Recommended actions:	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32C0	Report the error information described by the detailed data subvector (hex values 61 and 07):
Detailed data:	61	Data ID: adapter number
	hh	Adapter number
Detailed data:	07	Data ID: error code
	hh hh	Error code
LAN LCS:		Local individual MAC address

System action: operator caused LAN adapter to be reset alert

Name of subvector	Hexadecimal value in subvector	Description
Alert description:	3211	Open failure
Alert ID:	F7A6 2F59	
Probable causes:	7001	Resources not active
User causes:	3300	Adapter not ready
Recommended actions:	1300	Correct then retry
	2010	Review link detailed data
	3101	Contact Token Ring administrator for this LAN
	32A0	Report the error information described by the detailed data subvector (hex value 61):
Detailed data:	61	Data ID: adapter number

Link Alerts for SDLC and Token Ring

Link Statistics

For SDLC (Synchronous Data Link Control) and Token Ring connections, Host Integration Server maintains statistics on link usage and errors. Host Integration Server logs this information when a connection ends or when the counter for a particular error or timeout reaches its maximum value.

This section contains:

Format for Link Statistics

When an SDLC or Token Ring connection ends, or when an error counter reaches its maximum value, Host Integration Server records statistics on link usage. These statistics include information such as the adapter number, the date and time the link was established, and the counts of errors and timeouts. This data is also logged in NMVT (network management vector transport) format if a connection has been specified for carrying NetView data. The data is then sent if that connection and the server that owns the connection are both active.

This section contains:

SDLC Link Statistics

Link statistics are generated when a link is closed or when one of the wrap counters listed later in this section is about to wrap. Whenever a link statistics message is built, all the wrap counters are reset to 0. The cumulative counters are not reset; they provide statistics from the point at which the particular link service was started.

The NMVT generated has the following format:

NMVT header	
41 03 8D 00 00 00 00 00	NMVT Header

Major vector header	
00 69	Length of major vector
00 25	Link statistics major vector

Data link traffic counters subvector	
65 9A	Data Link Traffic Counters subvector
03	DLC type: SDLC
hh	Adapter number (01+04)

Date/time link established	
hh	Date
hh	Month
hh hh	Year
hh	Hour
hh	Minute
hh	Second
hh	Hundredths of a second
hh	Counter

Wrap counters	
hh	Transmit I-frames OK
hh	Transmit I-frames not OK
hh	Retransmit I-frames
hh	Received I-FCS OK
hh	Received I-FCS not OK
hh	Total frames sent

00	Reserved
hh	Lost data frames received
hh	FRMR conditions sent
00	Reserved
hh	CTS drop
00	Reserved
00	Reserved
hh	DSR drop out
hh	Inactivity timeouts
00	Reserved
hh	DMA underruns
00	Reserved
hh	Transmit fail timeouts
00	Reserved

Cumulative Counters

The cumulative counters are the same counters as the wrap counters, with reserved bytes in the same positions.

Alerts Used by Applications, NVAlert, and NVRunCmd

Application programs and the NVAlert and NVRunCmd services can generate alerts using the Common Service Verb (CSV) **TRANSFER_MS_DATA**. An application or service can supply subvectors, which are required to build an NMVT, or it can supply the complete NMVT. In both cases, the completed NMVT is logged locally, and may also be sent on the connection designated for NetView if the connection is configured and active. An application or service can also supply user-defined alert data, in which case the data is logged locally but cannot be sent.

This section contains:

Format for Alerts Used by Applications, NVAlert, and NVRunCmd

An application program or the NVAlert and NVRunCmd services can use the CSV **TRANSFER_MS_DATA** to issue alerts. The alerts are logged in a log file that can be viewed using the Windows Event Log service, and may also be sent on the NetView connection.

The data supplied to **TRANSFER_MS_DATA** may be in any of the following formats:

NMVT

The application or service supplies a complete NMVT, including the header information.

ALERT_SUBVECTORS

The application or service supplies the subvectors required for an alert, but without the NMVT header or major vector header. Host Integration Server adds the header information, as described in the next section.

PDSTATS_SUBVECTORS

The application or service supplies the subvectors required for a Problem Determination Statistics NMVT, but without the NMVT header or major vector header. Host Integration Server adds the header information, as described in the next section.

USER_DEFINED

The application or service supplies data in its own format. This data cannot be sent on the connection designated for NetView, but is logged in the same way as the other data formats.

The application or service can also request Host Integration Server to add the Product Set ID subvector (for all data types except USER_DEFINED), the Date/Time subvector, or both to the supplied data. The format of these added subvectors is described in the next section.

For all data types, the data (with added headers and subvectors, if appropriate) is logged locally in NMVT format, whether or not you specified a connection for NetView.

Local Logging of Network Management Data

Data is logged in a Windows Event Log service log file in two ways. First, the data from the alert is logged in a more readable format, using standard log messages. The format is specific to the alert type. For the message numbers used and explanations of the data, see the section in this documentation that relates specifically to that type of alert.

If a connection has been designated for carrying NetView data and the server that owns the connection is active, the alert NMVT containing the data is also logged in NMVT format as it would be sent. The NMVT appears as Message 540, followed by Message 541. Note that this logging occurs before Host Integration Server attempts to send the NMVT. The log is therefore no guarantee that the NMVT is sent successfully.

For more information about local logging of alert information, see the section in this documentation relating specifically to that type of alert.

Network Protocols and Client/Server Communication

This section explains how clients using different local area network (LAN) protocols can communicate with Host Integration Server computers. The section includes an overview of how network protocols are used on clients, and how client logons work. Also included are procedures for checking the setup options for Host Integration Server specified on a client or server. These setup options must be specified correctly in order for the client to communicate with a Host Integration Server computer. You will also find descriptions and illustrations of how clients using each of the possible protocols locate a Host Integration Server computer in the network.

In This Section

Overview of Network Protocols for Clients

Host Integration Server clients can communicate with servers through the following LAN protocols:

- Microsoft Networking (Named Pipes)
- IPX/SPX (the protocol used with NetWare)
- TCP/IP

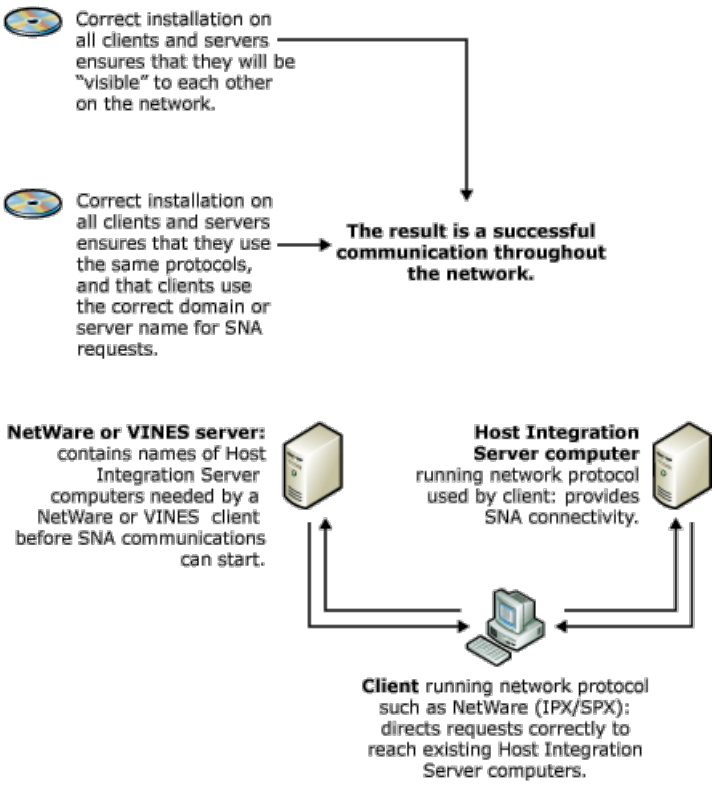
Important
In order for the different client/server protocols to be handled correctly by Host Integration Server, both clients and servers must have the network software and the Host Integration Server software installed correctly. Be sure to follow the installatio n instructions in this section carefully, and follow the installation instructions for other software you are using for example, W indows 2000 Server and the associated network software, Host Integration Server, and network software on clients.

Correct installation of network and Host Integration Server on servers and clients ensures that two essential aspects of communication work correctly:

- The servers and clients are visible to each other on the local area network (LAN). This results when the network software is installed correctly on all affected computers.
- The Host Integration Server computers communicate with clients over the correct LAN protocol, and the clients direct their communication to the correct domain name or, for some clients using Microsoft Networking or TCP/IP, to one or more correct server names. A Host Integration Server client must be set up to use the correct server or domain name or, for Microsoft Networking, set up to locate servers in the local domain. Otherwise, the client will not be able to locate a Host Integration Server computer.

For example, in order for a client to successfully communicate over Novell NetWare, there must be working communication between the client, a NetWare server, or a Windows Server running Microsoft File and Print Services for NetWare and any Host Integration Server computers in the network. Either server provides the client with names of Host Integration Server computers. In addition, for clients running NetWare 4.*x*, bindery emulation must be enabled. The following figure illustrates how correct installation is necessary for successful communication:

Diagram and explanation of how correct installation results in successful communication



For information about how Host Integration Server enables you to view and choose the domain and protocols to be used by Host Integration Server computers and clients, see Important Network Options on a Host Integration Server Computer. For details about how each of the network protocols works on a Host Integration Server client, see the section about that specific network protocol (for example, Clients Using TCP/IP).

In This Section

Client Logons and the Storing of Passwords

Types of Client Logons

Client Logons and the Storing of Passwords

For security reasons, a user at a client computer may have to log on several times before obtaining access through Host Integration Server to a mainframe or AS/400. Users may not always find this to be convenient. The logons are necessary because starting an SNA session requires several kinds of access: access to the Windows domain, access to a Host Integration Server computer, access to the mainframe or AS/400 and, possibly, access to programs on the mainframe or AS/400. An example of such a program is an AS/400 program that uses conversation security when communicating with 5250 emulators. Each layer of access may require an additional logon depending on the operating system and the client/server protocol used on the client.

The Host Security Integration feature of Host Integration Server can reduce or even eliminate these multiple logons on Windows -based networks. If you are not able to take advantage of this feature, users can avoid multiple logons by following the procedures outlined in the following sections.

See Also

Concepts

Types of Client Logons

Types of Client Logons

The number of logons required for establishing an SNA session from a client varies, depending mostly on what client/server protocol the client computer is using. The following list describes the logons:

Clients Using Microsoft Networking

A client using Microsoft Networking must log on to the Windows domain and then must perform any logons required on the mainframe or AS/400. For example, a client using Microsoft Networking and also using a 5250 emulator would log on once to the Windows domain, once to the AS/400 itself, and (in many cases) once to the AS/400 program that communicates with the 5250 emulator.

After clients using Microsoft Networking are logged on to the domain, no additional logon is needed for access to Host Integration Server computers in the domain. That is, Host Integration Server can securely confirm the domain logon without any additional action by the user.

Clients Using Novell NetWare

A client using NetWare must first log on to the NetWare network and then to the Host Integration Server computers. Finally, the client must perform any logons required on the mainframe or AS/400

Clients Using TCP/IP

A client using TCP/IP must log on to the Host Integration Server computers even if the client has already accessed other resources in the Windows domain, and then must perform any logons required on the mainframe or AS/400.

Overview of Network Protocols for Clients

Important Host Integration Server Network Options

The following two sections illustrate and describe important Host Integration Server network options for a Host Integration Server server or client. These options must be set correctly in order for clients to locate Host Integration Server computers and start sessions. If the options are set incorrectly, clients may use the wrong protocols or may search the wrong locations for Host Integration Server computers.

In This Section

Important Network Options on a Host Integration Server Computer

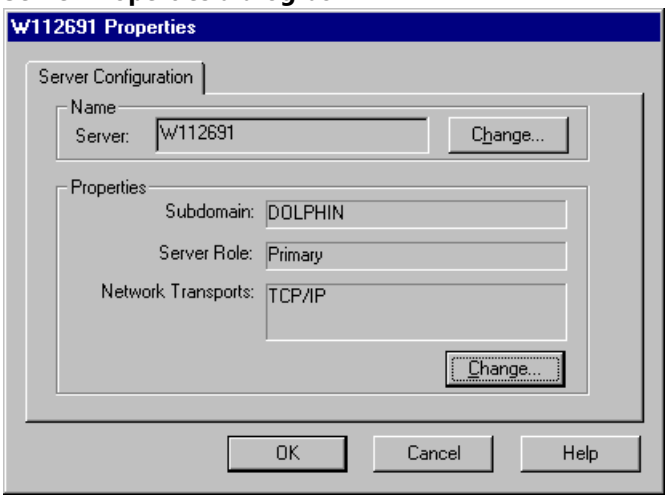
When Host Integration Server network options are specified correctly on a Host Integration Server computer, the server will use the appropriate protocol(s) for communicating with clients. Servers supporting NetWare, TCP/IP, or Microsoft Networking will have the correct domain name so that clients can locate the Host Integration Server computers.

Important
These changes do not take effect until the server is restarted. Do not change these settings while the server has active users.

To view or change client/server protocols and other network options on a Host Integration Server computer

1. In SNA Manager, select a Host Integration Server computer.
2. Right-click a server and then click **Properties**. The **Server Properties** dialog box appears.

   Server Properties dialog box

3. To change the Host Integration Server computer name, click **Change** in the **Name** box. The Host Integration Server computer must be in an off-line state before you can change the name.
4. To modify the client/server protocols and other network options, click **Change** in the **Properties** box, and then click **OK**.
5. Complete the Server SNA Resource wizard.

Note
If the server has TCP/IP installed and will communicate with clients that use TCP/IP, be sure that the selections in the Select Client/Server Protocols dialog box include TCP/IP. If Microsoft Networking (Named Pipes) is selected and TCP/IP is not, the server can communicate through Named Pipes over TCP/IP, a protocol combination that does not recover from error conditions as effectively as native TCP/IP.

If TCP/IP is selected, you can also select Microsoft Networking. In this situation, the Host Integration Server computer will use native TCP/IP with clients that use TCP/IP, and Microsoft Networking with clients that use Microsoft Networking.

Important Host Integration Server Network Options

Important Network Options on a Client

For Host Integration Server client software, several key options supply the information a client must have for locating Host Integration Server computers. These options specify which protocol the client uses to communicate with Host Integration Server computers if more than one protocol is available on the client, and which domain or server names the client will direct SNA requests to.

When a client makes an SNA request, the client must direct that request to a domain or to one or more Host Integration Server computers. The appropriate way for a client to direct requests depends on the protocol used and the relative location of clients and servers. The following table lists the ways clients direct SNA requests, and the information that will be requested by setup during client installation. For more detail about how a client directs requests and locates Host Integration Server computers, see the section about the appropriate type of client (for example, Clients Using TCP/IP).

Network protocol used on client	**How the client directs SNA requests**	**Information to find out before running client setup**
Microsoft Networking	Either to the local domain (if the Host Integration Server computers are in the same domain as the client), or to one or two specific Host Integration Server computers in a remote domain.	Whether the client is in the same domain as the Host Integration Server computers, and if not, one or two names of Host Integration Server computers.
Novell NetWare (IPX/SPX)	To a specific domain. The Host Integration Server computers must be located in this domain in order for the client to locate them.	The name of the Host Integration Server subdomain in which the Host Integration Server computers are located.
TCP/IP	Either to a domain name or to specific server name, depending on what is specified in the Host Integration Client Mode or Host Integration Server Location dialog box.	Contact your network administrator for additional information regarding a specific IP address for the Host Integration Server computer.

Important Host Integration Server Network Options

Adjusting Clients Running Windows for Workgroups

Clients running Windows for Workgroups have a very flexible set of options for network operation. As a result, these clients may require specific adjustments in order to communicate with Host Integration Server computers.

Clients running Windows for Workgroups and using Microsoft Networking (not other network software) must use domain and password settings that coordinate with settings in Host Integration Server Setup. For example, if the client's workgroup name does not match the server's domain name, options in Host Integration Server Setup must be set accordingly.

In This Section

Domain and Password Settings for Clients Running Windows for Workgroups

This section applies only to clients running Windows for Workgroups and using Microsoft Networking to communicate with Host Integration Server computers. Such clients must be configured so that any domain names, workgroup names, local passwords, and domain passwords all work together smoothly.

In This Section

Domain Settings with Windows for Workgroups

For domain names and workgroup names, use one of the following approaches:

- **Workgroup name differs from Host Integration Server domain name.**

  For clients where the workgroup name must be different from the server's domain name (the name of the Windows domain), in Host Integration Server Client Setup, you must use the Remote Domain setting. That is, in the Host Integration Server Location dialog box, select Remote Domain, and supply the name of one or two Host Integration Server computers to which the client will send requests.

  To view a client's workgroup name, in Control Panel, double-click the Network icon. The name is listed in the resulting dialog box.

- **Workgroup name matches Host Integration Server domain name.**

  For clients where the workgroup name is the same as the server's domain name (the name of the Windows domain), in Host Integration Server Client Setup, you can use the Local Domain setting. That is, in the Host Integration Server Location dialog box you can select Local Domain. When the client requests an SNA session, the request will reach the domain that has the same name as the client's workgroup.

  To view a client's workgroup name, in Control Panel, double-click the Network icon. The name is listed in the resulting dialog box.

Tasks
Password Settings with Windows for Workgroups

Password Settings with Windows for Workgroups

For Windows for Workgroups passwords and domain passwords, use one of the following approaches:

- **Enable logon to the Windows domain automatically at startup.** You can configure Windows for Workgroups to log the user on to the Windows domain automatically at startup.To do this, first make sure that a user account has been created for the user in the Windows domain, and obtain the assigned user name and password.

To configure Windows for Workgroups to logon to the Windows domain automatically at startup

1. On the client computer, from the Control Panel, double-click the **Network** icon and then click **Startup** .
2. In the **Startup Settings** dialog box, under **Options for Enterprise Networking**, find the check box labeled **Log On to Windows or LAN Manager Domain**. Select this check box, and type the domain name in the appropriate box.
3. Choose **OK** repeatedly until the dialog boxes are closed.

The next time Windows for Workgroups is restarted, the user will be prompted for both the local password and the domain password, and must type them correctly. Thereafter, only the local password is needed at startup, because the domain password is encrypted and stored (to be "unlocked" by the local password).

After domain logon has been set up, it is important for the user to understand the difference between the local Windows for Workgroups password and the actual domain password. The local Windows for Workgroups password unlocks the encrypted password list that has been stored for that user on that computer. This password list includes a copy of the domain password if the preceding configuration steps have been taken. The actual domain password is the password for that user's account on the Windows domain, as recorded on Windows servers that are domain controllers.

The user's domain account may be set up to require periodic changing of the password. If the domain password expiration date is getting close, when the user logs on to the domain, pop-up warnings will appear on the user's computer. Note that the user must try to log on in order for the pop-up warnings to appear. At this point, the user needs to understand the different buttons used for changing passwords with Windows for Workgroups. After choosing the Network option from the Control Panel, click the Password button. This only changes the password to unlock the user's local password list; it does not change the domain password.

To change the domain password, the user must choose the Startup button followed by the Set Password button. When the user changes the domain password using the Set Password button, the domain password is also changed in the local password file.

Make sure that users understand how to use these buttons correctly to change their local Windows for Workgroups password and to change their Windows domain password.

- **Log on only as needed, by using the net logon command.** If the user does not log on to the Windows domain at startup, the following command can be used before starting an SNA session. At the MS-DOS prompt (from within Windows for Workgroups), type

  net logon *username* **/domain:***domainname*

  After typing the command, the user is prompted for the domain password.

Domain Settings with Windows for Workgroups

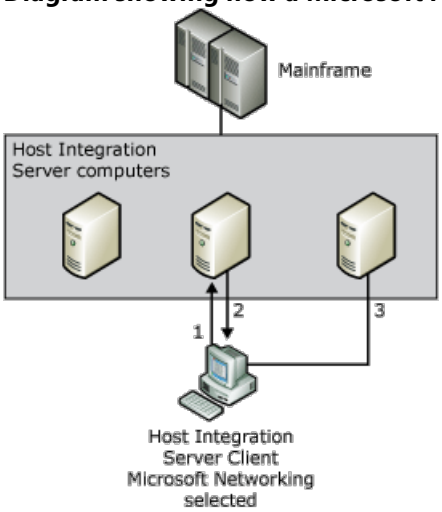
Details about How Clients Use Protocols

The following sections describe how each type of client works with Host Integration Server. The clients are listed according to the protocol used: Microsoft Networking (Named Pipes), Novell NetWare (IPX/SPX), and TCP/IP.

In This Section

Clients Using Microsoft Networking (Named Pipes)

Diagram showing how a Microsoft Networking client can connect to the mainframe



A Microsoft Networking (Named Pipes) client uses the following procedure for connecting to the mainframe:

1. You can choose between two methods by which a client searches for Host Integration Server computers.

   - Active Directory
   - Sponsor connections, locating servers by SNA subdomain or by server name.

   Client locates servers by subdomain means that the client locates the server through broadcasts in the local subdomain. Therefore, the client must be in the same physical network as the Host Integration Server computers, and must not be separated from the servers by a router.

   Client locates servers by name means that the client searches for Host Integration Server computers by name, and therefore need not be on the same side of any routers as the Host Integration Server computers. When connecting with Named Pipes over TCP/IP, and there is a router separating the Host Integration Server computer and the client, the client computer requires a method of resolving NetBIOS names to an IP address. A local LMHOSTS file or a Windows Internet Name Service (WINS) server may be used to perform this resolution.

Note
If Windows for Workgroups 3.11 is being used and the Microsoft IPX/SPX compatible transport is installed, add **Direct host=no** to the [network] section of SYSTEM.INI file on the Windows for Workgroups 3.11 client computer, and then r eboot the computer.

   If this is a routed network, Named Pipes is not recommended. TCP/IP is the recommended interface for this environment.

2. The Host Integration Server computer responds with a list of available Host Integration Server computers that are available to get a 3270 or APPC session with. This special connection is called the sponsor connection.

3. Finally, the client attempts to connect to each Host Integration Server computer in the list until a server is found that can handle the 3270 or APPC request.

Tasks

Microsoft Networking (Named Pipes) Errors

Microsoft Networking (Named Pipes) Errors

NAMED PIPES 5
Causes

One of the following has occurred:

- Access has been denied trying to create a connection to the Host Integration Server computer. The client/server interface connects to the Host Integration Server computer just like any other local area network (LAN) connection. It must be validated by Windows as a valid user in the domain.

- The Host Integration Server computer is unreachable. If using TCP/IP this could mean that the name to IP address resolution has failed.

NAMED PIPES 2
Causes

The client has connected to the Host Integration Server computer, but the SNABase service is not running on that machine. Start the SNABase service on the Host Integration Server computer to which you are trying to connect.

NAMED PIPES 121
Causes

The client is configured for **Client locates servers in an Host Integration Server 2009 Subdomain** and therefore, is sending out broadcast messages to discover a Host Integration Server computer. These broadcast messages will typically not be passed by a router that may be between your client and the server. In the client configuration select **Client locates server by name** and specify an IP address or computer name of one or more Host Integration Server computers.

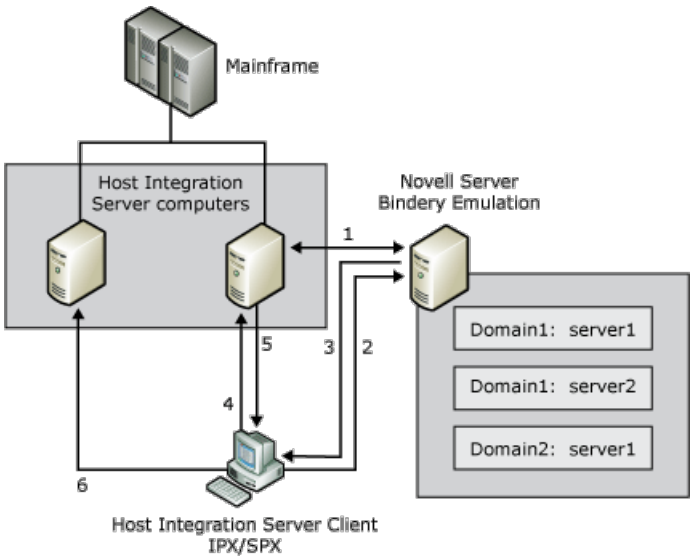
Concepts
Clients Using Microsoft Networking (Named Pipes)

Clients Using NetWare (IPX/SPX)

The following diagram shows how a client using NetWare can connect to the mainframe.



Novell NetWare (IPX/SPX) client computers use the following procedure for connecting to the mainframe:

1. At startup time, all Host Integration Server computers register their subdomain name and computer name with the NetWare Bindery. The subdomain name is configured in Setup for Host Integration Server. The computer name used is the Windows computer name.

2. Sometime later, a client requests an initial SNA session (3270 or APPC) by sending the request to the NetWare server requesting a list of registered Host Integration Server computers.

3. In response, the NetWare server sends the client the names of the Host Integration Server computers.

4. The client then selects one of the names from this list of Host Integration Server computers at random, and attempts to get a LAN connection with one of the Host Integration Server computers. The client must be configured for the same subdomain name as the Host Integration Server computers.

5. The Host Integration Server computer responds with a list of available Host Integration Server computers that are available to get a 3270 or APPC session with. This special connection is called the *sponsor connection*.

6. Finally, the client attempts to connect to each Host Integration Server computer in the list until a server is found that can service the 3270 or APPC request.

Tasks

Checklist for Clients Using NetWare (IPX/SPX)

NetWare Errors

Checklist for Clients Using NetWare (IPX/SPX)

When troubleshooting client problems, check that all of the following conditions have been met:

For Bindery

- **NetWare Servers**

  The NetWare server is properly installed and running, so that the bindery service is available.

- **Host Integration Server Computers**

  The Host Integration Server computer has registered its name in the bindery on the NetWare server. Several elements are required for this. The first element happens automatically: the installation of the NWLink IPX/SPX Compatible Transport on Windows. The second is matching the frame-type with the NetWare Server. For instance, if 802.2 is configured on the NetWare Servers, then the same frame type should be configured in the properties for the NWLink IPX/SPX Compatible Transport on Windows. Auto Frame Type is recommended.

  The correct subdomain name must be typed in the **Host Integration Server 2009 Subdomain Name** dialog box. The name is registered (along with the server name computer name) on the NetWare server. Only if the NetWare server is provided with the correct subdomain name can it respond to client requests and provide the clients with Host Integration Server names.

  Also, for the Host Integration Server computer to register its name on the NetWare server, Host Integration Server must be installed to work with IPX/SPX. This means that in Setup, the Novell NetWare (IPX/SPX) option must be selected in the Select Client/Server Protocols dialog box.

- **IPX Routers**

  In addition, for Bindery, any IPX routers between the two servers must be configured to allow NetWare Service Advertising Protocol broadcasts (SAP broadcasts)() to flow. IPX routers must propagate sockets 84C8 and 84C9 to support the communication needed by Host Integration Server computers and clients.

  To discover whether any Host Integration Server computers have been registered with NetWare Bindery, use the NetWare Rconcole utility against any NetWare Server that is using Bindery. For instance, if there are two Host Integration Server computers (Server1, Server2) that have successfully registered themselves with the NetWare Bindery and both servers are configured to be in a subdomain called Domain1, the entry in the NetWare Rconsole utility would be:

  - DOMAIN1!Server1
  - DOMAIN1!Server2

For Client

- Ensure that the client is using the same subdomain name as the Host Integration Server computers you want to connect to and has NWLink installed.

- **NDS Specific**

  The same concepts for Bindery apply to NetWare Directory Service (NDS), which the exceptions:

- **Host Integration Client**

  The NetWare Directory Service (NDS) logon credentials on the Host Integration Server computer must have the right to add an entry into the NetWare NDS tree structure. If this fails, there will be an event logged to the Windows Application Event Log.

The NDS Context and Tree Name must be provided by the client and server configurations in addition to the subdomain name in order for a client to connect successfully.

- **NetWare Servers**

  If using NetWare Directory Services (NDS), Host Integration Server requires NetWare version 4.11 or later. Earlier versions of NetWare are supported through the bindery emulation feature of NetWare version 4.0 or later.

Note
If NDS is selected on the client and an attempt to get a sponsor connection fails, it will automatically try Bindery.

See Also
Tasks
NetWare Errors

NetWare Errors

- **BINDERY 250**

  The Host Integration Server computer has contacted a NetWare Server and has enumerated a list of available Host Integration Server computers in the client's subdomain. However, the client cannot connect to any of the Host Integration Server computers in this list. There may be a network problem preventing a connection. Ensure that the same frame type is being used on the client and the other Host Integration Server computer.

- **BINDERY 252**

  The client has found that there are no Host Integration Server computers in this subdomain registered with the NetWare Bindery. Ensure that the clients and servers are using the same subdomain name and that SNABase service on the Host Integration Server computers has been started and registered with Bindery. To check whether SNABase has been registered with the NetWare Bindery use the NetWare Rconsole utility. For instance, if the Host Integration Server computer is configured to be in a subdomain called Seattle, and the computer name of the Host Integration Server computer is SNAS1, then the entry in Rconsole would be:

  SEATTLE!SNAS1

- **NDS 64935**

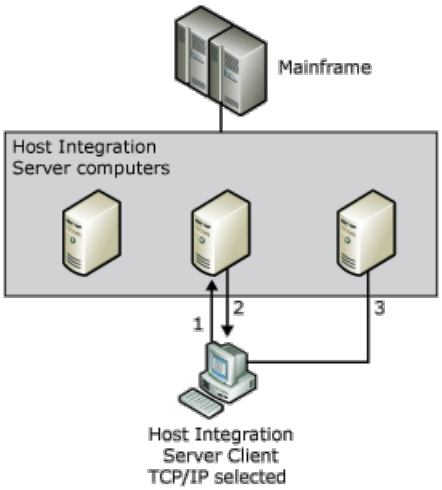
Tasks
Checklist for Clients Using NetWare (IPX/SPX)

Clients Using TCP/IP

The following figure shows how a TCP/IP client computer can connect to the mainframe.



A TCP/IP client computer uses the following procedure to connect to the mainframe:

1. With TCP/IP, you can choose between two methods by which a client searches for Host Integration Server computers.

   - **Client locate servers by subdomain** means that the client locates the server through broadcasts in the local subdomain. Therefore, the client must be in the same physical network as the Host Integration Server computers, and must not be separated from the servers by a router.

   - **Client locates servers by name** means that the client searches for Host Integration Server computers by name or IP address, and therefore need not be on the same side of any routers as the Host Integration Server computers. When using a name (instead of an IP address) and there is a router separating the Host Integration Server computer and the client, the client computer requires a method of resolving a name to an IP address. A local LMHOSTS file or a Windows Internet Name Service (WINS) server may be used to perform this resolution.

2. The Host Integration Server computer responds with a list of available Host Integration Server computers that are available to get a 3270 or APPC session with. This special connection is called the sponsor connection.

3. Finally, the client attempt to connect to each Host Integration Server computer in the list until a server is found that can service the 3270 or APPC request.

Note that before attempting to establish communication involving Host Integration Server, you can use the TCP/IP utility called **ping** to verify that contact can be established between client and server. This can help you identify basic TCP/IP problems, such as difficulties with name resolution or with routers. For information about the **ping** utility, see the TCP/IP documentation.

Note
Ensure that the logged-on user has sufficient user rights to access the Host Integration Server computer across the network. As with any other LAN connection, this is validated through the Windows Domain model.

Tasks
TCP/IP Errors

TCP/IP Errors

TCP/IP 11004
Causes

Your client is configured for Remote client locates servers by name, and you have selected a computer name instead of an IP address. The computer name to IP address resolution has failed, or the IP address resolved cannot be found on the network. Try inputting an IP address instead of a computer name into the client configuration. If this works, then there may be a problem with your local lmhosts file, DNS Server or WINS when using a computer name in the configuration. If this does not work, try pinging the address.

TCP/IP 10061
Causes

The SNABase service on Host Integration Server computer is not running or the IP address cannot be resolved, either because this Server is not on the network, the IP address is incorrect, or there is a router or network problem. Try pinging the address.

TCP/IP 121
Causes

The client is configured for Local Client locates servers in a Host Integration Server Subdomain and therefore, is sending out broadcast messages to discover a Host Integration Server computer. These broadcast messages will typically not be passed by a router that may be located in between your client and the server. Go into the client configuration and select Client locates server by name and specify an IP address or computer name of one or more Host Integration Server computers.

Concepts
Clients Using TCP/IP

Error Messages

The messages recorded in the event log for Host Integration Server are now available in a database. The Message Database file, included on the Host Integration Server CD-ROM at **\Documentation\Message Database\Snamsg.mdb**, requires Microsoft Access 97 or later for viewing. This database enables you to design your own queries and reports to gather and analyze information regarding Host Integration Server events. The message database includes the message identifier, severity level, symbolic message name, source, message, and an explanation where appropriate.

Some errors and events have additional information, such as debugging suggestions or recommended actions, available in the Error Message Database (EMDB). You can access the EMDB through the link provided in the error and event log. This link will take you directly to the error in the EMDB.

You can also access the entire EMDB at the following location:

http://go.microsoft.com/fwlink/?LinkId=33506

Finally, you can view events using the Windows Event Log service on the **Tools** menu in SNA Manager. Once you have the Windows Event Log service running, double-click an event to display the **Event Detail** dialog box. Then use the **Event Detail** dialog box to see more information about a selected event.

Administrator's Reference

Command-Line Interface

In addition to the graphical user interfaces provided by Host Integration Server Setup and the SNA Manager, Host Integration Server offers a command-line interface. The command-line interface can be useful in certain situations, such as when you want to view a configuration setting quickly without starting the graphical interface, or when you want to store configuration commands in a command file so that they can be carried out easily in the future.

Before using the command-line interface, you must install Host Integration Server and run the SNA Manager at least once. This initializes important elements of the Host Integration Server configuration that cannot be controlled with the command-line interface.

You can use the command-line interface to modify an offline configuration file (as well as a regular on-site configuration file). However, when you work with an offline configuration file, validation of server names, link names, and user names cannot take place, and errors may result. For information about specifying the name of the configuration file to modify with the command-line interface, see Specify the Subdomain Configuration File.

Other actions are also not available from the command-line. For example, you cannot use the command-line interface to configure ranges of LUs.

Certain Host Integration Server commands must be used with great care if the **/add** option is used with them. With these commands **snacfg server**, **snacfg link**, and **snacfg user** the information you type must match existing information in your system or on the Windows domain.

Important
If you specify server names, link service names, adapter properties, or user names by using the /add option with snacfg server, snacfg link, or snacfg user, these names or properties must match existing names and properties in your installation, or a nonfunctioning configuration may result. To protect against errors with these commands, use the SNA Manager instead.

In This Section

Snacfg Reference

Linkcfg Reference

Kerberos Support

In addition to NTLM, Kerberos support is now available. To use Kerberos support, it is necessary to set a Service Principal Name (SPN) for each server in the subdomain. You can do this through the command line as follows:

```
setspn -a hisservice/servername serviceaccount
```

An icon will appear in the status bar to verify that the system is using Kerberos. Kerberos support is compatible with previous versions of Host Integration Server.

Snacfg Reference

The following sections reference specific areas of Snacfg.

This section contains:

- Snacfg Server
- Snacfg TN3Server
- Snacfg TN5Server
- Snacfg TN3Session
- Snacfg TN5Session
- Snacfg TNIPID
- Snacfg User
- Snacfg Workstation
- Snacfg Error Messages

Task Order

Just as with the SNA Manager, configuration tasks must be carried out in a certain order with the command-line interface. For example, before configuring an LU, you must configure the connection that the LU will use. You can vary the interface you use for each configuration task, as long as you carry out the tasks in order, and as long as you have already installed Host Integration Server with the Host Integration Server Setup and then run the SNA Manager. For example, you can carry out tasks using the SNA Manager, then the command-line interface, then the SNA Manager again, as long as the tasks are done in the correct order.

The following table shows the order in which configuration tasks must be carried out, and the command used to carry out the task.

Task Order for Configuration Tasks

Configuration task (in order)	**Command that carries out task**
Add a server to the configuration	**snacfg server***
Configure link service(s) for the server(s)	**snacfg link***
Configure connection(s) for the server(s)	**snacfg connection**
Configure LU(s) for the connection(s)	**snacfg appcllu**, **snacfg appcrlu**, **snacfg lu**, **snacfg lua**, or **snacfg lud**
Create LU pool(s) (optional)	**snacfg pool**, **snacfg poola**, or **snacfg poold**
Assign LUs to pool(s) (optional)	**snacfg lu**, **snacfg lua**, or **snacfg lud**
Add users to the list used by Host Integration Server	**snacfg user***
Assign LU(s) or LU pool(s) to users	**snacfg user**

* It is recommended that you use the SNA Manager, not the command-line interface, for these tasks. Any errors in the typing of commands for these tasks can result in a nonfunctioning configuration.

Other Resources

Snacfg Reference

Specify the Subdomain Configuration File

Within a Host Integration Server command (a **snacfg** command), you can specify the path of the subdomain configuration file to access, or you can omit the path. If you omit the path, Host Integration Server attempts to access the configuration file in the normal location on the local system: \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG. To specify the path of the configuration file to access, type the **snacfg** command with the following syntax:

```
configpath command options
```

That is, follow the **snacfg** command with a space, a pound sign, then the configuration path, and then any additional command syntax.

For example, to view a listing of the connections stored in Program Files\Host Integration Server\SYSTEM\CONFIG\BACKUP.SNA, type

```
```

See Also

Other Resources

Snacfg Reference

Use a Command File

If you want to run a series of Host Integration Server configuration commands, you can remove the word **snacfg** from each command, place the new commands in a file called a command file, then use a single **snacfg** command to run the entire command file. This is similar to the way a batch file works; however, a command file opens and closes the configuration file fewer times than a batch file. When a command file is run, the configuration file is opened only once, at the beginning. Then all the commands are carried out, and the configuration file is closed. In contrast, when a batch file containing **snacfg** commands is run, the configuration file is opened and closed multiple times, once for every command in the file.

When creating a command file, do not include the following:

- The word **snacfg**
- A path for a configuration file
- A command path for another command file
- A backslash inside the text string for a comment

Also, you can include long, multiline commands in a command file by ending lines with a backslash (\ ). The backslash indicates that the string in the next line should be appended to the current command.

There are two steps for using a command file. First, create the file, either by typing the configuration commands into a plain text file, or by using the **/print** option as described in the next section. Then run the command file from the command prompt by typing a line with the following syntax:

```
        [configpath]commandpath []
```

In the preceding syntax line, *configpath* is the path of the configuration file on which commands should be carried out; precede this path with the **#** symbol. Similarly, *commandpath* is the path of the command file; precede this path with the **@** symbol. Use the **/v** (verbose) option to cause all informational messages (not just error messages) to be displayed when the command file is running. Without the **/v** option, only error messages are displayed.

For example, to run a series of commands that result in a listing of the links and connections in a configuration file, create a file called SNA_CMD1.TXT, containing the following lines:

```
link /list
connection /list
```

Create a Snacfg Command File from a Configuration File

To create lines for a **snacfg** command file, you can type them, or you can generate them by using the **/print** option. The **/print** option accesses an existing configuration file and generates the command-line(s) required to add an individual resource or (depending on syntax) the entire configuration file.

The output generated by the **/print** option does not contain the word **snacfg**. This means that the output can be included in a **snacfg** command file.

Snacfg Reference

General Syntax for the /print Option

The syntax lines in this section and the next section show ways to use the **/print** option. By default, the output is sent to the screen. To capture the output in a file, redirect it in the standard way, by adding a greater-than sign (>) to the end of the command, followed by the name of the file in which you want to capture the output.

With all the syntax lines, if the source configuration file is not in the default path \Program files\Host Integration Server\SYSTEM\CONFIG\COM.CFGthen for **#***configpath*, substitute a path, preceded by the pound sign (**#**). Do not type the square brackets. After the greater-than sign (**>**), type the name of the command file you want to create. (For information about using the greater-than sign or other methods of redirection, see your Windows documentation.)

The general syntax for the **/print** option is:

```
        [configpath] [resource [location]resourcename] cmdfile.ext
```

For *resource*, substitute the second word of a **snacfg** command (for example, **appcllu**, **connection**, or **server**). For *location*, if needed, substitute the server or connection name that uniquely locates a resource; for *resourcename*, substitute the name of the resource.

Snacfg Reference

Examples of Syntax for the /print Option

The following examples illustrate the use of the **/print** option.

- To create a command file that can recreate an entire configuration file, type a command of the following form:

```
[configpath] cmdfile.ext
```

- To create a command file from a particular connection in an existing configuration, type a command of the following form, substituting the name of the connection for *connectionname*:

```
[configpath] connectionnamecmdfile.ext
```

- To create a command file from a particular 3270 LU in an existing configuration, type a command of the following form, substituting the name of the LU for *luname*:

```
[configpath] lunamecmdfile.ext
```

After generating **snacfg** command files, you can modify them and then use them like any other **snacfg** command file.

Use the /print Option

The **/print** option can make it easier to carry out repetitive configuration actions, if you have a detailed understanding of Host Integration Server configurations and of the **snacfg** command. Here are some ways of using the **/print** option:

Creating a new configuration

You can generate a **snacfg** command file corresponding to an entire configuration file, modify the command file, and use it to create a new configuration file for another subdomain or site. To generate the commands for an entire configuration file, use the syntax shown in the first example in the previous section; that is, omit all **snacfg** modifiers (such as **connection** or **lu**).

Creating a template to use for expanding one or more configurations

You can generate a **snacfg** command file that corresponds to a useful element of an existing configuration (for example, a 3270 LU in a configuration). Then you can modify the file and use it to add one or many similar elements to an existing configuration. Such a command file acts as a template for the element that it contains.

Modifying a configuration

You can generate a **snacfg** command file that corresponds to some part of an existing configuration (for example, an 802.2 connection in a configuration), modify the command file, and use it to modify the configuration file from which it came. This involves removing the **/add** option from lines in the command file, and making other changes that require a detailed understanding of the commands in the file.

Snacfg Reference

Display the Contents of a Configuration File

You can create a display of the entire contents of a configuration file by using the **/display** option with the following syntax:

```
[configpath]
```

When you use the **/display** option, all the resources in the configuration file are displayed. For each resource, the display is the same as that from typing **snacfg** *resource resourcename*, where *resource* is the second word of a **snacfg** command (for example, **appcllu**, **connection**, or **server**), and *resourcename* is the name of the corresponding resource. (The exception to this is that the display of the "diagnostic" resource is the same as that from **snacfg diagnostic /list**.)

Concepts

Use the /print Option

General Syntax for the /print Option

Snacfg APPCLLU

Purpose

Allows you add, delete, modify, or view a local APPC LU. Also allows you to view the command that would create a specified local APPC LU.

Note
Configuration settings specified with snacfg appcllu correspond to local APPC LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] appcllu /list
```

Recommended Syntax

```
        [configpath]  servernameLUalias
[configpath]  LUalias servername [options]
[configpath]  servernameLUalias [options]
[configpath]  servernameLUalias  [configpath]  servernameLUalias
```

Other Available Syntax

```
        [configpath]  [configpath]  LUalias
[configpath]  LUalias [options]
[configpath]  LUalias  [configpath]  LUalias
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\System\CONFIG\COM.CFG.

/list

Generates a list of configured local APPC LUs.

servername **:** *LUalias*

Specifies the server name and LU alias of the local APPC LU on which to carry out actions. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

It is recommended that *servername***:** be included in **snacfg appcllu** commands (other than **/add** commands) that include *LUalias*. Without *servername***:**, if there is more than one local LU called *LUalias* in the subdomain, it is difficult to predict which of these LUs will be affected by the command. The **snacfg appcllu** command does not necessarily default to the local server if *servername* is omitted.

See the following paragraphs for details about characters permitted in the LU alias.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

LUalias

Specifies the LU alias of the local APPC LU on which to carry out actions. See the previous paragraphs and the syntax lists for recommendations about using the server name with the LU alias.

The LU alias can be from one through eight characters long, and can contain alphanumeric characters and the special characters %, $, #, and @. Lowercase letters are converted to uppercase. For a local APPC LU, the LU alias must be unique on the server.

Note

LUalias is used as the default LU name if **/luname:***text* is not specified.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

/add

Adds a local APPC LU called *LUalias*. To configure the LU, either specify other options after **/add**, or specify configuration options in additional **snacfg appcllu** commands (using the same *LUalias*).

/connection: *conn-name*

When adding or modifying a dependent local APPC LU, this option is used to specify the LU's connection assignment.

/delete

Deletes the LU called *LUalias*.

/print

Causes the display of the **snacfg** command that would create the specified local APPC LU. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file.

Options for Local APPC LUs

/server: *servername*

Specifies the server to which to assign or move the APPC LU. When **/add** is used, this option is required. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

/lunumber: *value*

Specifies the LU number. If an LU number of 0 is specified, the LU is configured as an independent local APPC LU.

/netname:" *text*"

Specifies a name for the network of this LU. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

If **/netname:***text* is not specified, the network name of the Host Integration Server on which the LU is located is used as the default.

Note

/luname:*text* also has a default (the LU alias). Therefore, the fully qualified LU name (network name plus LU name) can potent ially be created by default, if the LU alias and local network name are configured appropriately. A fully qualified LU name is r equired for an APPC LU.

/luname:" *text*"

Specifies the LU name. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. For a local APPC LU, the fully qualified LU Name (Network Name plus LU Name) must be unique on the server.

If **/luname:***text* is not specified, *LUalias* is used as the default LU name.

Note

/netname:*text* also has a default (the network name of the server on which the LU is located). Therefore, the fully qualified LU name (network name plus LU name) can potentially be created by default, if the LU alias and local network name are configu red appropriately. A fully qualified LU name is required for an APPC LU.

/comment:" *text*"

Adds an optional comment for the LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

/autopartner:{ yes| no }

Specifies whether this LU will automatically be partnered with other APPC LUs.

If automatic partnering is left unspecified, the default is **yes**.

/defaultpool:{ yes| **no }**

Specifies whether this LU will be in the default outgoing local APPC LU pool. This pool makes LUs available for invoking TPs that do not specify a local LU.

/impremotelu: *remoteLUname*

Specifies an existing remote LU to be used as an implicit incoming remote LU for the local LU.

/tptimeout: *value*

Specifies the number of seconds that Host Integration Server should wait for the invokable TP to respond to a start request from the invoking TP.

/addpartner: *LUalias* **,** *mode*[**,***connection*]

Partners the local LU with the specified LU and the specified mode. Both *LUalias* and *mode* must exist before they can be specified as partners. If *LUalias* specifies a remote LU that is not unique on the server, the connection used by the remote LU must also be specified; otherwise, Host Integration Server will randomly choose one of the remote LUs called *LUalias* to act on.

Only one **/addpartner** option can be used in each command.

/delpartner: *LUalias* **,** *mode*[**,***connection*]

Deletes the pair listing that includes this local LU, the specified partner LU, and the specified mode. (Does not delete any LUs or modes themselves.) If *LUalias* specifies a remote LU that is not unique on the server, the connection used by the remote LU must also be specified; otherwise, Host Integration Server will randomly choose one of the remote LUs called *LUalias* to act on.

Only one **/delpartner** option can be used in each command.

/syncpoint:{ yes | no }

Specifies if this Local APPC LU provides LU 6.2 SyncPoint support.

/clientname: "*text*"

Specifies client name if SyncPoint support is enabled.

Snacfg Reference

Snacfg APPCRLU

Purpose

Allows you add, delete, modify, or view a remote APPC LU. Also allows you to view the command that would create a specified remote APPC LU.

Note
Configuration settings specified with snacfg appcrlu correspond to remote APPC LU settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] appcrlu /list
```

Recommended Syntax

```
        [configpath]  connectionnameLUalias
[configpath]  LUalias connectionname [options]
[configpath]  connectionnameLUalias [options]
[configpath]  connectionnameLUalias  [configpath]  connectionnameLUalias
```

Other Available Syntax

```
        [configpath] LUalias [configpath] LUalias [options]
[configpath] LUalias [configpath] LUalias
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured remote APPC LUs.

connectionname **:** *LUalias*

Specifies the connection and LU alias of the remote APPC LU on which to carry out actions. You should include *connectionname***:** in **snacfg appcrlu** commands (other than **/add** commands) that include *LUalias*. Without *connectionname***:**, if there is more than one remote LU called *LUalias* in the subdomain, it is difficult to predict which of these LUs will be affected by the command. The **snacfg appcrlu** command does not necessarily default to a connection on the local server if *connectionname* is omitted.

See the following paragraphs for details about characters permitted in the LU alias.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

LUalias

Specifies the LU alias of the remote APPC LU on which to carry out actions. See the previous paragraphs and the syntax lists for recommendations about using the connection name with the LU alias.

The LU alias can be from one through eight characters long, and can contain alphanumeric characters and the special characters %, $, #, and @. Lowercase letters are converted to uppercase. For a remote APPC LU, the LU alias must be unique on the connection, and must not match that of a local LU on that server.

If no options are specified after *LUalias*, the configuration settings, partner LUs, and modes are displayed for the specified LU.

/add

Adds a remote APPC LU called *LUalias*. To configure the LU, either specify other options after **/add**, or specify configuration options in additional **snacfg appcrlu** commands (using the same *LUalias*).

/delete

Deletes the LU called *LUalias*.

/print

Causes the display of the **snacfg** command that would create the specified remote APPC LU. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

Options for Remote APPC LUs
/connection: *connectionname*

Specifies the connection to which to assign or move the APPC LU. When **/add** is used, this option is required.

/netname:" *text*"

Specifies a name for the network of this LU. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

If **/netname:***text* is not specified, the remote network name configured for the connection supporting this LU is used as the default.

Note
/luname:*text* also has a default (the LU alias). Therefore, the fully qualified LU name (network name plus LU name) can potentially be created by default, if the LU alias and remote network name are configured appropriately. A fully qualified LU name is required for an APPC LU.

/luname:" *text*"

Specifies the LU name. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. For a remote APPC LU, the fully qualified LU Name must be unique on the connection, and must not match that of a local LU on that server.

If **/luname:***text* is not specified, *LUalias* is used as the default LU name.

Note
/netname:*text* also has a default (the remote network name configured for the connection supporting this LU). Therefore, the fully qualified LU name (LU name plus network name) can potentially be created by default, if the LU alias and remote control point name are configured appropriately. A fully qualified LU name is required for an APPC LU.

/comment:" *text*"

Adds an optional comment for the LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

/autopartner:{ yes | no }

Specifies whether this LU will automatically be partnered with other APPC LUs.

If automatic partnering is left unspecified, the default is **yes**.

/parallelsess:{ yes | no }

Specifies whether the remote LU supports parallel sessions.

/uninterpname:" *text*"

Specifies the uninterpreted LU name, which is required only when using dependent APPC. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, @ and period (.).

/impmode: *modename*

Designates *modename* as the implicit incoming mode for this LU. A mode must exist before being specified as an implicit incoming mode.

/security:{ none| **hex,***text*| **char,***text* **}**

Configures session security for a remote LU using a cleartext key. The **none** option turns off session-level security. The **hex,***text* option specifies a 16-digit security key in hexadecimal. The **char,***text* option specifies an eight-character security key that can include uppercase and lowercase alphanumeric characters, and the special characters $, @, #, and the period (.).

/addpartner: *LUalias* **,** *mode*

Partners the remote LU with the specified local LU and the specified mode. Both the local LU and the mode must exist before they can be specified as partners. *LUalias* should specify a local LU, not a remote LU; otherwise, an error message is displayed, indicating that no such local LU can be found.

Only one **/addpartner** option can be used in each command.

/delpartner: *LUalias* **,** *mode*

Deletes the pair-listing that includes this remote LU, the specified local LU, and the specified mode. (Does not delete any LUs or modes themselves.)

Only one **/delpartner** option can be used in each command.

/securityex:{ none| **hex,***text*| **char,***text* **}**

Configures session security for a remote LU using a scrambled key. For security purposes, Snacfg displays the security key information in a scrambled format when the /securityex option is specified. To change the security key, use the /security option instead.

See Also

Other Resources

Snacfg Reference

Snacfg Connection

Purpose

Allows you to view, add, delete, or modify connections, including peer connections (necessary for APPC LUs) or downstream connections.

Before configuring a connection, you must configure the server and link service that the connection will use.

Note
Configuration settings specified with snacfg connection correspond to connection settings configured with the SNA Manager .

Syntax

```
          [configpath]  [configpath] connectionname [configpath] connectionname    servernam
  e{  [options]
   [configpath] connectionname [options]
   [configpath] connectionname /
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured connections.

connectionname

Specifies a name for the connection to be configured or viewed. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. A new connection name cannot be the same as any other connection name in the installation, and cannot be the reserved name SNASERVR.

If no options are specified after *connectionname*, the command-line interface displays a list of the configuration settings for the specified connection.

/add

Adds a connection called *connectionname*. To configure the connection, either specify other options after **/add**, or specify configuration options in additional **snacfg connection** commands (using the same *connectionname*).

/delete

Deletes *connectionname*.

Options Used with All Connection Types
/server: *servername*

Specifies the server to which to assign or move the connection. When **/add** is used, this option is required. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

/conntype:{ 802.2 | SDLC | X.25 | CHANNEL | TWINAX }

Specifies the connection type. When **/add** is used, this option is required.

/comment:" *text*"

Adds an optional comment for the specified connection. The comment can contain as many as 25 characters; enclose the comment in quotes.

/linkservice: *linkname*

Specifies the name of the link service to be used by *connectionname*. The link service type must match the connection type (802.2, SDLC, or X.25), or the **snacfg** command will not run.

In order for the link service to function correctly, it must be installed with the SNA Manager. Link services can also be installed with **snacfg link**; however, the SNA Manager is the recommended interface for installing link services, because it helps ensure that the resulting configuration is functional.

/activation:{ onserverstartup | ondemand | byadministrator }

For outgoing calls on *connectionname*, tells how the connection will be activated: on server startup, on demand, or by the administrator. (For incoming calls, activation is irrelevant, since the connection always begins listening for calls on server startup.)

If no value has been specified for **/activation**, the default for 802.2 (token ring or Ethernet) connections is **onserverstartup**. For all other connections, the default is **ondemand**.

/localblockno: *hexdigits*

Specifies the local block number, a three-digit hexadecimal number. The local block number forms the first part of the Local Node ID, an eight-digit hexadecimal number that identifies the local system.

Do not use 000 or FFF for the local block number. These values are reserved.

For connections to host systems, the local block number should match IDBLK in VTAM.

/localnodeno: *hexdigits*

Specifies the local node number, a five-digit hexadecimal number. The local node number forms the last part of the Local Node ID, an eight-digit hexadecimal number that identifies the local system.

For connections to host systems, the local node number should match IDNUM in VTAM.

/cpname: *text*

Specifies the control point name of the remote node, as it is represented in Format 3 XIDs. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

The control point name of the remote node works together with **netname**. If either of these parameters is supplied, the other should also be supplied.

When connecting to a host system and using a remote control point name, the name should match the SSCPNAME parameter in the VTAM Start command for the remote SSCP (the VTAM system).

/netname: *text*

Specifies the name of the network for the remote node, as it is represented in Format 3 XIDs. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

The **netname** parameter works together with the control point name of the remote node. If either of these parameters is supplied, the other should also be supplied.

/remoteblockno: *hexdigits*

Specifies the remote block number, a three-digit hexadecimal number. The remote block number forms the first part of the Remote Node ID, an eight-digit hexadecimal number that identifies the remote system.

Do not use 000 or FFF for the remote block number. These values are reserved.

/remoteend:{ Host | Ppeer | downstream | PUPassThrough}

Specifies whether the connection is to be a host, peer, downstream, or passthrough.

/remotenodeno: *hexdigits*

Specifies the remote node number, a five-digit hexadecimal number. The remote node number forms the last part of the Remote Node ID, an eight-digit hexadecimal number that identifies the remote system.

/xidtype:{ format0 | format3 }

Specifies the XID type, the type of identifying information for Host Integration Server to send. The choices are **format0** (Format 0) and **format3** (Format 3). Format 0 sends only the Node ID. Format 3 sends up to 100 bytes of identifying information, including the local node ID and control point name.

If no XID type has been specified, the default is **format3**.

/calldirection:{ Incoming | **Outgoing** | **Both }**

This option specifies the call direction.

/channeladdress: *hex string*

Specifies the channel sub address for channel attach connections. *Hex string* is a two-digit hexadecimal number, valid range 00..FF.

/localsap: *hexnum*

Specifies the local System Access Point (SAP). Enter a hexadecimal number between 04 and EC that is a multiple of 4. For example, *snacfg connection thisconn /localsap:7C*.

/localcpname: *text*

The Local Control Point Name works with the Network Name to identify a system. The maximum length is eight characters.

/localnetname: *text*

The Local Network Name works with the Local Control Point Name to identify a system. The maximum length is eight characters.

/compression:{ None | RLE | LZ9 }

These options offer progressively better compression, but at a progressively higher CPU usage cost.

/passthruconn: *text*

Specifies the name of the PU Passthrough connection.

/peerdlcrole:{ Primary | Secondary | Negotiable }

Specifies the role used in peer-to-peer communications.

/dynamicludef:{ yes | no }

Specifies that this connection supports dynamic remote APPC LU allocation.

Additional Options Used with Downstream Connections
/insert: *luname* **[,*luname*,]**

Assigns a downstream LU or pool to a downstream connection. Separate multiple LU or pool names with commas.

The downstream LU or pool named by ***luname*** must already exist. (A downstream LU can be created with **snacfg LUD**, and a downstream pool can be created with **snacfg poold**.) The connection named by *connectionname* must be a downstream connection. If these conditions are not met, the command is not processed.

/remove: *luname* **[,*luname*,]**

Removes the assignment of a downstream LU or pool to a downstream connection. Separate multiple LU or pool names with commas.

Additional Options Used with 802.2 (Token Ring or Ethernet) Connections
/remotenetaddr: *hexdigits*

Specifies the 12-digit hexadecimal network address of the remote host to which this connection provides access.

If no remote network address has been specified, the default is 400000000000.

/remotesapaddr: *hexdigits*

Specifies the remote SAP address, which is a two-digit hexadecimal number, a multiple of 4, between 04 and EC. A value of 04 is recommended for most installations.

If no remote SAP address has been specified, the default is 04.

/maxbtulen: *value*

Specifies the maximum length for the BTU, which is the number of bytes that can be transmitted in a single data-link control frame.

The range is from 265 through 16393. If no maximum BTU length has been specified, the default is 1929.

/receiveackthresh: *value*

Specifies the receive ACK threshold, the maximum number of frames that the local system can receive from the remote system before sending a response.

The range is from 1 through 127. If no receive ACK threshold has been specified, the default is 2.

/naksendlimit: *value*

Specifies the unacknowledged send limit, the maximum number of frames that the local system can send without receiving a response from the remote system.

The range is from 1 through 127. If no unacknowledged send limit has been specified, the default is 1.

/retrylimit: *value*

Specifies the retry limit, the number of times that the local system should retransmit a frame if no response is received from the remote system.

The range is from 0 through 255. A value of 0 means the system uses its internal default retry limit. If no retry limit has been specified, the default is 10.

/xidretries: *value*

Specifies the XID retries, the number of times that the local system should retransmit an XID (an identifying message) if no response is received from the remote system.

The range is from 0 through 30. If no XID retries value has been specified, the default is 3.

/t1timeout:{ Default| 200ms| 400ms| 600ms| 800ms| 1000ms | 1s| 2s| 3s| 4s | 5s}

Specifies the amount of time that the local system should wait for the remote system to respond to a transmission before the local system tries again.

The values used for **Default** for **t1timeout** are 400 milliseconds for a local ring and 2 seconds for a remote ring.

/t2timeout:{ Default| 40ms| 80ms| 120ms| 160ms| 200ms| 400ms| 800ms| 1200ms| 1600ms| 2000ms}

Select the maximum amount of time that should be allowed before the local system sends an acknowledgment of a received transmission.

The values used for **Default** for **t2timeout** are 80 milliseconds for a local ring and 800 milliseconds for a remote ring.

/titimeout:{ Default| 1s| 2s| 3s| 4s| 5s| 10s| 15s| 20s| 25s}

Select the amount of time that the link can be inactive before the local system treats it as nonfunctioning and shuts it down.

The values used for **Default** for **titimeout** are 5 seconds for a local ring and 25 seconds for a remote ring.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }

This value specifies the delay between successive attempts to activate a Host Integration Server connection.

/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }

This option specifies the number of times the server will try to activate a connection.

Additional Options Used with SDLC Connections
/dialdata: *value*

Specifies the phone number stored for this connection. For a modem that accepts a phone number from Host Integration Server that is, a modem attached to an SDLC adapter with a built-in serial (COM) port the dial data specifies the telephone number for Host Integration Server to send to the modem. In this case, the number should be in the format expected by the modem. For manually dialed modems, the dial data is displayed in a pop-up message when the connection is started, and can be in any format.

/encoding:{ NRZI | NRZ }

Specifies the encoding scheme to be used by the modem. The choices are **nrzi**, nonreturn to zero inverted, and **NRZ**, nonreturn to zero.

The modem must use the same encoding scheme as the modem at the remote computer. For connections to host systems, the encoding scheme must match the value in the LINE/GROUP definition in VTAM.

If no encoding scheme has been specified, the default is NRZI.

/duplex:{ half | full }

Specifies the modem duplex setting. The choices are **half**, for a half-duplex modem, and **full**, for a full-duplex modem. If you want to use the full-duplex setting, one or more of your adapters must have the constant carrier option set. The constant carrier option is set in the SNA Manager. The constant carrier option can also be set with **snacfg link**; however, the SNA Manager is the recommended interface for setting the constant carrier option and other link service options.

Most Host Integration Server computers will use the default for duplex, **half**.

/datarate:{ high | low }

Specifies the data rate for transmissions between the Host Integration Server communications adapter and the modem. This rate can only be set for certain kinds of modems and adapters; for specific information, see the adapter and modem documentation.

A data rate of **high** gives faster transmissions; **low** gives more reliable transmissions and prevents the transmission errors sometimes caused by poor-quality lines at the high rate.

If no data rate has been specified, the default is **high**.

/polladdress: *hexdigits*

Specifies the poll address, a two-digit hexadecimal number. For connections to a host, the local poll address should match the VTAM PU definition for the ADDR= parameter.

Do not use 00 or FF for the poll address; these values are reserved. If no poll address has been specified, the default is C1.

/idletimeout: *value*

Specifies, in tenths of a second, the idle time-out. The idle time-out is the length of time that the local system should wait for the host to respond to a transmission, before the local system tries again. Too small a time-out can cause connection problems.

The range is from 1 (one-tenth of a second) through 300 (30 seconds). If no idle time-out has been specified, the default is 300 (30 seconds).

/idleretrylimit: *value*

Specifies the idle retry limit, the number of times the local system should try to poll or send data to the host if there is no response.

The range is from 1 through 255. If no idle retry limit has been specified, the default is 10.

/contacttimeout: *value*

Specifies the contact time-out: the length of time, in tenths of a second, which the local system should wait between attempts to make a connection with a remote system.

The range is from 5 (five-tenths of a second) through 300 (30 seconds). If no contact time-out has been specified, the default is 300 (30 seconds).

/contactretrylimit: *value*

Specifies contact retry limit, the maximum number of times the local system should attempt to make a given connection.

The range is from 1 through 20. If no contact retry limit has been specified, the default is 10.

/switchedconntimeout: *value*

Specifies the switched connection establishment time-out; used for switched SDLC lines (standard telephone lines) only. The switched connection establishment time-out is the number of seconds that will be allowed for the user or modem to dial the remote computer's number.

This parameter is ignored by incoming calls.

The range is from 10 through 500 seconds. If no switched connection establishment time-out has been specified, the default is 300.

/multidropprimconn:{ yes | no }

Specifies whether this connection will be a multidrop primary connection.

A multidrop connection is one in which a primary node communicates with multiple secondary nodes concurrently over the same physical transmission medium.

/selectstandby:{ yes | no }

Specifies whether the modem's standby line is set to "on." Standby can only be set for certain kinds of modems; for specific information, see the modem documentation.

If no setting has been specified for standby, the default setting is **no**.

/sdlcmaxbtu: *value*

Specifies the maximum length for the BTU, which is the number of bytes that can be transmitted in a single data-link information frame.

The range is from 265 through 16393. If no maximum BTU length for SDLC has been specified, the default is 265.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }

This value specifies the delay between successive attempts to activate a Host Integration Server connection.

/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }

This option specifies the number of times the server will try to activate a connection.

Additional Options Used with SDLC Peer Connections
/multidropprimconn:{ yes | no }

Specifies whether this server is to be the primary station for a multidrop connection on a leased SDLC line.

/pollrate: *value*

Specifies the poll rate in polls per second.

The range is from 1 through 50. If no poll rate has been specified, the default is 5.

/activatedelay:{ Default | 5s | 10s | 15s | 20s | 25s | 30s | 35s | 40s | 45s | 50s | 55s | 60s | 65s | 70s | 75s | 80s | 85s | 90s | 95s | 100s | 105s | 110s | 115s | 120s | 125s | 130s | 135s | 140s | 145s | 150s | 155s | 160s | 165s | 170s | 175s | 180s | 185s | 190s | 195s | 200s | 205s | 210s | 215s | 220s | 225s | 230s | 235s | 240s | 245s | 250s | 255s }

This value specifies the delay between successive attempts to activate a Host Integration Server

/activateretrylimit:{ None | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 15 | 20 | 25 | 30 | 35 | 40 | 45 | 50 | 55 | 60 | 65 | 70 | 75 | 80 | 85 | 90 | 95 | 100 | 105 | 110 | 115 | 120 | 125 | 130 | 135 | 140 | 145 | 150 | 155 | 160 | 165 | 170 | 175 | 180 | 185 | 190 | 195 | 200 | 205 | 210 | 215 | 220 | 225 | 230 | 235 | 240 | 245 | 250 | 255 }

This option specifies the number of times the server will try to activate a connection.

Additional Options Used with X.25 Connections
/remotex25addr: *hexdigits*

Specifies the remote X.25 address, which identifies the remote system on an X.25 network. The address usually consists of 12 hexadecimal digits, but can contain up to 15 hexadecimal digits.

/x25maxbtu: *value*

Specifies the maximum length for the BTU, which is the number of bytes that can be transmitted in a single data-link information frame.

The range is from 265 through 16393. If no maximum BTU length for X.25 has been specified, the default (for host connections) is 265.

/virtualcircuit:{ perm | switched }

Specifies the type of virtual circuit used by the connection. The choices are **perm** and **switched**. A **perm** circuit is constantly active and uses a preset destination address. A **switched** circuit is called and cleared dynamically, and uses a destination address that is supplied when the circuit is called.

If no virtual circuit type has been specified, the default is **switched**.

/pvcalias: *value*(for PVC only)

Specifies the PVC alias, the number that identifies the PVC channel: 1 for the first channel, 2 for the second, and so on. Used for PVCs only.

The range is from 1 through the number of configured PVC channels. If no PVC alias has been specified, the default is 1.

/packetsize: *value*(for PVC only)

Specifies packet size, the maximum number of data bytes (not header bytes) to be sent in a frame on this X.25 network. Used for PVCs only.

The possible values are 64, 128, 256, 512, and 1024. If no packet size has been specified, the default is 128.

/windowsize: *value*(for PVC only)

Specifies window size, the maximum number of frames that the local system can send without receiving a response from the remote system, on this X.25 network. Used for PVCs only.

The range is from 1 through 7. If no window size has been specified, the default is 2.

/facilitydata: *text*(for SVC only)

Specifies the codes for any facility data required by the network provider or by the administrator of the remote system. Used for SVCs only. Facility data can include as many as 126 hexadecimal characters (63 hexadecimal bytes).

Facility data is a coded string of information often used to request nondefault functions from the X.25 network for a particular SVC connection.

/userdata: *text*(for SVC only)

Specifies the codes for any user data required by the network provider. Used for SVCs only. The user data must be an even number of hexadecimal characters, up to the maximum of 32 characters.

User data is a coded string of information, specifying items such as the communications protocol used by the X.25 network (for SNA, this protocol must be QLLC, specified by C3).

The default for user data is C3; this specifies the QLLC protocol.

/activatedelay:{ Default | **5s** | **10s** | **15s** | **20s** | **25s** | **30s** | **35s** | **40s** | **45s** | **50s** | **55s** | **60s** | **65s** | **70s** | **75s** | **80s** | **85s** | **90s** | **95s** | **100s** | **105s** | **110s** | **115s** | **120s** | **125s** | **130s** | **135s** | **140s** | **145s** | **150s** | **155s** | **160s** | **165s** | **170s** | **175s** | **180s** | **185s** | **190s** | **195s** | **200s** | **205s** | **210s** | **215s** | **220s** | **225s** | **230s** | **235s** | **240s** | **245s** | **250s** | **255s }**

This value specifies the delay between successive attempts to activate a Host Integration Server connection.

/activateretrylimit:{ None | **1** | **2** | **3** | **4** | **5** | **6** | **7** | **8** | **9** | **10** | **15** | **20** | **25** | **30** | **35** | **40** | **45** | **50** | **55** | **60** | **65** | **70** | **75** | **80** | **85** | **90** | **95** | **100** | **105** | **110** | **115** | **120** | **125** | **130** | **135** | **140** | **145** | **150** | **155** | **160** | **165** | **170** | **175** | **180** | **185** | **190** | **195** | **200** | **205** | **210** | **215** | **220** | **225** | **230** | **235** | **240** | **245** | **250** | **255 }**

This option specifies the number of times the server will try to activate a connection.

Additional Options Used with Channel Connections
/activatedelay:{ Default | **5s** | **10s** | **15s** | **20s** | **25s** | **30s** | **35s** | **40s** | **45s** | **50s** | **55s** | **60s** | **65s** | **70s** | **75s** | **80s** | **85s** | **90s** | **95s** | **100s** | **105s** | **110s** | **115s** | **120s** | **125s** | **130s** | **135s** | **140s** | **145s** | **150s** | **155s** | **160s** | **165s** | **170s** | **175s** | **180s** | **185s** | **190s** | **195s** | **200s** | **205s** | **210s** | **215s** | **220s** | **225s** | **230s** | **235s** | **240s** | **245s** | **250s** | **255s }**

This value specifies the delay between successive attempts to activate a Host Integration Server connection.

/activateretrylimit:{ None | **1** | **2** | **3** | **4** | **5** | **6** | **7** | **8** | **9** | **10** | **15** | **20** | **25** | **30** | **35** | **40** | **45** | **50** | **55** | **60** | **65** | **70** | **75** | **80** | **85** | **90** | **95** | **100** | **105** | **110** | **115** | **120** | **125** | **130** | **135** | **140** | **145** | **150** | **155** | **160** | **165** | **170** | **175** | **180** | **185** | **190** | **195** | **200** | **205** | **210** | **215** | **220** | **225** | **230** | **235** | **240** | **245** | **250** | **255 }**

This option specifies the number of times the server will try to activate a connection.

/controlunit: *value (0x0-0xf)*

Sets the value of the control unit image number.

Snacfg Reference

Snacfg CPIC

Purpose

Allows you add, delete, modify, or view a CPI-C symbolic destination name. Also allows you to view the command that would create a specified CPI-C symbolic destination name.

Note
Settings specified with snacfg cpic correspond to CPI-C symbolic destination names configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath] cpicname [configpath] cpicname
     { text  |  hexstring }
     { btexttext  |  text }
     text{  |  |  }
     [text] [text] [text]
   [configpath] cpicname []
   [configpath] cpicname [configpath] cpicname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured symbolic destination names.

cpicname

Specifies the symbolic destination name on which to carry out actions. A symbolic destination name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @.

If no options are specified after *cpicname*, the configuration settings for the specified symbolic destination name are displayed.

/add

Adds a symbolic destination name called *cpicname*. When you use the **/add** option, you must include the other options shown in the preceding syntax.

/delete

Deletes *cpicname*.

/print

Causes the display of the **snacfg** command that would create the specified symbolic destination name. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

Options for CPI-C Commands

/comment:" *text*"

Adds an optional comment for the symbolic destination name. The comment can contain as many as 25 characters; enclose the comment in quotes.

Partner TP options(use one or the other, but not both):

/appltpname:"**text**"

Specifies that the partner TP is an application TP, and provides the name. The name can be from 1 through 64 characters

long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.

If you specify both an application TP name and a service TP name in the same command, the command is rejected. If you specify an application TP for an existing symbolic destination name, it overrides any previous TP name (whether application TP or service TP).

/svcetpname:**hexstring**

Specifies that the partner TP is a service TP, and provides the hexadecimal string identifying the TP. The string can be from one through eight hexadecimal digits long.

If you specify both a service TP name and an application TP name in the same command, the command is rejected. If you specify a service TP for an existing symbolic destination name, it overrides any previous TP name (whether application TP or service TP).

Partner LU options(use one or the other, but not both):

/netname:"**text**" /luname:"**text**"

Identifies the partner LU by fully qualified LU name (network name plus LU name). Each part of the fully qualified name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.

If you specify both a fully qualified LU name and an LU alias in the same command, the command is rejected. If you specify a fully qualified LU name for an existing symbolic destination name, it overrides any previous LU setting (whether name or alias).

/lualias:"**text**"

Identifies the partner LU by LU alias. The alias can be from one through eight characters long, and can contain alphanumeric characters and the special characters %, $, #, and @. Lowercase letters are converted to uppercase.

If you specify both an LU alias and a fully qualified LU name in the same command, the command is rejected. If you specify an LU alias for an existing symbolic destination name, it overrides any previous LU setting (whether name or alias).

/modename:" *text*"

Specifies the mode. The mode must already exist.

/seckeytype:{ none| **same**| **program}**

Sets the conversation security type. If **program** is specified, one or both of the following options can be set:

/secuserid:" **text**"

Specifies the user ID to use when the security type is **program**. The ID can contain from 1 through 10 characters.

/secpassword:" **text**"

This parameter is optional; it specifies the password to use with the user ID. The password can contain from 1 through 10 characters. A password need not be specified even if the security type is **program** and the user ID is set. If a display is created showing the symbolic destination name, the password will not be displayed.

Snacfg Reference

Snacfg Diagnostic

Purpose

Allows you to view and configure settings for event logging (auditing), and view or change the connection designated to receive NetView alerts.

Note
Configuration settings specified with snacfg diagnostic correspond to diagnostic settings configured with the SNA Manager.

Syntax

```
snacfg [#configpath] diagnostic /list
snacfg [#configpath] diagnostic [options]
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list that tells the settings for event logs (auditing), the name of the NetView management connection (if one has been specified), and the default connection for the **DISPLAY** verb (if one has been specified).

/logserver: *servername*

Specifies a centralized server on which event logs for this Host Integration Server installation should be stored.

If **/logserver:** is typed without *servername*, the setting reverts to the default, which is to store event logs for the local server on the local server.

/auditlevel:{ 6| 8| 10| off}

Sets the level of Host Integration Server events to be recorded in the Windows Event Log. These events can be viewed with the Windows Event Viewer, which is described in the Windows documentation. The following table describes the available levels:

Level	Description	Events to be recorded
6	Detailed problem analysis	All events that can be recorded
8	General information messages	General activity but not all events
10	Significant system events	Major events only
off	Auditing disabled	No events

/popupserver: *servername*

Specifies the server to which pop-up error messages for this Host Integration Server installation should be routed.

Pop-up messages will always appear on the local server; routing them to a remote server means they will appear on both the remote and local server.

If **/popupserver:** is typed without *servername*, the setting reverts to the default, which is the local server.

/netviewconn: *connectionname*

Specifies the name of the connection through which NetView alerts are sent. The connection called *connectionname* must already exist.

If **/netviewconn:** is typed without *connectionname*, the setting is cleared so that the configuration contains no NetView connection name.

/cnosdisplayconn: *connectionname*

Specifies the default connection to be used for the **DISPLAY** verb when no connection is provided. The connection called *connectionname* must already exist.

If **/cnosdisplayconn:** is typed without *connectionname*, the setting is cleared so that the configuration contains no default connection for the **DISPLAY** verb.

Snacfg Reference

Snacfg LINK

Purpose

Allows you to view, delete, or modify adapters.

Note
This command has been superseded by **Linkcfg**, as described in Linkcfg.

Important
If you specify adapter properties with **snacfg link**, these properties must match existing properties in your installation, or a n onfunctioning configuration may result. To protect against errors with **snacfg link**, use the SNA Manager instead.

Before configuring link services, you must use the SNA Manager to add the server on which the link services will be located.

Syntax

```
        [configpath]
```

Recommended Syntax

```
        [configpath]servernamelinkname [configpath]servernamelinkname [options]
[configpath]servernamelinkname [options]
[configpath]servernamelinkname
```

Other Available Syntax

```
        [configpath]linkname [configpath]linkname [options]
[configpath]linkname [options]
[configpath]linkname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured link services.

servername

Specifies the name of the server on which to view or change link services. Separate the name of the server from the name of the link service with a colon (**:**). It is recommended that *servername* be included in every **snacfg link** command that includes *linkname*. Without *servername*, if there is more than one link service called *linkname* in the installation, it is difficult to predict which link service called *linkname* will be affected by the command. The **snacfg link** command does not necessarily default to the local server if *servername* is omitted.

linkname

Specifies the name of the link service to view, modify, or delete. Link services names can contain from one through eight alphanumeric characters.

For adding link services, the recommended method is to use the SNA Manager, not **snacfg link**.

If no options are specified after *linkname*, the result is a list of the configuration settings for the specified link.

/add

Adds a link service called *linkname*. To configure the link service, either specify other options after **/add**, or specify configuration options in additional **snacfg link** commands (using the same *servername***:***linkname* combination).

For adding link services, the recommended method is to use the SNA Manager, not **snacfg link**.

/delete

Deletes *linkname*.

Options for Link Services
/server: *servername*

Specifies the server on which to install the link service.

/linktype:{ Token| **Ether**| **SDLC**| **X25**| **Channel | Twinax }**

Specifies the type of adapter with which *linkname* works.

/linetype:{ leased| **softdial**| **manual}**(for SDLC lines only)

Specifies the type of SDLC line (and, where applicable, the modem) that the link service will use:

- A **leased** line is a telecommunications line committed solely to SDLC communications with a particular remote system.
- A **softdial** line is a switched SDLC line on which the modem is dialed automatically by Host Integration Server. Such a modem must be attached to an SDLC adapter with a built-in serial (COM) port. Otherwise it is considered a **manual** modem.
- A **manual** line is a switched SDLC line on which the modem stores a phone number, or on which the modem is dialed manually.

/carrier:{ on| **off}**(for SDLC lines only)

Specifies whether the constant carrier option for an SDLC line is **on** or **off**.

Snacfg LU

Purpose

Allows you to view, add, delete, or modify 3270 LUs, on three types of connections: 802.2, SDLC, and/or X.25. Also allows you to assign 3270 LUs to LU pools that have already been configured.

Before configuring an LU, you must configure the connection that the LU will use. Also, before assigning an LU to an LU pool, you must create the LU and the LU pool.

Note
Configuration settings specified with snacfg lu correspond to 3270 LU settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] luname [configpath] lunameconnectionnamevalue [options]
  [configpath] luname [options]
  [configpath] luname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured 3270 LUs.

luname

Specifies the name of the 3270 LU to view, add, modify, or delete. A 3270 LU name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. A 3270 LU name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

If no options are specified after *luname,* the result is a list of the configuration settings for the specified LU.

/add

Adds a 3270 LU called *luname*. To configure the 3270 LU, either specify other options after **/add**, or specify configuration options in additional **snacfg lu** commands (using the same *luname*).

/delete

Deletes *luname*.

Options for 3270 LUs
/connection: *connectionname*

Specifies the connection to which the 3270 LU should be assigned or moved. When **/add** is used, this option is required.

/lunumber: *value*

Specifies the LU number, which identifies the LU on its connection. When /**add** is used, this option is required. Check with the administrator of the host system for the correct value; it should match the LOCADDR= parameter of the LU definition in VTAM or the NCP Gen on the host.

If the number that you specify has already been assigned to an LU or an APPC LU-LU pair on the intended connection, the command fails.

The range is from 1 through 254.

/pool: *poolname*

Assigns or moves the 3270 LU to *poolname*. A 3270 LU can be assigned to only one pool.

The pool specified with *poolname* must already exist. A 3270 LU pool can be created with the **snacfg pool** command.

If **/pool:** is typed without *poolname*, the specified LU is removed from whichever pool it is assigned to.

/lutype:{ display | printer }

Specifies whether the 3270 LU will be used for **display** (terminal emulation) or a **printer** (that is, a local printer or a local-area network printer, attached to a PC).

If no LU type has been specified, the default is **display**.

/displaymodel:{ mod2 | mod3 | mod4 | mod5 | 2 | 3 | 4 | 5 }

Specifies the display model; applies only when the **lutype** is **display**. The following display types are available:

- Model 2 is 24 lines by 80 characters.
- Model 3 is 32 lines by 80 characters.
- Model 4 is 43 lines by 80 characters.
- Model 5 is 27 lines by 132 characters.

Some emulators can only emulate certain display models. For more information, see your emulator documentation.

When a 3270 display LU is assigned to a 3270 LU pool, the display model setting of the pool overrides the setting of the LU.

If no display model has been specified, the default is Model 2.

/allowmodeloverride:{ yes | no }

Specifies whether the user is allowed to override the display model type by using the 3270 terminal emulation program.

When a 3270 display LU is assigned to a 3270 LU pool, the model override setting of the pool overwrites the setting of the LU.

If no setting has been specified for this parameter, the default is **no**.

/associate:" *text*"

This allows you to associate a specific 3270 printer LU with a 3270 display LU. Any user or group with permission to use the display LU will also have access to the associate printer LU. The text is the printer LU name.

/unassociate:" *text*"

This allows you to unassociate a 3270 printer LU from a 3270 display LU. It is not necessary to enter any text. **Snacfg** will ignore the text and unassociate the LU. To unassociate the printer LU, use the display LU name.

/comment:" *text*"

Adds an optional comment for the specified LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg LUA

Purpose

Allows you to view, add, delete, or modify LUA LUs on three types of connections: 802.2, SDLC, and/or X.25. Also allows you to assign LUA LUs to LU pools that have already been configured.

Before configuring an LU, you must configure the connection that the LU will use. Also, before assigning an LU to an LU pool, you must create the LU and the LU pool.

Note
Configuration settings specified with snacfg lua correspond to LUA LU settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] luname [configpath] lunameconnectionnamevalue [options]
  [configpath] luname [options]
  [configpath] luname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured LUA LUs.

luname

Specifies the name of the LUA LU to view, add, modify, or delete. An LUA LU name can be from one through eight characters long and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. An LUA LU name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

If no options are specified after *luname*, the result is a list of the configuration settings for the specified LU.

/add

Adds an LUA LU called *luname*. To configure the LUA LU, either specify other options after **/add**, or specify configuration options in additional **snacfg lua** commands (using the same *luname*).

/delete

Deletes *luname*.

Options for LUA LUs

/connection: *connectionname*

Specifies the connection to which the LUA LU should be assigned or moved. When **/add** is used, this option is required.

/lunumber: *value*

Specifies the LU number, which identifies the LU on its connection. When **/add** is used, this option is required. Check with the administrator of the host system for the correct value; it should match the LOCADDR= parameter of the LU definition in VTAM or the NCP Gen on the host.

If the number that you specify has already been assigned to an LU or an APPC LU-LU pair on the intended connection, the command fails.

The range is from 1 through 254.

/pool: *poolname*

Assigns or moves the LUA LU to *poolname*. An LUA LU can be assigned to only one pool. The pool specified with *poolname* must already exist. An LUA LU pool can be created with the **snacfg poola** command.

If **/pool:** is typed without *poolname*, the specified LU is removed from whichever pool it is assigned to.

/highpriority:{ yes | no }

Specifies whether this LU will be given priority over low-priority LUs.

When an LUA LU is assigned to an LUA LU pool, the priority setting of the pool overwrites the priority setting of the LU.

/comment:" *text*"

Adds an optional comment for the specified LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg LUD

Purpose

Allows you to view, add, delete, or modify downstream LUs. Also allows you to assign downstream LUs to LU pools that have already been created, and allows you to view the command that would create a specified downstream LU.

Note
Configuration settings specified with **snacfg lud** correspond to downstream LU settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] luname [configpath] lunameconnectionnamevalue [options]
  [configpath] luname [options]
  [configpath] luname [configpath] luname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured downstream LUs.

luname

Specifies the name of the downstream LU to view, add, modify, or delete. A downstream LU name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other LU or pool name that uses this connection.

If no options are specified after *luname*, the result is a list of the configuration settings for the specified LU.

/add

Adds a downstream LU called *luname*. To configure the downstream LU, either specify other options after **/add**, or specify configuration options in additional **snacfg lud** commands (using the same *luname*).

/delete

Deletes *luname*.

/print

Causes the display of the **snacfg** command that would create the specified downstream LU. The displayed command does not contain the word **snacfg**, so it can be redirected to a command file. See the information about command files earlier in this section.

Options for Downstream LUs
/connection:connectionname

Specifies the connection to which the downstream LU should be assigned or moved. When **/add** is used, this option is required.

/lunumber: *value*

Specifies the LU number, which identifies the LU on its connection. When **/add** is used, this option is required. Check with the administrator of the host system for the correct value; it should match the LOCADDR= parameter of the LU definition in VTAM or in the NCP Gen.

The LU number identifies the LU to the host system.

If the number you specify has already been assigned to an LU or an APPC LU-LU pair on the intended connection, the

command fails.

The range is from 1 through 254.

/pool: *poolname*

Assigns or moves the downstream LU to *poolname*. A downstream LU can be assigned to only one pool. The pool specified with *poolname* must already exist. A downstream LU pool can be created with the **snacfg poold** command.

If **/pool:** is typed without *poolname*, the specified LU is removed from whichever pool it is assigned to.

/comment:" *text*"

Adds an optional comment for the specified LU. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg Reference

Snacfg Mode

Purpose

Lets you add, delete, modify, or view an APPC mode. Also lets you to view the command that would create a specified mode.

Note
Configuration settings specified with snacfg mode correspond to APPC mode settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] modename [configpath] modename [options]
  [configpath] modename [options]
  [configpath] modename [configpath] modename
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured modes.

modename

Specifies the name of the mode on which to carry out actions. A mode name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The mode name cannot be the same as any other mode name in the subdomain of the server.

If no options are specified after *modename*, the configuration settings for the specified mode are displayed.

/add

Adds a mode called *modename*. To configure the mode, either specify other options after **/add**, or specify configuration options in additional **snacfg mode** commands (using the same *modename*).

/delete

Deletes *modename*.

/print

Causes the display of the **snacfg** command that would create the specified mode. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

Options for APPC Modes
/comment:" *text*"

Adds an optional comment for the mode. The comment can contain as many as 25 characters; enclose the comment in quotes.

/sessionlim: *value*

Specifies the parallel session limit.

The range is from 1 through 254. If no parallel session limit has been specified, the default is 1.

/conwin: *value*

Specifies the minimum contention winner limit.

The range is from 0 through the parallel session limit. If no minimum contention winner limit has been specified, the default

is 0.

/conlose: *value*

Specifies the partner minimum contention winner limit.

The range is from 0 through the parallel session limit. If no partner minimum contention winner limit has been specified, the default is 0.

/autoact: *value*

Specifies the automatic activation limit.

The range is from 0 through the minimum contention winner limit.

/autopartner:{ yes | no }

Specifies whether this mode will be used in automatic partnering of APPC LUs.

If automatic partnering is left unspecified, the default is **yes**.

/highpriority:{ yes | no }

Specifies whether communication with this mode will be given preference over low-priority communication.

If the high-priority setting is left unspecified, the default is **yes**.

/pacesendcnt: *value*

Specifies the pacing send count. A value of 0 represents an unlimited number of frames.

The range is from 0 through 63. If no pacing send count has been specified, the default is 4.

/pacerecvcnt: *value*

Specifies the pacing receive count. A value of 0 represents an unlimited number of frames.

The range is from 0 through 63. If no pacing receive count has been specified, the default is 4.

/maxsendru: *value*

Specifies the maximum size for RUs sent by the TP(s) on the local system.

The range is from 256 through 16384. If no maximum send RU size has been specified, the default is 1024.

/maxrecvru: *value*

Specifies the maximum size for RUs received from the TP(s) on the remote system.

The range is from 256 through 16384. If no maximum receive RU size has been specified, the default is 1024.

/maxsendcomp:{ None | RLE | LZ9}

These options offer progressively better compression, but at a progressively higher CPU usage cost.

/maxrecvcomp:{ None | RLE | LZ9}

These options offer progressively better compression, but at a progressively higher CPU usage cost.

/allowcomp:{ yes | no}

If LZ9 is used, this option controls whether data is compressed using RLE before being further compressed using LZ9.

/endpointcomp:{ yes | no}

This option controls whether intermediate nodes may use compression if one of the endpoints does not support compression or does not want to use it.

Snacfg Reference

Snacfg Pool

Purpose

Allows you to view, add, delete, or modify 3270 LU pools.

To assign existing 3270 LUs to a 3270 LU pool, first configure the pool with the **snacfg pool** command (including options), then add the LUs with the **snacfg lu** command (using the **/pool:***poolname* option).

Note
Configuration settings specified with snacfg pool correspond to 3270 LU pool settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] poolname [configpath] poolname [options]
  [configpath] poolname [options]
  [configpath] poolname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured 3270 LU pools.

poolname

Specifies the name of the 3270 LU pool to view, add, modify, or delete. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other pool name or LU name (other than APPC LU names) in the installation.

If no options are specified after *poolname*, the result is a list of the configuration settings for the specified pool.

/add

Adds a 3270 LU pool called *poolname*. To configure the 3270 LU pool, either specify other options after **/add**, or specify configuration options in additional **snacfg pool** commands (using the same *poolname*).

/delete

Deletes *poolname*.

Options for 3270 LU Pools

/displaymodel:{ mod2 | mod3 | mod4 | mod5 | 2 | 3 | 4 | 5 }

Specifies the model number of the LUs that will be added to this pool. (Only display LUs can be pooled; printer LUs cannot be pooled.) The following display models are available:

- Model 2 is 24 lines by 80 characters.
- Model 3 is 32 lines by 80 characters.
- Model 4 is 43 lines by 80 characters.
- Model 5 is 27 lines by 132 characters.

Some emulators can only emulate certain display models. For more information, see your emulator documentation.

The display model setting of a pool overwrites the setting of any 3270 LU assigned to the pool.

If no display model has been specified for a pool, the default is Model 2.

/allowmodeloverride:{ yes | no }

Specifies whether the user is allowed to override the display model type of the LU by using the 3270 terminal emulation program.

The model override setting of a pool overwrites the setting of any 3270 LU assigned to the pool.

If no setting has been specified for this parameter, the default is **no**.

/comment:" *text*"

Adds an optional comment to the specified 3270 LU pool. The comment can contain as many as 25 characters; enclose the comment in quotes.

/assocprint:{ yes | no }

Specifies that the LU pool contains display LUs with associated 3270 printers.

Snacfg Reference

Snacfg PoolA

Purpose

Allows you to view, add, delete, or modify LUA LU pools.

To assign existing LUA LUs to an LUA LU pool, first configure the pool with the **snacfg poola** command (including options), then add the LUs with the **snacfg lua** command (using the **/pool:***poolname* option).

Note
Configuration settings specified with snacfg poola correspond to LUA LU pool settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] poolname [configpath] poolname [options]
  [configpath] poolname [options]
  [configpath] poolname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured LUA LU pools.

poolname

Specifies the name of the LUA LU pool to view, add, modify, or delete. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other pool name or LU name (other than APPC LU names) in the installation.

If no options are specified after *poolname*, the result is a list of the configuration settings for the specified pool.

/add

Adds an LUA LU pool called *poolname*. To configure the LUA LU pool, either specify other options after **/add**, or specify configuration options in additional **snacfg poola** commands (using the same *poolname*).

/delete

Deletes *poolname*.

Options for LUA LU Pools

/highpriority:{ yes | no }

Specifies whether LUs in this pool will be given priority over low-priority LUs. The priority setting of a pool overwrites the setting of any LUA LU assigned to the pool.

/comment:" *text*"

Adds an optional comment to the specified LUA LU pool. The comment can contain as many as 25 characters; enclose the comment in quotes.

See Also

Other Resources

Snacfg Reference

Snacfg PoolD

Purpose

Allows you to view, add, or delete downstream LU pools. Also allows you to view the command that would create a specified downstream LU pool.

To assign existing downstream LUs to a downstream LU pool, first configure the pool with the **snacfg poold** command; then add the LUs with the **snacfg lud** command (using the **/pool:***poolname* option).

Syntax

```
          [configpath]  [configpath] poolname [configpath] poolname [] [text]
   [configpath] poolname [configpath] poolname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured downstream LU pools.

poolname

Specifies the name of the downstream LU pool to view, add, or delete. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other pool name or LU name (other than APPC LU names) in the subdomain.

If no options are specified after *poolname*, the result is a list of the configuration settings for the specified pool.

/add

Adds a downstream LU pool called *poolname*.

/delete

Deletes *poolname*.

/print

Causes the display of the **snacfg** command that would create the specified downstream LU pool. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. See the information about command files earlier in this section.

/comment:" *text*"

Adds an optional comment to the specified downstream LU pool. The comment can contain as many as 25 characters; enclose the comment in quotes.

Snacfg Reference

Snacfg PrintServer

Purpose

Allows you to add, delete, or view printer servers from one subdomain or multiple subdomains.

Note
Configuration settings specified with snacfg printserver correspond to settings configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath] servername [configpath] servername
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of print servers in the Host Integration Server subdomain.

/add

Adds the print server name of the Host Integration Server computer that is running the Host Integration Server Host Print Service. To configure the server name, specify the name after the **/add**. The print server name must match the computer name of the computer running Host Print Service.

You can add print servers for Host Integration Server computers that do not yet exist. For example, you can prepare a configuration file to be used at another location and add the server names using this parameter. Until the computers are configured with Host Integration Server running Host Print Service, SNA Manager will show them as offline.

/delete

Deletes the print server.

See Also

Other Resources

Snacfg Reference

Snacfg PrintSession3270

Purpose

Allows you to add, delete, modify, or view 3270 print sessions defined in the Host Print Service.

Note
Configuration settings specified with snacfg printsession3270 correspond to local print server settings configured with the SNA Manager.

Note
The /feedignorefinal option is no longer supported. By default, this value is enabled. A PDF file can be used to control this behavior if required.

Syntax

```
          [configpath]  [configpath]  [configpath] printsession3270nameservernameLUname[opti
  ons]
   [configpath] printsession3270name [options]
   [configpath] printsession3270name
```

where

***#** configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of 3270 print sessions.

/print

Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a print session to the Host Print Service. To configure the print session, you must specify the server name and the configured 3270 printer LU name after the **/add** using the **/server:***servername* and **/luname:***Luname* options.

/delete

Deletes the printer session. To delete the print session, you must specify the server name and the configured 3270 printer LU name after the **/delete**.

Options for 3270 Print Sessions
/autoactivate:{ yes | no }

Specifies whether the printer session will automatically activate when Host Integration Server is started. The default is yes.

/bestfit:{ yes | no }

Specifies whether to scale the output to the paper size. The default is **yes**.

/codepage: {Country | Custom}

This defines the host code page language in which the print jobs are output. The default is **Country** and the default language is **English (United States) [037]**. To change the default language, provide the number of the host code page of the country/region you want with the **/country** option.

If you want to use a custom file for the host code page, you must use **/customfile:***text,* where the *text* value is the name of

the file containing the specifications for the print job.

/collate:{ yes | no }

Adds an option to collate pages sequentially.

/color:{ yes | no }

For color printers, printing will be gray scale if nothing is selected.

/comment:" *text*"

Adds an optional comment for the printer session. It can contain as many as 25 characters; enclose the comment in quotes.

/copies: *value*

Specifies the number of copies for printing.

/country: *value*

Specifies the language in which the print jobs are printed.

/customfile:" *text*"

Specifies the name of the file containing the custom language translation information. Use this option if you specify **/codepage:custom**.

/devicename:" *text*"

Specifies the name of the destination printer.

/duplex: *simplex* | *horizontal* | *vertical*

Specifies printing on two-sided paper.

/filterfile:" *text*"

The **/filterfile** is a defined programming API that allows you to pass the printer data stream to a third party or user supplied DLL. Enter text to signify where the printer data stream should go.

/font:" *text*"

Specifies the font to be used in the printer sessions. This can be any available font installed on the computer.

/formname: *string*

Specifies the name for the form.

/margin: *left, right, top, bottom*

Specifies the margins of the page in inches in the order of left, right, top, bottom. The default margins are 0".

/orientation: *portrait, landscape*

Specifies the page layout as portrait or landscape.

/papersize: *value*

Specifies the size of the paper for printing.

Valid Values and Descriptions for Papersize

Value	Constant Name (from wingdi.h)	Description

1	DMPAPER_LETTER	Letter, 8.5" x 11"
2	DMPAPER_LETTERSMALL	Letter Small, 8.5" x 11"
3	DMPAPER_TABLOID	Tabloid, 11" x 17"
4	DMPAPER_LEDGER	Ledger, 17" x 11"
5	DMPAPER_LEGAL	Legal, 8.5" x 14"
6	DMPAPER_STATEMENT	Statement, 5.5" x 8.5"
7	DMPAPER_EXECUTIVE	Executive, 7.25" x 10.5"
8	DMPAPER_A3	A3 Sheet, 297 x 420mm
9	DMPAPER_A4	A4 Sheet, 210 x 297mm
10	DMPAPER_A4SMALL	A4 Small Sheet, 210 x 297mm
11	DMPAPER_A5	A5 Sheet, 148 x 210mm
12	DMPAPER_B4	B4 Sheet, 250 x 354mm
13	DMPAPER_B5	B5 Sheet, 182 x 257mm
14	DMPAPER_FOLIO	Folio, 8.5" x 13"
15	DMPAPER_QUARTO	Quarto, 215 x 275mm
16	DMPAPER_10X14	10" x 14" Sheet
17	DMPAPER_11X17	11" x 17" Sheet
18	DMPAPER_NOTE	Note, 8.5" x 11"
19	DMPAPER_ENV_9	#9 Envelope, 3.875" x 8.875"
20	DMPAPER_ENV_10	#10 Envelope, 4.125" x 9.5"
21	DMPAPER_ENV_11	#11 Envelope, 4.5" x 10.375"
22	DMPAPER_ENV_12	#12 Envelope, 4.75" x 11"
23	DMPAPER_ENV_14	#14 Envelope, 5" x 11.5"
24	DMPAPER_CSHEET	C Sheet, 17" x 22"
25	DMPAPER_DSHEET	D Sheet, 22" x 34"
26	DMPAPER_ESHEET	E Sheet, 34" x 44"
27	DMPAPER_ENV_DL	DL Envelope, 110 x 220mm

28	DMPAPER_ENV_C5	C5 Envelope, 162 x 229mm
29	DMPAPER_ENV_C3	C3 Envelope, 324 x 458mm
30	DMPAPER_ENV_C4	C4 Envelope, 229 x 324mm
31	DMPAPER_ENV_C6	C6 Envelope, 114 x 162mm
32	DMPAPER_ENV_C65	C65 Envelope, 114 x 229mm
33	DMPAPER_ENV_B4	B4 Envelope, 250 x 353mm
34	DMPAPER_ENV_B5	B5 Envelope, 176 x 250mm
35	DMPAPER_ENV_B6	B6 Envelope, 176 x 125mm
36	DMPAPER_ENV_ITALY	Italy Envelope, 110 x 230mm
37	DMPAPER_ENV_MONARCH	Monarch Envelope, 3.875" x 7.5"
38	DMPAPER_ENV_PERSONAL	6.75 Envelope, 3.625" x 6.5"
39	DMPAPER_FANFOLD_US	US Standard Fanfold, 14.875" x 11"
40	DMPAPER_FANFOLD_STD_GERMAN	German Standard Fanfold, 8.5" x 12"
41	DMPAPER_FANFOLD_LGL_GERMAN	German Legal Fanfold, 8.5" x 13"

Additional values, supported by Windows

42	DMPAPER_ISO_B4	B4 (ISO) 250 x 353mm
43	DMPAPER_JAPANESE_POSTCARD	Japanese Postcard 100 x 148mm
44	DMPAPER_9X11	9" x 11"
45	DMPAPER_10X11	10" x 11"
46	DMPAPER_15X11	15" x 11"
47	DMPAPER_ENV_INVITE	Envelope Invite 220 x 220mm
48	DMPAPER_RESERVED_48	Reserved -- do not use
49	DMPAPER_RESERVED_49	Reserved -- do not use
50	DMPAPER_LETTER_EXTRA	Letter Extra, 9.275" x 12"
51	DMPAPER_LEGAL_EXTRA	Legal Extra, 9.275" x 15"
52	DMPAPER_TABLOID_EXTRA	Tabloid Extra, 11.69" x 18"
53	DMPAPER_A4_EXTRA	A4 Extra, 9.27" x 12.69"

54	DMPAPER_LETTER_TRANSVERSE	Letter Transverse, 8.275" x 11"
55	DMPAPER_A4_TRANSVERSE	A4 Transverse, 210 x 297mm
56	DMPAPER_LETTER_EXTRA_ TRANSVERSE	Letter Extra Transverse, 9.275" x 12"
57	DMPAPER_A_PLUS	SuperA / A4, 227 x 356mm
58	DMPAPER_B_PLUS	SuperB / A3, 305 x 487mm
59	DMPAPER_LETTER_PLUS	Letter Plus, 8.5" x 12.69"
60	DMPAPER_A4_PLUS	A4 Plus, 210 x 330mm
61	DMPAPER_A5_TRANSVERSE	A5 Transverse, 148 x 210mm
62	DMPAPER_B5_TRANSVERSE	B5 (JIS) Transverse, 182 x 257mm
63	DMPAPER_A3_EXTRA	A3 Extra, 322 x 445mm
64	DMPAPER_A5_EXTRA	A5 Extra, 174 x 235mm
65	DMPAPER_B5_EXTRA	A5 Extra, 174 x 235mm
66	DMPAPER_A2	A2, 420 x 594mm
67	DMPAPER_A3_TRANSVERSE	A3 Transverse, 297 x 420mm
68	DMPAPER_A3_EXTRA_TRANSVERSE	A3 Extra Transverse, 322 x 445mm

/paperlength: *value*

Specifies the length of the paper for printing. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/paperwidth:value

Specifies the width of the paper. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/pdtfile:" *text*"

Specifies the name of a printer definition file.

/provider:" *text*"

This parameter maps to one of the two print provider DLLs (PPD3270.DLL or PPD5250.DLL) and tells the Host Printer Service which DLL to load to do the printer communications (ppd3270.dll or ppd5250.dll). The text for **snacfg printsession3270** is PPD3270.

/printtofile:" *text*"

Specifies the name of a text file to which the output is to be sent. When information is entered into this parameter, the print job is saved into a file on the hard drive instead of being sent to the printer.

/quality: *high, medium, low, draft*

Specifies the quality of print.

/scalefactor: *value*

Specifies the amount by which the printed output is to be scaled from the physical page size, divided by 100. For example, a

scale factor of 50 would make the printed output half its normal size, 10 would be one tenth, etc.

/server:" *text*"

Specifies the name of the server to which the session should attach. This is usually the name of an Host Integration Server computer that is running the Host Print Service in the subdomain. When **/add** is used, this option is required.

/truetype: *bitmap, download, substitute*

Specifies TrueType fonts or substitutes.

/uniqueextension:{ yes | no }

When the **/printtofile** option is used, specifying YES enables the Host Print Service to generate a unique output file extension for each print job.

/overridefontsize:{ yes | no }

Specifies whether or not the default font size can be overridden.

/fontsize:*value*

Specifies the size of the font (in points) used for output.

/charset:*value*

Specifies the font face used for output.

/bypassgdi:{ yes | no }

This allows print jobs that are formatted with host software to bypass the Windows printing format system. All the data from the host is passed directly to the printer. The default is **no**.

/charsperline:*value*

Specifies the number of characters printed per line.

/feedperjob:{ yes | no }

If set to **yes**, it will issue a form feed between each print job. The default is **no**.

/feedignoreinitial:{ yes | no }

If set to **yes**, the beginning form feed in a print job will be ignored. The default is **no**.

/jobtermination:{ EndBracket | UnBind }

The print job will terminate when either a **When End Bracket Received** or a **When Unbind Received** command is received by the printer. The default is **EndBracket**.

/linespacing:*value*

Specifies the space (in points) between printed lines.

/linesperinch:{ 6 | 8 }

This specifies the number of lines per inch (either six or eight) in the print job. The default is **6**.

/linewrap:{ yes | no }

Specifies whether the text will automatically wrap at the end of a line.

/luname:" *text*"

The name of the configured 3270 printer LU. When **/add** is used, this option is required.

/monitorjob:{ yes | no }

If **yes** is specified, this feature sends a message to the host computer stating that the print job is completed. The default is **no**.

/pagewidth:{ 80 | 132 | 158 }

Specifies the default page width in number of characters per line. The values can be 80, 132, or 158 characters. The default is 80.

/skipblanklines:{ yes | no }

If there are blank lines in the print job, it will not print them if **yes** is specified. The default is **no**.

/timeout: *value*

Specifies the time limit, in seconds, for terminating print jobs.

/transparencyascii:{ yes | no }

This sets a flag that indicates that the transparent data from the host is in ASCII format and does not need translation from EBCDIC. The default is **no**.

/transparencycustom: *value*

Specifies the custom byte that sends the data stream in transparent mode. The IBM standard value is 0x35, but if the host print job uses another value, such as 0x36, then this should be specified.

Snacfg Reference

Snacfg PrintSessionAPPC

Purpose

Allows you to add, delete, modify, or view APPC print sessions defined in the Host Print Service.

Note
Configuration settings specified with snacfg printsessionAPPC correspond to local print server setting configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath]  [configpath] printsessionAPPCnameservernamelocalLUname
  [options]
   [configpath] printsessionAPPCname [options]
   [configpath] printsessionAPPCname
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of APPC print sessions.

/print

Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a print session to the Host Print Service. To configure the print session, you must specify the server name and the configured APPC local LU alias name after the **/add**. The required options are **/server:***servername*and **/localLUalias:***localLUname*

/delete

Deletes the printer session. To delete the print session, you must specify the server name and the configured local LU alias after the **/delete**.

Options for APPC Print Sessions
/autoactivate:{ yes | no }

Specifies whether the printer session will automatically activate when Host Integration Server is started. The default is **yes**.

/bestfit:{ yes | no }

Specifies whether to scale the output to the paper size. The default is **yes**.

/codepage: {Country | Custom}

This defines the host code page language in which the print jobs are printed. The default is **Country** and the default language is **English (United States) [037]**. To change the default language, provide the number of the host code page of the country/region you want using the **/country** option.

If you want to use a custom file for the host code page, you must use **/customfile:***text,* where the text value is the name of the file containing the specifications.

/collate:{ yes | no }

Adds an option to collate pages sequentially.

/color:{ yes | no }

For color printers, printing will be gray scale if nothing is selected.

/comment:" *text*"

Adds an optional comment for the printer session. It can contain as many as 25 characters; enclose the comment in quotes.

/country: *value*

Specifies the language in which the print jobs are printed.

/customfile:" *text*"

Specifies the name of the file containing the custom language translation information. Use this option if you specify **/codepage:custom**.

/devicename:" *text*"

Specifies the name of the destination printer.

/duplex: *simplex* | *horizontal* | *vertical*

Specifies printing on two-sided paper.

/filterfile:" *text*"

This parameter is a defined programming API that allows you to pass the printer data stream to a third-party or user-supplied DLL. Enter the text of the file to which the printer data stream should go.

/font:" *text*"

Specifies the font to be used in the printer sessions. This can be any available font installed on the computer.

/formname: *string*

Specifies the name for the form.

/margin: *left, right, top, bottom*

Specifies the margins of the page, in inches, in the order of left, right, top, bottom. The default margins are 0".

/orientation: *portrait, landscape*

Specifies the page layout as portrait or landscape.

/pagewidth: *value (0-255)*

Specifies the width of page in characters.

/papersize: *value*

Specifies the size of the paper for printing.

/paperlength: *value*

Specifies the length of the paper for printing. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/paperwidth:v *alue*

Specifies the width of the paper. The values for paperlength and paperwidth are in tenths of a millimeter, and override the papersize setting.

/pdtfile:" *text*"

Specifies the name of a printer definition file.

/provider:" *text*"

This parameter maps to one of the two print provider DLLs (PPD3270.DLL or PPD5250.DLL) and tells Host Printer Service which DLL to load for the printer communications (ppd3270.dll or ppd5250.dll). The text for **snacfg printsessionappc** is PPD5250.

/printtofile:" *text*"

Specifies the name of a text file to which the output is to be sent. When information is entered into this parameter, the print

job is saved into a file on the hard drive instead of sending it to the printer.

/quality: *high, medium, low, draft*

Specifies the quality of print.

/scalefactor: *value*

specifies the amount by which the printed output is to be scaled from the physical page size, divided by 100. For example, a scale factor of 50 would make the printed output half its normal size, 10 would be one tenth, etc.

/server:" *text*"

Specifies the name of the server to which the session should attach. This is usually the name of an Host Integration Server computer that is running the Host Print Service in the subdomain. When **/add** is used, this option is required.

/systemtype: {AS400 | System36}

Specifies the type of system being used.

/truetype: *bitmap, download, substitute*

Specifies TrueType fonts or substitutes.

/uniqueextension:{ yes | no }

When the **/printtofile** option is used, the Host Print Service can generate a unique output file extension for each print job.

/overridefontsize:{ yes | no }

Specifies whether or not the default font size can be overridden.

/fontsize:*value*

Specifies the size of the font (in points) used for output.

/charset:*value*

Specifies the font face used for output.

/as400devicename:" *text*"

Specifies the name of the AS/400 computer that will be sending the print job.

/locallualias:" *text*"

Specifies the previously configured local LU alias. This is a required parameter when using **/add**.

/remotelualias:" *text*"

Specifies the default remote APPC LU. If an LU is specified here, do not enter text into **/remotefqname**.

/remotefqname:" *text*"

Specifies the fully qualified name or alias of a remote APPC LU. The fully qualified name is the network name and LU name. If text is entered here, do not enter text into **/remotelualias**.

/modename:" *text*"

The default mode name is QPCSUPP. The other mode names available are: #INTERSC, BLANK, and QSERVER.

/username:" *text*"

Specifies the authorized user.

/password:" *text*"

Specifies the user password.

/hostprinttransform:{ yes | no }

Enter *yes* to activate the Host Print Transform feature.

/msgqname:" *text*"

Specifies the qualified name of the message queue to which operational messages for this device are sent.

/msglibname:" *text*"

Specifies the library in which the message queue is located.

/hostprintertype:" *text*"

Specifies the type of host printer.

/copies:*value*

Specifies the number of copies to print.

/papersrc1:{ continuous | cut | autocut }

Specifies the type of paper used in the output device.

Snacfg Reference

Snacfg Server

Purpose

Allows you to view or change settings for servers. Can also be used to add a server, although the SNA Manager is the recommended interface for adding servers.

Note
Configuration settings specified with snacfg server correspond to server settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] servername [configpath] servername [options]
  [configpath] servername [options]
  [configpath] servername
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the servers on the local subdomain.

servername

Specifies the name of the server on which settings will be viewed or changed. The server name should be in the format machine_name or \\machine_name\snaservr (for specifying the primary node on the machine) and \\machine_name\snasrv02 (or snasrv03, snasrv04, etc.) for specifying the secondary nodes on the machine.

/add

Adds a Host Integration Server computer called *servername*. For adding a server, the recommended method is to use the SNA Manager, not **snacfg server**.

Before you can add connections to the server, link services must also be configured for the server. The recommended interface for configuring link services is the SNA Manager.

/delete

Deletes *servername*.

Options for Servers

/netname:" *text*"

Specifies the local network name, which identifies the SNA network of the local server. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. If the local network name is specified, the local control point name must also be specified (using the **/cpname** option).

/cpname:" *text*"

Specifies the local control point name, which identifies the local system to other control points (nodes) on the SNA network. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. If the local control point name is specified, the local network name must also be specified (using the **/netname** option).

When connecting to a host system and using a local control point name, the name should match the CPNAME = parameter in the host's PU definition.

/comment:" *text*"

Adds an optional comment for the specified server. The comment can contain as many as 25 characters; enclose the comments in quotes.

Snacfg Reference

Snacfg TN3Server

Purpose

Allows you to view, add, delete, or modify TN 3270 servers. This command can also be used to add a TN 3270 server, though the SNA Manager is the recommended interface for adding servers.

Note
Configuration settings specified with snacfg tn3server correspond to server settings configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath] TN3Servername [configpath] TN3Servernname [configpath]
  TN3Servernname [options]
   [configpath] TN3Servername [options]
   [configpath] TN3Servername
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the TN 3270 servers on the local subdomain.

tn3servername

Specifies the computer name of the TN 3270 server on which settings will be viewed or changed.

/print

Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a TN 3270 Server computer called *tn3servername*. For adding a server, the recommended method is to use the SNA Manager, not **snacfg tn3server**.

Before you can add connections to the server, link services must also be configured for the server. The recommended interface for configuring link services is the SNA Manager.

/delete

Deletes *tn3servername*.

Options for TN 3270 Servers

/logauditevents:{ yes | no }

Specifies whether the TN service uses the event log to log informational messages as well as error conditions. These are messages that log successful client connection and successful client termination.

/snaeventlog:{ yes | no }

Specifies whether the TN service uses the same event log as the SNA Manager. If this is set to *yes*, all TN3270 service event messages are written to the event log being used by the Host Integration Server system. If this is set to *no*, all TN3270 service event messages are written to the Windows Event Log on the local machine.

/nameresolution:{ yes | no }

Name resolution should only be selected if you are running a domain name resolver. A domain name resolver catalogs IP addresses and corresponding network names of connected computers. The domain name resolver allows you to enter the

name of a computer rather than the IP address when an IP address is required.

/closelistensocket:{ yes | no }

By default, the TN3270 Service always has a socket open for listening for incoming requests. If this option is turned on, the TN3270 Service stops listening on this socket once all of its defined LUs are in use. The purpose of this is to work with emulators that can try to connect to a number of computers running TN3270 Service and that connect to whichever computer accepts their connection attempt. In this case, it is useful if a computer with no LUs available is not listening.

/tn3270modeonly:{ yes | no }

The TN3270 Service now supports TN3270E, an enhancement to TN3270. When a client first connects to a computer running TN3270 Service, it negotiates which functions they both support. TN3270 emulators should be able to negotiate with TN3270 Service, if only to state that they do not support TN3270E. However, some TN3270 emulators are unable to negotiate properly with TN3270 Service, causing the negotiation to fail. For this reason the TN3270 Service has an option to default to TN3270 mode and not to use TN3270E features, so that these TN3270 negotiation problems do not occur.

/printerflowcontrol:{ yes | no }

If a TN3270 Server adheres strictly to the specification described in RFC 1647, there is no way of implementing flow control between a computer running TN3270 Service and a TN3270 client. In practice this causes no problems for display emulators, but it does cause a problem for printer emulators, which can be swamped with data and have no way of notifying the TN3270 Service that they cannot process any more messages. If this option is turned on, the TN3270 Service sends all messages to a TN3270 printer client as RESPONSE-REQUIRED, and does not send any messages until it has received a response for the previous message.

/idletimeout: *value 1-1440*

Specifies time limits in seconds. If the session is inactive for this length of time, then TN3270 Service disconnects the client.

/initstatusdelay: *value (0-86400)*

Specifies time limits. This is the delay between the time when TN3270 Service connects to a host session and the time the TN3270 Service starts updating the client screen. There are often a large number of startup messages when the TN3270 Service first connects to a host session, and this option gives the user the opportunity not to receive them all.

/msgclosedelay: *value (0-86400)*

Specifies time limits. When TN3270 Service forces a client to disconnect (for example, when the Host Integration Server session to the host has been lost), it sends the client an error message to be displayed on the screen. This value specifies the time between sending the message to the client and closing the socket with the client (which causes some clients to clear the screen, and so erase the message).

/refreshcycletime: *value (0-60)*

Specifies time limits. This is the delay between updates of the status on the display.

/inboundrusize: *value (256-32768)*

This controls the RU size (SNA message size) used by the TN3270 Service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

/outboundrusize: *value (256-32768)*

This controls the RU size (SNA message size) used by the TN3270 Service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

/portnumber: *value*

Specifies the port number associated with telnet. You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/comment:" *text*"

Adds an optional comment for the specified server. The comment can contain as many as 25 characters; enclose the comments in quotes.

Snacfg Reference

Snacfg TN5Server

Purpose

Allows you to view, add, delete, or modify TN 5250 servers. the SNA Manager is the recommended interface for adding TN 5250 servers.

Note
Configuration settings specified with snacfg tn5server correspond to server settings configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath] TN5Servername [configpath] TN5Servernname [configpath]
  TN5Servernname[options]
   [configpath] TN5Servername [options]
   [configpath] TN5Servername
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the TN 5250 servers on the local subdomain.

Tn5servername

Specifies the computer name of the TN 5250 server on which settings will be viewed or changed.

/print

Displays a list of the configuration settings of a print session. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a Host Integration Server computer called *tn5servername*. For adding a TN 5250 server, the recommended method is to use the SNA Manager, not **snacfg tn5server**.

Before you can add connections to the server, link services must also be configured for the server. The recommended interface for configuring link services is the SNA Manager.

/delete

Deletes *tn5servername*.

Options for TN 5250 Servers
/portnumber: *value*

Specifies the port number associated with telnet (e.g., port number 23). You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/comment:" *text*"

Adds an optional comment for the specified server. The comment can contain as many as 25 characters; enclose the comments in quotes.

Snacfg Reference

Snacfg TN3Session

Purpose

Allows you to view, add, delete, or modify TN 3270 sessions. the SNA Manager is the recommended interface for adding sessions.

Note
Configuration settings specified with snacfg tn3session correspond to session settings configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath]  luname [configpath] luname  [configpath] luname[option
  s]
   [configpath] luname [options]
   [configpath] luname
```

where

#configpath

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the sessions on the local subdomain.

luname

Specifies the LU name on which the session will be activated.

/print

Displays a list of the configuration settings of a print session. The displayed command does not contain the word snacfg, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a TN 3270 session called luname. For adding a session, the recommended method is to use the SNA Manager, not snacfg tn3session.

/delete

Deletes lu*name*.

Options for TN 3270 Sessions

/tn3server: *tn3servername*(required)

Specifies the computer name of the TN 3270 server on which settings will be viewed or changed. The *tn3servername* is required.

/assocname:" *text*"

Printer LUs can be marked as associated instead of generic or specific. To associate a printer LU with a terminal LU, type the Associated LU name. When this option is selected, the **terminal name** will default to IBM-3287-1. The quotes must be included.

/portnumber: *value*

Specifies the port number associated with telnet (e.g., port number 23). You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/pooltype: *pooltype*

The values for pooltype are: GenericTerminal, SpecificTerminal, GenericPrinter, SpecificPrinter, AssocPrinter.

/maxsessions: *value*

Specifies the maximum number of LU-LU sessions that one independent LU can support. The limit set by maxsessions prevents an independent LU from using up too many unreserved session control blocks.

/modeltypes: *model*[,model,]

Values for TN3270 model types are:

Model2, Model3, Model4, Model5,

3275_2, 3276_2, 3277_2, 3278_2, 3278_2_E, 3279_2, 3279_2_E,

3276_3, 3278_3, 3278_3_E, 3279_3, 3279_3_E,

3276_4, 3278_4, 3278_4_E, 3279_4, 3279_4_E,

3278_5, 3278_5_E, 3279_5, 3279_5_E,

Dynamic, 3287_1

Snacfg Reference

Snacfg TN5Session

Purpose

Enables you to view, add, delete, or modify TN 5250 sessions. the SNA Manager is the recommended interface for adding sessions.

Note
Configuration settings specified with snacfg tn5session correspond to session settings configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath] appcrlualias [configpath] appcrlualias [configpath] app
  crlualias[options]
   [configpath]  appcrlualias [options]
   [configpath] appcrlualias
```

where

#configpath

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the sessions on the local subdomain.

appcrlualias

Specifies the APPC remote LU alias name on which the session will be activated.

/print

Displays a list of the configuration settings of a print session. The displayed command does not contain the word snacfg, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a TN 5250 session called *appcrlualias*. For adding a session, the recommended method is to use the SNA Manager, not snacfg tn5session.

/delete

Deletes *appcrlualias*.

Options for TN 5250 Sessions
/tn5server: *tn5servername*(required)

Specifies the computer name of the TN 5250 server on which settings will be viewed or changed.

/locallu: *appclualias*(required)

Specifies the name of the APPC LU alias to view, add, modify, or delete. An APPC LU alias name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The APPC LU alias name cannot be the same as any other APPC LU alias name or pool name on the server.

/mode: *modename*

Specifies the name of the mode on which to carry out actions. A mode name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The mode name cannot be the same as any other mode name in the subdomain of the server.

If no options are specified after modename, the configuration settings for the specified mode are displayed.

/user: *username*

Specifies the name of the user to view, change settings for, or delete. For adding TN 5250 users, the recommended method is to user the SNA Manager, not **snacfg tn5session**. If you are adding a user, *username* must match the name in the user's account on the Windows domain or on the local system.

/password: *password*

Specifies the current password for the user's account identified in *username*.

/modeltypes: *model*(,model,)

Specifies the model type. Values for TN5250 model types are:

5555_C01, 5555_B01, 3477_FC, 3477_FG

3180_2, 3179_2, 3196_A1

5292_2, 5291_1, 5251_11

/portnumber: *value*

Specifies the port number associated with telnet (e.g., port number 23). You can type another port number to override the default value for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client to connect to multiple host computers.

/comment:" *text*"

Optionally, type a comment of up to 25 characters.

Snacfg Reference

Snacfg TNIPID

Purpose

Allows you to view, add, delete, or modify telnet IP (Internet Protocol) addresses. the SNA Manager is the recommended interface for adding TNIPIDs.

Note
Configuration settings specified with snacfg tnipid correspond to session settings configured with the SNA Manager.

Syntax

```
          [configpath]  [configpath] tnipid [configpath] tnipid  [configpath] tnipid [option
  s]
   [configpath] tnipid [options]
   [configpath] tnipid
```

where

#configpath

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the TNIPIDs on the local subdomain.

tnipid

Specifies the TN Internet Protocol (IP) address.

/print

Displays a list of the configuration settings of valid telnet IP addresses. The displayed command does not contain the word snacfg, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds a TNIPID called *tnipid*. For adding a *tnipid*, the recommended method is to use the SNA Manager, not snacfg tnipid.

/delete

Deletes *tnipid*.

Options for TNIPID

/session: *text*

Specifies the session name for the specified telnet IP address.

/subnet: *tnipaddress*

Specifies the TN Internet Protocol (IP) address. If a tnipid parses as "n.n.n.n," it will be treated as an IPADDRESS. Otherwise, it will be treated as an IPNAME.

Snacfg Reference

Snacfg User

Purpose

Enables you to view, modify settings for, or delete users recognized by Host Integration Server. Also lets you assign LUs or LU pools to 3270 users, or assign default LUs to 5250 users.

In addition, **snacfg user** enables you to add users to the list recognized by Host Integration Server. However, it is recommended that you use the SNA Manager, not **snacfg user**, when adding users.

Important
If you add user names by using the **/add** option with **snacfg user**, these names must match existing user account names in t he Windows domain, or a nonfunctioning configuration may result. To protect against errors with **snacfg user**, use the SNA Manager, instead.

Before assigning LUs or LU pools to users, you must first configure the LUs or LU pools.

Note
Configuration settings specified with snacfg user correspond to user or group settings configured with the SNA Manager.

Syntax

```
        [configpath]  [configpath] username [configpath] username [options]
   [configpath]  [configpath] username [options]
   [configpath] username
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of the 3270 users recognized by Host Integration Server.

domain/username

Specifies the domain and name of the user to add, view, change settings for, or delete.

For adding 3270 users, the recommended method is to use the SNA Manager, not **snacfg user**. If you are adding or removing a user, *username* must match the name in the user's account on the Windows domain specified by *domain*.

/add

Adds a user called *username* to the list of 3270 users recognized by Host Integration Server. The user must already have an account on the Windows domain or on the local system.

For adding 3270 users, the recommended method is to use the SNA Manager, not **snacfg user**.

/validate

Attempts to fill in any SIDs that are missing from user or group listings in the Host Integration Server configuration file. If the SIDs can be obtained from user accounts in the Windows domain for each user, the SIDs will be added to the listings in the Host Integration Server configuration.

Run **snacfg user /validate** after working offline and adding users to the configuration, so that the user listings in Host Integration Server will be functional.

/delete

Deletes *username*.

Options for Users of 3270 Emulators

/insert: *luname*[, *luname*,...]

Assigns the specified 3270 or LUA LUs or pools to the user. Separate multiple names with commas.

/remove: *luname*[, *luname*,...]

Deletes the assignment of 3270 or LUA LUs or pools to the user. Separate multiple names with commas.

/insertrlu: *luname*[, *luname*,...]

Assigns APPC Remote LUs to the user. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/removerlu: *luname*[, *luname*,...]

Deletes the assignment of APPC Remote LUs to the user. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/domain: *domainname*

Specifies the Windows domain in which the user account is found. For all actions involving the domain name associated with a user account, the recommended method is to use the SNA Manager, not **snacfg user**. If an incorrect domain name is specified with **snacfg user**, a nonfunctioning configuration may result.

/comment:" *text*"

Adds an optional comment for the specified user. The comment can contain as many as 25 characters. The quotes must be included.

/encrypt:{ yes | no }

Specify YES to enable data encryption between the server and client.

Options for Users of TPs or 5250 Emulators

/defloclu: *LUalias*

Specifies the default local APPC LU for this user or group. Both the user (or group) name and the LU alias must already be configured in Host Integration Server. If **/defloclu:** is typed without *LUalias*, the user or group record is cleared of any default local LU.

/defremlu: *LUalias*

Specifies the default remote APPC LU for this user or group. Both the user (or group) name and the LU alias must already be configured in Host Integration Server. If **/defremlu:** is typed without *LUalias*, the user or group record is cleared of any default remote LU.

Snacfg Reference

Snacfg Workstation

Purpose

The workstation assignment feature allows you to add, delete, modify, or view workstations. You can specify parameters such as IP address, workstation name, and define access parameters to the workstation.

Note
Configuration settings specified with snacfg workstation correspond to local workstation settings configured with the SNA M anager.

Syntax

```
          [configpath]  [configpath] workstationid [configpath] workstationid [configpath] w
  orkstationid [options]
   [configpath] workstationid [options]
   [configpath] workstationid
```

where

*configpath*

Specifies the path of the configuration file to view or change. If the configuration path is omitted, Host Integration Server will attempt to access the configuration file on the local system, using the path \Program Files\Host Integration Server\SYSTEM\CONFIG\COM.CFG.

/list

Generates a list of configured workstations.

/print

Displays a list of the configuration settings of a workstation. The displayed command does not contain the word **snacfg**, so that it can be redirected to a command file. Command files are discussed earlier in this section.

/add

Adds the workstation ID using a either a name or IP address to identify the workstation. The workstation ID is usually the workstation name.

If using an IP address to identify the workstation, the **/address** option is a required parameter.

To configure the workstation, either specify other options after **/add** or specify configuration options in additional **snacfg workstation** *workstationid* commands.

/delete

Deletes the workstation.

Options for Workstation
/insert: *luname*[,*luname,*]

Assigns the specified 3270 or LUA LUs or pools to the workstation. Separate multiple names with commas.

/remove: *luname*[,*luname,*]

Deletes the assignment of 3270 or LUA LUs or pools to the workstation. Separate multiple names with commas.

/insertrlu: *luname*[, *luname*,...]

Assigns APPC Remote LUs to the workstation. Separate multiple names with commas. The name *rluname* can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/removerlu: *luname*[, *luname*,...]

Deletes the assignment of APPC Remote LUs to the workstation. Separate multiple names with commas. The name *rluname*

can be either the RLU alias or its fully-qualified name of the form "*netname.luname*".

/comment:" *comment*"

Sets the workstation's comment field. The quotes must be included.

/wkstaonly:{ yes | no }

If **yes**,it restricts resources available on the computer to the LUs assigned to the workstation. Users will not be able to access LUs assigned to them unless the LU is also assigned to the workstation. If **no**, it allows users access to the LUs assigned to the workstation and the LUs assigned to the user. The default is **no**.

/address:{ yes | no }

If **yes**, Host Integration Server will look for an IP address in place of an alphanumeric name for the workstation ID. This parameter must be set to **yes** if using an IP address. The default is **no**.

Snacfg Error Messages

This section lists the error codes and their corresponding messages used by Snacfg commands.

Error Code	Message
3841	Insufficient privilege to run the SNA Manager program in this domain.
3842	The activation value is invalid.
3843	The link service is invalid.
3844	The allocation timeout is invalid.
3845	The audit level is invalid.
3846	The Control Point Name is invalid. The name can be from one through eight alphanumeric characters long.
3847	The Switched Connection Establishment Timeout is invalid. The range is from 10 through 500 seconds; the default is 300.
3848	The Contact Retry Limit is invalid. The range is from 1 through 20; the default is 10.
3849	The Contact Timeout is invalid. The range is from 5 (five-tenths of a second) through 300 (30 seconds). The default is 300 (30 seconds).

3850	The Partner Min Contention Winner Limit is invalid. The range is from 0 through the parallel session limit; the default is 0.
3851	The Minimum Contention Winner Limit is invalid. The range is from 0 through the parallel session limit; the default is 0.
3852	The default connection for the display verb is invalid.
3853	The DLC type is invalid.
3854	The domain name is invalid.
3855	The duplex value is invalid.
3856	Internal : Bad existing record.
3857	Facility Data is invalid. Facility Data can include as many as 126 hexadecimal digits.
3858	The configuration file is corrupt or does not have correct structure.
3859	The configuration file name is invalid. Verify that a primary or backup server is running in the domain you are trying to ad minister.
3860	Internal : Bad File Handle.

3861	The Idle Retry Limit is invalid. The range is from 1 through 255; the default is 10.
3862	The Idle Timeout is invalid. The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is 300 (30 seconds).
3863	The Automatic Activation Limit is invalid. The range is from 0 through the Minimum Contention Winner Limit.
3864	The Security Key Type is invalid.
3865	The Line Type is invalid.
3866	The LU Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. Names for APPC LUs must be different from one another, and names for non-APPC LUs must be different from one another.
3867	The LU Number is invalid. The range is from 1 through 255. The LU Number cannot be the same as that for any other LU using the connection, including local APPC LUs paired with remote APPC LUs that use the connection.
3869	The Mode Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.
3870	The Display Model is invalid.
3871	The Name or Alias is invalid.
3872	The LU Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. Names for APPC LUs must be different from one another.

3873	The NetView connection is invalid.
3874	The Network Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.
3875	The Network Name is invalid. The name can be from one through eight characters long, and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase.
3876	The value for 'Model can be overridden' is invalid.
3877	The Packet Size is invalid. The possible values are 64, 128, 256, and 512. The default is 128.
3878	The LU Partner is invalid.
3879	The password is invalid. A password can contain from one through 10 characters.
3880	The Poll Address is invalid. The address is a two-digit hexadecimal number; the address cannot be the reserved values 00 or FF.
3881	The Poll Rate is invalid. The range is from 1 through 50 polls per second; the default is 5.
3882	The Poll Retry Limit is invalid. The range is from 1 through 255; the default is 10.
3883	The Poll Timeout is invalid. The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is 10 (1 second).

3884	The Port is invalid.
3885	Internal : Invalid record.
3886	The Remote X.25 Address is invalid. The address usually consists of 12 hexadecimal digits, but can contain up to 15 hexadecimal digits.
3887	The Role Type is invalid.
3888	The RTM Timers Run Until value is invalid.
3889	The first three digits of the Remote Node ID are invalid. These digits, also called the Block Number, can be any three hexadecimal digits except 000 or FFF, which are reserved.
3890	The last five digits of the Remote Node ID are invalid. These digits, also called the Node Number, can be any five hexadecimal digits.
3891	The Max Receive RU Size is invalid. The range is from 256 through 16384; the default is 1024.
3892	The Pacing Receive Count is invalid. The range is from 0 through 63; the default is 4.
3893	The Remote SAP Address is invalid. The address can be a 2-digit hexadecimal number that is a multiple of 04, between 04 and EC. The default is 04.
3894	The Security Key is invalid. For a Security Key in Hex, type a 16-digit hexadecimal number. For a Security Key in Characters, type an eight-character string consisting of alphanumeric characters and/or $, @, #, and the period (.).

3895	The server name is invalid.
3896	The Parallel Session Limit is invalid. Legal values are between 1 and 10000 inclusive.
3897	The Parallel Session Limit is invalid. Legal values are between 1 and 10000 inclusive.
3898	The Timeout for Starting TPs is invalid. The range is from 1 through 3600 seconds; the default is 60 seconds.
3899	The Timeout for Starting TPs is invalid. The range is from 1 through 3600 seconds; the default is 60 seconds.
3900	The Maximum BTU Length is invalid. The range is from 265 through 16393; the defaults are: Token Ring:\t1929Ethernet:\t1493Channel:\t4105SLDC:\t\t265X25:\t\t1033.
3901	The Remote Network Address is invalid. The address is a 12-digit hexadecimal value.
3902	The Retry Limit is invalid. The range is from 0 through 255; the default is 10. A value of zero means the system uses its internal default retry limit.
3903	The Receive ACK Threshold is invalid. The range is from 1 through 127; the default is 2.
3904	The Unacknowledged Send Limit is invalid. The range is from 1 through 127; the default is 8.
3905	The XID Retries value is invalid. The range is from 0 through 30; the default is 3.

3906	The first three digits of the Local Node ID are invalid. These digits, also called the Block Number, can be any three hexadecimal digits except 000 or FFF, which are reserved.
3907	The last five digits of the Local Node ID are invalid. These digits, also called the Node Number, can be any five hexadecimal digits except 00000, which is reserved.
3908	The Max Send RU Size is invalid. The range is from 256 through 16384; the default is 1024.
3909	Minimum Send RU is invalid.
3910	The Pacing Send Count is invalid. The range is from 0 through 63; the default is 4.
3911	User Data is invalid. User Data consists of an even number of hexadecimal charters, up to the maximum of 32 characters. The default is C3; this specifies the Qualified Logical Link Control (QLLC) protocol.
3912	The User ID is invalid. The User ID can contain from one through 10 characters.
3913	The PVC Alias is invalid. The range is from 1 through the number of configured PVC channels; the default is 1.
3914	The configuration file has been created by newer version of Host Integration Server. The Admin program only supports newer versions in read only mode.
3915	The Window Size is invalid.
3917	The connection cannot be modified when there are downstream LUs associated with it.

3918	There is already a 3270 LU with this name.
3919	There is already a 3270 Pool with this name.
3920	There is already a Link Service with this name.
3921	Multiple implicit partners or modes are not allowed for a local LU.
3922	There is already an LU with this LU Number.
3923	There is already an LUA LU with this name.
3924	There is already an LUA Pool with this name.
3925	The name or alias has already been used.
3926	There is already a Host Integration Server with this name.
3927	There is already a Downstream LU with this name.
3928	There is already an Downstream LU Pool with this name.

3929	The LU-LU pair already exists, or the adapter assignment already exists for the connection.
3930	There is already a user with this name.
3931	Unable to read the file.
3932	Unable to write the file.
3933	Field conflict. Unable to change.
3934	Writing to active file is not allowed.
3935	Configuration file was not found.
3936	Limit reached on objects associated with this item.
3937	Internal: Configuration is invalid.
3938	Session Limit conflicts with contention settings.
3939	Line Types do not match.

3940	Unable to write to active configuration file.
3941	Lost contact with remote domain.
3942	Unable to allocate memory.
3943	Internal: Memory corruption has occurred. Please reload configuration file.
3944	The number of LUs or connections for this Host Integration Server has been exceeded. Each Host Integration Server is capable of supporting 250 connections and 15000 dependent LUs.
3945	Internal: LUs are on different servers.
3946	Implicit partner or mode is not implicit.
3947	Internal: The item to be deleted is already absent from this grouping.
3948	Internal: Record has already been added to the configuration.
3949	A connection must have an associated link service.
3950	The Initially Active value must be zero for Local/Local Partners.

3951	The diagnostics record could not be found in the configuration file.
3952	Parallel Sessions are not supported on this LU.
3953	When a link service is to be used by multiple connections, and the connections accept incoming calls, the NRZ/NRZI settings for all the connections must match.
3954	The configuration file is an older config file.
3955	Internal: Target record already has an owner.
3956	The internal control record for the configuration file has exceeded its maximum size.
3957	During the conversion of an old Comm Server configuration file, COM.SEC was found to be corrupt, or of the wrong version type.
3958	Insufficient privilege or the configuration file is locked for read\\write access.
3959	Limit reached on number of objects in a configuration file.
3960	Limit reached on number of objects of this type.
3961	Internal: Invalid record type.

3962	Unable to change this record.
3963	The connection cannot be modified when there are LUs associated with it.
3964	The Session Limit is invalid.
3965	One of the DLC timeout values is invalid.
3966	This Return code is not used.
3967	The LU Alias has already been used. The LU Alias cannot be the same as any other APPC LU on its server.
3968	Unable to configure domain because the primary Host Integration Server for the domain is not active.
3969	The same Remote Network Address and SAP have already been specified for this link service in connection %s. To create more than one connection to the same remote machine, add one or more 802.2/DLC link services via Host Integration Server Setup over the same adapter with different local SAP addresses. This will automatically create additional connections in SNA Manager. Alternatively, if further SAPs are available at the remote machine, choose a different Remote SAP for this connection.
3970	No users or groups have been defined with Full Control Administration Access privileges. At least one user or group must be configured with permissions to alter the configuration.
3971	The Fully Qualified LU Name has already been used. The combination of the Net Name and LU Name cannot be the same as any other APPC LU on the server.
3972	Another Incoming Connection for this Link Service is already configured for XID 0. Multiple Incoming connections for one Link Service can only be configured if the connections use XID 3.

39733	Another incoming connection for this link service is configured for a different NRZ/NRZI setting. Multiple incoming connections for one link service must use the same NRZ/NRZI setting.
39734	Another Incoming Connection for this Link Service is configured for a different Poll Address. Multiple Incoming connections for one Link Service must use the same Poll Address.
39735	Another Primary Multidrop Connection for this Link Service is configured for this Poll Address. Primary Multidrop connections for the same Link Service must use different Poll Addresses.
39736	Another Primary Multidrop Connection for this Link Service is configured for a different NRZ/NRZI setting. Primary Multidrop connections for the same Link Service must use the same NRZ/NRZI setting.
39737	Another Primary Multidrop Connection for this Link Service is configured for a different Maximum BTU Length. Primary Multidrop connections for the same Link Service must use the same Maximum BTU Length.
39844	Another Primary Multidrop Connection for this Link Service is configured for a different XID Type. Primary Multidrop connections for the same Link Service must use the same XID Type.
39845	Another Primary Multidrop Connection for this Link Service is configured for a different Duplex setting. Primary Multidrop connections for the same Link Service must use the same Duplex setting.
39846	Another Primary Multidrop Connection for this Link Service is configured for a different Data Rate. Primary Multidrop connections for the same Link Service must use the same Data Rate.
39847	Another Primary Multidrop Connection for this Link Service is configured for a different Data Rate. Primary Multidrop connections for the same Link Service must use the same Data Rate.
39888	Another Primary Multidrop Connection for this Link Service is configured for a different Poll Timeout. Primary Multidrop connections for the same Link Service must use the same Poll Timeout.
39889	Another Primary Multidrop Connection for this Link Service is configured for a different Poll Retry Limit. Primary Multidrop connections for the same Link Service must use the same Poll Retry Limit.

3990	Another Primary Multidrop Connection for this Link Service is configured for a different Contact Timeout. Primary Multidrop connections for the same Link Service must use the same Contact Timeout.
3991	Another Primary Multidrop Connection for this Link Service is configured for a different Contact Retry Limit. Primary Multidrop connections for the same Link Service must use the same Contact Retry Limit.
3992	Leased SDLC connections cannot support Incoming Calls. Leased connections do not require either end to initiate the connection, therefore both ends treat the connection as Outgoing Calls only.
3993	The Partner LU specified for the CPI-C Symbolic Destination Name does not exist.
4000	The Mean time between broadcasts is invalid. The range is from 45 through 65535 seconds; the default is 60.
4001	No protocols have been defined to send Server Broadcasts. At least one protocol must be configured to send Server Broadcasts.
4002	The Channel Address is invalid.
4003	Could not perform the necessary privilege lookup to enable the required privileges in your process.
4004	Could not perform the necessary operations on the process token to enable the required privileges.
4005	You do not have the privileges required to set system ACLs on files.
4006	Unable to get or set security information on the config file.

4007	All connections on this SDLC Link Service must have their multidrop primary flag set the same way.
4008	Unable to obtain a write lock on the config file.
4009	The config file has become out of date and you must reload it.
4010	Bad parameter to function.
4011	The LU Alias has already been used. The LU alias cannot be the same as any other APPC LU on its server.
4012	You do not have the privileges necessary to lock the config file.
4013	Only a primary 3.0 or later computer can write a pre-3.0 configuration file.
4014	This configuration contains un-partnered dependent Local LU(s). These LU(s) have been discarded.
4015	The primary configuration file could not be located. The primary Host Integration Server may be unavailable. No configuration changes may be made at this time.
4016	This LU is already assigned to this user.
4017	There is already a dependent Local APPC LU with this LU number.

4018	There is already a 3270 LU with this LU number.
4019	Insufficient privilege to modify the config file.
4020	A 3270 LU name must be provided.
4021	The AS/400 device name must be provided.
4022	The Local LU Alias must be provide
4023	The Remote LU Alias or Fully Qualified Name must be provided.
4024	The mode must be provided.
4025	A Workstation with the same ID exists. Please use a different ID.
4026	The page width must be between 40 and 512.
4027	This LU is already assigned to this workstation.

Linkcfg Reference

The following sections reference specific areas of Linkcfg.

This section contains:

- About Linkcfg
- Linkcfg Error Messages
- Demo SDLC Link Service
- Distributed Link Service
- DLC 802.2 Link Service

Linkcfg

Purpose

Allows you to install and delete link services from the command prompt. Linkcfg allows you to build script files to add link services. If you need to uninstall or reinstall Host Integration Server, you can reinstall link services by running the Linkcfg script files.

To view the list of link services you can install using Linkcfg, type the command linkcfg. The following appears:

```
LINKCFG [ LINKSVC /LSTYPE:{
"Andrew Twinax Link Service"|
"Atlantis/SAGEM SDLC Link Service"|
"Atlantis/SAGEM X.25 Link Service"|
"DCA ISCA SDLC Link Service"|
"DCA ISCA X.25 Link Service"|
"DEMO SDLC Link Service"
"Distributed Link Service"|
"DLC 802.2 Link Service"|
"IBM SDLC Link Service"|
"IBM Twinax Link Service"|
"IBM X.25 Link Service"|
"MicroGate SDLC Link Service"|
"MicroGate X.25 Link Service" } ]
 [ @commandfile ]
```

Note

If one of the link services was not copied during Setup, it will not appear on the list.

When setting the parameters for each of the link services, you must type the link service exactly as it appears above.

The configurable parameters for each link service are provided in the command-line help. To see the parameters for each, type the following:

LINKCFG LINKSVC /LSTYPE:"name of link service" where the name is one of those listed above. The available parameters will appear on the screen. The following sections list the available parameters for each link service.

Linkcfg Error Messages

The LinkCfg command utility returns the following codes and their corresponding messages. If you use the Windows Command Prompt, you only see the message. If you use Microsoft's System Management Server (SMS) to distribute link services across clients, you see the message and return code.

Error Code	Message
0	success.
160	command-line arguments are invalid.
1114	Unable to initialize Link Service DLL.
1157	Unable to locate DLL file.

In addition, LinkCfg will return error codes from GetLastError() calls for all file I/O operations.

Linkcfg Reference

Demo SDLC Link Service

Linkcfg options for the Demo SDLC link service. You can install the 3270 Continuous Demo, the 3270 File Transfer Demo, the 3270 Logon Demo, the AS400 Demo, and the LU1 and LU3 Printing Demos. Each of these demos is a script file that is run to demonstrate access to mainframe and AS/400 computers.

Note
Configuration settings specified with LINKCFG correspond to local link configuration settings in the SNA Manager.

Syntax

```
LINKCFG LINKSVC "title" (The quotes must be included.)
     /SERVER:servername
     /LSTYPE:"DEMO SDLC Link Service"
     /SCRIPTFILE: {"3270 Continuous Demo.dem"   |
                   "3270 File Transfer Demo.dem" |
                   "3270 Logon Demo.dem"         |
                   "AS400 Demo.dem"              |
                   "LU1 Printing Demo.dem"       |
                   "LU3 Printing Demo.dem"}
     /DISTRIBUTABLE:
```

/LINKSVC" *title*" (The quotes must be included.)

Enter the name of the service title. The quotes must be included. While any title name can be used, it is recommended that one of the following titles be used:

/LSTYPE:"Demo SDLC Link Service"

This parameter is used to list the available options for the Demo SDLC link service. You must type in the exact string as shown above for it to work correctly. The quotes must be included.

/SERVER: *servername*

This is the name of the computer on which the link service is to be installed.

/SCRIPTFILE:" *script file*"

This is the name of the demonstration script. Host Integration Server provides the following scripts:

- `"Continuous Demo.dem"` - this is the 3270 continuous demo script..
- `"File Transfer Demo.dem"` - this is the file transfer demo script.
- `"3270 Logon Demo.dem"` - this is the 3270 logon demo script.
- `"AS400 Demo.dem"` - this is the 5250 demo script.
- `"LU1 Printing Demo.dem` "- this is the demo script showing LU1 printing.
- `"LU3 Printing Demo.dem"` - this is the demo script showing LU3 printing. (The quotes must be included.)

Linkcfg Reference

Distributed Link Service

Linkcfg options for distributed link service.

Note
Configuration settings specified withlinkcfgcorrespond to local link configuration settings in the SNA Manager.

Syntax

```
LINKCFG LINKSVC "title"
     /SERVER:servername
     /LSTYPE:"Distributed Link Service"
     /REMOTELINKTYPE:{ Channel | Ethernet802.2 | LeasedSDLC |
                       SwitchedSDLC | TokenRing802.2 | Twinax | X.25QLLC }
     /REMOTELIST:\\server\service[;\\server\service;...]
     /ALTLIST:\\server\service[;\\server\service;...]
     /DOMAIN:domain
     /USERID:userid
     /PASSWORD:password
```

/LINKSVC" *title*"

Enter the name of the distributed link service. The quotes must be included. Any title name can be used.

/SERVER: *servername*

This is the name of the computer on which the link service is to be installed.

/LSTYPE:"Distributed Link Service"

This parameter is used to list the available options for the distributed link service. You must type in the exact string as shown above for it to work correctly. The quotes must be included.

/REMOTELINKTYPE:{ Channel | Ethernet 802.2 | LeasedSDLC | SwitchedSDLC | TokenRing802.2 | Twinax | X.25 }

This parameter defines the remote link type for the distributed link service.

/REMOTELIST:\\ *server*\ *service*[;\\ *server*\ *service*;]

This is the name of the remote link service, for example \\SNASERV1\SNADLC1;\\SNASERV2\SNADLC1.

/ALTLIST: \\server\service[;\\server\service;]

These are the names of alternate (backup) link services using the preceding format and example.

/DOMAIN: *domain*

Enter the name of the Host Integration Server subdomain. This is a required parameter if Host Integration Server is installed on a system account, not a local account.

/USERID: *userid*

Enter the name of the userid for the system account. This is a required parameter if Host Integration Server is installed on a system account, not a local account.

/PASSWORD: *password*

Enter the password of the system account. This is a required parameter if Host Integration Server is installed on a system account, not a local account.

Linkcfg Reference

DLC 802.2 Link Service

Linkcfg options for the DLC 802.2 link service.

Note
Configuration settings specified withlinkcfgcorrespond to local link configuration settings in the SNA Manager.

Recommended Syntax

```
LINKCFG LINKSVC "title" (The quotes must be included.)
     /SERVER:servername
     /LSTYPE:"DLC 802.2 Link Service"
     /ADAPTERTYPE:adaptertype
     /SAP:hexvalue
     /DISTRIBUTABLE:
```

/LINKSVC" *title*"

Enter the name of the service title. The quotes must be included. Any title name can be used.

/SERVER: *servername*

This is the name of the computer on which the link service is to be installed.

/LSTYPE:"DLC 802.2 Link Service"

This parameter is used to list the available options for the DLC 802.2 link service. You must type in the exact string as shown above for it to work correctly. The quotes must be included.

/ADAPTERTYPE: *adaptertype*

This parameter specifies the adapter type (using the adapter name) for the link service. Type the name of the adapter. This is an optional parameter and does not need to be defined if there is only one adapter installed. If there are multiple adapters in the computer and this parameter is not specified, it will use the first adapter it finds in the Registry, and only if the adapter has been bound with the DLC protocol.

The adapter name can be located in the registry using the following path:

```
HKEY_LOCAL_MACHINE
   SOFTWARE
      Microsoft
         Windows NT
            CurrentVersion
                NetworkCards
                   number
                      NetRules
```

The value is:

Bindform:REG_SZ: "*short name of adapter*" *yes yes container*

/SAP:hexvalue

Enter the SAP address using a hexadecimal value. For example, an acceptable value is 0x4, or 0xC.

/DISTRIBUTABLE:{ yes | no }

This parameter is used to specify whether the link service will be distributed. The Distributed Link Service feature provides a method for a Host Integration Server computer to connect with a host using a link service installed on a different Host Integration Server computer.

Sample Host Definitions

This section presents some sample host definitions used for establishing a Host Integration Server computer connection to IBM S/370 (host) systems. The samples show configuration values for Host Integration Server computer connections of the following types:

Connection type	Connection use	Host system
Token Ring	3270 emulation	Virtual Telecommunications Access Method (VTAM)
SDLC switched	3270 emulation	VTAM
SDLC leased	3270 emulation	VTAM
X.25	3270 emulation	VTAM
Any type	LU 6.2	Customer Information Control System (CICS)

Note

The VTAM listings in this topic omit the column 72-continuation character.

In This Section

Token Ring Definition

The following table shows a VTAM definition for a connection between a Host Integration Server computer and an IBM 9370 host computer across a Token Ring local area network (LAN).

VTAM Token Ring definitions

Name	Description	Parameters
LANODE	VBUILD	TYPE=LAN
R011100	PORT	CUADDR=100,MACADDR=400001701100, LANCON=(5,2),MAXDATA=2012, MAXSTN=32,SAPADDR=04
G011100	GROUP	DIAL=YES,ISTATUS=ACTIVE,LNCTL=SDLC
L011100A	LINE	CALL=INOUT
P011100A	PU	MAXLU=254
L011100B	LINE	CALL=INOUT
P011100B	PU	MAXLU=254
SWLAN	VBUILD	TYPE= SWNET,MAXGRP=5,MAXNO=12
SERVER01	PU	ADDR=C1,IDBLK=05D,IDNUM=00001, ANS=CONTINUE,MAXDATA=265, MAXOUT=7,MAXPATH=7,PACING=0, VPACING=0,SSCPFM=USSSCS, LANACK=(0,0),LANCON=(5,2), LANINACT=4.8,LANRESP=(5,2), LANSDWDW=(7,1),LANSW=YES, MACADDR=4000000000FD,PUTYPE=2, DISCNT=(NO),ISTATUS=ACTIVE, SAPADDR=04
E011100A	PATH	DIALNO=0004400001701100, GRPNM=G01100,GID=1,PID=1,USE=YES
T011100 00	LU	LOCADDR=002,DLOGMOD=D4C32782

T0 11 00 01	LU	LOCADDR=003,DLOGMOD=D4C32782
T0 11 00 02	LU	LOCADDR=004,DLOGMOD=D4C32782
T0 11 00 03	LU	LOCADDR=005,DLOGMOD=D4C32782
T0 11 00 04	LU	LOCADDR=006,DLOGMOD=LU33286S

The following table defines key parameters for Token Ring.

VTAM parameter descriptions for Token Ring

VTAM parameter	Corresponding Host Integration Server parameter	Description
IDBLK=	First three digits of local node ID (basic connection setting)	A three-digit hexadecimal value that, together with IDNUM, identifies the Host Integration Server computer. The values 000 and FFF cannot be used; these values are reserved.
IDNUM=	Last five digits of local node ID (basic connection setting)	A five-digit hexadecimal value that, together with IDBLK, identifies the Host Integration Server computer.
MAXDATA= (in the PU definition for SERVER01)	Max basic transmission unit (BTU) Length (advanced 802.2 setting)	The maximum length of a BTU sent or received; BTUs are also known as I-frames. Max BTU Length should be less than or equal to MAXDATA.
MACADDR= (in the PORT definition)	Remote Network Address (basic 802.2 setting)	The media access control address, a 12-digit hexadecimal address.
SAPADDR= (in the PU definition)	Remote service access point (SAP) Address (advanced 802.2 setting)	The system access point address, a two-digit hexadecimal number, a multiple of 4, between 04 and EC.
LOCADDR= (in the LU definition)	Local unit (LU) Number	The LU local address at the physical unit (PU). For independent LUs that communicate with a host, the LOCADDR parameter must be set to 0. For dependent LUs with VTAM, the LOCADDR must be at least 2. Also, for dependent LUs, the LU Numbers set in the Host Integration Server computer must match the LOCADDR values on the host.

The GRPNM value shown in the sample above is a group name; group names must match the label of a VTAM group definition. The DLOGMOD values shown in the sample are the logon mode table entries from the mode table. For descriptions of the group macros used in these samples and a complete listing of default mode table entries, see the documentation for your IBM product.

L01BA0	LINE	ADDRESS=BA0,PAUSE=0.4,REPLYTO=2.0, RETRIES=7
P01BA0A	PU	

The following table shows the sample IBM 9370 VTAM switched definition for the SNAGROUP label.

VTAM switched definition for SNAGROUP

Label	Operation	Operands
SWNODE	VBUILD	TYPE=SWNET,MAXGRP=0,MAXNO=0

SWPU1	PU	ADDR=C1,IDBLK=017,IDNUM=DC006, DISCNT=NO,PASSLIM=2,PUTYPE=2, MAXDATA=265,MAXOUT=2, USSTAB=MSUSSTAB
T01BA000	LU	LOCADDR=2,DLOGMOD=D4C32782
T01BA001	LU	LOCADDR=3,DLOGMOD=D4C32782
T01BA002	LU	LOCADDR=4,DLOGMOD=D4C32782
T01BA003	LU	LOCADDR=5,DLOGMOD=D4C32782
T01BA004	LU	LOCADDR=6,DLOGMOD=LU33286S

The following table describes key parameters for SDLC.

VTAM Parameter Descriptions for SDLC

VTAM parameter	Corresponding Host Integration Server parameter	Description
ADDR=	Poll Address (advanced SDLC setting)	A two-digit hexadecimal value that identifies the control unit that the host uses to poll.
IDBLK=	First three digits of Local Node ID (basic connection setting)	A three-digit hexadecimal value that, together with IDNUM, identifies the Host Integration Server computer. The values 000 and FFF cannot be used; these values are reserved.
IDNUM=	Last five digits of Local Node ID (basic connection setting)	A five-digit hexadecimal value that, together with IDBLK, identifies the Host Integration Server computer.
MAXDATA= (in the PU definition for SWPU1)	Max basic transmission unit (BTU) Length (advanced SDLC setting)	The maximum length of a BTU sent or received; BTUs are also known as I-frames.
LOCADDR=	LU Number	The LU local address at the PU. For independent LUs that communicate with a host, the LOCADDR parameter must be set to zero. For dependent LUs with VTAM, the LOCADDR must be at least 2. Also, for dependent LUs, the LU Numbers set in the Host Integration Server computer must match the LOCADDR values on the host.

The DLOGMOD values shown in the example are the logon mode table entries from the mode table. For a complete listing of default mode table entries, see the documentation for your IBM product.

P01AOOF	PU	MAXLU=32

The following table shows the sample IBM 9370 VTAM switched definition for the X25GROUP label.

VTAM switched definition for X25GROUP

Label	Operation	Operands
X25	VBUILD	TYPE=SWNET,MAXGRP=5,MAXNO=12
USER01	PU	ADDR=C1,IDBLK=05D,IDNUM=00025, ANS=CONTINUE,MAXDATA=265, MAXOUT=7,MAXPATH=0,PACING=0, VPACING=0,SSCPFM=USSSCS, IRETRY=YES,USSTAB=MSUSSTAB, PUTYPE=2,DISCNT=YES,ISTATUS=ACTIVE
T01A0002	LU	LOCADDR=002,DLOGMOD=D4C32792
T01A0003	LU	LOCADDR=003,DLOGMOD=D4C32792
T01A0004	LU	LOCADDR=004,DLOGMOD=D4C32792
T01A0005	LU	LOCADDR=005,DLOGMOD=D4C32792
T01A0006	LU	LOCADDR=006,DLOGMOD=LU33286S

The following table defines key parameters for X.25.

VTAM Parameter Descriptions for X.25

VTAM parameter	Corresponding Host Integration Server parameter	Description
IDBLK=	First three digits of Local Node ID (basic connection setting)	A three-digit hexadecimal value that, together with IDNUM, identifies the Host Integration Server computer. The values 000 and FFF cannot be used; these values are reserved.
IDNUM=	Last five digits of Local Node ID (basic connection setting)	A five-digit hexadecimal value that, together with IDBLK, identifies the Host Integration Server computer.
DIALNO= (in the PORT definition)	Remote X.25 Address	An address that identifies an X.25 system. The address consists of from 1 through 15 hexadecimal digits. If a 15-digit address is used, the final 3 digits are used for routing between stations with the same 12-digit address.

MAXDATA= (in the PU definition for USER01)	Max BTU Length (advanced X.25 setting)	The maximum length of a BTU sent or received.
LOCADDR=	LU Number	The LU local address at the PU. For independent LUs that communicate with a host, the LOCADDR parameter must be set to 0. For dependent LUs with VTAM, the LOCADDR must be at least 2. Also, for dependent LUs, the LU numbers set in the Host Integration Server computer must match the LOCADDR values on the host. In Table A.4, the LU numbers range from 002 to 006.

Sample Host Definitions

CICS and VTAM Sample Definitions for LU 6.2

This topic presents sample definitions for CICS (version 1.6) and VTAM (version 3.2) for Host Integration Server computer connections to an IBM host system for LU 6.2 operation.

To configure a CICS host system for LU 6.2 operation with a Host Integration Server system, you configure the following information at the host:

- The remote systems with which CICS is able to communicate.
- The name used by VTAM to communicate with each remote system.
- The transaction programs (TPs) available on the CICS system.
- The programming language (PL/I, COBOL, or Assembler) in which each program is written.

This information is configured in CICS and VTAM tables. This topic provides sample definitions that show how to configure CICS for LU 6.2 using these CICS and VTAM tables.

In This Section

CICS Tables

CICS uses the following tables to define LU 6.2 information:

- Terminal Control Table (TCT)—defines the remote systems to CICS.
- Program Control Table (PCT)—defines the local TPs to CICS.
- Program Processing Table (PPT)—defines the load module characteristics to CICS.

The following sections describe these tables, and include sample definitions to illustrate how they are used.

Note
These samples assume there are four TPs residing on CICS written in PL/I with the following names: TRAN0, TRAN1, TRAN2, and TRAN3.

This section contains:

Terminal Control Table

The sample Terminal Control Table (TCT) defines the remote systems to CICS. Each remote system is specified using a DFHTCT definition, which includes both the name by which CICS knows the system (the SYSIDNT field), and the name by which VTAM knows the system (the NETNAME field).

Sample CICS terminal control table entries

Label	Definition	Operands
TP11	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU6207,SYSIDNT=DC11, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)
TP12	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU6208,SYSIDNT=DC12, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)
TP13	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU6209,SYSIDNT=DC13, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)
TP14	DFHTCT	TYPE=SYSTEM ACCMETH=VTAM, FEATURE=SINGLE,TRMTYPE=LUTYPE62, NETNAME=TPLU620A,SYSIDNT=DC14, MODENAM=LU62,CONNECT=AUTO, BUFFER=256,RUSIZE=256, TRMSTAT=(TRANSCEIVE)

CICS Tables

Program Control Table

The Program Control Table (PCT) defines the local transaction programs (TPs) to CICS. Each TP is specified using a DFHPCT definition that includes the name by which the TP is invoked (the TRANSID field) and the corresponding load module name from the CICS library of TPs.

Sample CICS program control table entries

TP Label	Definition	Operands
TRAN0	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0000, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN0
TRAN1	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0001, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN1
TRAN2	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0002, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN2
TRAN3	DFHPCT	TYPE=ENTRY PROGRAM=TRAN0003, TWASIZE=1000,SPURGE=NO,TPURGE=NO, RSL=00,RSLC=NO,MODENAM=NORMAL, TRANSID=TRAN3

* ****** * PROFILE TO BE USED IN LU6.2 ALLOCATE * ****** *

TP Label	Definition	Operands
	DFHPCT	TYPE=PROFILE, PROFILE=DFHCICSA, INBFMH=ALL,MODENAME=LU62

CICS Tables

Program Processing Table

The Program Processing Table (PPT) defines the load module characteristics to CICS.

Each load module is defined using the DFHPPT definition, which includes the name of the load module (the PROGRAM field), and the language in which the module has been written. Examples are PL/I, Assembler, or COBOL (the PGMLANG field).

Sample CICS program processing table entries

Definition	Program name	Language
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0000	PGMLANG=PL/I
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0001	PGMLANG=PL/I
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0002	PGMLANG=PL/I
DFHPPT TYPE=ENTRY	PROGRAM=TRAN0003	PGMLANG=PL/I

CICS Tables

VTAM Definitions

Each remote system must be defined to VTAM in its table of Network Addressable Units, (NAUs), using logical unit (LU) definitions.

If a LOGAPPL parameter is specified on the LU definition naming the CICS system, CICS will attempt to establish a session to that LU whenever it becomes active. This is necessary if TPs residing in CICS do not use the **ALLOCATE** verb with RETURN_CONTROL=WHEN_SESSION_ALLOCATED to establish sessions. There must also be a VTAM mode table definition present for LU 6.2, although CICS does not use the values specified here.

Sample VTAM network control program (NCP) definition for LU 6.2

Label	Operation	Operands
TPPU62	PU	ADDR=C1,IBLK=03E,IDNUM=01A1A, IRETRY=YES,DISCNT=NO,ISTATUS=ACTIVE, MAXDATA=265,SSCPFM=USSSCS, MODETAB=MRNDS,USSTAB=USSNDN1, MAXOUT=7,PASSLIM=7,PUTYPE=2
TPLU6207	LU	LOCADDR=7,DLOGMOD=LU62, USSTAB=USSNOMSG
TPLU6208	LU	LOCADDR=8,DLOGMOD=LU62, USSTAB=USSNOMSG
TPLU6209	LU	LOCADDR=9,DLOGMOD=LU62, USSTAB=USSNOMSG
TPLU620A	LU	LOCADDR=A,DLOGMOD=LU62, USSTAB=USSNOMSG

The following table shows NCP mode table entries for LU 6.2.

Sample NCP mode table entries for LU 6.2

Label	Operation	Operands
	MODETAB	
LU62	MODEENT	LOGMODE=NORMAL
	. . .	
	MODEEND	

Note

It is recommended that the mode used by LU 6.2 be listed first, as shown by the LU62 example in the preceding table.

Concepts

TP Coding Requirements

TP Coding Requirements

To work with CICS, TPs must be coded to specify a SYSID parameter on the **ALLOCATE** request that matches the defined SYSIDNT parameter configured in the DFHTCT tables. This request must be in the following format:

```
EXEC CICS ALLOCATE SYSID('DC11')
```

The SYSID field must match the SYSIDNT field specified for a CICS program by the DFHTCT definition in the TCT (Terminal Control Table). The TCT then uses the NETNAME parameter to refer to a specific LU in the VTAM table of the NAUs (Network Addressable Units). This parameter is used by the TP to communicate with the remote system.

Sense Codes

This section lists the sense codes used by Host Integration Server.

Host Integration Server sense codes are sent on either a negative response to an outbound data stream or an LUSTAT that notifies the host of a change in the secondary logical unit (LU) state. The sense codes generated by a 3270 emulator program are shown in the following tables.

Negative response sense codes

Value	Meaning
0802	Intervention required (LU 1/LU 3 printer soft error).
0814	Bracket bid reject RTR forthcoming.
081B	Receiver in transmit mode.
081C	Request not executable (hard error).
0821	Invalid session parameters (negotiable BIND request).
0829	Change direction required.
082B	Presentation space integrity lost.
082D	LU busy (usually local copy print in progress).
082E	Intervention required (local copy print soft error).
082F	Request not executable (local copy print hard error).
0843	WCC print command bit not sent (RQD or RQE, CD, EB).
0863	Referenced character set does not exist.
0871	Read partition state error (SLU in retry state).
1003	Function not supported.
1005	Parameter modifying a control function is invalid.
1007	Category not supported (SSCP data for host printer).

LUSTAT sense codes

Value	Meaning
0001 B000	Host initialized local copy soft error recovery.
081C 0000	Soft error changed to hard error (LU 1/LU 3).
081C B000	Soft error changed to hard error (local copy).
082B 0000	LU session changed from SSCP to PLU (SYSREQ).

Host Print Service Character Translation Table Format

Host Print Service Character Translation Table Format

The character translation table that can be used by the custom code page option of Host Print service is a 512-byte file, split into two 256-byte regions. Bytes 0255 are the mapping bytes for data from the host; bytes 256511 map data to the host.

For example, the following illustrates standard translation tables for the 037 EBCDIC code page:

```
   | 00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
---------------------------------------------------
00| 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
10| 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
20| 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
30| 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
40| 20 a0 e2 e4 e0 e1 e3 e5 e7 f1 a2 2e 3c 28 2b 7c
50| 26 e9 ea eb e8 ed ee ef ec df 21 24 2a 29 3b ac
60| 2d 2f c2 c4 c0 c1 c3 c5 c7 d1 a6 2c 25 5f 3e 3f

```

Bytes 0-255: Data from Host

Each byte that is received represents a location, that is, a byte offset, in the appropriate table. For example, if the value 0xC1 (the EBCDIC value for the letter A) is received from the host, it is converted to the value in position 0xC1 in the first table; that is, to 0x41 (the ASCII value for the letter A). This is shown in bold in the preceding table.

Similarly, if the letter *Z* (ASCII value 0x5A) is to be transmitted to the host, it is first converted to the value located in position 0x5A in the second table, which is 0xE9 (the EBCDIC value for Z). This is shown in bold in the table below:

```
   | 00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
00| 00 01 02 03 37 2d 2e 2f 16 05 25 0b 0c 0d 0e 0f
10| 10 14 24 04 b6 15 32 26 18 19 00 27 1c 1d 1e 1f
20| 40 5a 7f 7b 5b 6c 50 7d 4d 5d 5c 4e 6b 60 4b 61
30| f0 f1 f2 f3 f4 f5 f6 f7 f8 f9 7a 5e 4c 7e 6e 6f
40| 7c c1 c2 c3 c4 c5 c6 c7 c8 c9 d1 d2 d3 d4 d5 d6
50| d7 d8 d9 e2 e3 e4 e5 e6 e7 e8  ba e0 bb b0 6d

Bytes 256511: Data to Host

Currently, only the first table (bytes 0255) is used by Host Print service. However, the file must be exactly 512 bytes in length, so the final 256 bytes must be present, even if they are set to zero.

Troubleshooting

A variety of diagnostic methods and tools are available to troubleshoot Microsoft Host Integration Server. These methods and tools can provide information about the status of services, connections, 3270, APPC and LUA sessions, and performance. Data can be obtained from the SNA Manager, NetView, RTM, System Monitor, and trace files.

In This Section

Troubleshooting Tools and Tips

Using the Host Integration Server management console, SNA Manager, you can view the status and properties of services, connections, 3270 sessions, APPC sessions, LUA sessions and the number of active users. Server status information includes Active, Inactive, Pending, Stopping, Active [Out of Date] or Error. If the server is active, the number of licensed users and licensed sessions is also shown

If you have an Active [Out of Date] status, the server needs to be restarted to bring the internal parameters up to date with the latest configuration changes. The Error status indicates that an unexpected condition has made the server inaccessible to the SNA Manager.

Connection status can be Active, Pending, Stopping, or Inactive. On Demand connections can also show a status of "On Demand", meaning that the connection will become active when needed. Incoming connections can also show "Incoming", meaning that the connection is available to receive incoming calls.

The status of a non-APPC LU can be Inactive, In Session, SSCP, Available, or Pending. A downstream LU can also have a status of Unavailable. The SSCP status indicates that the LU is in use but is not yet bound to a specific host application. The Available status indicates that the LU is recognized by the host as an available LU. Pending status indicates that a user is trying to access the LU but either the connection is inactive or the mainframe does not recognize the LU.

NetView is helpful for reporting system alerts between mainframes and Host Integration Server. For more information about NetView, see Network Management Support NetView uses NVAlert to provide the ability for the host system console to receive and display alerts generated by Windows 2000 and applications running on the Windows 2000 computer. NVRunCmd provides the ability to command Host Integration Server from the host system console.

Response Time Monitor (RTM) measures the amount of time it takes for a host to respond during 3270 display sessions. RTM is only supported by certain emulators. You can specify the times at which RTM should send data, as well as the trigger that will cause RTM to register that the host has responded. For more information, see Monitoring Mainframe Response Times.

When a problem occurs on Host Integration Server, the Windows 2000 event logs can tell you the sequence and type of events that led up to the problem. For more information about event logs, see Status and Performance Tools.

System Monitor allows you to measure the performance of your computer or other computers on the network. You can monitor connections, LU sessions, and adapters with System Monitor. For more information, see Status and Performance Tools.

Tracing is the action of recording activity between or within components of Host Integration Server. Tracing can provide detailed information of internal activities on the Server. It is helpful in isolating problems and is frequently used by product support personnel.

Four Most Common Problems

The four most common problems reported are as follows:

1. **Setup or Upgrades**: The most frequently asked Host Integration Server questions are related to setup or upgrade issues. If you are connecting to an AS/400 via Token-Ring or Ethernet, make sure you read KB article Q112158 found at http://go.microsoft.com/fwlink/?LinkId=14394. If you are connecting to an AS/400 via an SDLC card, KB Article Q112159 found at http://go.microsoft.com/fwlink/?LinkId=14395 can be helpful. Examples of VTAM configurations for connecting to a mainframe can be found in the Host Configuration section. The configuration file (COM.CFG) contains almost all of the configuration information for the Host Integration Server environment. It is extremely important to back up this file before making changes.

2. **Connectivity Issues**: If you are having a problem connecting to the host, determine where the problem originates. Because Host Integration Server is the middle piece of a three-part connection, it helps to narrow the problem down to a Host Integration client, Host Integration Server issue, or a Host Integration Server host issue.

3. **Host Printing**: For more information, see Host Print Service Problems.

4. **APPC or LUA Application Failures**: See APPC or LUA Application Failures.

APPC or LUA Application Failures

These applications may be written internally, or may be commercial applications. If an error code is produced on an APPC application, it is documented in the "APPC Applications."

An LUA application may produce error codes which are found in the "LUA Applications," or the IBM SNA Formats Guide.

If you are able to test a 3270 or 5250 connection, that can help you determine whether you are experiencing a connectivity problem or a problem with the application itself.

Adapters and Link Service Problems

The following three adapters may have problems associated with installation and configuration. Some of the common problems and solutions are identified in the respective sections.

In This Section

802.2 Adapters and Link Services: Installation Pointers

SDLC Adapters and Link Services: Installation Pointers

X.25 Adapters and Link Services: Installation Pointers

802.2 Adapters and Link Services: Installation Pointers

An 802.2 link service enables the Host Integration Server software to communicate with an Ethernet, Token-Ring, or FDDI adapter. The following pointer highlights an important step for installing an 802.2 adapter and link service:

When you install a new adapter, check the interrupt, port address, and direct memory access (DMA) settings, to avoid conflicts with other adapters in the computer. The normal method for adjusting the settings among your adapters is through EISA configuration programs, jumpers on the motherboard, or configuration utilities. Windows 2000 provides the Device Manager. You may also use configuration utilities supplied with your adapters.

One way of viewing the settings used by various adapters in your computer is to start WINMSD.EXE, the Windows 2000 Diagnostics utility, which includes an IRQ/Port Status button and a DMA/Memory button.

Note
Device drivers provided by Host Integration Server report any interrupt, port address, or DMA conflicts they detect in the Windows 2000 System Event Log. The events are listed under a Source of Service Control Manager or a driver name.

SDLC Adapters and Link Services: Installation Pointers

An SDLC link service enables the Host Integration Server software to communicate with the SDLC adapter. For detailed information about using a particular SDLC adapter or a particular modem (or DCE), see the adapter, modem, or DCE documentation.

The following pointers highlight important steps for installing an SDLC adapter and link service:

- Selecting the Constant RTS option in the **IBM SDLC Link Service Properties** dialog box equates to the NCP LINE macro:

  ```
  DUPLEX=FULL
  ```

  This configuration is recommended for all SDLC connections except tributary connections on multidrop SDLC lines. This configuration improves performance by eliminating several seconds of line turnaround delay after each transmission.

  The Constant RTS option is mandatory if the line is used for full duplex, but it can also enhance performance on a half-duplex line.

- When choosing an SDLC adapter, pay close attention to the speed and duplexing capabilities. Greater speed and/or full-duplexing capabilities allow an adapter to carry greater loads. Note that an adapter that lacks a coprocessor cannot handle

  full-duplex transmission at high transmission speeds, that is, greater than 9600 baud. (Examples of adapters lacking a coprocessor are the IBM SDLC, IBM MPCA, and MicroGate adapters. For these adapters, half-duplex transmission is recommended.)

- Configuring adapters that lack a coprocessor to half duplexing, although slower, has the advantage of requiring substantially less central processing unit (CPU) time. The device driver via DMA will process transmitted information as frames. In contrast, if you use full duplexing with such adapters, the device driver must handle interrupts as characters, placing more load on the CPU. However, if the CPU can handle the load, full duplex provides substantially faster throughput, if the host VTAM configuration also specifies full duplex (DATMODE=FULL in the PU definition).

- After installation of the adapter and link service, you will need to configure the connection with the correct duplex setting. For details, see the next section, X.25 Adapters and Link Services: Installation Pointers.

- Stop all existing services that use the SDLC adapter before attempting to configure the link service properties. For example, stop the Remote Access Service if it uses the SDLC adapter. Only when these services are stopped can SNA Manager successfully autodetect the adapter.

- If you attempt to install an SDLC link service for an adapter that you know is physically installed in the computer, and a pop-up message appears saying that SNA Manager cannot detect the adapter, click **Cancel**. The message indicates that a service is currently using the SDLC adapter. Find out which service it is, stop the service, and then try to install the link service again.

  SNA Manager can detect the adapter only if no other service is using that adapter. If you do not click **Cancel** when the pop-up message appears, SNA Manager continues the installation process using default values (not values attuned to that adapter, since SNA Manager cannot detect it). As described in the preceding paragraph, to correct this situation, stop the service using the SDLC adapter and then reinstall the link service.

  When you install a new adapter, check the interrupt, port address, and direct memory access (DMA) settings, to avoid conflicts with other adapters in the computer. The normal method for adjusting the settings among your adapters is through EISA configuration programs, jumpers on the motherboard, or configuration utilities. Windows 2000 provides the Device Manager. You may also use configuration utilities supplied with your adapters.

  One way of viewing the settings used by various adapters in your computer is to start WINMSD.EXE, the Windows 2000 Diagnostics utility, which includes an IRQ/Port Status button and a DMA/Memory button.

- Device drivers provided by Host Integration Server report any interrupt, port address, or DMA conflicts they detect to the Windows 2000 System Event Log. The events are listed under a Source of Service Control Manager or a driver name.

- To ensure that the line speed is set correctly through hardware or software settings, study the documentation for the modem or DCE. (Do not confuse setting the line speed with selecting the Data Rate, configurable through the **SDLC Connection Properties** dialog box, on the **SDLC** tab, in SNA Manager. The Data Rate setting controls the speed of transmissions between the SDLC adapter and the modem only.)

- If you want to use a server-stored number, check that both the link service and the modem are configured correctly. This applies to MicroGate adapters, or any adapter that can handle a server-stored number. On the modem, it may be necessary to override the setting that causes the modem to autodial from its own stored number. (In modem terminology, when Data Terminal Ready — DTR — is raised, the modem must wait, not dial.) To find out how to override modem autodialing, see your modem or DCE documentation.

X.25 Adapters and Link Services: Installation Pointers

An X.25 link service enables the Host Integration Server software to communicate with the X.25 adapter. The following pointers highlight important steps for installing an X.25 adapter and link service:

- When choosing an X.25 adapter, pay close attention to the speed capabilities. Greater speed allows an adapter to carry greater loads. Note that an adapter that lacks a coprocessor cannot handle high-speed transmission with full duplexing; the duplexing type used by Host Integration Server X.25 connections. (Examples of adapters lacking a coprocessor are the IBM SDLC and IBM MPCA adapters. For these adapters, the transmission speed must be 9600 baud or less.)

- Contact your X.25 carrier or network administrator for information needed for your X.25 link service. The following table lists some important parameters you will need to know:

Parameters from X.25 carrier	**Corresponding parameter in Connection Properties**	**Typical value(s)**
Local X.25 address	Local NUA Address	Varies
Level 3 window size	Default L3 Window Size	2
Level 3 packet size	Default L3 Packet Size	512
Level 2 window size	L2 Window Size	7
Channel ranges (Outgoing SVC, Two-Way SVC, Incoming SVC, and/or PVC)	Channel Ranges (Outgoing SVC, Two-Way SVC, Incoming SVC, and/or PVC)	Vary

  Note that the encoding setting (NRZ or NRZI) is almost always NRZ on X.25 networks. This setting must match the equivalent setting on the host. For connections to mainframes, the NRZI setting is found in the LINE/GROUP definition in VTAM or NCP. If VTAM does not specify the NRZI setting, it defaults to NRZI=YES. For connections to AS/400 computers, the NRZI setting is in the Line Description.

- When you install a new adapter, check the interrupt, port address, and direct memory access (DMA) settings, to avoid conflicts with other adapters in the computer. The normal method for adjusting the settings among your adapters is through EISA configuration programs, jumpers on the motherboard, or configuration utilities. Windows 2000 provides the Device Manager. You may also use configuration utilities supplied with your adapters.

  One way of viewing the settings used by various adapters in your computer is to start WINMSD.EXE, the Windows 2000 Diagnostics utility, which includes an IRQ/Port Status button and a DMA/Memory button.

- Device drivers provided by Host Integration Server report any interrupt, port address, or DMA conflicts that they detect to the Windows 2000 System Event Log. The events are listed under a Source of Service Control Manager or a driver name.

- Ignore the option labeled "Switched: Server-Stored Number" in the **X.25 Link Service Properties** dialog box. This option does not match capabilities currently available with X.25 link services. If chosen, the option behaves the same way as "Switched: Modem-Stored Number."

- With X.25 link services, you can also adjust the T1 timeout and N2 retry limit. However, the defaults for these are appropriate for most networks. Therefore, it is recommended that you do not adjust them unless you have a specific reason for doing so, and that you understand the characteristics of your network as well as the way that the timeout works.

Connection Problems

In This Section

Client to Host Integration Server Problems

When you are troubleshooting an issue between the workstation and the Host Integration Server server, the first step is to verify that the client workstation computer can connect to other network resources on the Windows 2000 Server that has Host Integration Server installed. If you cannot map a network drive at the workstation, then you should troubleshoot this problem as a workstation to Windows 2000 Server issue.

If you can map a network drive at the workstation but cannot get an emulation session, you should determine what protocol is being used. Host Integration Server supports client connections over any of the network protocols. In addition, IPX and TCP/IP connections may be either named pipes or sockets. If you are unsure, run Host Integration Server Setup or Configuration at the client. If TCP/IP or IPX/SPX has been selected, the connection is sockets-based.

If the protocol chosen is "Microsoft Networking," Named Pipes is being used. Depending on which protocols are installed, "Microsoft Networking" will use IPX/SPX, NetBEUI, or TCP/IP.

A common problem preventing workstations from connecting to the Host Integration Server over TCP/IP is failed NetBIOS name resolution. If you can ping the TCP/IP address of the server, but not its NetBIOS name, then you are probably having trouble with WINS or an LMHOSTS file. Configure the client for the IP address rather than the NetBIOS name.

IPX/SPX clients must be able to see the SNA Manager service registered in the Novell Bindery. If the Novell server is version 4.x, Bindery emulation must be enabled except when using the feature in Host Integration Server that supports name resolution via NDS under Netware 4.x. The SNA Manager service registers itself through SAP 444. It is important to verify a router on the network is not filtering this SAP. It is recommended that client workstations be configured for sockets if you are using TCP/IP or IPX/SPX. A configuration of "Remote" causes the client to connect directly to the server. "Local" connects via a broadcast method.

If TCP/IP is being used, the IP address should be entered in the "Primary Server" field rather than the NetBIOS name.

5250 emulation utilizes LU type 6.2 on the AS/400. Often, an error message on the client will include return codes. These codes are documented in the Host Integration Server Message Database included on the CD-ROM.

When using a third-party emulator, the error messages returned by the application will vary. If possible, you should reproduce the error with the client emulator provided with the Host Integration Server and Client software. This will help you verify whether the problem is in the emulator, as well as providing an error message that will probably be documented.

Host Integration Server to Host Problems

Host Integration Server cannot connect to a host over the NetBEUI or IPX/SPX network protocols. DLC, SDLC, and increasingly TCP/IP are the protocols most commonly used to connect from the server to a host. If you cannot get an emulation session at the server itself, check the status of the connection using the SNA Manager. If the status is "Active", but you cannot access an emulation session, there may be a configuration problem. If the connection to an AS/400 is "Pending", it may be useful to go through the KB articles Q112158 found at: http://go.microsoft.com/fwlink/?LinkId=14394 or Q112159 found at: http://go.microsoft.com/fwlink/?LinkId=14395 or browse other KB articles available from the Web site http://go.microsoft.com/fwlink/?LinkId=14396 to make sure that you have all the required information.

If the status is "Inactive" or "Pending", the communication between the server and the host is failing.

Check the Application and System Event Logs. Most often, "Pending" or "Inactive" connections will produce an event in the Applications Log – usually an event 230 or 23. The text of these messages varies and can indicate the nature of the problem. If the problem is the result of hardware failure, the event will usually be logged in the System Log. If the connection has been functional in the past, there may be a communications problem. For example, an SDLC connection may fail due to phone line problems.

Settings to Check for All Connection Types

When you are configuring a new Host Integration Server connection or troubleshooting an existing connection, regardless of the connection type, the identifiers must match between the Host Integration Server computer and the host. The type of identifier (ID or name) is as follows:

For most mainframe connections

Node ID is the identifier used when exchanging identification (XIDs) with most mainframes. Check to make sure that the following items match; if they do not, the Host Integration Server computer is not identifying itself in a way that the host can recognize.

Identifier used on mainframe	Identifier to configure on Host Integration Server
IDBLK and **IDNUM** in the PU definition	Two parts of the **Local Node ID** (configured on the connection)

For other mainframe connections

There are some situations in which the mainframe does not use Node ID in XIDs, but instead uses Network Name and Control Point Name. These situations include mainframes communicating through LU 6.2, and mainframes that call up the Host Integration Server computer (meaning that the Host Integration Server computer accepts incoming calls on that mainframe connection). In these situations, the following parameters must match.

Note
Change the following identifiers only when necessary. The local Network Name and the local Control Point Name should be changed only when the host requires a specific Network Name and Control Point Name that differ from those configured in t he server properties.

Identifier used on mainframe (in unusual cases only)	Identifier to configure on Host Integration Server
NETID in the VTAM Start command for the local SSCP **CPNAME** in the PU definition**NETID** and **SSCPNAME** in the VTAM Sta rt command for the remote SSCP (VTAM system)	**Local Network Name** (configured on the server) **Local Control Point Name** (configured on the server) **Remote Network Name** and **Remote Control Point Name** (configured on the connection)

For AS/400 connections

Network Name and Control Point Name (used together and called the fully qualified name) are the identifiers used when exchanging identification (XIDs) with AS/400 computers. Check to make sure that the following items match. If they do not, the Host Integration Server is not identifying itself in a way that the AS/400 can recognize.

Note
Change the following identifiers only when necessary. To support multiple connections to the same AS/400, you must provid e a unique local Network Name and local Control Point Name for each connection. In addition, you can change the local Net work Name and the local Control Point Name if the host requires a specific Network Name and Control Point Name that diff er from those configured in the server properties.

Identifier used on AS/400	Identifier to configure on Host Integration Server
RMTNETID (usually; often set to APPN); **RMTCPNAME**	**Local Network Name** and **Local Control Point Name** (confi gured on the server)
RMTNETID (often set to APPN); **CP Name** (shown in the "Disp lay network attributes" screen)	**Remote Network Name** and **Remote Control Point Name** (configured on the connection)

802.2 Connection Pointers

Connections are configured through Host Integration Server SNA Manager. The steps for configuring an 802.2 connection are described in detail in Important Connection Information. The following pointers indicate items that require special attention:

- As with all connections, the identifiers must be configured correctly. For details, see Settings to Check for All Connection Types.

- Pay close attention to the Remote Network Address (which can be viewed on the **Address** tab of **Connection Properties**). It should match the 12-digit hexadecimal network address of the remote host, peer, or downstream system. The following guidelines may help:

For...	Set the Remote Network Address to...
Connections to a 3174 controller	The value in the configuration response 900 of the controller's customization program.
Connections to a 3720, 3725, or 3745 front-end processor	LOCADDR in the NCP LINE macro.
Connections to an IBM mainframe	MACADDR in the VTAM PORT definition
Connections to an AS/400	ADPTADR in the Line Description on the AS/400

- Check the Max BTU Length setting, found on the **DLC 802.2** tab of **Connection Properties**. A BTU is also called an I-frame. It is the number of bytes that can be transmitted in a single data-link information frame.

  Set the Max BTU Length so that it matches the capacity of the adapter and the host or downstream system. Otherwise, when the mainframe or AS/400 sends a logon screen, the BTU length (frame size) that is used will be unworkable, causing the connection to be dropped. The following table provides guidelines:

Adapter type	Max BTU Length to use
Token-Ring adapter that transmits at 4 Mbps (megabits per second)	Less than or equal to 4195.
Token-Ring adapter that transmits at 16 Mbps	The appropriate value for the host or downstream system; the adapter itself can handle the greatest Max BTU Length available with Host Integration Server, 16393.
Ethernet adapter	Less than or equal to 1493.

Connection type	Max BTU Length to use
Connection to a mainframe	Equal to MAXDATA in the PU definition on the mainframe (recommended).
Connection to an AS/400	Equal to MAXFRAME on the AS/400 (recommended).
Connection to a downstream system	Less than or equal to the maximum value supported by the downstream system.

Setting the Max BTU Length correctly is especially important for downstream connections.

With 802.2 connections, you can adjust a variety of other settings, especially timeout and retry settings. However, the defaults for the timeouts and retries are appropriate for most networks. Therefore, it is recommended that you do not adjust these settings unless you have a specific reason for doing so, and unless you understand the characteristics of your network, and the way that the timeouts work.

Connection Problems

Troubleshooting 802.2 Connections

The following table outlines some ways to interpret symptoms of a nonfunctioning 802.2 connection:

Symptom	Configuration item to check
Symptom: Host Integration Server will not start; the System Event Log (viewable through the Event Viewer) contains messages about a link service failing to start.	**Recommendation**: Check that all existing link services are configured to work with functioning adapters. The server service cannot start if any existing link service cannot start, even if that link service is not being used by any connection.
Symptom: Host Integration Server will not start; System Event Log contains messages about conflicts in port addresses, IRQs, or DMA addresses.	**Recommendation**: Check the port address, IRQ setting, or DMA address of your 802.2 adapter, which may be conflicting with those of another adapter or port in your computer. Change the settings on one of the adapters or ports, if possible, or remove the conflicting adapter.
Symptom: Connection can only reach "Pending" status, and Application Event Log contains event 230.	**Recommendation**: Check that the identifiers (IDs or names) and/or the network address used by the host match the corresponding parameters in SNA Manager. (To view these parameters, double-click the connection in the left pane and then click **System Identification**.) The identifiers or addresses must match in order for the exchange of identifiers (XIDs) and test frames to complete successfully. For more information about identifiers, see the preceding section.
Symptom: Connection (especially downstream connection) may become "Active," but reverts to "Pending" when first user attempts to start a session.	**Recommendation**: Check the Max BTU Length setting for the connection (to see the setting, in SNA Manager, double-click the connection in the left pane and then click **DLC 802.2**). For details about the correct setting to use, see the preceding section and Settings to Check for All Connection Types.
Symptom: Connection reaches "Active" status, but reverts to "Pending;" event 23 is generated in the Application Event Log.	**Recommendation**: Possible causes include LAN or router problems, or actions by the remote system (for example, an AS/400 disconnecting because of lack of activity).

Note

With 3270 LUs, if one or more of the LUs never become active even when users are attempting to start sessions, the LOCADDR settings in the LU definitions in VTAM or NCP may not match the Host Integration Server LU numbers, or some or all of the LUs may be inactivated in VTAM or NCP. To correct this, consult with the administrator of the host system.

SDLC Connection Pointers

Connections are configured through the SNA Manager. The steps for configuring an SDLC connection are described in detail in Important Connection Information. The following pointers indicate items that require special attention:

As with all connections, the settings must be configured correctly. For details, see Settings to Check for All Connection Types.

If possible, configure the connection to use constant RTS. See the recommendations in SDLC Adapters and Link Services: Installation Pointers.

The duplex setting is found in the **SDLC** tab of **SDLC Connection Properties**. Duplex can be half or full; the setting must not exceed the capabilities of the adapter and modem. For more information about the factors to consider when choosing the setting for duplex, see the preceding section.

Check the encoding setting, which is either nonreturn to zero (NRZ) or nonreturn to zero inverted (NRZI). The setting is on the **Address** tab of **SDLC Connection Properties**. This setting must match the equivalent setting on the host. For connections to mainframes, the NRZI setting is found in the LINE/GROUP definition in VTAM or NCP. (If VTAM does not specify the NRZI setting, it defaults to NRZI=YES.). For connections to AS/400 computers, the NRZI setting is in the Line Description.

When multiple SDLC connections accept incoming calls and use the same link service, the encoding (NRZ/NRZI) settings for all the connections must match.

Check the Max BTU Length setting, found on the **SDLC** tab of the **SDLC Connection Properties** dialog box. A BTU is also called an I-frame; it is the number of bytes that can be transmitted in a single data-link information frame.

Set the Max BTU Length so that it matches the capacity of the adapter and the host or downstream system. Otherwise, when the mainframe or AS/400 sends a logon screen (typically a full screen), the BTU length (frame size) that is used will be unworkable, causing the connection to be dropped. The following table provides guidelines:

For...	**Set the Max BTU Length to...**
IBM SDLC adapter	521 or less.
Connection to a mainframe	Equal to MAXDATA in the PU definition on the mainframe (recommended).
Connection to an AS/400	Equal to MAXFRAME on the AS/400 (recommended).
Connection to a downstream system	Less than or equal to the maximum value supported by the downstream system.

Setting the Max BTU Length correctly is especially important for downstream connections.

With SDLC connections, you can adjust a variety of other settings, especially timeout and retry settings. However, the defaults for the time-outs and retries are appropriate for most networks. Therefore, it is recommended that you do not adjust these settings unless you have a specific reason for doing so, and you understand the characteristics of your communications lines as well as the way that the time-outs work.

Troubleshooting SDLC Connections

To begin troubleshooting an SDLC connection, it is helpful to look at two simple indicators of activity: the server and connection status shown in SNA Manager, and the modem lights. Event logs also provide important information. The following table outlines some ways to interpret symptoms of a nonfunctioning SDLC connection.

Symptom	Configuration item to check
Symptom: Host Integration Server will not start; the System Event Log (viewable through the Event Viewer) contains messages about a link service failing to start.	**Recommendation**: Check that all existing link services are configured to work with functioning adapters. The SNA Manager service cannot start if any existing link service cannot start, even if that link service is not being used by any connection.
Symptom: Host Integration Server will not start; System Event Log contains messages about conflicts in port addresses, IRQs, or DMA addresses.	**Recommendation**: Check the port address, IRQ setting, or DMA channel of the SDLC adapter, which may be conflicting with those of another adapter (for example, a sound system adapter) or port in your computer. Change the settings on one of the adapters or ports, if possible, or remove the conflicting adapter. For more information, see SDLC Adapters and Link Services: Installation Pointers.
Symptom: Modem lights may flash but the connection remains at "Pending" and does not go to "Active."	**Recommendation**: Check the DMA channel setting (jumpers) on the adapter and compare this to the setting in the link service properties dialog box. If this setting specifies a nonexistent address, data cannot flow.
Symptom: Modem appears to make the connection ("receive data" light flashes, but "transmit data" light does not). The connection status reaches "Pending" and then the connection is dropped.	**Recommendation**: Check the cables; then check the Encoding (NRZ/NRZI) setting used by the host and compare this to the setting in the connection properties dialog box. If the NRZ/NRZI settings do not match, the two ends of the connection begin negotiating but cannot interpret each others signals correctly. For more information, see the preceding section.
Symptom: Modem lights are flashing but the connection can only reach "Pending" status. Also, the Application Event Log contains event 182.	**Recommendation**: Check that the identifiers (IDs or names) used by the host match the ones used in the **Connection Properties** dialog box. If the identifiers do not match, the exchange ID (XID) process cannot complete successfully. For more information about identifiers, see Settings to Check for All Connection Types.
Symptom: Connection (especially downstream connection) may become "Active," but reverts to "Pending" when first user attempts to start a session.	**Recommendation**: Check the Max BTU Length setting in the **Connection Properties** dialog box. For details about the correct setting to use, see the preceding section.

If one or more 3270 LUs never becomes active, even when users are attempting to start sessions, the LOCADDR settings in the LU definitions in VTAM or NCP may not match the Host Integration Server LU numbers, or some or all of the LUs may be inactivated in VTAM or NCP. To correct this, consult with the administrator of the host system.

X.25 Connection Pointers

An X.25 connection uses a packet-switching network, and communicates through the Qualified Logical Link Control (QLLC) protocol. Connections are configured through SNA Manager. The steps for configuring an X.25 connection are described in detail in Important Connection Information. The following pointers indicate items that require special attention:

- As with all connections, the identifiers must be configured correctly. For details, see Settings to Check for All Connection Types.

- Pay close attention to the **Remote X.25 Address** on the **Address** tab of the **Connection Properties** dialog box; it should match the address of the remote host, peer, or downstream system. The address consists of from 1 through 15 hexadecimal digits. If a 15-digit address is used, the final 3 digits are used for routing between stations with the same 12-digit address. For connections to a host using VTAM, the address should match the DIALNO parameter in the PORT definition. For connections to an AS/400, the address should match the local address of the AS/400 (assigned by the X.25 carrier).

- Check the Max BTU Length setting, found in the **Connection Properties** dialog box. A BTU is a data-link information frame.

- Set the Max BTU Length so that it matches the capacity of the adapter and the host or downstream system. Otherwise, when the mainframe or AS/400 sends a logon screen, the BTU length (frame size) that is used will be unworkable, causing the connection to be dropped. The following table provides guidelines:

For...	**Set the Max BTU Length to...**
IBM SDLC adapter	521 or less.
Connection to a mainframe	Equal to MAXDATA in the PU definition on the mainframe (recommended).
Connection to an AS/400	Equal to MAXFRAME on the AS/400 (recommended).
Connection to a downstream system	Less than or equal to the maximum value supported by the downstream system.

- Setting the Max BTU Length correctly is especially important for downstream connections.

- For SVC connections, check that the codes in **User Data** include C3, which specifies the QLLC protocol (the X.25 protocol used by SNA Manager). To view **User Data** codes, right-click the connection in the left pane, then click **Properties**, then click the **X.25** tab in the **Connection Properties** dialog box. For information about other user data codes, contact your X.25 network administrator.

- If each attempt at connection activation incurs cost as you access the X.25 network, you may want to limit the number of these attempts. To do this, double-click the connection, and then click the **X.25** tab. In the **Maximum Retries** list, select an appropriate maximum number of attempts. (The default is No Limit.)

Troubleshooting X.25 Connections

The following table outlines some ways to interpret symptoms of a nonfunctioning X.25 connection.

Symptom	Configuration item to check
Symptom: Host Integration Server will not start; the System Event Log (viewable through the Event Viewer) contains messages about a link service failing to start.	**Recommendation**: Check that all existing link services are configured to work with functioning adapters. The SNA Manager cannot start if any existing link service cannot start, even if that link service is not being used by any connection.
Symptom: Host Integration Server will not start; System Event Log contains messages about conflicts in port addresses, IRQs, or DMA addresses.	**Recommendation**: Check the port address, IRQ setting, or DMA address of your X.25 adapter, which may be conflicting with those of another adapter or port in your computer. Change the settings on one of the adapters or ports, if possible, or remove the conflicting adapter. For more information, see X.25 Adapters and Link Services: Installation Pointers.
Symptom: Connection can only reach "Pending" status, and the Application Event Log contains Event 23 with an outage code of 0x62 (for SVC) or 0x61 (for PVC).	**Recommendation**: Check that the identifiers (IDs or names) and/or the X.25 address used by the host match the corresponding parameters on the **System Identification** tab of the **Connection Properties** dialog box. The identifiers or addresses must match in order for the exchange of identifiers (XIDs) and test frames to complete successfully. For more information about identifiers, see the preceding section and Settings to Check for All Connection Types.
Symptom: Connection (especially downstream connection) may become "Active," but reverts to "Pending" when first user attempts to start a session.	**Recommendation**: Check the **Max BTU Length** setting for the connection on the **X.25** tab of the **Connection Properties** dialog box. For details about the correct setting to use, see the preceding section.

If one or more 3270 LUs never becomes active, even when users are attempting to start sessions, the LOCADDR settings in the LU definitions in VTAM or NCP may not match the Host Integration Server LU numbers, or some or all of the LUs may be inactivated in VTAM or NCP. To correct this, consult with the administrator of the host system.

Settings to Check on Channel Connections

The number of parameters involved in channel connections is fewer than with other types of connections. The key parameters to note are those specifying addresses and, for channel connections, the Max BTU Length.

If one or more 3270 LUs never becomes active, even when users are attempting to start sessions, the LOCADDR settings in the LU definitions in VTAM or NCP may not match the Host Integration Server LU numbers, or some or all of the LUs may be inactivated in VTAM or NCP. To correct this, consult with the administrator of the host system.

Event and Error Problems

In This Section

Additional Help with Events and Errors

Microsoft provides troubleshooting information about specific product event and error messages. For Microsoft Windows XP and Microsoft Windows Server 2003 operating systems, you can access event message documentation by using the link inside the property window of an event. Microsoft also provides this content on the Web at http://go.microsoft.com/fwlink/?LinkId=20869.

The information provided on the Web site includes:

- The text of the event or error message, so you can confirm you have located the correct message
- A detailed explanation of what caused the event or error
- Recommended actions, if any, for you to take to correct the problem.

For Microsoft Windows 2000, Microsoft Windows XP, and Microsoft Windows Server 2003 operating systems, you can also access additional information about an event by using the Event Viewer or additional information about an error directly from the Microsoft website.

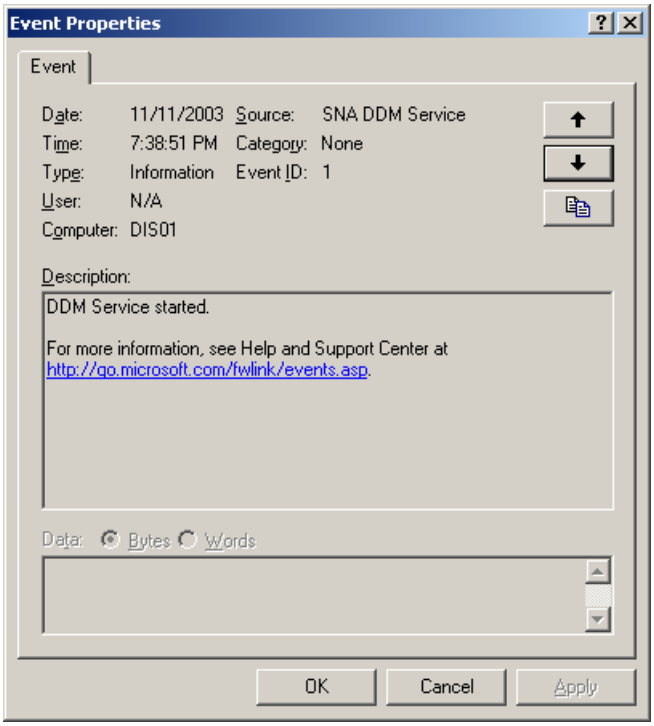
To access additional information about events through the Windows 2000 Event Viewer

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Event Viewer**.
2. Expand the **Event Viewer (Local)** folder. You should see at least three logs: **Application**, **Security**, and **System**.
3. Click the **Application log** to view its list of events.
4. Double-click the event of interest.
5. Under **Description**, look for **For more information, see Help and Support Center at http://go.microsoft.com/fwlink/events.asp**, and then click the link.
6. In the **Event Viewer** dialog box, click **Yes**.
7. When the results appear, select the message text that matches the message you received. Any relevant Knowledge Base articles are also available on the page.

To access additional information about events through the Windows XP/Windows Server 2003 Event Viewer

1. Click Start, point to Programs, point to Administrative Tools, and then click Event Viewer.
2. Expand the Event Viewer (Local) node.
3. Click Application to view a list of events.
4. Double-click an event.
5. Under the Description text box, click http://go.microsoft.com/fwlink/events.asp.

   Event Properties for Event Viewer



6. In the **Event Viewer** dialog box, click **Yes**.

Note
Clicking **Yes** allows your computer to send information across the Internet.

Note
The **Help and Support Center** dialog box displays the event ID event source, detailed explanation, and recommended actions.

Information about errors and events, as well as relevant Knowledge Base articles, are also available directly from the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=20869.

Microsoft continually updates the troubleshooting information about specific product event and error messages and posts this information to http://go.microsoft.com/fwlink/?LinkId=20869. The following table lists the event and error ID numbers that had additional information available on the Web at the time Host Integration Server was released. Microsoft recommends that you check the Web site for the additional messages that have been added since product release.

Connection Initialization Sequence

When troubleshooting pending DLC Connections, it is helpful to review the connection initialization sequence that occurs between the Host Integration Server computer and the host platform.

The following diagram applies to both AS/400 and mainframe connections:

Connection initialization sequence

CONNECTION INITIALIZATION: Ethernet 802.2

Connection Initialization Overview

Connection Initialization occurs in a sequential fashion. Each step builds upon the preceding step. After all steps have completed correctly, an Active connection is established between Host Integration Server and a remote host, either an AS/400 or a mainframe.

Every connection requires that a number of parameters match between the two platforms. Throughout this overview, these parameters, indicated in bold type, are displayed using the actual field names used by Host Integration Server and a remote host (that is, upper/lower case is preserved).

Steps 1 and 2

Verify basic network connectivity - can Host Integration Server communicate with the host's network adapter card?

Does the **Remote Network Address** on the **Address** tab of the **Connection Properties** dialog box match the **Local Adapter Address** defined in the AS/400 line description, or the **Switched Line** in the VTAM definition?

Steps 3 and 4

Verify host SSAP - is the host listening on the correct Source Service Access Port?

Does the **Remote SAP Address** on the **Address** tab of the **Connection Properties** dialog box match the **LAN SSAP** defined in the APPC Controller Description, or the **Switched Line** in the VTAM definition?

Steps 5 and 6

Verify local parameters - do the Host Integration Server "Local" parameters on the **System** tab of the **Connection Properties** dialog box match the "Remote" parameters in the host APPC controller, or VTAM PU, definition?

Step 7

Verify remote parameters - do the Host Integration Server "Remote" parameters, also defined on the **System** tab of the **Connection Properties** dialog box, match the "Local" parameters in the host APPC controller, or VTAM PU definition?

Connection initialization is a complex, sequential process that includes a wealth of details.

For more information, see Connection Initialization Details.

Connection Initialization Details

For an overview, refer to the topic Connection Initialization Overview.

Step 1, outbound

When Host Integration Server attempts to activate a DLC connection, it first sends out an LLC TEST frame to the host's network adapter address to initiate the link level connection, and to verify the link station to link station transmission path.

This TEST command is sent by the SNADLC 802.2 link service via the Window's DLC driver.

Host Integration Server issues this TEST command at the start of every 802.2 connection. Although this command does not cause connection activation, its failure precludes continuing the activation.

This TEST command causes the remote link station to return a TEST Response. This will not affect the mode or state of the remote link station.

TOKEN-RING CONNECTIONS:

The TEST command is sent to the local ring first.

If Host Integration Server does not receive a reply to this TEST command within 0.5 seconds, it resends it, with the "all routes broadcast" setting enabled, causing it to be forwarded to adjacent rings by any source routing bridges which are present on the ring. The SNADLC link service will send a total of three all-routes broadcast TEST commands if the remote station (host) is not responding.

ETHERNET CONNECTIONS:

The TEST command does not contain any source-routing information.

Host Integration Server sends four TEST commands to the host's network adapter address.

1. 802.3 to the regular MAC address
2. 802.3 to the bit flipped MAC address
3. DIX format to the regular MAC address
4. DIX to the bit flipped MAC address

Step 2, inbound

The success of the TEST command indicates that the host's network interface adapter is accessible, and is configured for SNA communication.

The failure to receive a response to the TEST command will result in an Event 230 "No response to TEST commands".

What does this failure imply?

1. The **Remote Network Address**, which is the host's network adapter address, is incorrectly configured on the Host Integration Server Connection Properties dialog box, Address Tab. It should match the **Local Adapter Address** defined in the AS/400 line description, or the **Switched Line** in the VTAM definition.
2. Multiple Network Adapter Cards: If the Host Integration Server computer has multiple network adapter cards, say one for the SNA Link Service, and the other for Windows 2000/NT domain connectivity, and the SNA Link Service is configured to communicate over the NT domain adapter, there obviously will be no AS/400 response.
3. Intermediate bridges or routers are not passing the DLC Protocol between the Host Integration Server computer and the host. DLC traffic cannot reach the segment or ring on which the AS/400's network address resides because the intermediate locater is not forwarding the LLC frames.
4. The host is not enabled for SNA communication (this occurs rarely).

Step 3, outbound

Verify that the host's **LAN SSAP** matches the Host Integration Server **Remote SAP Address** property.

A NULL XID command is sent to the host. This is required as part of link level connection establishment. This command is sent to the host's **LAN SSAP** (which is referred to in the Host Integration Server environment as the **Remote SAP Address**). This is the port that the host 'listens to', when receiving messages from the Host Integration Server computer. SNA protocol uses a default **LAN SSAP** of 0x04.

Step 4, inbound

The success of the NULL XID command is indicated when Host Integration Server receives back a RQOS (Request Open Station) XID response.

The failure to receive a RQOS command will also result in the generation of an Event 230 – "No Response to XID Commands".

This indicates that the Host Integration Server timed out before the RQOS command was received, because:

- The Host Integration Server **Remote SAP Address** was incorrect.
- The AS/400 was unable to create a new APPC Controller for some reason. For example, AUTOCRTCTL is disabled.
- The AS/400 APPC Controller or VTAM PU is in an Error State, or Inactive Status.

On Ethernet and Token-Ring networks, if the host does not reply to the XID command, then the connection remains in a pending condition, and an Event 230 will be logged in the NT Event Viewer Application log. The Host Integration Server computer will continually attempt connection startup, though only the first Event ID 230 will be logged with the Event Viewer, to prevent the log from filling up.

Step 5, outbound

Verify that the Host Integration Server computer's "Local Parameters" match an APPC Controller, or VTAM PU, description on the host.

An XID command is sent to the host. This XID contains the Host Integration Server computer's "Local Parameters". The parameters of interest are the Host Integration Server computer's network adapter address, "Local" **Network Name**, and "Local" **Control Point Name**.

Step 6, inbound

The success of the "Local Parameters" XID is indicated when Host Integration Server receives back a "Remote Parameters" XID from the host containing its "Local Parameters".

The failure to receive this "Remote Parameters" XID from the host will result in the generation of an Event 56 - "XID rejected by remote computer

The host failed to match the parameters sent in Step 5 to a known APPC controller or VTAM PU definition.

Host Integration Server logs Event 56 when it receives an XID Negotiation Error (X'22') Control Vector from the host. This control vector includes an offset pointer into the XID that was sent to the host in Step 5, where the offset points to the parameter in error. If the offset is "2" (pointing to the Local Node ID parameter), then an Event 47 is logged. If the offset is 19 (pointing to the link role parameter), then an Event 46 is logged. These two events are very rare. If some other offset is received (99.9% of the time), then Event 56 is logged.

For the purpose of discussion, lets assume an APPC Controller already exists on the host containing:

- The address of the network adapter in the Host Integration Server computer, which is referred to on the AS/400 as the **LAN remote adapter address** (ADPTADR).
- A specific **Remote network identifier** (for example, APPN).
- A specific **Remote control point** (for example, TEST1).

The XID sent in step 5 will be rejected under the following circumstances:

1. There is already an APPC controller defined on the AS/400 with the same name as the name defined in Host Integration

Server SNA Manager, but it has a different **LAN remote adapter address** (ADPTADR)" associated with it.

Another way of saying the same thing is: The Host Integration Server computer attempted to connect with an invalid **"Local" Network Name**. For example: ESSLAB, where the AS/400 was expecting APPN.

(There is a source of potential confusion here. The **Remote Network Identifier** in the APPC Controller description corresponds to the **"Local" Network Name** on the Host Integration Server **Connection Properties** dialog box, **System** tab. However, on the AS/400 Display Networks Attributes screen, you will very likely see that the value for the **Local network ID** is identical to the APPC **Remote Network Identifier**. The confusion exists because the Host Integration Server **"Local" Network Name** is apparently referred to by two different field names on the AS/400. However, these two AS/400 fields *are not* the same. The AS/400 **Remote Network Identifier** *must* match the Host Integration Server **"Local" Network Name.** The AS/400 **Local network ID** does not have to match. It is usually defaulted to the same name as the **Remote Network Identifier** for the sake of convenience, however, the name actually refers to the AS/400's "local" network ID, *not* the "local" network name on Host Integration Server).

2. There is already a different controller name defined on the AS/400 with the same "**LAN remote adapter address** (ADPTADR)" (Autocreate Controller (AUTOCRTCTL) is set to YES in the AS/400 Line Description).

   In other words, The Host Integration Server computer attempted to connect with an invalid **"Local" Control Point Name**. For example: TESTXXX, where the AS/400 was expecting TEST1.

3. The **Remote Control Point Name** in the Host Integration Server **Connection Properties** dialog box does not match the **Local Control Point Name** in the AS/400 Network Attributes screen.

4. The Host Integration Server computer is configured with XID Type: Format 0, when the AS/400 requires XID Type: Format 3.

Step 7

Host Integration Server uses a four-step algorithm to match the hosts "Local parameters". If a step succeeds, any remaining steps are bypassed, and the activation sequence continues to step 8.

1. The **Network Name** and **Control Point Name** from the host XID are compared to the **Network Name** and **Control Point Name** in the "Remote" Node Name section of the Host Integration Server **Connection Properties** dialog box, **System Identification** tab.

2. If the host XID does not contain a network name and control point name (format 0 XID) or those fields are blank in the Host Integration Server **Connection Properties** dialog box, the matching will proceed to the next step. If the comparison fails, the XID will be rejected and event ID 49 is generated. If the comparison is successful, the XID will be responded to in step 8.

3. If Host Integration Server is unable to match the **Network Name** and **Control Point Name**, it will compare the IDBLK and IDNUM (Node ID) in the XID to the "Remote" Node ID field in the Host Integration Server **Connection Properties** dialog box. If this field is blank, the matching will proceed to the next step. If the comparison fails the XID is rejected and NT Event ID 49 is generated.

Note
All XIDs must contain an IDBLK and IDNUM.

   If the comparison is successful, the XID will be responded to in step 8.

4. Host Integration Server then compares the network address contained within the incoming XID to the **Remote Network Address** configured in the Host Integration Server **Connection Properties** dialog box. For x.25 the Remote X.25 address is used. If this comparison fails, the XID is rejected and NT Event ID 49 is generated. For SDLC the XID is simply accepted.

If the comparison process fails, an Event 49 is generated by Host Integration Server, and logged with the NT Event Service.

Step 8

The connection eventually goes active.

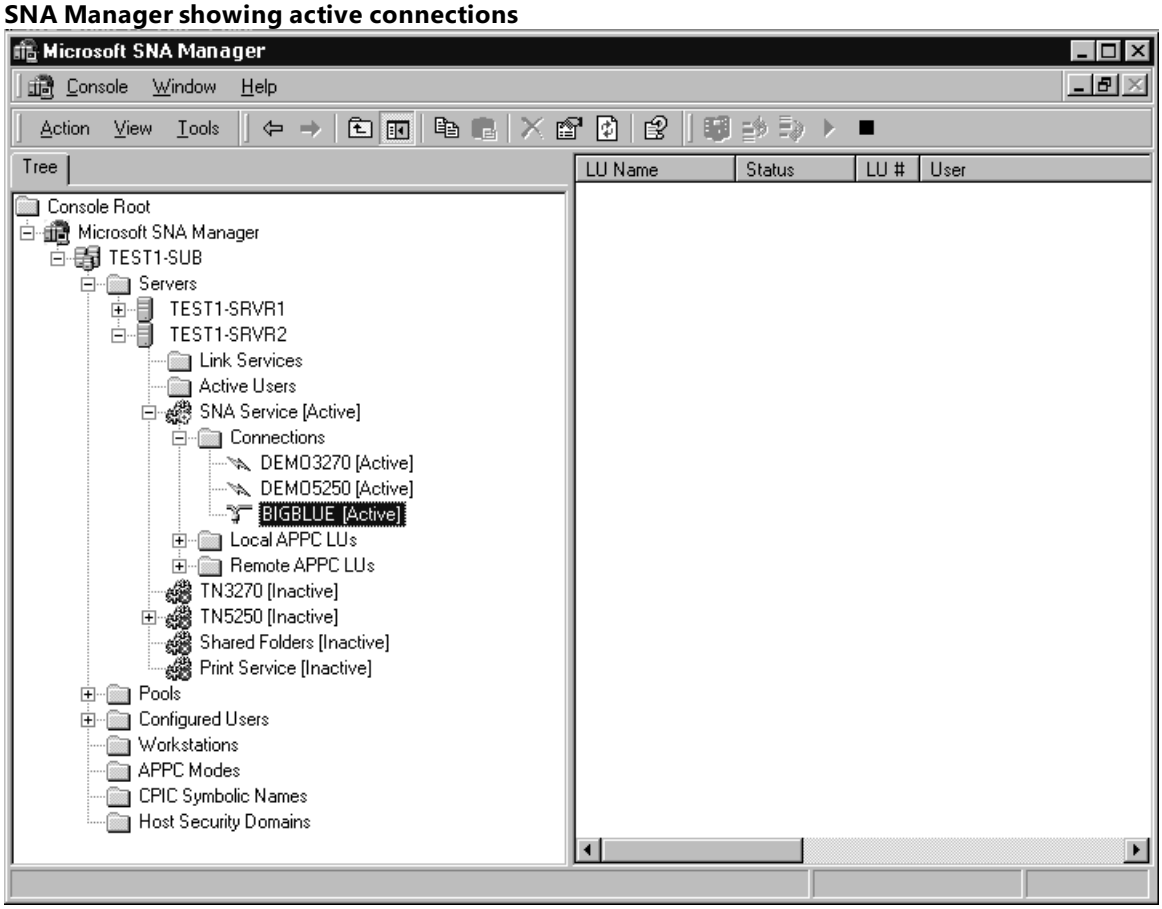
Host Integration Server Screens

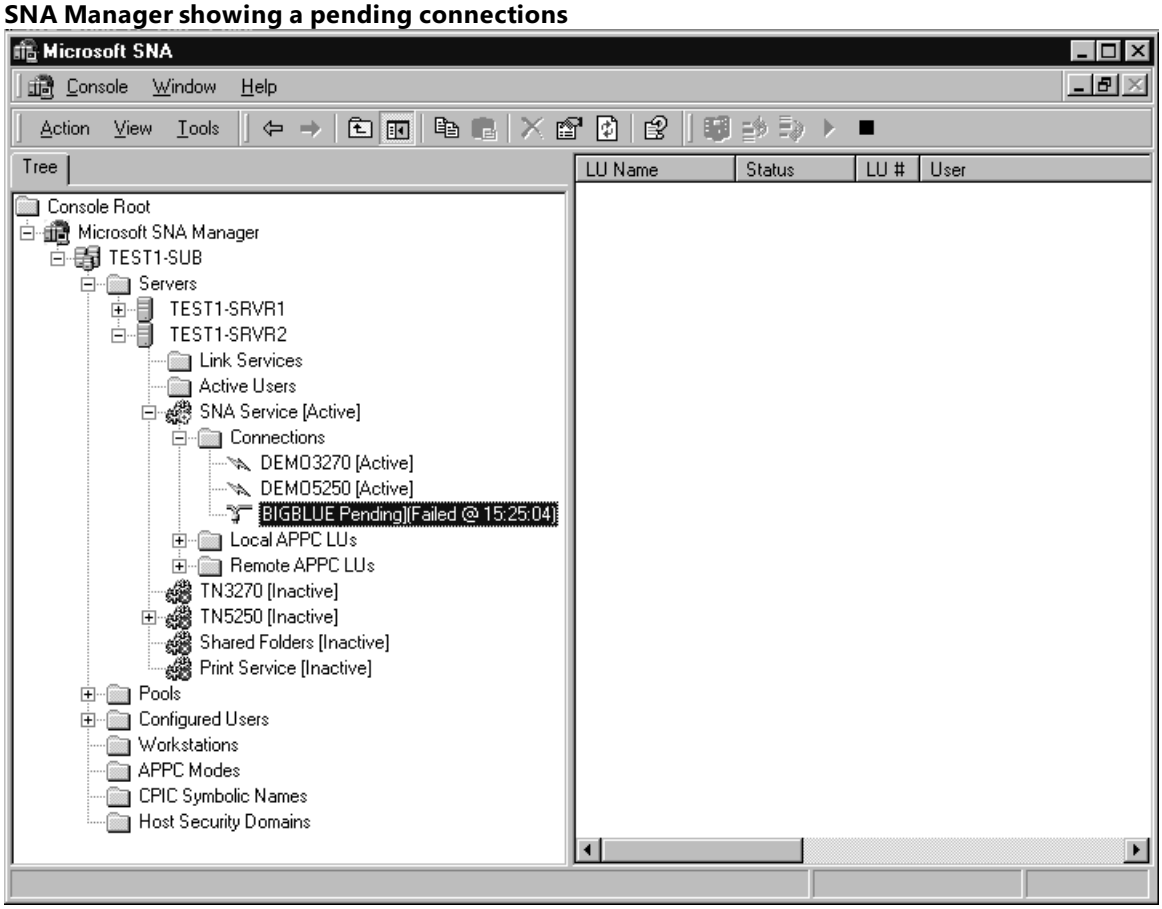
Here is the SNA Manager showing active connections:

SNA Manager showing active connections



Here is the SNA Manager showing a pending connection:

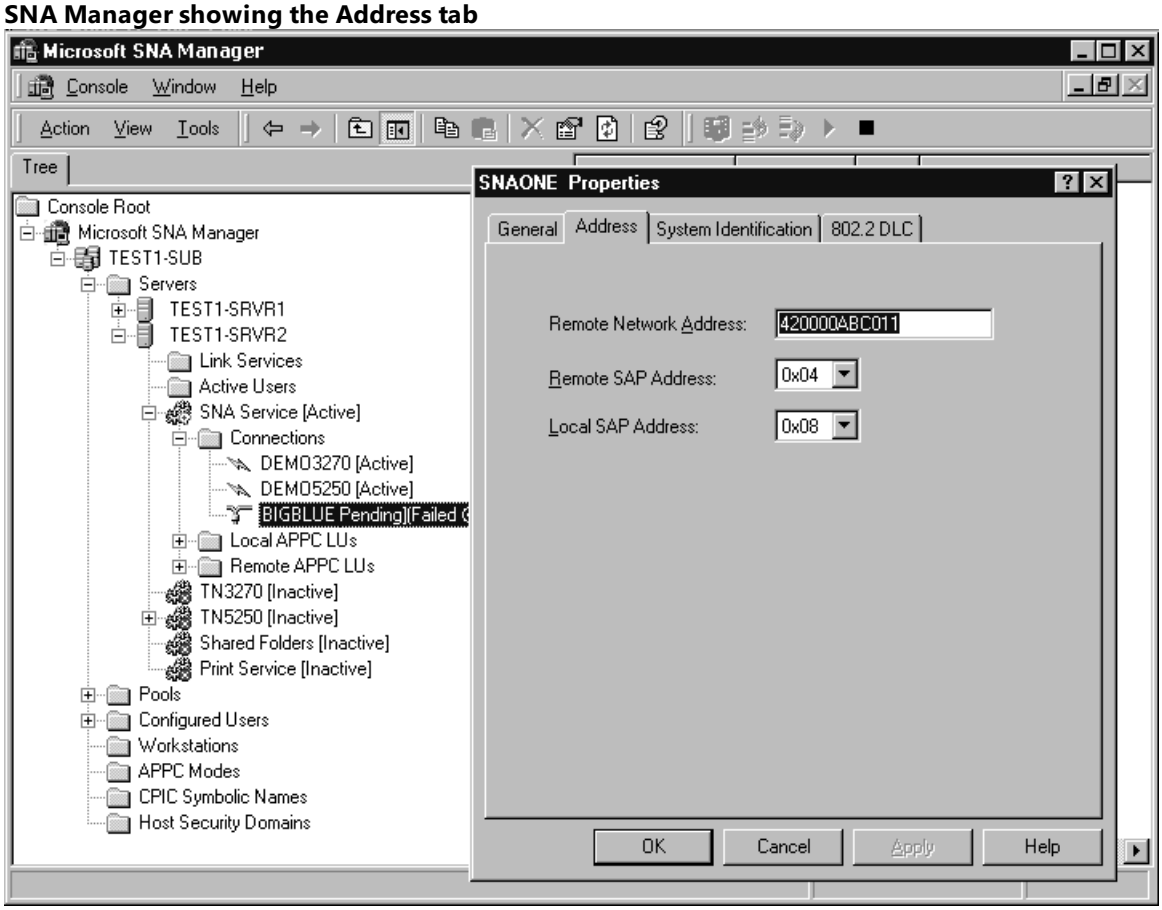
SNA Manager showing a pending connections



Right-click the pending connection, and then click **Properties**.

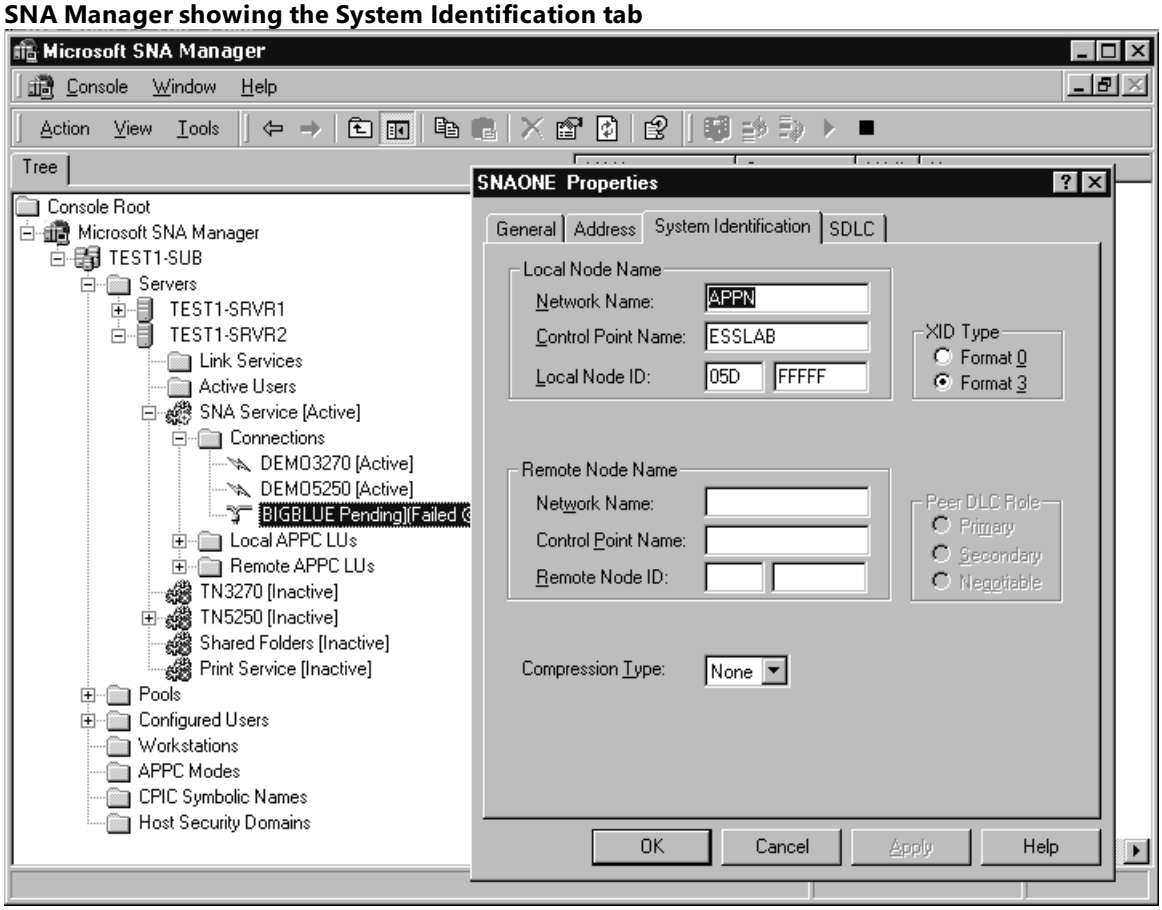
Here is the SNA Manager with the **Address** tab selected:

SNA Manager showing the Address tab



Here is the SNA Manager with the **System Identification** tab selected.

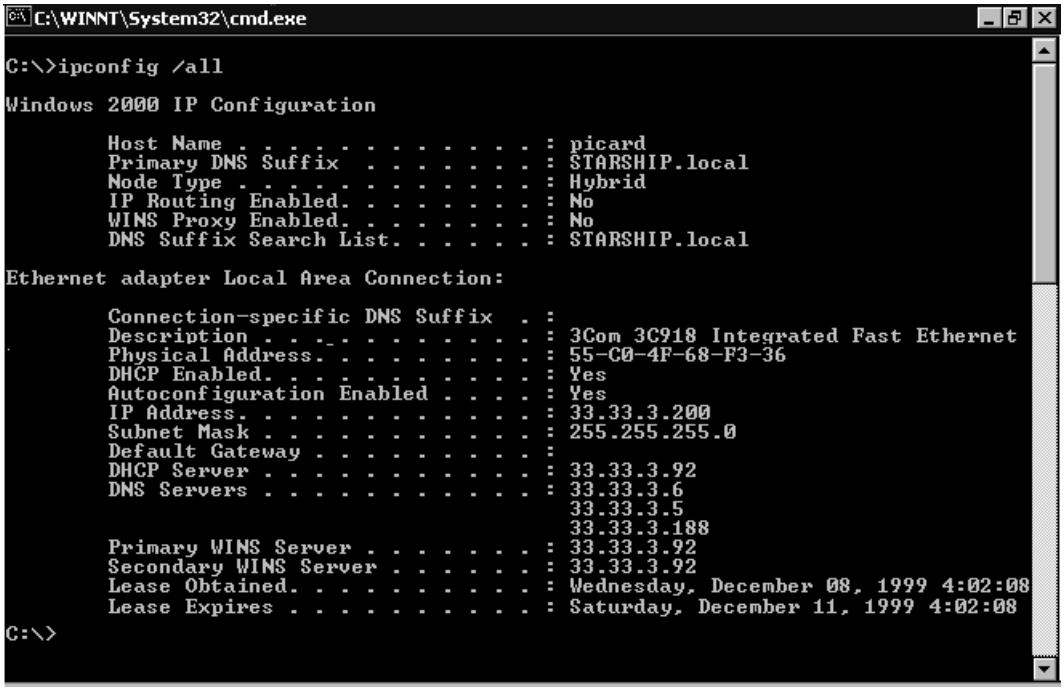
SNA Manager showing the System Identification tab



- Host Integration Server "Local" Network Name must match the AS/400 Remote network identifier.
- Host Integration Server "Local" Control Point Name must match the AS/400 Remote control point.

Here is a command window on the Host Integration Server computer. The command **ipconfig/all** has been entered to display the Host Integration Server computer's local network adapter address.

The command window



The network adapter address is also referred to as the Physical Address.

It is also possible to enter the command **net config workstation**.

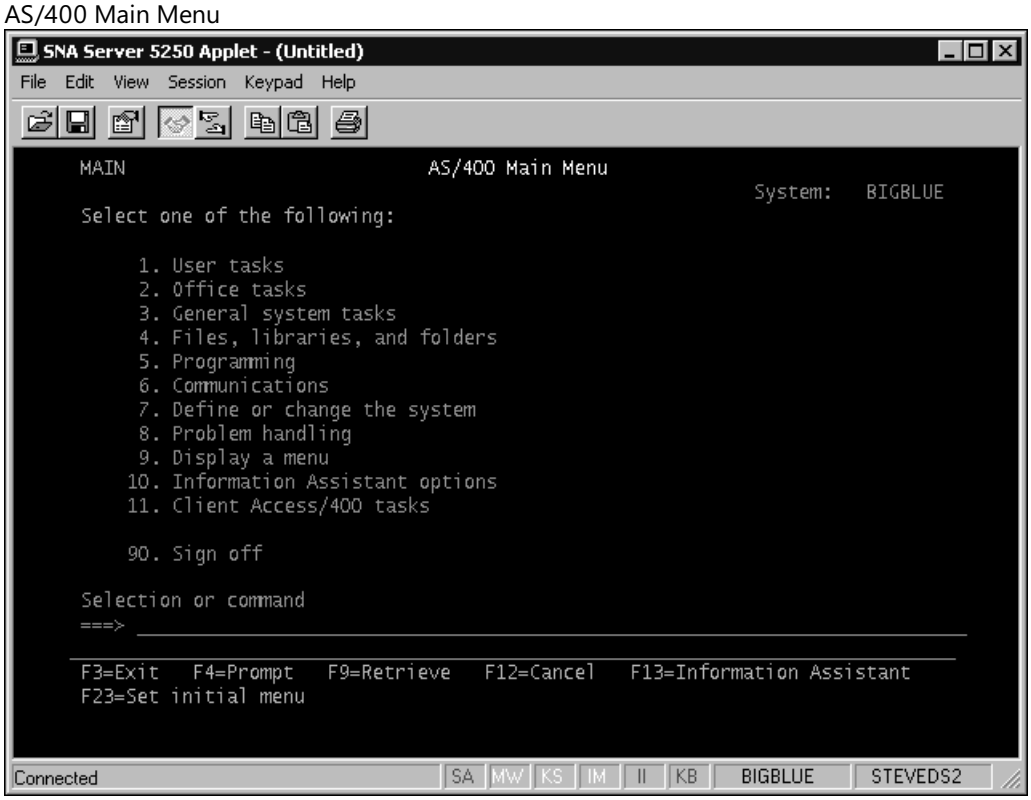
Both methods will work, but only if TCP/IP is bound to the adapter that Host Integration Server (and DLC) is using, for example, a NetBIOS-compatible transport is bound to the address used by the Host Integration Server computer. If it is not bound to it, then there is no easy way to determine the address.

Another way of saying this is: Assume there are two network adapter cards in the Host Integration Server computer. One is used for Windows domain connectivity, the other, to communicate with an AS/400. Since **ipconfig /all** will only report the address of the card used for domain connectivity, it will be difficult to find the address used for AS/400 connectivity.

AS/400 Screen Walkthrough

The starting point on the AS/400 is the **AS/400 Main Menu**:

AS/400 Main Menu



From here, you can display/work with Line and Controller descriptions, and modify configuration status fields.

What would you like to do?

Lines:

1. Display Line Descriptions
2. Change Line Descriptions
3. Change Line Status

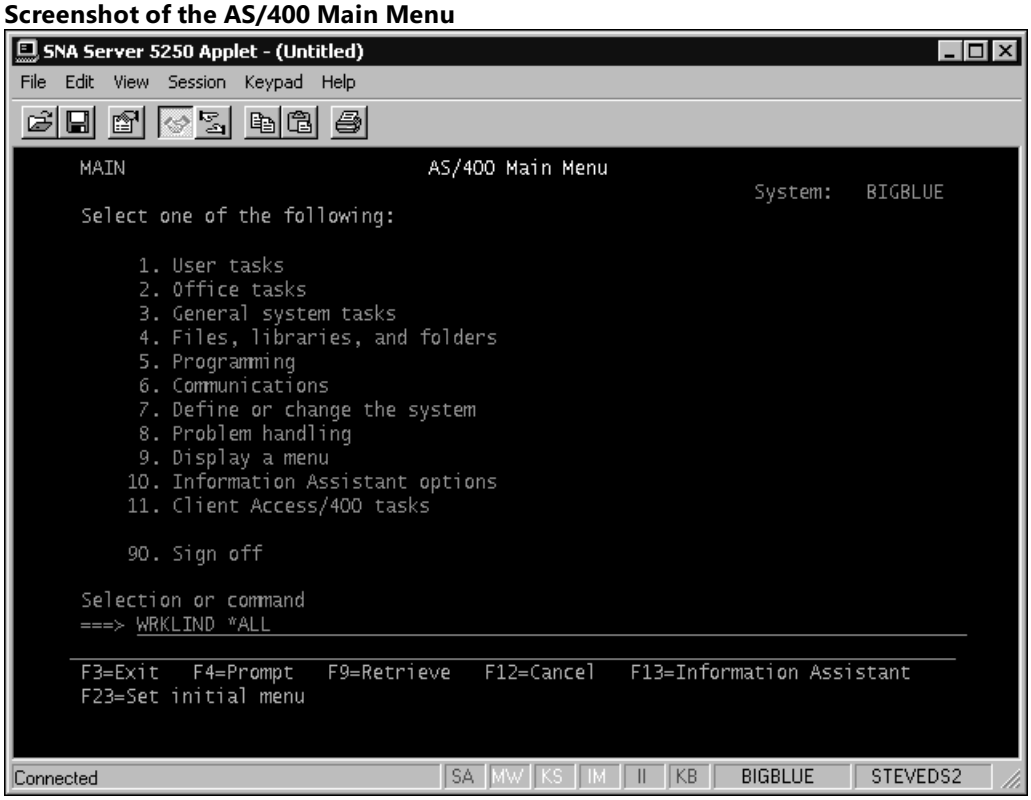
Controllers:

1. Display Controller Descriptions
2. Change Controller Descriptions

Display Line Descriptions

Open the **AS/400 Main Menu**:

Screenshot of the AS/400 Main Menu

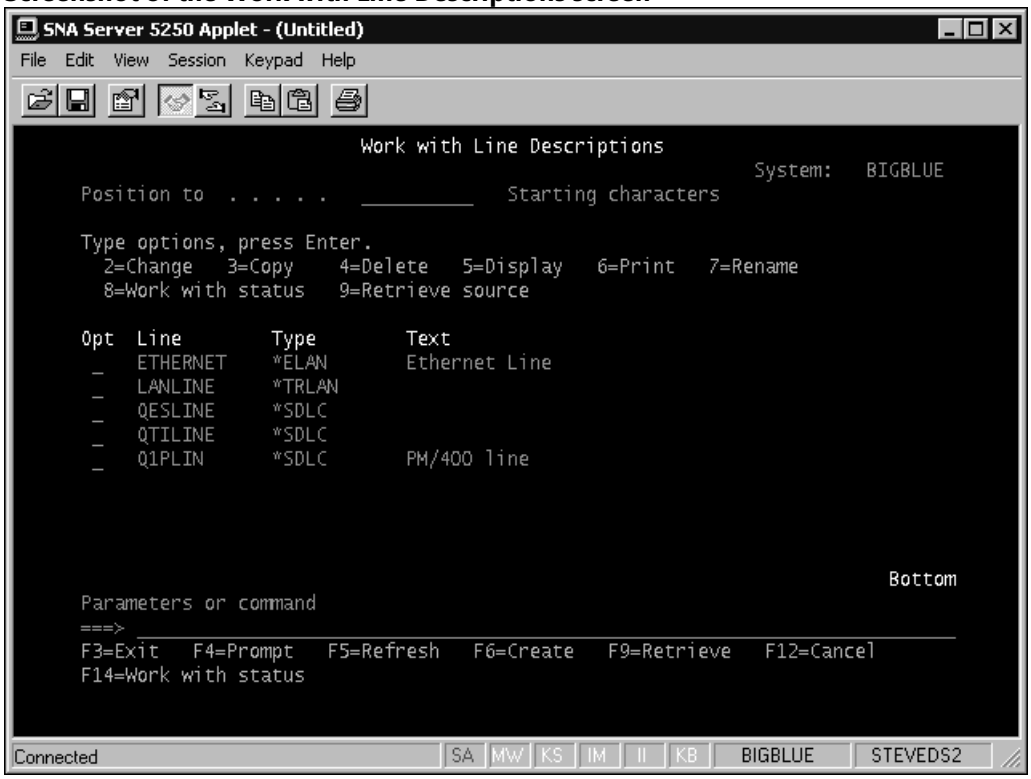


Enter **WRKLIND *ALL** at the command prompt.

Note
The AS/400 command line is case-insensitive.

This will bring up the **Work With Line Descriptions** screen:

Screenshot of the Work with Line Descriptions screen



There are three types of Lines that may be displayed on this screen: Ethernet (ELAN), Token-Ring (TRLAN), and Synchronous Data Link Control (SDLC).

The line names shown here are for illustration purposes only and may not correspond to the names displayed on your AS/400 screens.

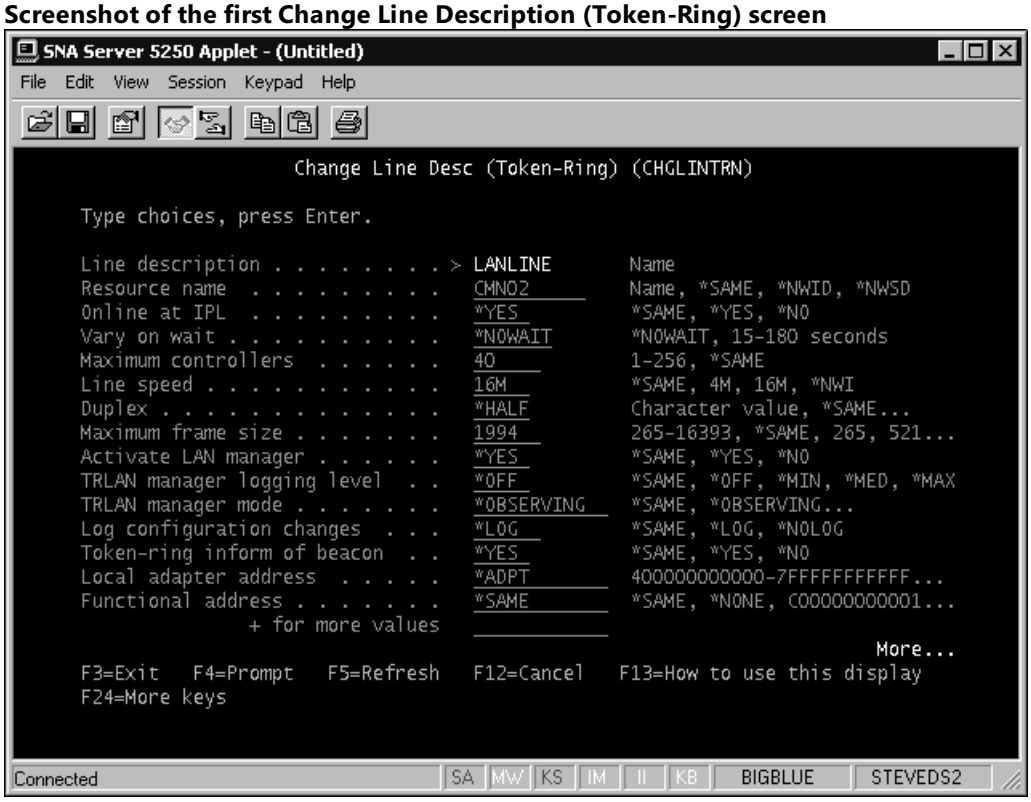
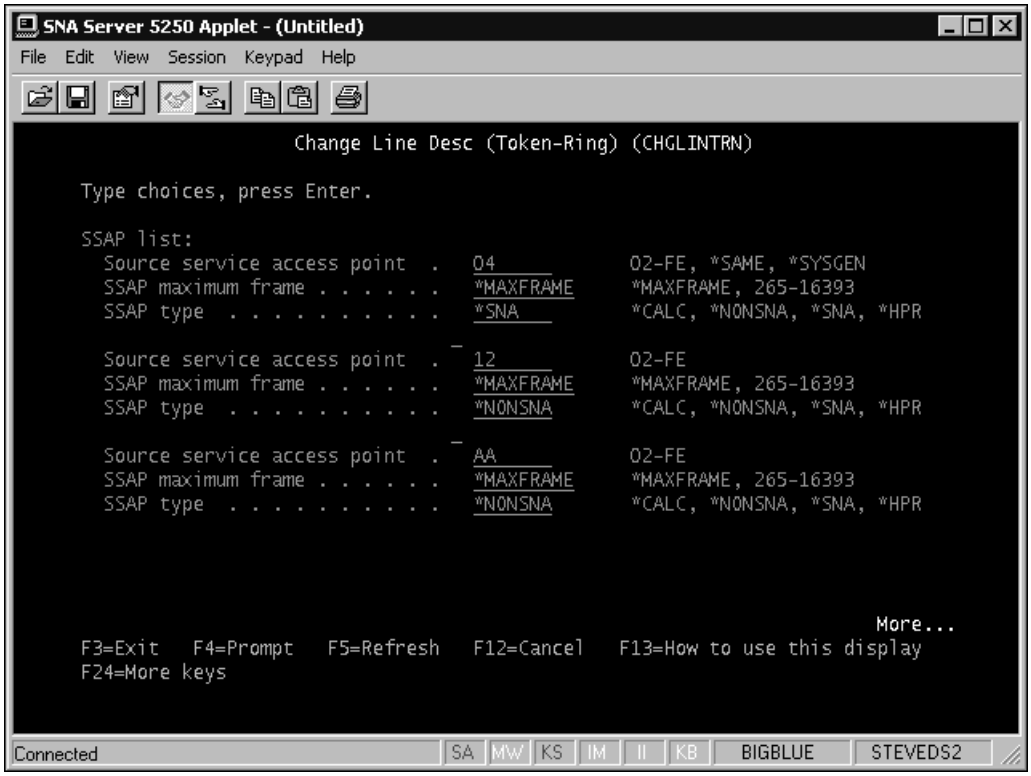
Screenshot of the first Change Line Description (Token-Ring) screen



Press the **PAGEDOWN** key to scroll to the second screen.

Here is the second of four AS/400 **Change Line Description (Token-Ring)** screens:

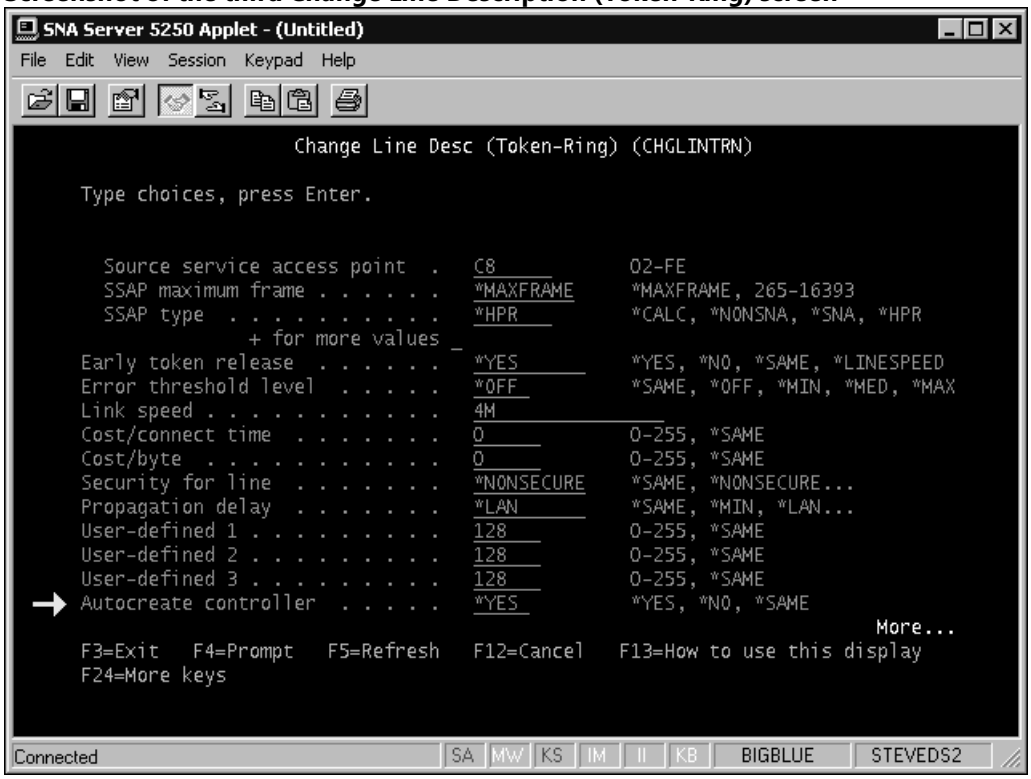
Screenshot of the second Change Line Description (Token-Ring) screen



Press the **PAGEDOWN** key to scroll to the third screen.

Here is the third of four AS/400 **Change Line Description (Token-Ring)** screens:

Screenshot of the third Change Line Description (Token-Ring) screen

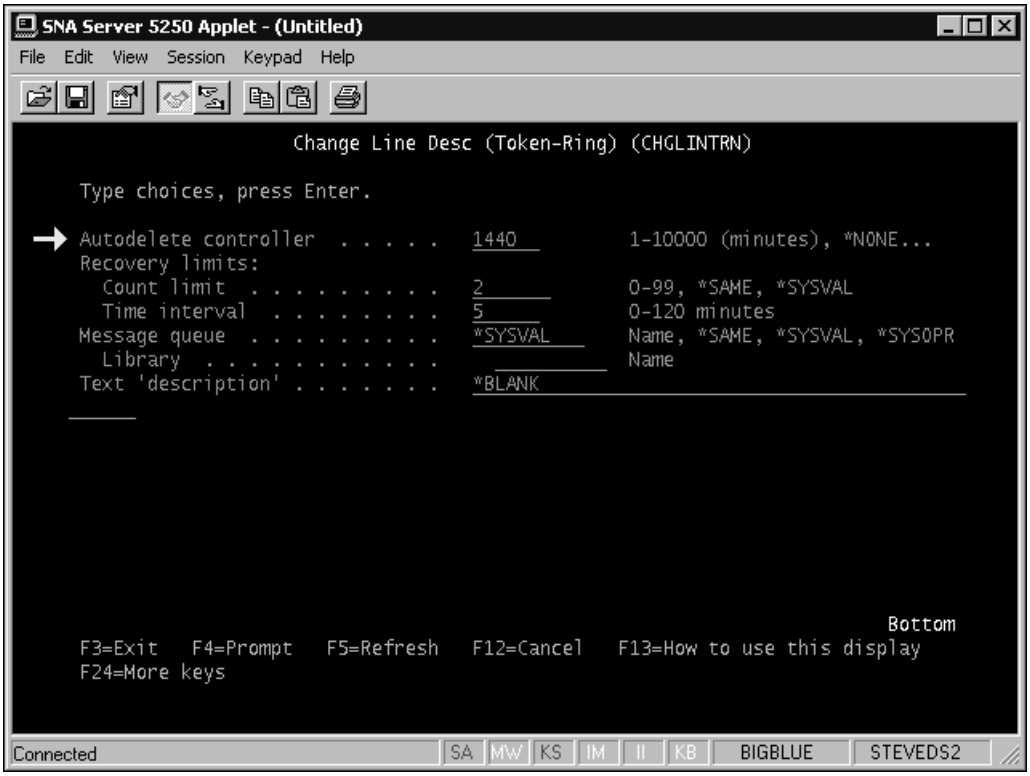


The **Autocreate controller** parameter can be set on this screen.

Press the **PAGEDOWN** key to scroll to the fourth screen.

Here is the last of four AS/400 **Change Line Description (Token-Ring)** screens:

Screenshot of the fourth Change Line Description (Token-Ring) screen

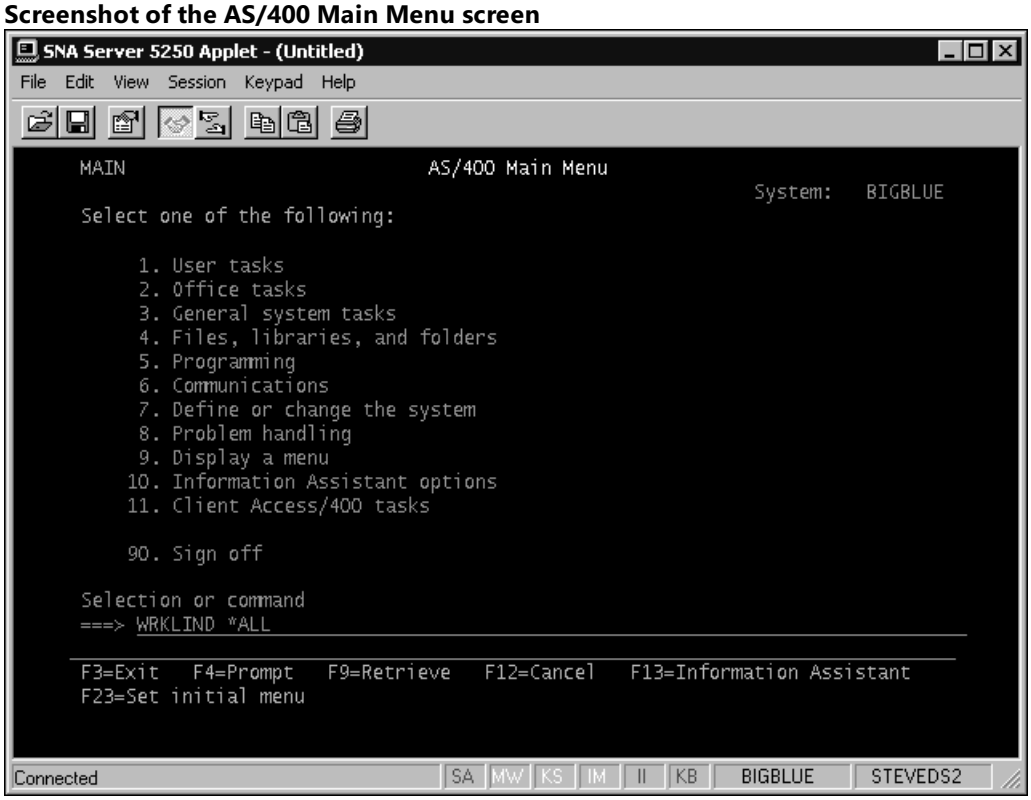


The Autodelete controller parameter can be set on this screen.

Change Line Status

Open the **AS/400 Main Menu**:

Screenshot of the AS/400 Main Menu screen

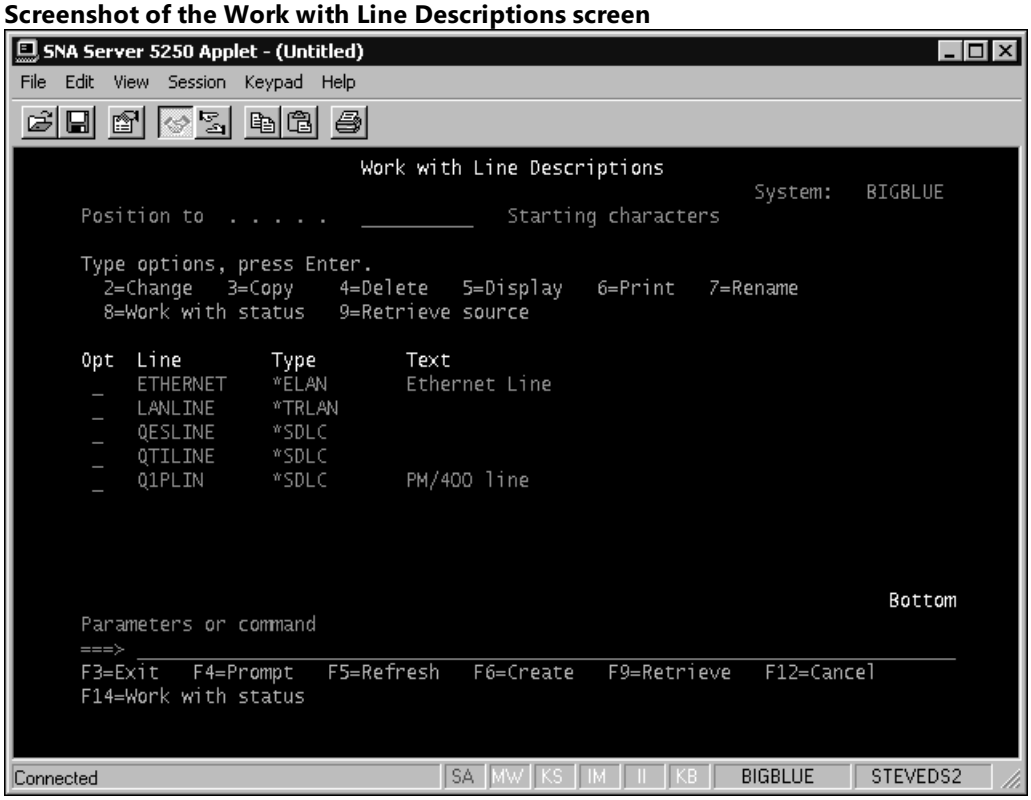


Enter **WRKLIND *ALL** at the command prompt.

Note
The AS/400 command line is not case-sensitive).

This will bring up the **Work With Line Descriptions** screen:

Screenshot of the Work with Line Descriptions screen

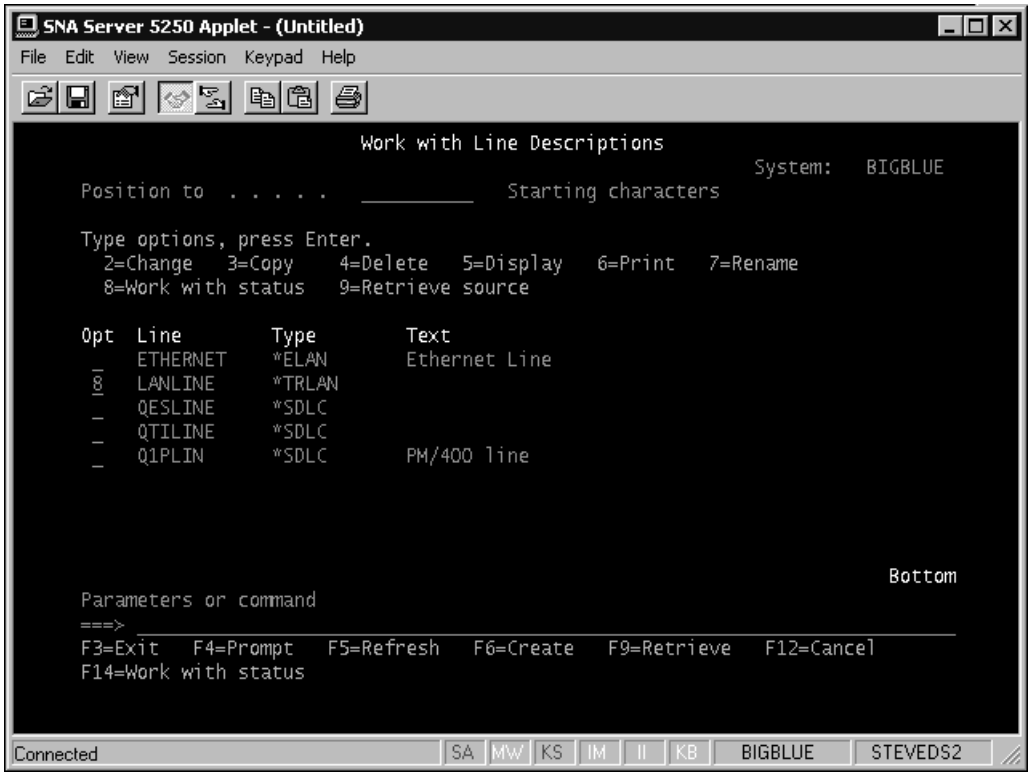


What would you like to do?

1. Change an Ethernet Line's Status
2. Change a Token-Ring Line's Status

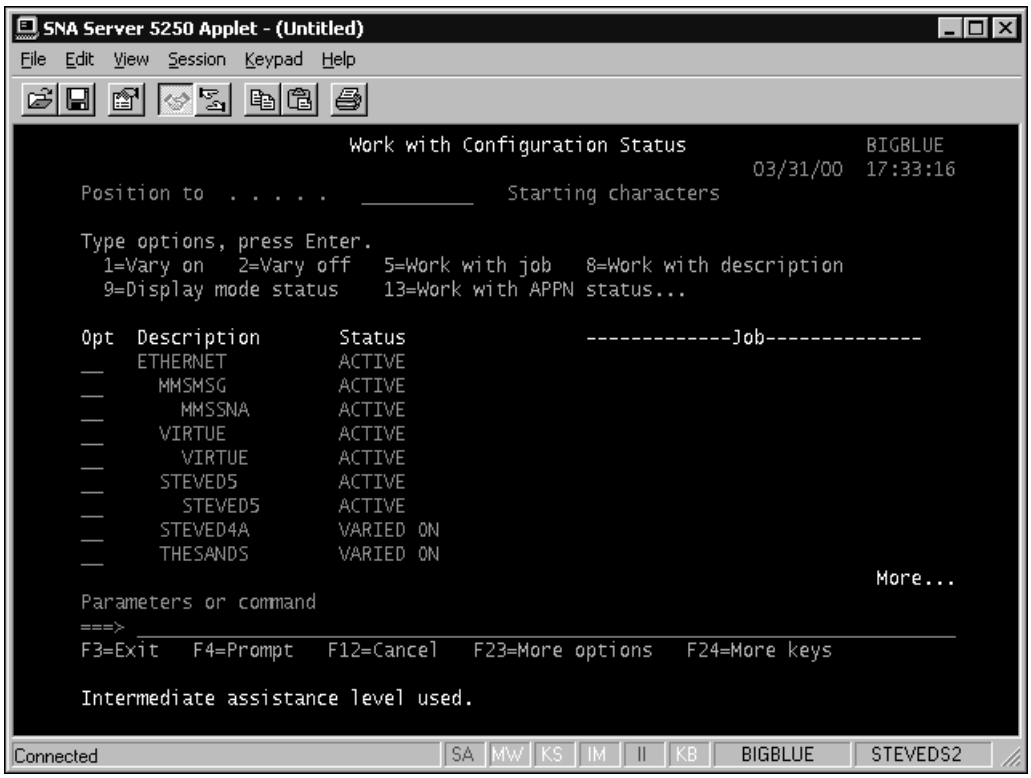
Change an Ethernet Line's Status

Here is the AS/400 **Work With Line Descriptions** screen:



Choose the **Status** option for the desired line by entering the number 8 in the **Opt** column, next to the Ethernet Line you want to change.

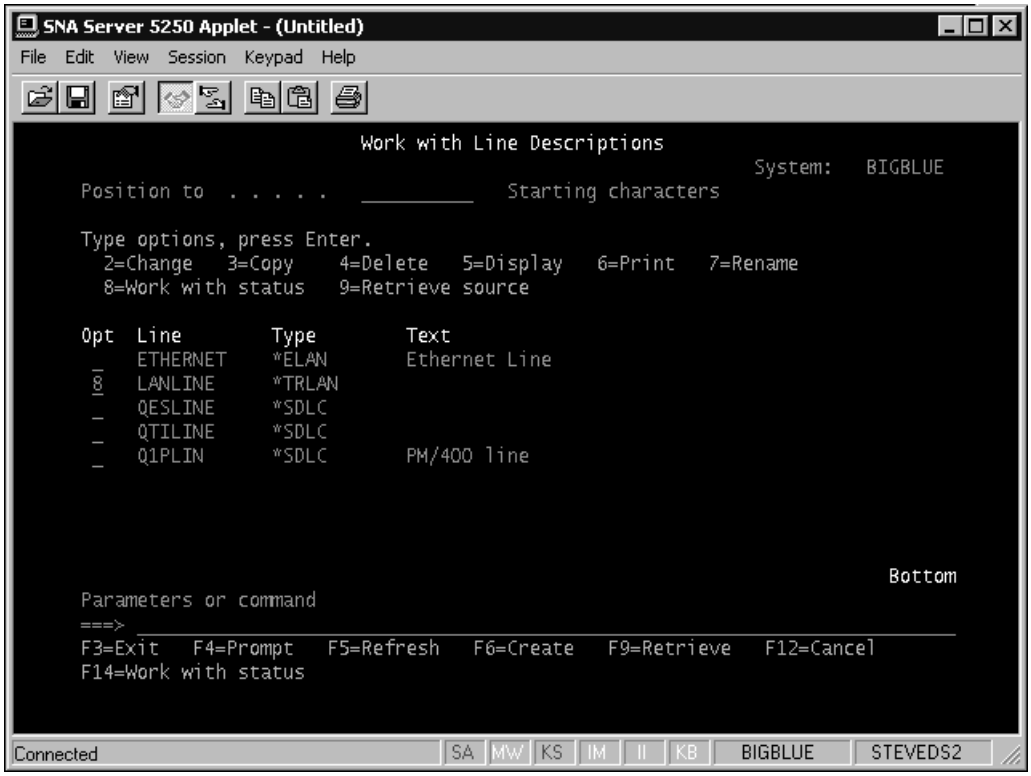
Here is the AS/400 **Work with Configuration Status** screen:



Select option 2 to vary the Line status off, and option 1 to vary the Line status back on.

Change a Token-Ring Line's Status

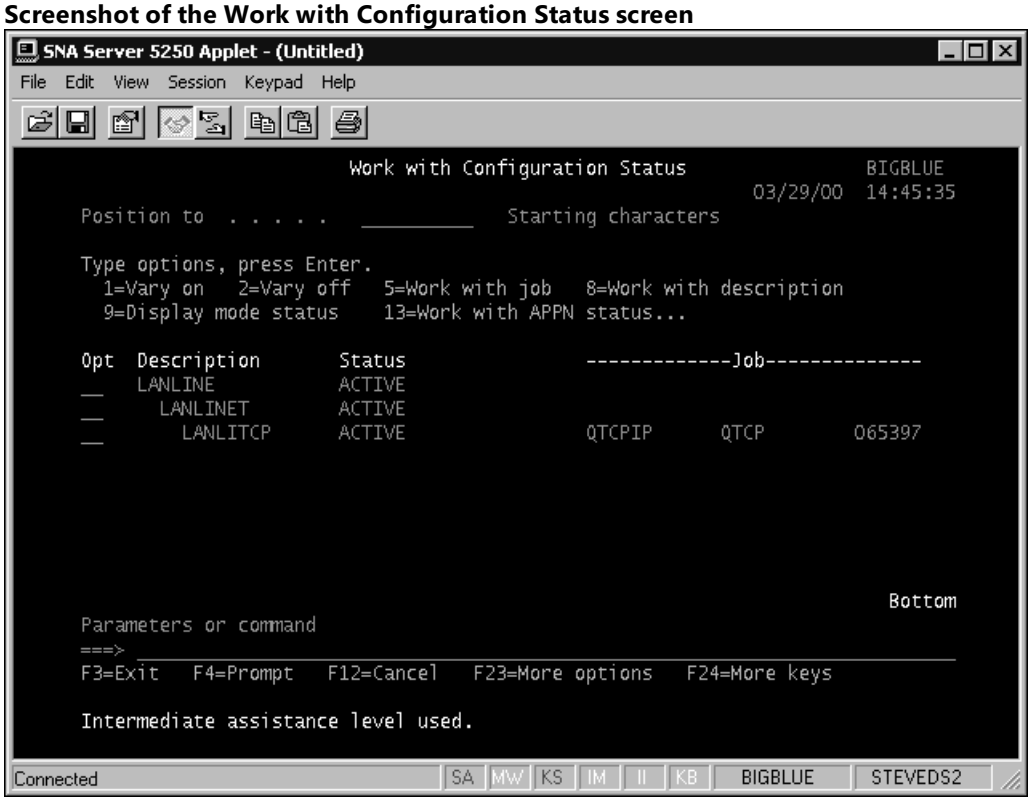
The following figure shows the AS/400 **Work With Line Descriptions** screen:



Choose the **Status** option for the desired line by entering the number **8** in the **Opt** column, next to the Token-Ring Line you want to change.

The AS/400 **Work with Configuration Status** screen appears:

Screenshot of the Work with Configuration Status screen



Select option 2 to vary the Line status off, and option 1 to vary the Line status back on.

Display Controller Descriptions

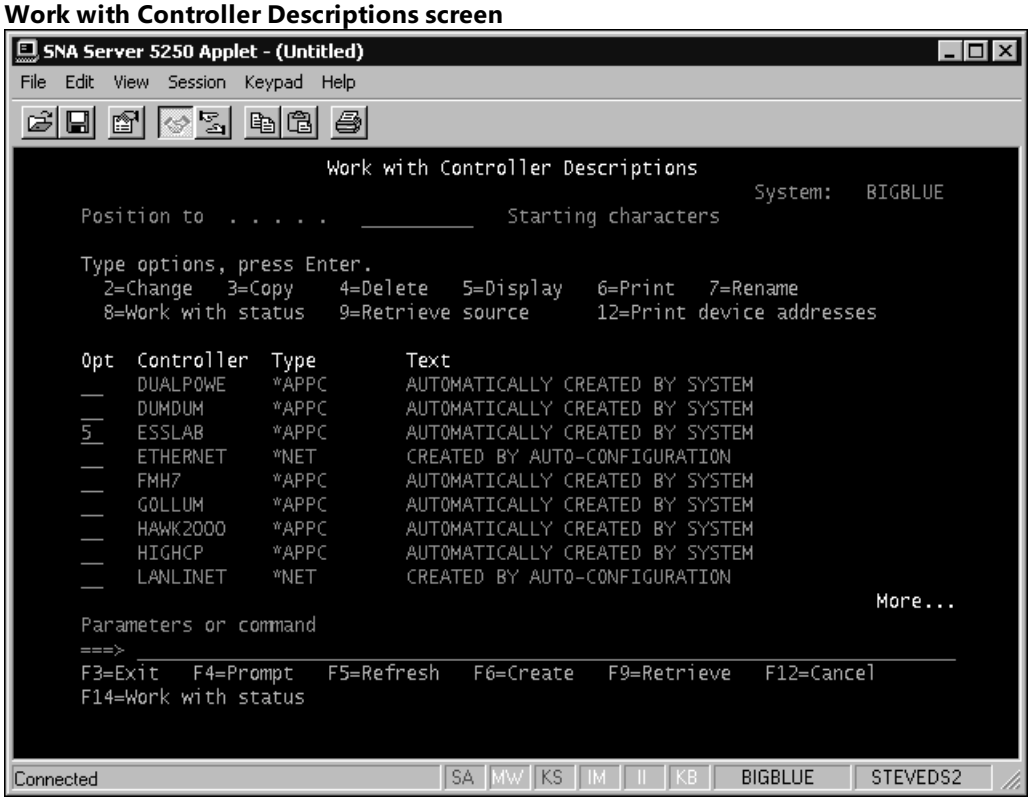
Open the **AS/400 Main Menu**:

AS/400 Main Menu screen

Enter **WRKCTLD *ALL** at the command prompt.

This will bring up the **Work With Controller Descriptions** screen, which lists available AS/400 Controller Descriptions:

Work with Controller Descriptions screen

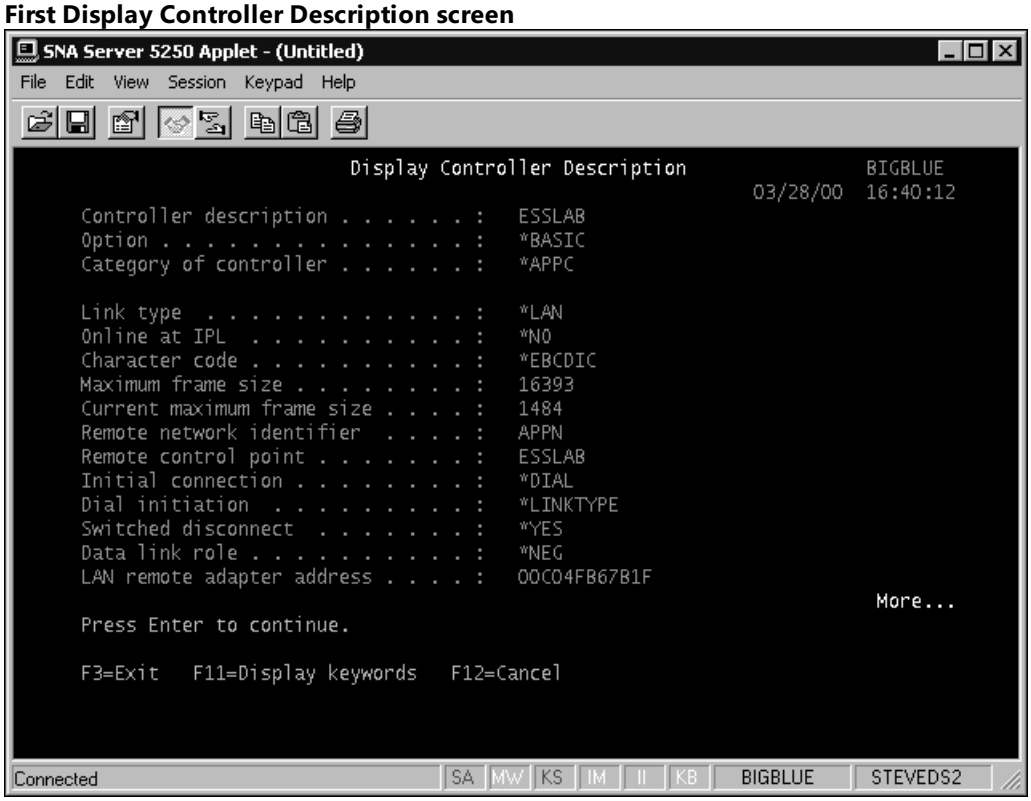


The controller names shown here are for illustration purposes only and may not correspond to the names displayed on your AS/400 screens.

Choose the **Display** option by entering the number 8 next to the Controller that you want to display.

Here is the first of two **Display Controller Description** screens:

First Display Controller Description screen



There are three important non-modifiable fields displayed on this screen:

AS/400 Field Name	Host Integration Server Field name
Remote network identifier	"Local" Network Name
Remote control point	"Local" Control Point
LAN remote adapter address	Network adapter address

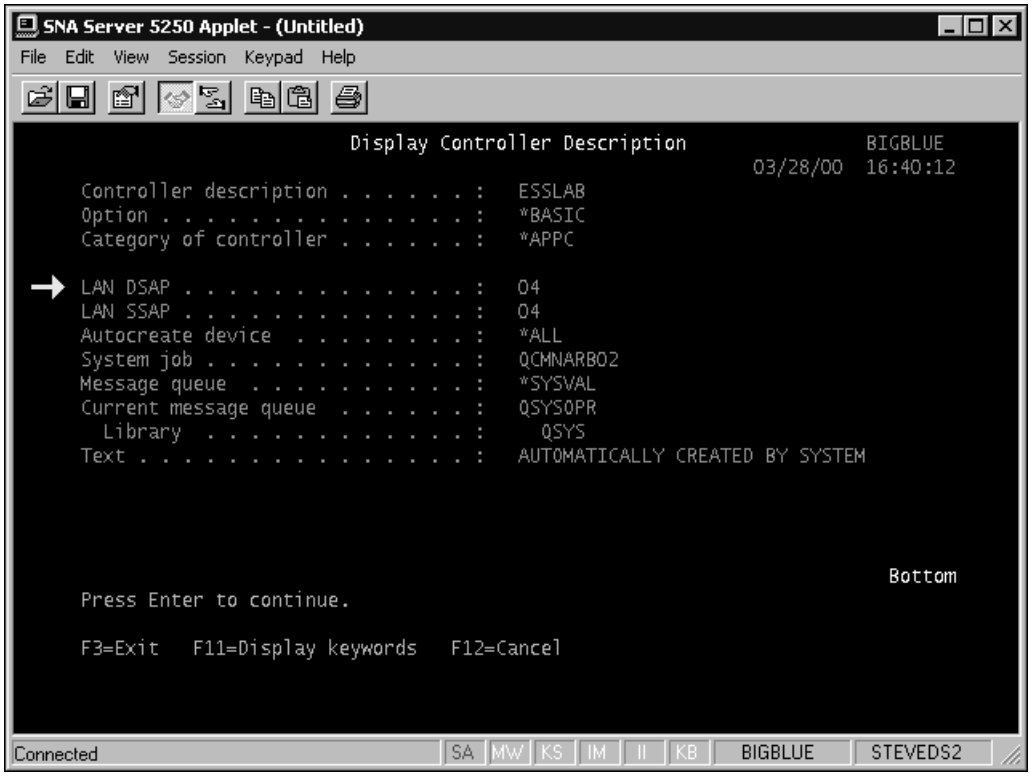
Note

The **LAN remote adapter address** corresponds to the Host Integration Server computers local network adapter address, *no t* to the AS/400s local network adapter address.

Press the **PAGEDOWN** key to display the second **Display Controller Description** screen.

Here is the second **Display Controller Description** screen:

Second Display Controller Description screen



There are two important non-modifiable fields on this screen:

AS/400 Field Name	Host Integration Server Field name
LAN DSAP	Local SAP Address
LAN SSAP	Remote SAP Address

Change Controller Descriptions

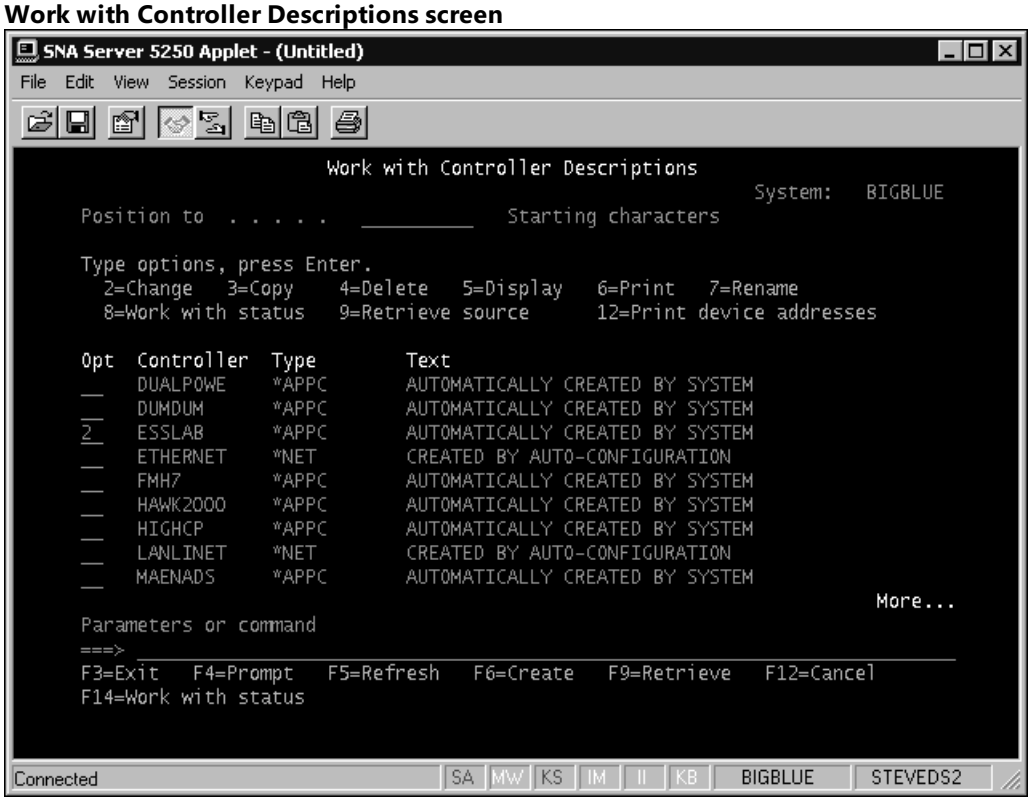
Open the **AS/400 Main Menu**:

AS/400 Main Menu screen

Enter **WRKCTLD *ALL** at the command prompt.

This will bring up the **Work With Controller Descriptions** screen, which lists available AS/400 Controller Descriptions:

Work with Controller Descriptions screen

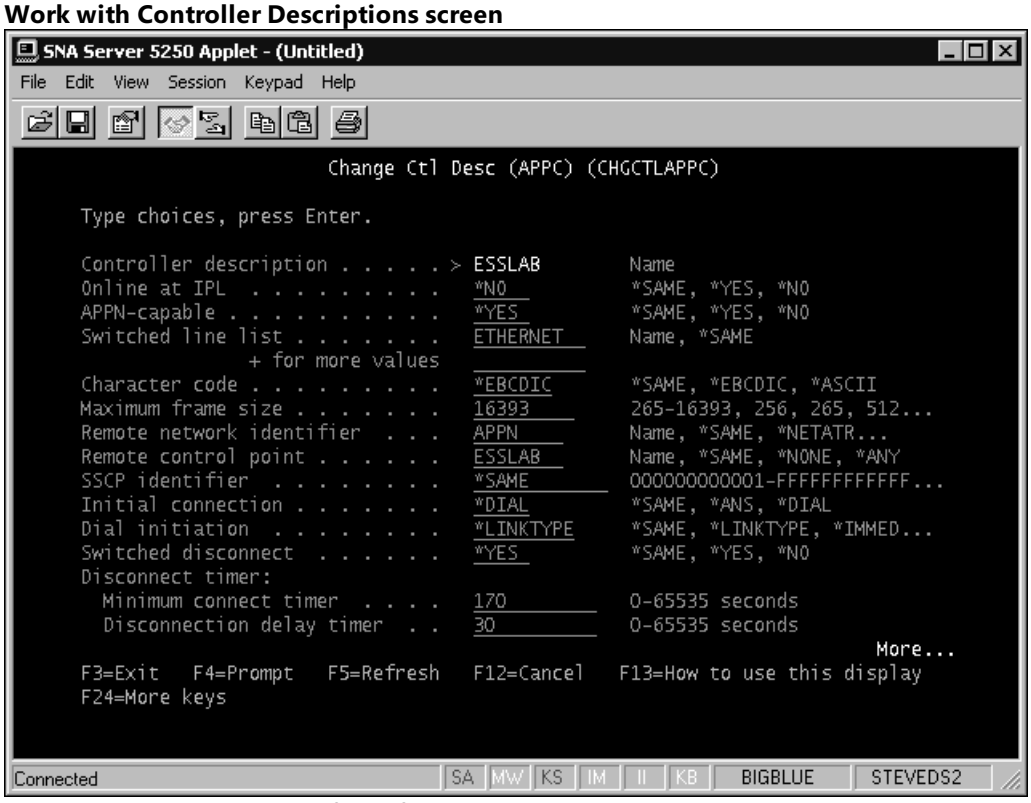


The controller names shown here are for illustration purposes only and may not correspond to the names displayed on your AS/400 screens.

Select the **Change** option (option 2) for the Controller you want to change.

Here is the first of four AS/400 **Chng Ctl Desc (APPC)** screens:

Work with Controller Descriptions screen



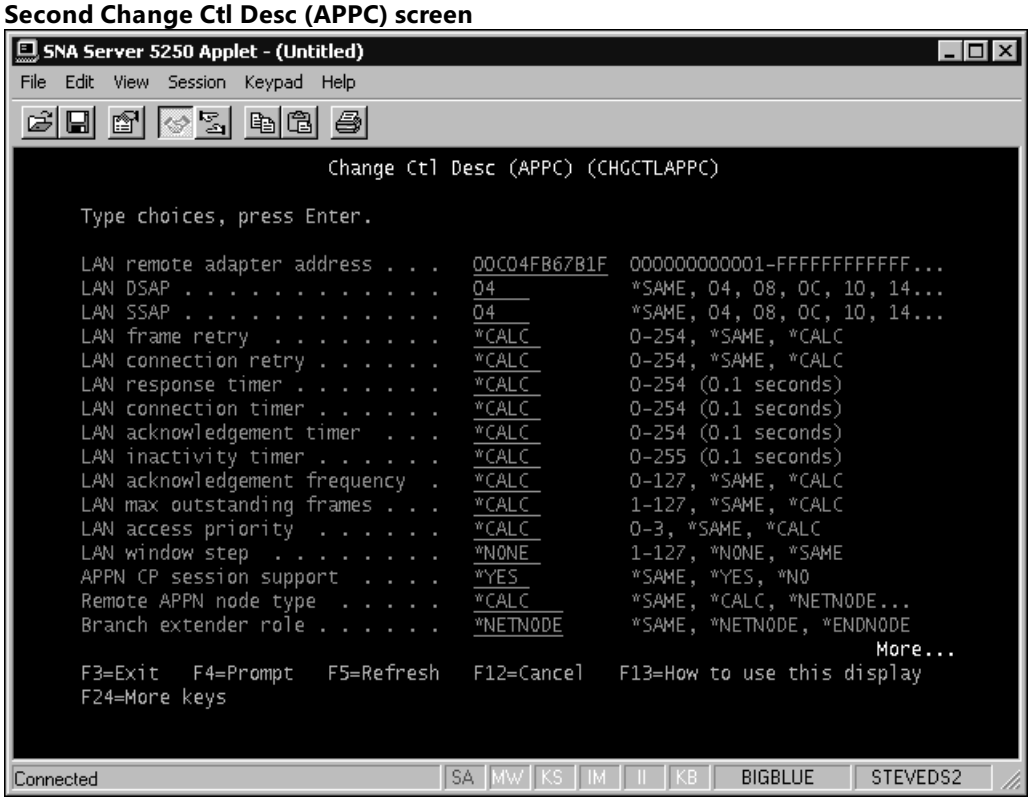
There are two important modifiable fields on this screen:

AS/400 Field Name	Host Integration Server Field name
Remote network identifier	"Local" Network Name
Remote control point	"Local" Control Point Name

Press the **PAGEDOWN** key to scroll to the second screen.

Here is the second of four **Chng Ctl Desc (APPC)** screens:

Second Change Ctl Desc (APPC) screen



There are three important modifiable fields on this screen:

AS/400 Field Name	Host Integration Server field name

LAN remote adapter address	Network adapter address (see Note 2)
LAN DSAP	**Local SAP Address**
LAN SSAP	**Remote SAP Address**

Note

The Host Integration Server computers **Remote Network Address MUST NOT** match the AS/400 controllers **LAN remote adapter address**. The AS/400 controllers **LAN remote adapter address** is the Host Integration Server computers local net work (MAC) address. This is a common mistake.

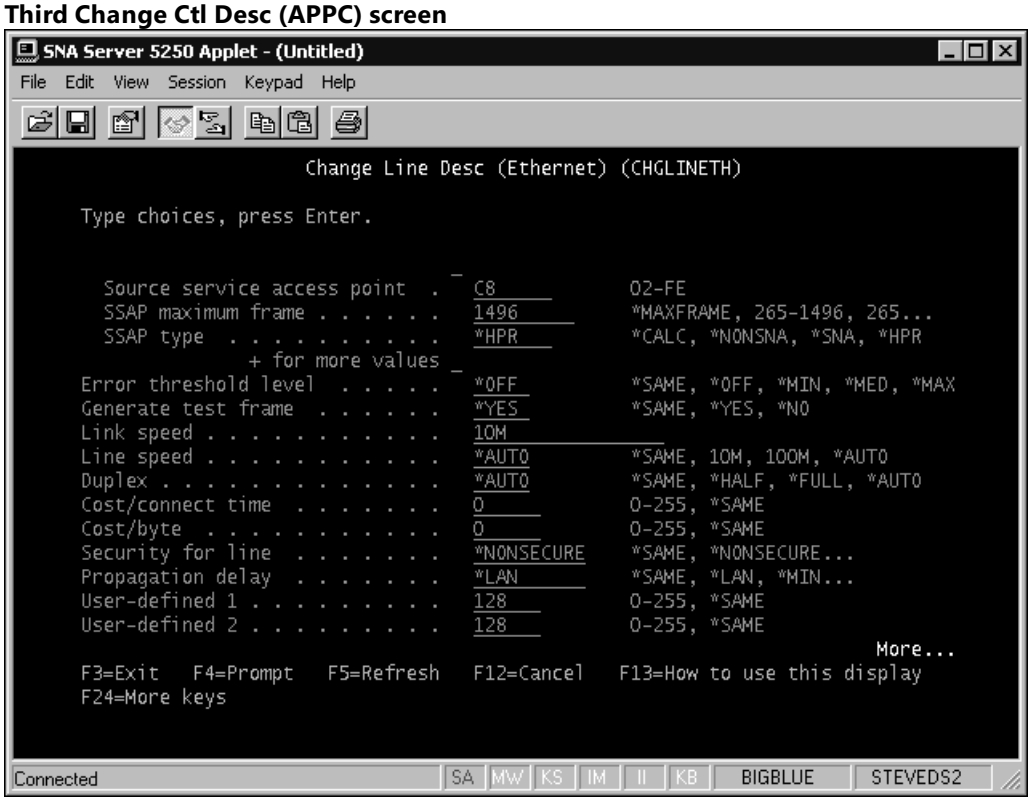
Note

The field name "Network adapter address" does not actually exist within Host Integration Server. This is why it is not in bold t ype. This field name refers to the address of the network adapter on the Host Integration Server computer.

Press the **PAGEDOWN** key to scroll to the third screen.

Here is the third of four AS/400 **Chng Ctl Desc (APPC)** screens:

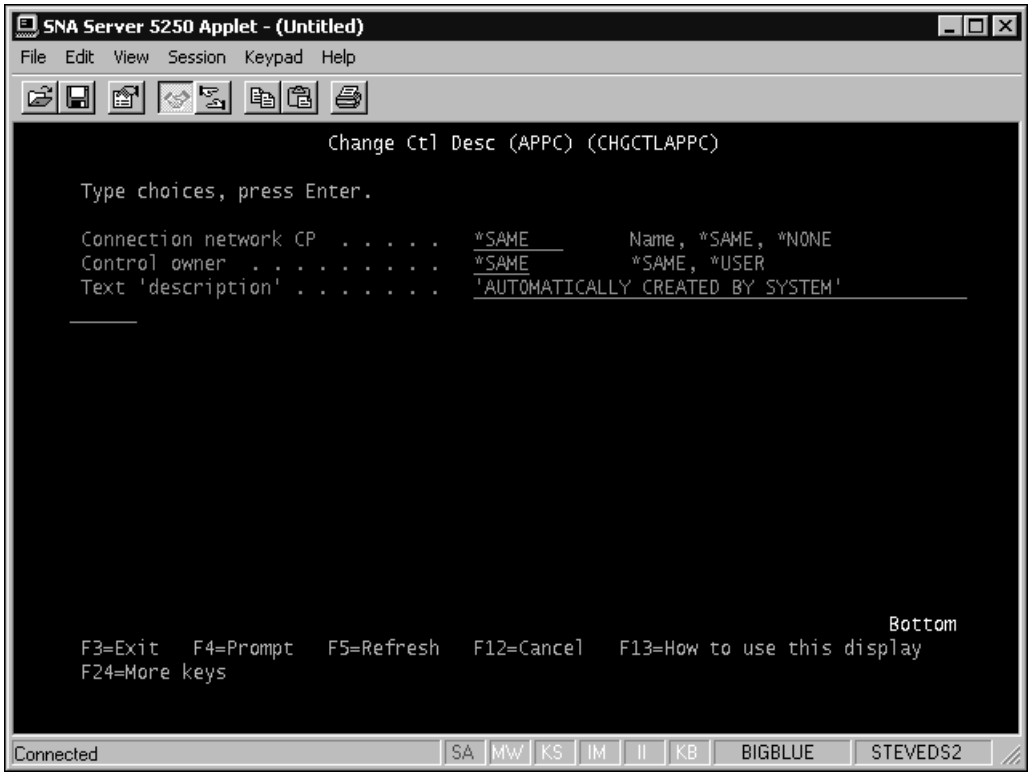
Third Change Ctl Desc (APPC) screen



Press the **PAGEDOWN** key to scroll to the fourth screen.

Here is the last of four AS/400 **Chng Ctl Desc (APPC)** screens:

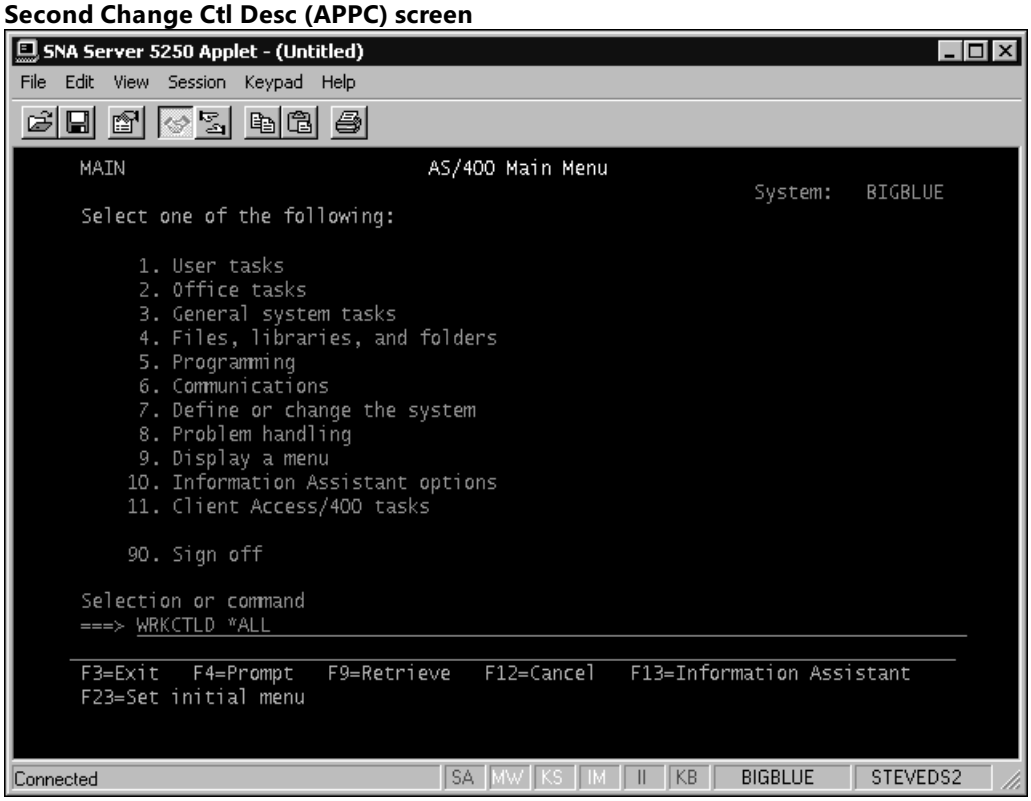
Fourth Change Ctl Desc (APPC) screen



Change Controller Status

Open the **AS/400 Main Menu**:

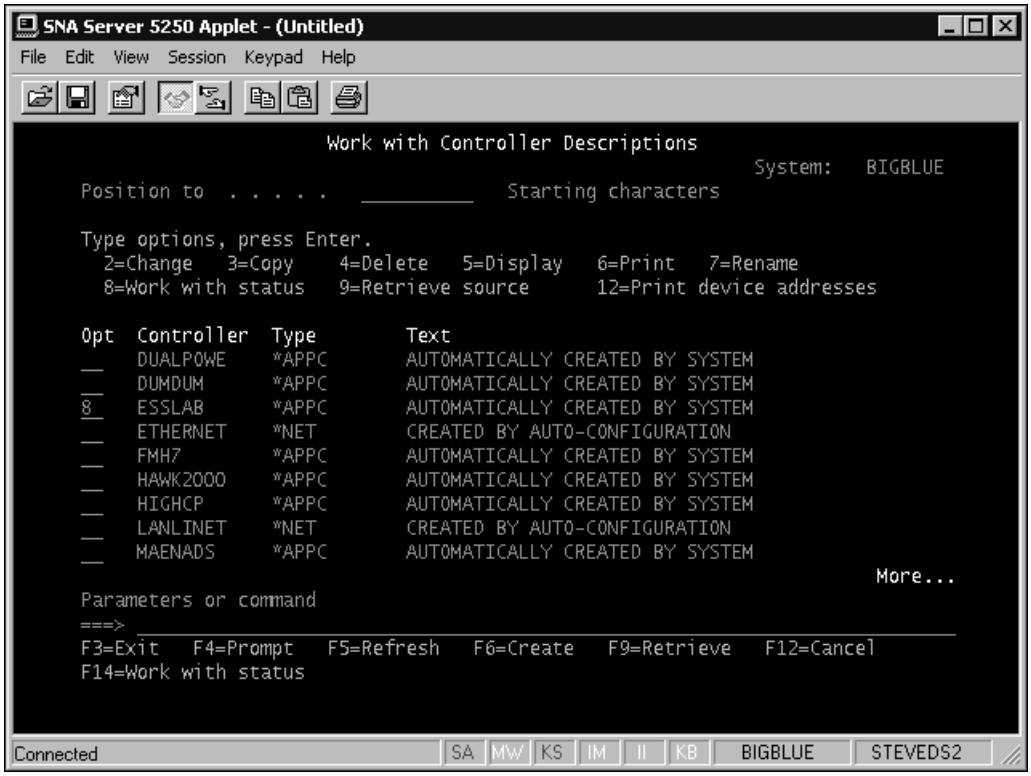
Second Change Ctl Desc (APPC) screen



Enter **WRKCTLD *ALL** at the command prompt.

This will bring up the **Work with Controller Descriptions** screen:

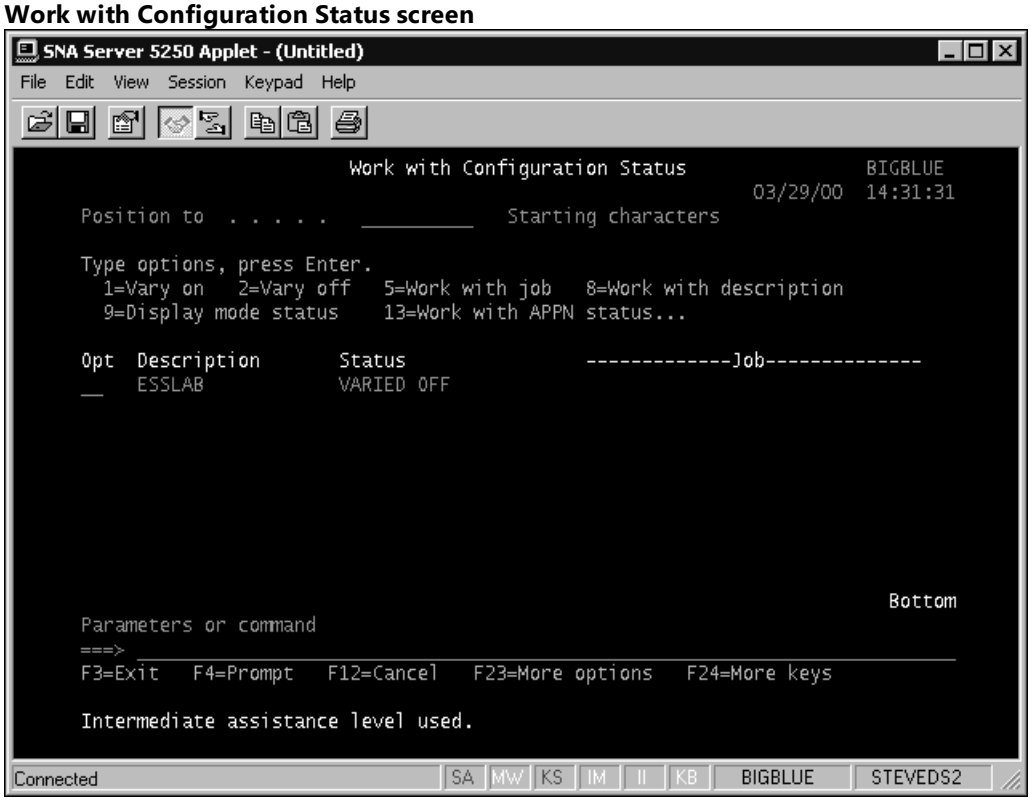
Work with Controller Descriptions screen



Choose the **Status** option for the desired controller by entering the number 8 next to the Controller that you want to change.

Here is the AS/400 **Work with Configuration Status** screen:

Work with Configuration Status screen



Select option 2 to vary the controller status off, and option 1, to vary the controller status back on.

802.2 Connection Failures

- Event ID 23
- Event ID 230
- Event ID 56
- Event ID 49

Event ID 23

Troubleshooting Mainframe and AS/400 Active to Pending DLC Connections

When a connection is Active and reverts to Pending, you should check the Event Viewer Application log for Event ID 23 and outage conditions described in the message. The qualifier reported in the Event 23 message is a DLC status code returned by the DLC interface as response to the SNA Manager 802.2 link service. This status code is interpreted by the link service and mapped to the actual "qualifier" that is reported in Event 23.

Possible causes for Event 23 Link Lost Outage Code AF and DISC Received outage code AE include LAN or router problems, timeouts or actions that need to be performed by the remote system. To diagnose bridge or router related problems we suggest using a Network Monitor to read the DLC Packets from Host Integration Server to the Host to determine the device that is causing the connection to break.

Another recommendation would be to check the Max BTU Length setting for the connection found on the **DLC 802.2** tab of the **Connection Properties** dialog box. The Max BTU is also called an I-frame; it is the number of bytes that can be transmitted in a single data-link information frame. Set the Max BTU Length so that it matches the capacity of the adapter and the host or downstream system. Otherwise, when the mainframe sends a logon screen, the BTU length that is used will be unworkable, causing the connection to drop. The MAX BTU length setting in the **Connection Properties** should equal the MAXDATA parameter in the PU definition on the mainframe or equal the MAXFRAME parameter on the AS/400. For Token-Ring Adapter Type that transmits at 4 Mbps the MAX BTU setting should be set to less than or equal to 4195. For Token-Ring Adapter that transmits at 16 Mbps, you can specify 16393. For Ethernet Adapter Type you can specify less than or equal to 1493.

With 802.2 connections, you can adjust other settings such as 802.2 Timeouts and Retry Limit settings found on the **DLC 802.2** tab of the **Connection Properties** dialog box in Host Integration Server Manager. However, the defaults for the timeouts and retries are appropriate for most networks. Knowledge Base Article Q129786 explains the details on how connection timers function and the settings to adjust if timeouts on the DLC connection are causing the connection to drop.

Other Event 23 qualifiers include:

- Outage code 29 = Remote node not active
- Outage code AB = SABME received while connection active
- Outage code AC = Frame reject sent
- Outage code AD = Frame reject received

Frame rejects occur when the receiver or sender acknowledges or detects that a DLC frame is out of sequence or invalid. We recommend taking Network Monitor traces to diagnose what intermediate device on the network is causing the frame reject to occur.

Event ID 230

This troubleshooter walks you through the process of changing a pending status to an active status for a Windows 2000 Event ID 230 connection error.

Host Integration Server generates Event ID 230 when it encounters the following conditions:

- The DLC connection to the host did not activate, and reached Pending status.

  -or-

- A connection outage (which additionally generates an Event ID 23) caused a connection to change from Active to Inactive, and finally to Pending.

Complete the following steps to troubleshoot Event ID 230:

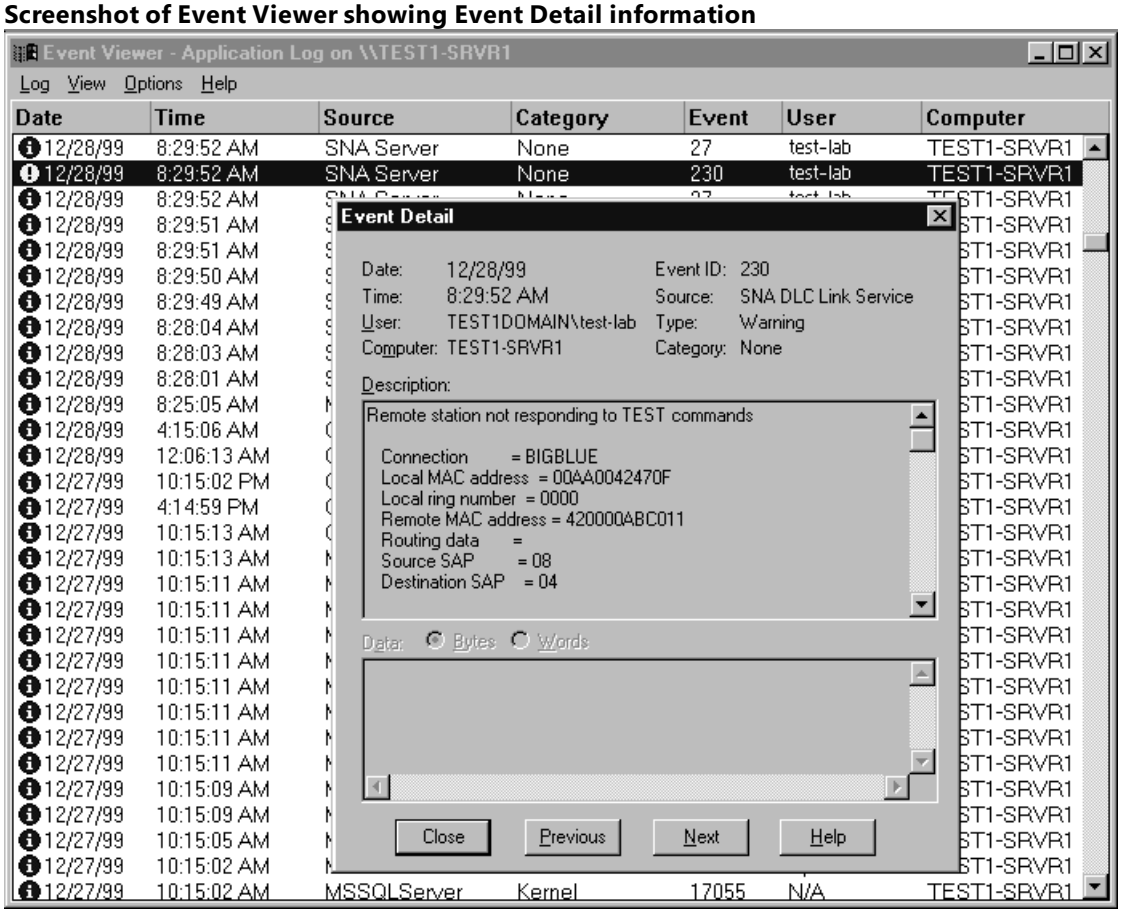
1. Review the topic Connection Initialization Sequence, especially steps 1 through 4.
2. Review the topic Finding Relevant Information.
3. Examine the Windows Application Event Log.
4. Resolve the problem: Failure Conditions and Solutions.

Windows Application Event Log

If a DLC connection fails to activate and reaches Pending status, and Host Integration Server determines that the activation failure is due to an Event ID 230 error, the following entry will be created in the Windows 2000 Application Event Log.

Note
The values displayed are for illustration purposes only.

Screenshot of Event Viewer showing Event Detail information



Failure Conditions and Solutions

There are several failure conditions that will cause an 802.2 connection to reach Pending status, with an associated Event ID 230 Application Log entry:

Failure Condition 1 — Remote Network Address mismatch

Problem: The **Remote Network Address** (Host Integration Server **Connection Property** dialog box, **Address** Tab), does not match the AS/400 **Local adapter address**.

Solution: You cannot change the AS/400 **Local adapter address** without changing its network adapter, in which case it will likely still not match. However, you can simply update the **Remote Network Address** so that it matches the AS/400 **Local adapter address**.

Failure Condition 2 — Improperly configured SNA Link Service

Problem: If the Host Integration Server computer has multiple network adapters, verify that the network adapter used to communicate with the host is properly configured with the SNA Link Service.

Failure Condition 3 — Network or Bridge Issues

Problem: Network addresses match, and SNA Link Service is properly configured on the correct network adapter, but still no response to the TEST XID command.

Solution: The connection may not be able to locate the remote network address due to Network or Bridge related issues. Try to capture a Microsoft Network Monitor or Sniffer™ trace from server to host, and determine the device that is not responding, or forwarding, the DLC Test command.

Failure Condition 4 — Remote SAP Address Mismatch

Problem: The **Remote SAP Address** on the **Address** tab of the **Connection Properties** dialog does not match the **LAN SSAP** defined in the APPC Controller Description.

Solution:

Manually edit either the AS/400 fields, or the Host Integration Server fields such that the parameters match.

Failure Condition 5 — Unable to create new APPC Controller

Problem: The AS/400 was unable to create a new APPC Controller for some reason.

Solution: If you are creating a new APPC Controller - perhaps bringing up a connection for the first time, or maybe you have tried to bring up a new APPC Controller several times, and the initialization state is now indeterminate:

1. Delete the current controller configuration on the AS/400.
2. Set the **Autocreate controller** parameter in the **AS/400 Line Description** to **Yes**.
3. Re-establish a connection, and allow the AS/400 to dynamically create a new APPC Controller.

Failure Condition 6 — Error States

Problem: The AS/400 APPC Controller or VTAM PU is in an Error State, such as Inactive or Pending Status, perhaps because there were several attempts to start the connection which were unsuccessful.

Solution: Delete the current controller configuration, set **Autocreate controller** to **Yes**, and right-click the connection, and then click **Start**.

Failure Condition 7 — Recovery Pending Status

Problem: The AS/400 line or the APPC controller is in an RCYPND (Recovery Pending) Status.

Solution:

- Check if the AS/400 line or the APPC controller is in an RCYPND (Recovery Pending) Status, when a connection is not responding to XID commands. To check for the status of the connection found in the AS/400 line description, issue the following AS/400 command:

```
" WRKCFGSTS *lin <line name> or WRKLIND <line name>
```

It is also possible to start from the AS/400 Main Menu, enter "WRKLIND *ALL", then choose the **Status** option on the line description that you want to check.

- Alternatively, you can check for an RCYPND status by issuing "WRKCTLD *ALL", then choose the **Status** option on the controller you want to check.

If the AS/400 line status is RCYPND

1. Stop the Server connection from the Host Integration Server Manager.
2. From the AS/400 WRKCFGSTS screen, choose option 2 to vary off the line status. Wait for the line to show a status of Varied Off. (Press F5 to refresh the screen).
3. Select **option 1** to Vary On the line description. Press F4 for the **Vary Configuration** dialog box. The last option in this box is **Reset**, which is "No" by default. Change to "Yes". This will reset the Ethernet Card in the AS/400. Status should then change on the AS/400 to Vary On Pending.
4. Restart the Host Integration Server Connection.

Common Connection Failure Scenarios

Scenario One:

You have a new machine and an old adapter card. This is probably the single most common cause of an Event ID 230 failure: You just upgraded your Host Integration Server computer platform and removed the C: drive. In attempting to restart a data link connection, you get an Event ID 230, "Not responding to XID commands" in your NT Event log. The AS/400 controller that you are trying to connect to is expecting to be connected with the old network adapters address. To correct this, delete the controller on the AS/400 side, (or manually change it to match your new adapter address although this is not advisable). Then, set **Autocreate Controller** on, and reconnect from the SNA side. The AS/400 will create a new controller description based upon the network adapter address of your *new* network adapter.

Scenario Two:

In a similar situation, you have a new machine and an old COM.CFG file. Your Host Integration Server computer platform is upgraded. Rather than reuse your old C drive, you reinstall the product on the new machine, and copy over the old Host Integration Server computer COM.CFG file. This causes the same problem. The old adapter address is contained in the COM.CFG file. When the AS/400 attempts to answer your NULL XID, it cannot match the parameters. The new network adapters address is contained in the NULL XID, but the AS/400 is expecting to see the old adapter address. To correct this, delete the controller on the AS/400 side, set **Autocreate Controller** on, and reconnect.

Scenario Three:

You need to restart Host Integration Server computer several times and experience problems. If the Host Integration Server computer's AS/400 connection is restarted several times in close succession (within a few minutes), then the AS/400s APPC controller may get hung in an RCYPND state. This requires manual intervention on the AS/400 to clear it.

Event ID 56

This troubleshooter walks you through the process of changing a pending status to an active status for an Event ID 56 connection error.

Host Integration Server generates Event ID 56 when it receives an XID Negotiation Error (X22) Control Vector from the host. This control vector includes an offset pointer into the XID that was sent to the host. This offset pointer points to the parameter that the host did not like.

Complete the following steps to troubleshoot Event ID 230:

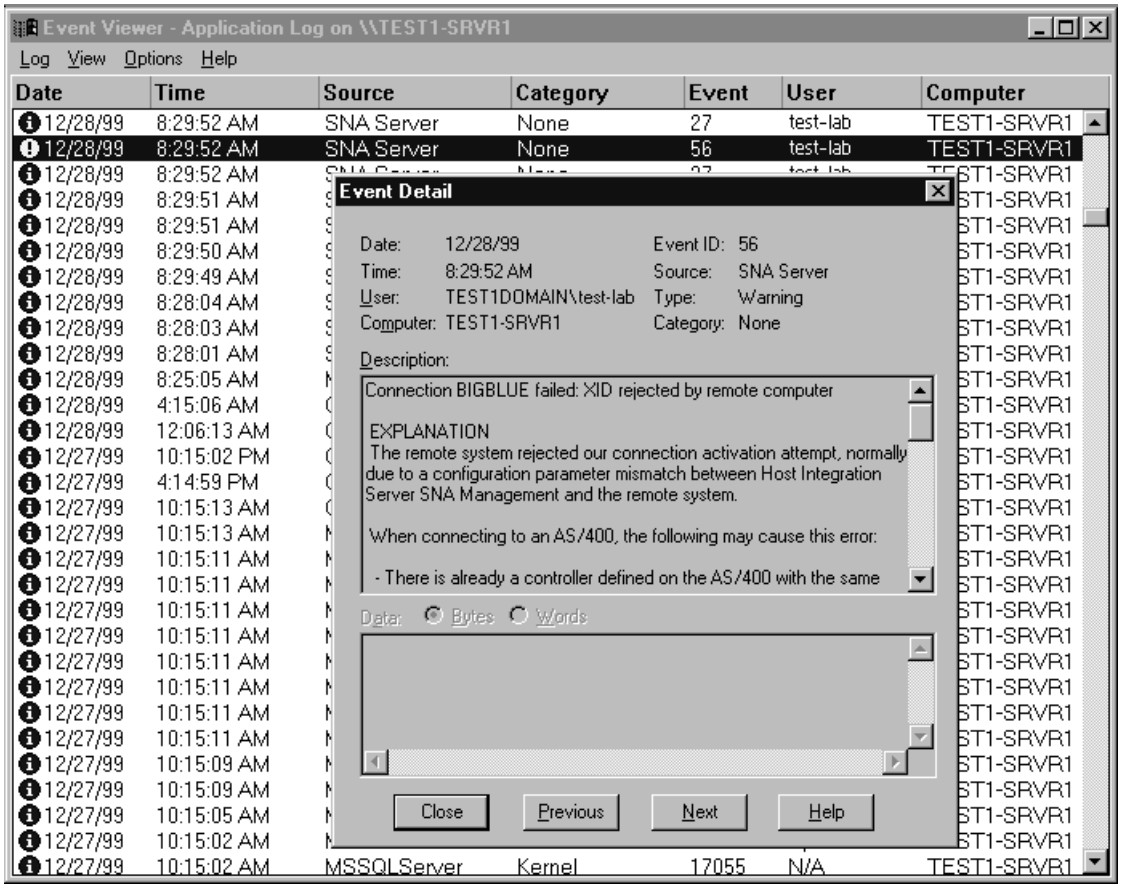
1. Review the topic Connection Initialization Sequence, especially steps 5 and 6.
2. Review the topic Finding Relevant Information.
3. Windows 2000 Application Event Log.
4. Resolve the problem: Failure Conditions and Solutions.

Windows 2000 Application Event Log

If a DLC connection fails to activate and reaches Pending status, and Host Integration Server determines that the activation failure is due to an Event ID 56 error, the following entry will be created in the Windows 2000 Application Event Log.

Note
The values displayed are for illustration purposes only.

Event Viewer with Event Detail information



Failure Conditions and Solutions

There are four failure conditions that can cause an 802.2 connection to reach Pending status, with an associated Event ID 56 Application Log entry:

Three of the failures are caused by a mismatch between a Host Integration Server configuration field, and an AS/400 field, and the last is due to an XID format mismatch.

This table summarizes the fields that must match between the Host Integration Server, and the AS/400, for a given connection:

Failure Condition	Host Integration Server field name	AS/400 Field Name
1	"Local" Network Name	Remote network identifier
2	"Local" Control Point Name	Remote control point
3	Local network adapter address (see note)	LAN remote adapter address

Failure Condition 1 — Local Network Name Mismatch

Problem: The **"Local" Network Name** on the System Identification tab of the Connection Properties dialog box does not match the **Remote network identifier** in the APPC Controller Description.

Solution: Manually update the parameter on either platform, or delete/recreate the APPC Controller, as in Failure Condition 3.

Failure Condition 2 — Local Control Point Name Mismatch

Problem: The **Local Control Point Name** on the System Identification tab of the **Connection Properties** dialog does not match the **Remote control point** defined in the APPC Controller Description.

Solution: Manually update the parameter on either platform, or delete/recreate the APPC Controller, as shown in Failure Condition 3.

Failure Condition 3 — Local Adapter Address Mismatch

Problem: The Host Integration Server computer's network adapter address (found via ipconfig /all via DOS box) does not match the AS/400 **LAN remote adapter**.

Solution: It is possible to manually edit the AS/400 **LAN remote adapter**, so that it matches the network adapter address of the Host Integration Server computer. However, it is not advisable, due to the possibility of creating parameter mismatches. Instead, perform the following procedure.

1. Delete the current controller configuration on the AS/400.

2. Set the **Autocreate controller** parameter in the AS/400 Line Description to Yes.

3. Re-establish a connection, allowing the AS/400 to dynamically create a new APPC controller that correctly binds the Host Integration Server computer's local network adapter address to the SNA Managers **"Local" Network Name**, and **"Local" Control Point Name**.

Failure Condition 4 — Invalid XID format type

1. Problem: The Host Integration Server computer is configured with XID Type: Format 0, when the AS/400 requires XID Type: Format 3.

2. Solution: Select the XID Type 3 radio button on the System Identification tab of the Connection Properties dialog.

Event ID 49

This troubleshooter walks you through the process of changing a pending status to an active status for an Event ID 49 connection error.

Host Integration Server generates Event ID 49 when it receives an XID from an AS/400 or mainframe host that contains invalid "local" parameters (as seen from the host).

Complete the following steps to troubleshoot Event ID 49:

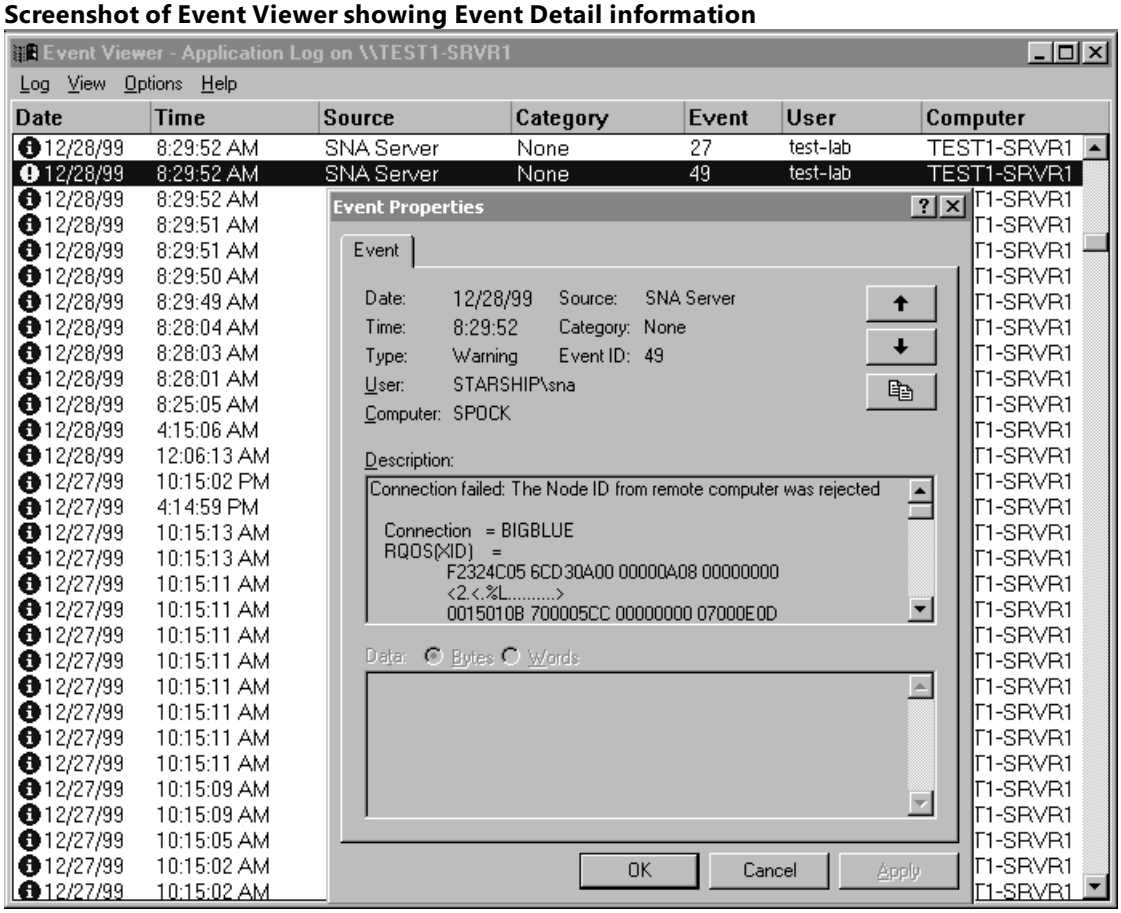
1. Review the topic Connection Initialization Sequence, especially step 7.
2. Review the topic Finding Relevant Information.
3. Examine the Windows 2000 Application Event Log.
4. Resolve the problem: Failure Conditions and Solutions.

Windows 2000 Application Event Log

If a DLC connection fails to activate and reaches Pending status, and Host Integration Server determines that the activation failure is due to an Event ID 49 error, the following entry will be created in the Windows 2000 Application Event Log.

Note
The values displayed are for illustration purposes only.

Screenshot of Event Viewer showing Event Detail information



Failure Conditions and Solutions

There are three failure conditions that can cause an 802.2 connection to reach Pending status, with an associated Event ID 49 Application Log entry:

This table summarizes the fields that must match between Host Integration Server, and the AS/400, for a given connection:

Failure Condition	Host Integration Server field name	AS/400 Field Name
1	"Local" Network Name	Remote network identifier
2	"Local" Control Point Name	Remote control point
3	Network Adapter Address	LAN remote adapter address

- These parameters are located on the Host Integration Server Connection Properties dialog box, System Identification tab, in the lower group box.

Note
The field name "Network adapter address" is not an actual field within Host Integration Server. Network adapter address refers to the address of the network adapter on the Host Integration Server computer.

Solution:

When connecting against an AS/400, these parameters should be left BLANK (i.e., empty), since they are not needed when connecting to an AS/400. However, if they were configured, and they dont match the values that the AS/400 is sending, Host Integration Server will reject the XID and log Event 49, followed by one or more Event 56s.

The main benefit that these fields provide is the ability for Host Integration Server to distinguish connection attempts by different remote systems.

Most connections are set for "outgoing". But for "incoming" connections, Host Integration Server "listens" for incoming connection attempts, and then uses the configuration information to determine who is trying to talk to it. When communicating to hosts and AS/400s, it is extremely rare for the remote system to invoke the connection. In 99% of the cases, the Host Integration Server computer establishes the connection to the remote system (i.e., an "outgoing" connection). As such, these fields should be left empty.

Step-by-Step Configuration Instructions

The following information was extracted from the Knowledge Base query "Configuring Host Integration Server computer to Talk to AS/400 Over 802.2" http://go.microsoft.com/fwlink/?LinkId=14394. This will walk you through the Host Integration Server - AS/400 connection configuration process.

This article describes how to configure a Host Integration Server computer to communicate with an AS/400 over 802.2 (Token-Ring or Ethernet), to support 5250 emulation. Both Host Integration Server and AS/400 configuration parameters are discussed.

These instructions assume the following:

- The DLC transport driver has been installed and is bound to the correct network adapter.
- The Host Integration Server computer's DLC link service has been installed using the Host Integration Server Setup program.
- The system has been restarted.

To configure the following entries using the Host Integration Server SNA Manager

1. In the **SNA Manager**, right-click **SNA Service**, and select **Properties**.
2. Enter the following parameters:

   Network Control Point Name:

   Network Name = APPN (or Remote Network ID, RMTNETID value on the AS/400).

   Control Point Name = This is the remote control point name (RMTCPNAME) value in the AS/400 APPC controller definition. For simplicity, this should be set to the local Windows 2000 computer name.

   Click **OK**.
3. Right-click **Local APPC LUs**, point to **New**, click **Local LU**, and then enter the following parameters:

LU 6.2 Type	**Independent**
LU Alias	For simplicity, this should be the same as the Local LU Name below.
Network Name	APPN (same as network name above)
LU Name	This is the remote control point name in the AS/400 APPC controller description (RMTCPNAME).

   All other entries can remain at default values.

Note
It is most efficient for all Host Integration Server computer users to use the same Local APPC LU. However, it is possible to create a unique LU for each user if desired, where the LU alias and LU name above could be replaced with the actual user name (though this requires additional administration to maintain).

   Click **OK**.
4. Right-click **Connections**, point to **New**, click **802.2**, and then enter the following parameters.

   Link Service = SnaDlc1 (or name specified during SNA setup)

   Remote End = Peer System

   Activation = If set to "On Server Startup" (default), then the Switched disconnect (SWTDSC) value on the AS/400 controller definition should be set to NO. This causes the underlying link to stay active even if there are no active sessions. Otherwise, if SWTDSC is YES, then Host Integration Server computer should be set to "On Demand" activation.

Allowed Directions = Outgoing calls. Check Incoming Calls if you want the AS/400 to activate the link.

Zoom on the Setup button:

Remote Network Address = Set to the network adapter address of the AS/400 (ADPTADR), located in the AS/400 line description.

Local Node ID = EXCHID value on the AS/400 controller description (if not specified on the AS/400, leave at default - 05D FFFFF).

Remote Node Name:

Network Name = APPN (or remote network ID RMTNETID value on the AS/400)

Control Point Name = AS/400 local control point name, configured in the AS/400 **Display Network Attributes** screen.

Remote Node ID = Not used (leave blank).

Advanced options can be left at their default settings.

Click **OK**.

5. Add a new Remote APPC LU off the connection by choosing the Insert button and enter the following parameters:

   LU Alias = For simplicity, this should be the same as the Remote APPC LU Name below.

   Network Name = APPN (or remote network id RMTNETID value on the AS/400).

   LU Name = Must be set to the AS/400 local control point name (set in the AS/400 Display Network Attributes screen).

   Uninterpreted LU Name = Not used (leave at default setting).

   Select Supports Parallel Sessions (required).

   Zoom on the Partners button. The Remote APPC LU must be partnered with the Local APPC LU created above, using the QPCSUPP mode. Because Enable Automatic Partnering is enabled by default for APPC LUs, this pairing will already be added.

   Click **OK**.

6. Save the Host Integration Server computer configuration file and restart the Host Integration Server computer service. Once the Host Integration Server computer service is Active, all connections configured to activate on server startup will go into a Pending state, then switch to Active.

Note
If the connection stays in Pending mode and doesn't activate:

7. Check the Windows 2000 Application Event log (using Event Viewer) to see the reason why the connection is not activating. For example, if the AS/400 is not responding to TEST commands, then the remote network address may not be correct.
8. Double check the configuration entries above with your AS/400 system administrator and make sure the AS/400 line is active. If all appears okay, check the Host Integration Server computer controller description on the AS/400. For LAN-based connections (such as Token-Ring or Ethernet), the AS/400 defaults to auto configuration for new controllers, so manual generation on the AS/400 is not required.
9. Check to see if the AS/400 is logging any errors when Host Integration Server computer attempts to establish the connection.
10. If the connection activates but users are unable to open 5250 sessions, zoom on the Status button on the Local APPC LU, which should show the following (when working correctly):

Partner LU	**Mode**	**User Name**	**Client**	**Limit**
<remote LU>	SNASVCMG	<User Name>	<Client Name>	2
<remote LU>	QPCSUPP	<User Name>	<Client Name>	64

This means that up to 64 sessions are available for use, though no sessions are currently active.

11. At this point, a 5250 user can then open any valid APPC LU/LU pair supported by any Host Integration Server computer in the domain. However, in order to simplify 5250 user access through Host Integration Server, there are various options available to a Host Integration Server computer administrator and the 5250 user, including the following:

    - Default AS/400 session for a user: On the Host Integration Server computer user/group record, the administrator can define default local and remote APPC LUs. If defaults are configured, and the 5250 client is used, this is the LU/LU pair the 5250 user will open when the 5250 client local and partner APPC LU names are left blank.

    - If default APPC LUs are not preassigned to a user/group, here is how to configure pools of Local APPC LUs and Remote (partner) APPC LUs to simplify 5250 user access to one or more AS/400's supported by Host Integration Server.

    - Local APPC LU pool: Define the Local APPC LU as a "Member of Default Outgoing Local APPC LU Pool". If a 5250 user does not enter a Local APPC LU when opening a session, the user will access one of the available Local LUs in this pool.

    - Remote APPC LU pool: The Remote APPC LU pool is determined by the Remote LUs that are partnered with the Local APPC LU and the QPCSUPP mode. So, if a Local APPC LU is specified, but the Remote APPC LU is left blank, a 5250 session will be allocated from an available Remote APPC LU with which it is partnered.

Sample AS/400 Configuration

The following AS/400 configuration screens are shown below, along with their corresponding configuration setting for SNA. This includes the AS/400 network attributes screen, Token-Ring line description, APPC controller, and virtual device description.

Many of the configuration settings are not relevant for communications to function, though are shown here for completeness.

AS/400: Display Network Attributes screen

Current system name	BIGBLUE
Pending system name	
Local network ID	APPN (must match the remote network name on the Host Integration Server computer connection)
Local control point name	BIGBLUE (must match the remote network name on the Host Integration Server computer connection)
Default local location	BIGBLUE
Default mode	BLANK
APPN node type	*ENDNODE
Maximum number of intermediate sessions	200
Route addition resistance	128
Server network ID/control point name	APPN BLUE

Local adapter address	ADPTADR 494061026052
Functional address + for more values	FCNADR *SAME

Note

The **Local adapter address** must match the remote network address on the Host Integration Server computer connection.

Also, the Local Adapter Address (ADPTADR) parameter on the line description (for Token-Ring or Ethernet) has a default of *ADPT. AS/400 Administrators can choose to enter their own locally administered address or the *ADPT inserts the burned-in adapter card address. The following information includes advantages of both options.

Locally Administered Address:

Advantages: The address is permanent and will not change. It is important to pick a unique address so that there are no network conflicts. This is the IBM recommended option.

***ADPT Address:**

Advantages: The adapter address is inserted into the line description when the line is varied on. Afterward, you can display the line description and see the adapter card address. This address is a unique address and you are insured there will be no duplicates on your network.

Disadvantages: If the Adapter card has a hardware problem and is replaced, you need to have a new address when the line is varied on for the first time. All users who connect using the address will not be able to communicate unless they change their configuration accordingly. This can cause problems if you have many users because they all reference the same adapter address.

AS/400: Change Line Desc (Token-Ring) (CHGLINTRN), screen 2

Source Service Access Point	04
SSAP maximum frame	*MAXFRAME
SSAP type for more values	*SNA
Early token release	ELYTKNRLS *YES
Error threshold level	THRESHOLD *OFF
Link speed	LINKSPEED 16M
Cost/connect time	COSTCNN 0
Cost/byte	COSTBYTE 0
Security for line	SECURITY *NONSECURE
Propagation delay	PRPDLY *LAN
User-defined 1	USRDFN1 128
User-defined 2	USRDFN2 128
User-defined 3	USRDFN3 128
Autocreate controller	AUTOCRTCTL *YES

Note
For 16-MB Token-Ring, note the **Early Token Release** setting. This should match the early token release setting used on you r local network adapter (set using the **Network** program in **Control Panel**).

Autocreate controller: This setting controls whether the APPC controller definition and virtual device definition (listed below)

are automatically created by the AS/400 on this line. For Token-Ring or Ethernet lines, this is the default.

AS/400: Change Line Desc (Token-Ring) (CHGLINTRN), screen 3

Autodelete controller	AUTODLTCTL 1440
Recovery limits:	CMNRCYLMT
Count limit	2
Time interval	5
Text 'description'	TEXT 'LAN Line description'

Note

If AUTOCRTCTL (Autocreate controller) is YES (in the line description above), then the APPC controller and virtual device definitions below do not have to be generated. In this case, the Host Integration Server computer configuration settings noted below will cause these AS/400 configuration entries to be automatically generated.

AS/400: Change Ctl Desc (APPC) (CHGCTLAPPC), screen 1

Controller description	CTLD	> TRUTH00
Online at IPL	ONLINE	*NO
APPN-capable	APPN	*YES
Switched line list + for more values	SWTLINLST	LANLINE
Character code	CODE	*EBCDIC
Maximum frame size	MAXFRAME	16393

Note

Device descriptionThis device name corresponds with the Host Integration Server computer Local APPC LU name (in this cas e, TRUTH), plus a two-digit device number, generated by the AS/400 (but not configured in Host Integration Server computer).

Mode description - This should not be changed; this is the default mode name for IBM PC Support clients (and Host Integration Server computer).

Maximum sessions - This is the number of sessions supported by the QPCSUPP mode, and should match the Host Integration Server computer session limit configured on the QPCSUPP mode entry, configured using the Host Integration Server computer setup program (zoom on Local or Remote LU, zoom on **Partners** button, then choose the **Modes** button).
Maximum conversations - This should match the **Maximum sessions** setting.

Solution: Vary off, then on, the controller, as previously outlined.

Troubleshooting Mainframe Pending DLC Connections - Event ID 230

If a DLC connection to the mainframe does not activate and reaches "Pending" status, you should view the Event Viewer Application Log for errors. Event 230 is an event in the application log that occurs when a connection is not responding to XID commands. We recommend checking the identifiers and/or the network address used by the host match with the corresponding parameters in Host Integration Server Manager. The identifiers or addresses must match in order for the exchange of identifiers (XIDs) and test frames to complete successfully.

The Remote Network Address (which can be viewed on the Address tab of the Connection Properties dialog box); should match the 12-digit hexadecimal network address of the remote host, peer, or downstream system. The MACADDR parameter in the VTAM PORT definition, or in the NCP Gen must match the Remote Network Address configured in the Host Integration Server Connection.

Node ID is the identifier used when exchanging identification (XIDs) with most mainframes. Check to make sure that the Node ID matches. If they do not, the Host Integration Server is not identifying itself in a way that the host can recognize. The IDBLK and IDNUM host parameters are located in the PU definition and must match the Local Node ID configured in the System Identification Tab in the Server Connection properties. We also recommend checking to see that the PU in VTAM is active.

There are some situations in which the mainframe does not use Node ID in XIDs, but instead uses Network Name and Control Point Name. These situations include mainframes communicating through LU 6.2, and mainframes that call up the Host Integration Server computer (meaning that the SNA Server computer accepts incoming calls on that mainframe connection). In these situations, the following parameters must match:

- The NETID in the VTAM Start command for the local SSCPNAME configured in the PU definition must match the Local Network Name configured on the Server. The CPNAME in the PU definition must match the Local Control Point Name configured on the server. The NETID and SSCPNAME in the VTAM Start command must match the Remote Network Name and Remote Control Point Name configured in the Connection Properties.

If all connection settings above match the corresponding host parameters, then the connection may not be able to locate the remote network address due to Network or Bridge related issues. When the DLC connection first tries to activate, it sends out an LLC TEST frame to the remote network address to initiate the link level connection. If the Server does not receive a reply to the local TEST command within 0.5 seconds, it sends an all-routes broadcast TEST command. The link service will send a total of three all-routes broadcast TEST commands if the remote station it not responding.

On a Token-Ring network, the local ring is tried first. If there is no response to the TEST frame, the Server resends the TEST frame with the "all routes broadcast" setting enabled which is then forwarded by source routing bridges.

In an Ethernet network, the Test command does not contain any source-routing information. The Server sends TEST and XID frames to both the configured remote network address and the bit-flipped address, in both DIX and 802.3 formats.

If the remote station does not reply to the TEST frame then the connection remains in a pending condition and an Event 230 gets logged in the Event Viewer Application log.

To diagnose the cause of the Test command failing we recommend capturing a Microsoft Network Monitor or SnifferTM trace from Server to host and determine which device is not responding or forwarding the DLC Test command.

Troubleshooting AS/400 Pending SDLC Connections

If the SDLC connection to the mainframe does not activate and reaches "Pending" status shown in Host Integration Server, you should view the Event Viewer Application and System Log for SDLC Link Service and Adapter errors and to check the modem light indicators. We also suggest enabling detailed Problem Analysis found on the Error/Audit Logging tab in the Subdomain properties dialog box.

If a switched connection failure occurs, we recommend checking the identifiers used by the host match to the one used by the Host Integration Server connection. The Local Node ID found on the System Identification Tab of the Connection Properties needs to match the EXCHID value on the AS/400 controller description.

When these conditions occur, the Event Viewer Application Log will contain Event ID 182 if an IBM SDLC Link Service is used.

Connection pending conditions can also occur if the AS/400 APPC controller does not match the Local Control Point Name in Host Integration Server. We recommend comparing the controller value found on the RMTCPNAME field in the AS/400 controller definition with the Local Control Point Name located on the System Identification tab in the Host Integration Server connection properties. The Network Name in the connection properties also must match the setting found in the RMTNETID value on the AS/400.

We suggest checking to see if the Encoding (NRZ/NRZI) setting in the AS400 line description matches the setting on the Address Tab in the connection properties dialog box. If the NRZ/NRZI settings do not match, the two ends of the connection begin negotiating but cannot interpret each others signals correctly. The Poll Address found on the Address Tab in the connection properties dialog box, should also be verified to match the Station address (STNADR) setting on the AS/400 controller definition. The duplex setting on the AS/400 line description must also match the Duplex setting on the SDLC tab of the connection properties in Host Integration Server Manager.

If the modem "receive data" light flashes, but "transmit data" light does not and the connection status reaches "Pending" and then the connection is dropped, we recommend checking the cables to verify that the correct V.35 or RS232 connector is used for the adapter installed in the machine. If the SDLC connection is a leased line and is a multi-drop line, we suggest checking that all devices sharing the line are set for half-duplex and that Constant RTS should be disabled.

We also suggest checking the DMA channel setting on the adapter if supported and compare this to the setting in the link service properties dialog box. If this setting specifies a nonexistent address, data cannot flow. The modem configuration should also be checked to make sure that its configured to use Synchronous instead of Asynchronous communications.

If problem persists, we recommend capturing a synchronous line trace using a third party Line Monitor and an SDLC Link Service Trace to diagnose the cause of the SDLC connection failing. The Host Integration Server Trace Program can be found on the Tools menu in Host Integration Server Manager. Select the Link Service Properties and enable data link control and Level 2 Messages from the Message Trace Tab and enable all Internal traces from the Internal Trace Tab. To analyze the traces, we suggest that you open an incident with Microsoft and send the traces to the Support Specialist.

Troubleshooting Mainframe Pending SDLC Connections

If the SDLC connection to the mainframe does not activate and reaches "Pending" status shown in Host Integration Server, it is recommended to view the Event Viewer Application and System Log for SDLC Link Service and Adapter errors and to check the modem light indicators. We also suggest enabling detailed Problem Analysis found on the Error/Audit Logging tab in the Subdomain properties dialog box.

If a switched connection failure occurs, we recommend checking to ensure the identifiers used by the host match the one used by the Host Integration Server connection. The Local Node ID found on the System Identification Tab of the Connection Properties needs to match the IDBLK and IDNUM host parameters located in the PU definition. The connection failure can also occur if the XID is already in use. We recommend verifying that the Local Node ID is not already in use and that the PU is enabled in VTAM. When these conditions occur, the Event Viewer Application Log will contain Event ID 182 if an IBM SDLC Link Service is used.

We suggest checking the Encoding (NRZ/NRZI) setting used by the host and compare this to the setting on the Address Tab in the connection properties dialog box. The NRZI setting on the Mainframe can be found in the LINE/GROUP definition and it defaults to YES. If the NRZ/NRZI settings do not match, the two ends of the connection begin negotiating but cannot interpret each others signals correctly. The Poll Address found on the Address tab in the Connection Properties dialog box, should also be verified to match the ADDR parameter found in the PU definition.

If the modem "receive data" light flashes, but "transmit data" light does not and the connection status reaches "Pending" and then the connection is dropped, we recommend checking the cables to verify that the correct V.35 or RS232 connector is used for the adapter installed in the machine. If the SDLC connection is a leased line and is a multi-drop line, we suggest checking that all devices sharing the line are set for half-duplex and that Constant RTS should be disabled.

We also suggest checking the DMA channel setting on the adapter if supported and to compare this to the setting in the link service properties dialog box. If this setting specifies a nonexistent address, data cannot flow. The modem configuration should also be checked to make sure that its configured to use Synchronous instead of Asynchronous communications.

If problem persists, we recommend capturing a synchronous line trace using a third party Line Monitor and an SDLC Link Service Trace to diagnose the cause of the SDLC connection failing. The Host Integration Server Trace Program can be found on the **Tools** menu in SNA Manager. Select the Link Service Properties and enable data link control and Level 2 Messages from the Message Trace tab and enable all Internal traces from the Internal Trace tab. To analyze the traces, we suggest that you open an incident with Microsoft and send the traces to the Support Specialist.

Performance Problems

In This Section

Maximizing Communications Performance

Servers used primarily for communications need to provide fast network performance, but do not need to provide fast file access (such as a server used primarily as a file server). Faster network communication can be achieved if portions of memory are set aside for communications by configuring "nonpaged memory". Nonpaged memory is portions of memory that are never swapped to disk, but remain available for immediate use at all times.

In Windows 2000, you can view or change network performance options, as described in the following procedures. For a Host Integration Server computer, you may not need to change this option, because Host Integration Server Setup automatically sets the option to maximize throughput for network applications.

To view or change network communication options for a Windows 2000 Server

1. Click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Network and Dial-up Connections**.
2. Double-click **Local Area Connection** and click **Properties**.
3. Click **File and Printer Sharing for Microsoft Network**, and click **Properties**.
4. For a server dedicated to communications, select **Maximize data throughput for network applications**.
5. Click **OK**, and then click **OK** again. Click **Close**.

If you made a change, the **Network Settings Change** message box appears. To put the changes into effect right away, restart the computer. To put the changes into effect later (at next startup), do not restart the computer now.

Maximizing Background Processing on Host Integration Server Computers

Servers used primarily for communications run many important background processes (processes not related to user actions in the current window). These servers generally do not need to run foreground processes at maximum speed. Therefore, Host Integration Server throughput can be increased by making the operating system more responsive to background processes and less responsive to foreground processes.

As would be expected, a server that is less responsive to foreground processes will run local applications such as word-processing software, spreadsheets, or SNA Manager more slowly. Tasking is most appropriate for servers used primarily to support clients, not servers used locally as desktop computers.

To optimize background processing for a Windows 2000 server

1. Click Start, point to **Settings**, click **Control Panel**, and then double-click **System**.
2. Select the **Advanced** tab.
3. In the **Performance** box, click **Performance Options**.
4. In the **Application response** box,select **Background services**.
5. Click **OK**, and then click **OK** again.

Host Print Service Problems

In This Section

Common Problems

The Host Print Service runs under a Windows 2000 user context. The Host Print Service (SnaPrint) may not be running under a Windows 2000 user context that has authority to open a session to the destination printer. Confirm the user context of the Host Print Service, and/or try re-entering the password within the Services Control Panel for SnaPrint Startup, within "Log On As: This Account:". In addition the user's rights can be confirmed by logging on to Host Integration Server as that user and attempting to print from Notepad.

The Generic/Text only printer driver has several limitations. Please see the following Microsoft Knowledge Base articles (available from the Web site http://go.microsoft.com/fwlink/?LinkID=99570):

168233: http://support.microsoft.com/kb/168233

166000: http://support.microsoft.com/kb/166000

162616: http://support.microsoft.com/kb/162616

154322: http://support.microsoft.com/kb/154322

Transparent sections in print jobs will be discarded unless a PDT file is configured. When such sections are discarded, an Even is logged in the Event Log, with a sample of the discarded data. This logging can be disabled globally from the Properties Page of the Print Server in SNA Manager.

HP PCL escape sequences in transparent sections should use all ASCII characters.

In addition the session property **Transparent is ASCII** must be selected.

If printing through cascaded Windows 2000 print servers, it may be necessary to add the printer share name to the NullSessionShares Registry entry on the Windows 2000 computer to which the Host Print Service is printing:

```
HKEY_LOCAL_MACHINE
   System/CurrentControlSet
     Services
       LanmanServer
          Parameters
             NullSessionShares:  REG_MULTI_SZ:  <sharename>
```

Where <sharename> is the share name associated with the Windows printer. Note that each share name must be listed on a separate line within the REGEDT32 "Multi-String editor". The Windows 2000 computer must be rebooted to enable this change. See Microsoft Knowledge Base article 121853 at: http://support.microsoft.com/kb/121853.

Print Tracing Problems

Host Integration Server incorporates extensive tracing within the Host Print Service components and the messages that flow between them. The Host Integration Server Print Service communicates over two well-defined SNA APIs - FMI (Functional Management Interface) and the APPC (Application Program to Program Communication) API FMI is used for 3270 printing, while APPC API is used for AS/400 printing.

For problems where the output is not correct

1. If possible, isolate this print job by stopping all printing to other printer sessions. This will make it easier for support personnel to analyze when viewing traces.
2. Stop the print session(s) in question.
3. Enable the following traces using the SNA Manager Trace Utility:
4. Select **SNAPrint**: Internal Trace Tab (Custom Events), Message Trace (all). Custom Events enables a new type of tracing called Advanced Job Logging. It traces each byte of the data stream.

   Select **SNAServer**. Message Trace (Data Link Control, 3270 Messages, LU 6.2 Messages).

   Reproduce the problem.

   Turn the traces off **immediately** by selecting Clear All Traces button in the Tracing Items Tab.

Print another job to this Print Session, this time changing the Destination to File. This can be done in the Printing Tab for this Print Session.

For all other problems

1. If the problem manifests itself with only one print job, isolate this job by stopping all printing to other print sessions, if possible. This will make it easier for support personnel to analyze when viewing traces.
2. Stop the print session(s) in question.
3. Enable the following traces using the SNA Manager Trace Utility:

   Select **SNAPrint**: Internal Trace (all; with the exception of Custom Events), Message Trace (all).

   Select **SNAServer**. Message Trace (Data Link Control, 3270 Messages, LU 6.2 Messages).

   Reproduce the problem.

   Turn the traces off immediately by selecting **Clear All Traces** in the **Tracing Items** tab.

Collecting Information for support personnel

1. %snaroot%\system\config\com.cfg.
2. All traces in the %snaroot%\traces directory.
3. Application Event log.
4. Printer output file in cases where the problem is wrong output.
5. Hard copy output from the physical printer.
6. An output file and / or a hard copy output of a "successful" job. This might be another print emulator or an output from an actual IBM device.

Note
Before contacting product support, obtain the following information:

3270 Printing Problems

The 3270 datastream was not designed for proportional fonts. This can cause problems in some print jobs, resulting in characters that overlap. The advanced settings of the Print Server Properties page allows you to configure Host Print Service to use a different method of positioning characters.

Problems with Form Feeds

One commonly seen problem with Host Print Service is extra or missing form feeds (FF). Some of these issues involve how SNA Print handles explicit form feeds. Other issues relate to using the number of lines per page, in place of a FF character, to cause a page break (form feed).

When Host Print Service receives a FF character in the host data stream ('0x0C'), it holds this character until it receives additional data, either control codes (SCS or 3270 orders) or printable characters. If it receives additional data, the FF is sent to the printer and the additional data is processed. If no further data is received, meaning we are at the end of the job, the FF is dropped. At this point the SNA Print will complete the outstanding job by calling either **EndDoc** for sessions not using a PDT or **EndDocPrinter**, for sessions using a PDT. When **EndDoc** is called, a FF is added to the end of the job. When **EndDocPrinter** is called, no FF is added. In this latter case, whether SNA Print adds a FF to the end of the job depends on how the END_JOB parameter is configured in the PDT. An alternative to using the PDT is to change the default data type for the print processor in the Windows NT Printer properties. If the default data type is set to RAW [auto FF], the print driver checks for the presence of a FF and adds one if necessary.

It is possible to force SNA Print to not drop the final FF when using a PDT. This requires the Registry entry FlushFF be added and set to TRUE.

```
FlushFF:  REG_SZ
   HKEY_LOCAL_MACHINE
     SYSTEM
       CurrentControlSet
          Services
             SnaPrint
               Parameters
```

FF at End of Job	PDT	FF added	End results
Yes	No	Yes	FF
No	No	Yes	FF
Yes	Yes	No	(depends on PDT)
No	Yes	No	(depends on PDT)

Many older host print jobs rely on the number of lines per page to determine page breaks. They assume for example that a job will use 66 lines per page, so add enough blank lines after the text to bring the total number of lines to 66 before starting the text that should be on the next page. If there were 30 lines of text, 36 blank lines would be added before the text intended for the next page. The drawback of this method is it depends on the printable area of the printer, the lines per inch, the lines per page, and the top margin set for the job. If by default only 65 lines will fit per page, the resulting printout will show "page creep," where the last blank line is pushed to the top of the next page, and then two lines to the top of the third page, etc. This "page creep" can be remedied within the PDT file by having the START_JOB parameter set the top margin to zero and the lines per page to 66. In addition the Printer Session properties should have the lines per inch set to 6.

For example with a printer using HP PCL the following would be added to the PDF:

In the macros section:

```
TOP    EQU 1B 26 6C 30 45    /* Top Margin set to 0 */
STL    EQU 1B 26 6C 36 36 46        /* Set Text Length to 66 */
```

For Start Job

```
START_JOB = TOP0 STL
```

Host Print Service is designed to execute a form feed (FF) included in an LU 3 print job when any of the following conditions are met:

- If the FF is inserted as the first character after the WCC in a 3270 Erase/Write or Erase/Write Alternate command.
- If the FF is located after a valid NL (New Line) order.
- If the FF is located after the last printable character position of any print line.

A registry entry is available that will force Host Print Service to honor all form feed characters in an LU 3 print job, even if they do not meet the above conditions. To add this entry, find the following key using REGEDT32:

```
HKEY_LOCAL_MACHINE
   SYSTEM
    CurrentControlSet
      Services
        SnaPrint
          Parameters
```

Add the following entry to this key:

```
Value Name:
Data Type:
String:
```

DoAllLU3FFs should be set to **TRUE**. The system checks to see if this registry entry exists. Any value entered for the string will enable this feature.

Non-printable Character Problems

Characters below 0x40 in the 3270 datastream are considered "non-printable" characters. Some of these values are used by 3270 Orders and SCS codes. By default, if Host Print Service encounters a non-printable character that is not an SCS code or 3270 Order, it rejects the frame, or in some cases translates the character to an ASCII space and continues on. To force Host Print Service to process all characters, and translate them to their ASCII equivalents according to the code page being used, a registry entry has been made available. To add this entry, find the following key using REGEDT32:

```
HKEY_LOCAL_MACHINE
   SYSTEM
     CurrentControlSet
       Services
         SnaPrint
           Parameters
```

Add the following value to this key:

```
Value Name:  HonorCharsUnder0x40
Data Type:  REG_SZ
String:  TRUE
```

Configuration Problems

In This Section

Config Lock and Out-of-Date Messages in the Status Bar

The SNA Manager will only lock the configuration file when you initiate a configuration change. If the lock is obtained, the status bar will flash 'CONFIG LOCK'. When you complete the change and save the configuration file, the lock will be released and the status bar will be cleared.

The tree pane will display **'[Out Of Date]'** on other servers in the domain. To refresh the status on the out-of-date servers, on the **Service** menu, click **Stop**, and then click **Start**. The status bar will display **'OUT OF DATE'** if SNA Manager is out-of-date. On the **File** menu, click **Refresh**.

Saving Configuration Changes

If the SNA Manager is opened in the domain, it will attempt to obtain an exclusive lock on the configuration file when it is opened (unless opened in read-only mode). It is recommended that you do not run SNA Manager until all servers in the domain have been upgraded to Host Integration Server.

SNA Manager will lock the configuration file when a configuration change is initiated. When the change is completed and the configuration file is saved, then the configuration file lock will be released. The status bar will display **OUT OF DATE** on other servers in the domain. To refresh the status on the out-of-date servers, SNA Manager must be closed and reopened.

Server Configuration Setup Problems

If a server is set up incorrectly, SNA Manager allows the administrator to make changes. Right-click on the server you want to modify.

1. Open SNA Manager, and select a server.

2. On the **Server Properties** page, click on the **Server Configuration** tab.

3. Click **Change**. From **Server Configuration**, you can change the subdomain, role, and transport protocol.

4. Restart the server for the changes to take effect.

Problems with Other Features

In This Section

DLS Status Problems

If you get a message stating that no DLS service is available for a given server, you may not have access to the Registry for that server. For DLS status (or **dlsstat** on the command line) to display the available link services, you need to have access to the Registry on the system that you specify in DLS status.

To correct this problem, see if you have any access to the Registry keys in the HKEY_LOCAL_MACHINE window for a remote server: run **regedt32** on the Host Integration Server computer on which you ran dlsstat and connect to one of the remote computers. If everything in the Registry window is unavailable (dimmed out), dlsstat will not work properly. Make sure you have access to the Registry before running DLS status again.

Virus-Checking Tool Problems

When you are running Host Integration Server with some independent software vendor virus checking tools, SNA link services might fail to start due to the following error:

Event 128: "Can't load IHV DLL xxx.dll"

where xxx.dll is the specific DLL

It is recommended that any "real-time scanning" options be disabled on the virus checker before starting Host Integration Server to prevent local file access slowdowns.

Troubleshooting Network Integration

In This Section

Troubleshooting IP-DLC Link Services

IP-DLC uses the Host Integration Server Trace Utility.

Troubleshooting Transaction Integrator

Use the information in this section to troubleshoot problems in your COM-based or .NET Framework-based client application and Transaction Integrator (TI).

General Tips

Here are some general tips to help you troubleshoot problems with COM-based applications:

- Collect and analyze error message information.

- Collect and analyze Windows Event Log information. Gather all available error information: HRESULT values, error strings, and information in the Windows Logs. For more information, see Checking the Windows Event Logs for Errors.

COM Error Messages

To understand COM application error messages, you need to understand the roles of HRESULT and failfast.

At the end of every method call, the called object sends a four-byte status code (an HRESULT) to its client. For example, most methods return a value of 0x00000000, which signifies that the call completed successfully. However, other numbers can be returned, each of which has a specific meaning. Often these numbers are displayed to the user, in which case they can help you understand the problem and how to correct it.

If a grave error occurs, COM can shut down the process that caused the problem. This sort of behavior is called a *failfast*. It is performed to guard system and data integrity. A general protection fault (GPF) or an Access Violation in a COM+ application causes a failfast. When a failfast occurs, there is no error message; Windows just shuts down the offending process. When a failfast occurs, COM logs a lot of error information to the event log. Thus it is important to search the event log for data if a problem is occurring.

To find out more about specific error messages:

- Search for the error text in this document as well as on the Web. For more information, see Additional Help with Events and Errors.

- Identify the HRESULT values. If you see a long number along with the error message, that number is probably an HRESULT. All HRESULT values are displayed in either hexadecimal or decimal format. In hexadecimal format, an HRESULT is eight hexadecimal digits (0-9, A-F.), such as 0x400FAB23 or 0x80001234. In decimal format. An HRESULT is a ten-digit number, and it will probably be negative, such as -2146889713.

  The thirty-two bits in an HRESULT are numbered from 31 to 0, and bit 31 is the highest bit.

- Once you have the HRESULT, use it to:

  - Confirm that the HRESULT signals failure. If bit 31 is 0, then this is a success or an informational HRESULT. For example, 0x00000000 signals success. If bit 31 is not zero, the HRESULT signals a warning or an error. For example, 0x80000000 is an error HRESULT.

  - Look for the source of the problem. HRESULT values contain a facility code that specifies the error source. The facility code is in bits 16-27 of the HRESULT. In the hexadecimal format, the facility code is in the Z positions in 0x0ZZZ0000. Following are the meanings of the various facility codes: 0 = COM, 1 = RPC, 2 = Dispatch, 3=Storage, 4 = ITF/?, 7 = Win32, 8 = Windows, 9=SSPI, 0xA=ActiveX Controls/MDAC/user code/?, 0xB=Certification, 0xC = Internet, 0xD=Mediaserver, 0xE = MSMQ, 0xF=SetupAPI, 0x10 = Scard, 0x11 = COM+.

How to Check the Windows Event Logs for Errors

The Windows Event Log keeps a record of the system's behavior. It contains:

- Informational events that signal normal system function. For instance, certain services log an event whenever they start or shut down.
- Warning events that signal issues that can be problematic but are not actual errors.
- Errors. If you find any error events in your logs, this indicates a problem.

COM+ and .NET often log error events when they detect a problem in an application. This is their main way of signaling a problem or giving diagnostic information. Therefore, understanding a COM+ or .NET problems begins with searching the event log for errors.

To search for errors in the event logs

1. Look for a red circle that contains an x. Errors generally indicate a serious problem, so you should troubleshoot them before moving on to the specific problem.
2. Search the event logs for COM+ errors. COM+ generally logs its events in the Application and System logs. You can determine which errors are from COM+ by looking at the Source column. Errors with a source heading of COM+ or MSDTC are COM+ errors. Explore the COM+ errors by double-clicking the error to bring up an error dialog box that contains all the error information: Source, Machine, Date, Time, and Event ID. At the bottom of the error dialog box is an error description. Read this carefully as it will explain the error and even recommend a remedy. Also, check the Data area on the error dialog box; it may contain additional useful binary information. If you find an HRESULT, analyze it.
3. Determine whether the error contains a call stack. A call stack is a piece of text describing what the application was doing when the error occurred. It begins with a Call stack line. If there is a call stack, determine which .dll file caused the error. Each line in the call stack begins with the name of a .dll file and ends with an exclamation mark or a plus sign.

   The call stack shows a cause and effect chain. The .dll file listed in the top line in the call stack is the direct cause of the error, and .dll files listed on lines below it are indirect causes of the error.

Tracing and Debugging

Transaction Integrator (TI) provides low impact performance monitoring for call volumes, processing time, and data throughput capable of isolating each major participant (host, TI, the .NET Framework, and client) to the granularity of transaction type and programming model supported. This support is turned on or off by the administrator online.

Using the SNA Trace Utility

Client Application Does Not Start but No Error Given

If you double-click the .exe file for your Visual Basic client application and nothing happens but no error message appears, the problem may be that you did not deploy the TI component that your client application is attempting to use.

Normally, if a TI component type library is not registered (that is, it has not been deployed in a COM+ application), you will receive error message number 429 that says, "ActiveX component cannot create object." However, no error appears at all if the unregistered TI component contains a user-defined type (UDT) and that UDT is referenced in the Visual Basic client application.

To resolve this problem, deploy the TI component in a COM+ application to automatically register it. Then your Visual Basic client application will work.

Trouble Defining a Recordset for Web-Based Applications

In TI, a *recordset* consists of tabular data defined in COBOL source code on the mainframe. Tabular data is defined by a group item containing an OCCURS clause in the COBOL data area. When you import a COBOL data area into TI Designer, the following COBOL-to-Automation conversions take place:

- The COBOL data area defines the parameters of the newly created method and the members of any recordsets.
- The group item that defines the table (contains the OCCURS clause) is represented as both the type definition of the method's recordset and a method parameter.
- Other group items are represented as method parameters.
- Elemental data items (definitions of the table fields) are represented as the recordset's members.

The following COBOL data area describes the type library for a Web-based application that uses a CICS LINK remote environment. The application returns information on up to six accounts for each customer name and matching PIN entered as input.

```
01          DFHCOMMAREA.
*                     ACCTINFO IS (INPUT, OUTPUT)
            05        ACCTINFO OCCURS 6 TIMES.
                      10 ACCOUNTNUMBER                    PIC X(6).
                      10 ACCOUNTTYPE                      PIC X(20).
                      10 CURRENTBALANCE                   PIC S9(13)V9(2) COMP-3.

                      10 INTERESTBEARING                  PIC S9(4) COMP.
                      10 INTERESTRATE                     COMP-1.
                      10 MONTHLYSVCCHG                    PIC S9(13)V9(2) COMP-3.

*                     NAME IS (INPUT, OUTPUT)
                      05                                 NAMEPIC X(30).
*                     PIN IS (INPUT, OUTPUT)
                      05                                 PIN PIC X(10).
```

When imported into TI Designer, the data area's group items are treated as the parameters of the newly created method. However, because of Remote Data Service (RDS) requirements for Web-based applications, the group item that defines the table must be defined as the method's return value, not as a method parameter. To define the method correctly, you must manually redefine this group item (ACCTINFO in the previous example) as a return value.

Before you import the COBOL data area, note the number of rows specified in the OCCURS clause. After you have imported the COBOL data area, use the following procedure to define a recordset for Web-based applications.

To define a recordset for a Web-based application

1. Start TI Designer.
2. In the console tree, double-click the **Recordsets** folder to verify that TI Designer created the type definition of the recordset. The type definition's name is taken from the group item that defined the table in the COBOL source code.
3. Double-click the **Methods** folder, and click the method's name. Verify that the recordset parameter is displayed in the details pane. The parameter name should match the name of the recordset's type definition.
4. On the **Edit** menu, click **Unlock** to unlock the method.
5. In the details pane, delete the recordset parameter.
6. Right-click the method, click **Properties**, and then click the **Automation Definition** tab.
7. Click the name of the recordset's type definition in the **Return Type** box.

8. Click the **Recordsets** tab.
9. In the **Group-Item Maximum** box, type the number of rows specified in the COBOL source code, and then click **OK**.

For detailed information about recordsets, see the ActiveX Data Objects (ADO) and Remote Data Service (RDS) documentation included when you installed Microsoft Data Access Components (MDAC).

Cannot Use Save Command in TI Designer

Before updating a Transaction Integrator (TI) component, consider how your changes affect applications that call the component's methods. If, for example, you add a parameter to an existing method or change the direction of a parameter, current applications will no longer be able to call the method successfully. To prevent unintended overwrites of TI components, the **Save** command in TI Designer is disabled for any component that has been added to a COM+ Application.

To save modified components that no longer need to work with existing applications, first display the properties of the component's interface and change the component's ProgID (*programmatic ID* in Visual Basic terminology). Then use the **Save As** command to save the component under a different file name. The new component can be used with later applications, and the original component can be used with existing ones.

You can modify a component in such a way that it will continue to work with existing applications. (For example, you can add a method to the component's interface without breaking existing applications.) In this case, how you save the modified component depends on whether existing applications connect to the component through declarative binding or late binding. Declarative-bound applications connect to a component when the application is compiled. Declarative-bound applications recognize a required component by the component's class identifier (CLSID). Late-bound applications connect to a component at run time. Late-bound applications recognize a required component by the component's ProgID.

If you modify a component accessed by a late-bound application, you can save your modifications with the Save As command. As long as you do not change the component's ProgID, existing late-bound applications can still access the component. (It is recommended that you change the component's minor version number on the properties page for the component's interface. The minor version number is the number to the right of the decimal point in the Version box on the properties page.)

Because the Save As command changes a component's CLSID, you must use the Save command to save modifications to any component that will continue to support existing declarative-bound applications. This means that before you open the component's .tlb file in TI Designer, you must delete the component from its COM+ application. Use the following procedure to modify a TI component currently deployed in a COM+ application.

To modify a TI component currently deployed in a COM+ application

1. Before opening the component in TI Designer, start TI Manager.
2. In the **Component Services** folder of TI Manager, shut down the server process on the computer where the TI component's COM+ application resides.
3. Delete the TI component from its COM+ application.
4. In TI Designer, open the TI component's .tlb file.
5. Modify the TI component, and then change the component's minor version number on the properties page for the component's interface.
6. Save the component. Because you deleted the component from its COM+ application before opening it in TI Designer, the **Save** command is enabled.
7. Deploy the new version of the TI component in a COM+ application.

Note

If you modify the TI component before deleting it from its COM+ application, your only recourse is to close the component's .tlb file without saving it, and then follow the procedure.

Note

If you are not sure whether the component is used by late-bound or declarative-bound applications, you can protect existing applications by using the above procedure instead of using the **Save As** command.

Trouble Creating an Object

When running your application, if you encounter the message "ActiveX component cannot create object," try the following to correct the problem:

- Verify that the TI component library is deployed in a COM+ application.
- Verify that the application references the correct ProgID.
- Verify that ActiveX Data Objects (ADO) is installed. This is necessary if the object you want to create is a recordset object. ADO is a subcomponent of Microsoft Data Access Components (MDAC), which is an integral part of Windows 2000 or Windows Server 2003.

Case Discrepancies in Assigned Names

Use care when assigning names to any part of a type library in TI Designer. You can assign case-sensitive variants of the same name. For example, you can assign a name of *myparam* to a parameter of one method, and *MyParam* to a parameter of another method. However, when you save the type library, the name of the second parameter will be changed to match the case of the first. In the previous example, both parameters would be saved as *myparam*. Such unexpected changes in case are potentially confusing, although they will not affect the operation of your application.

Visual Basic Limitation on Number of Parameters Per Method

If you attempt to compile a Visual Basic 6.0 application containing a component with more than 60 parameters per method, you can encounter the following error: "Subscript out of range." This error occurs with applications that connect to the component through declarative binding. You can avoid this error by switching to late binding. If, for the sake of performance, you want to maintain declarative binding, you can modify the component to aggregate its parameters within a single recordset. The recordset will then be treated as a single parameter and will not cause the error the next time you compile.

How to Resolve Transactions Manually

The following procedures describe how to resolve a transaction manually when it cannot be committed or aborted by the system due to a resynchronization failure following restoration of services between the Windows 2000 or Windows Server 2003 and IBM LU 6.2 systems. Such resynchronization failures can occur, for example, if CICS makes a heuristic decision to commit or abort a transaction. CICS versions prior to 5 will do this. Typically, TI and Microsoft Distributed Transaction Coordinator (DTC) will automatically resolve all in-doubt transactions when service between the systems is restored. However, if resynchronization and recovery cannot be automatically achieved for any reason, you can resolve transactions manually by using one of the following procedures.

To resolve a transaction manually

1. For transactions in the **Only Failed Remain to Notify** state or in the **Cannot Notify Committed** state:

   The Only Failed Remain to Notify and the Cannot Notify Committed states indicate that the transaction has committed, but some subordinate Microsoft DTC or IBM LU 6.2 systems have not been notified.

   a. Start TI Manager, and navigate to **Transaction List** in the console tree's **Component Services** folder in Windows 2000 or Windows Server 2003.

   b. In the **Transaction List** details pane, right-click the transaction that is in the Only Failed Remain to Notify or Cannot Notify Committed state.

      This will display the parent DTC and the subordinate DTC and IBM LU 6.2 systems for the transaction.

   c. Force the transaction to commit on each subordinate system.

   d. Return to the DTC that shows the Only Failed Remain to Notify or Cannot Notify Committed state, and force that DTC to forget the transaction.

Caution
Do not manually forget a transaction until all subordinate systems have been notified of the transaction outcome.

2. For transactions in the **Aborted** state or in the **Cannot Notify Aborted** state:

   The Aborted and Cannot Notify Aborted states indicate that the transaction has aborted. If a transaction remains in one of these states for an extended period of time, this indicates that some subordinate DTC or IBM LU 6.2 systems have not been notified of the transaction's outcome.

   a. Start TI Manager, and navigate to **Transaction List** in the console tree's **Component Services** folder in Windows 2000 or Windows Server 2003.

   b. In the **Transaction List** details pane, right-click the transaction that is in the Aborted or Cannot Notify Aborted state. This will display the parent DTC and the subordinate DTC and IBM LU 6.2 systems for the transaction.

   c. Force the transaction to commit on each subordinate system.

   d. Return to the DTC that shows the **Aborted** or **Cannot Notify Aborted** state, and force that DTC to forget the transaction.

Caution
Do not manually forget a transaction until all subordinate systems have been notified of the transaction outcome.

For more information about resolving transactions manually, see the Windows 2000 or Windows Server 2003 documentation.

Note

Resolving a transaction manually does not apply to TCP/IP because the IBM TCP/IP protocol does not currently support ACID (atomic, consistent, isolated, durable) transactions.

Mainframe Issues Affecting Transaction Recovery

In some situations, TI cannot process new transactions with a remote environment. This can be correct behavior. For example, if TI exception 1227 is returned to a client application or logged in an event, and the HRESULT is 8004D110, it indicates that new transactions with this remote environment cannot be accepted because previous transactions were not resolved after a communications failure.

When the two-phase commit process does not complete, CICS must hold the transaction in the In-Doubt state until communications are re-established. Then TI will perform recovery protocols to ensure that the transaction is in the same state at all nodes. CICS must be configured correctly for this to occur.

If CICS terminates unexpectedly, and then is restarted in a cold state, there is no memory in its log of any transactions that have not completed. Therefore, these transactions cannot be automatically recovered to a consistent state. Verify that all transactions have completed before stopping CICS, or configure CICS for a warm restart using the same log so that any pending transactions can be recovered.

CICS Transaction Server allows the administrator to specify a Wait Time in the In-Doubt Attributes of a transaction. Be sure to specify a value that is adequate to allow communications to be re-established in most cases. If this timeout elapses before all transactions left in the In-Doubt state have been recovered, CICS will make a heuristic decision to resolve them locally. If this decision conflicts with the decision made for the transactions by Microsoft DTC (Distributed Transaction Coordinator), new transactions cannot be started until the outcome of the previous transactions have been manually overridden.

In CICS versions prior to CICS Transaction Server, there is no Wait Time in the Recovery attributes. Assigning the Wait value to the In-Doubt attribute does not cause CICS to place the transaction in the state requested by TI when recovery is attempted. If you are using these versions of CICS, set the In-Doubt attribute to Backout or Commit. If a resulting heuristic decision is incorrect and prevents new transactions from beginning, override the outcome of the transaction using DTC.

Examine the Windows Event Log for messages from the SNA LU 6.2 Resync TP service indicating that transactions were not recovered successfully. Follow the suggested actions. Use Microsoft Transaction Server's Transaction List window to show pending transactions. Right-click the transaction to show its properties. Resolve it to agree with the state that CICS was configured to select heuristically, or to the backed-out or aborted state if CICS terminated unexpectedly and started up cold. The event in the log identifies the transaction and the state chosen by CICS.

Note
This does not apply to TCP/IP because TCP/IP does not support ACID (atomic, consistent, isolated, and durable) transactions.

Tasks
How to Resolve Transactions Manually

Allocation Failure

If you used one of the modes that come pre-packaged with Host Integration Server, that mode can attempt to dynamically create a session with the partner. This fails with an abnormal CNOS reply, "mode name not recognized." The error returned by the APPC API is ALLOCATION FAILURE - RETRY. This leads to an error stating: "The TI LU 6.2 transport failed to allocate conversation, make sure that host LU (hostname) is active, and retry the operation."

You will see this same error when you try to create a session with a CICS region that is not active.

To avoid this problem, upon entering SNA Manager in Host Integration Server, add the LUs and modes that you will be using and delete any pre-supplied modes that you will not be using.

How to Start and Stop DTC or SNA LU 6.2 Resync TP

If necessary, you can manually stop and start the Microsoft Distributed Transaction Coordinator (DTC) and/or the SNA LU 6.2 Resync TP services by clicking **Services** in the **Administrative Tools** menu in Windows 2000 or Windows Server 2003.

Use the following procedures to start or stop services in Windows 2000 or Windows Server 2003. It is important to start and stop the services in the precise order given.

To stop DTC or SNA LU 6.2 Resync TP in Windows 2000 or Windows Server 2003

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**.
2. Right-click **SNA LU 6.2 Resync TP**, and then click **Stop**. If prompted, click **Yes**.
3. Right-click **SnaBase**, and then click **Stop**. If prompted, click **Yes**.
4. Right-click **DTC**, and then click **Stop**. If prompted, click **Yes**.

To start DTC or SNA LU 6.2 Resync TP in Windows 2000 or Windows Server 2003

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**.
2. Right-click **DTC**, and then click **Start**.
3. Right-click **SnaBase**, and then click **Start**.
4. Right-click **SNA LU 6.2 Resync TP**, and then click **Start**.

Newly Deployed Components Not Recognized

You can deploy new components in a COM+ application while other components within that application are servicing clients. However, the Component Services run-time environment will not recognize and service these newly deployed components until the Component Services server process associated with the application is stopped. As a result, the following error is returned: "An attempt was made to launch a server process for a package that was already actively supported by another server process on this computer."

To avoid this problem, run the **Shutdown Server Processes** command after each test run and before adding a new component to a COM+ application to do another test run. This stops the active process for the package.

⚠Warning
The **Shutdown Server Processes** command interrupts all components in all COM+ applications for a given machine. Theref ore, you should carefully consider the consequences of this action.

Data Type Conversion Errors

A message indicating that a data type conversion could not take place uses a numeric code to identify the data type. The following tables translate the numeric codes into their equivalent variant data types (for Visual C++) and Automation data types (for Visual Basic).

Numeric Code	Variant Data Type	Automation Data Type
0x0000	VT_EMPTY	nothing
0x0002	VT_I2	2-byte signed int
0x0003	VT_I4	4-byte signed int
0x0004	VT_R4	4-byte real
0x0005	VT_R8	8-byte real
0x0006	VT_CY	currency
0x0007	VT_DATE	date
0x0008	VT_BSTR	OLE Automation string
0x0009	VT_DISPATCH	IDispatch * (currently only for recordset pointer)
0x000b	VT_BOOL	True=-1, False=0
0x000c	VT_VARIANT	VARIANT *
0x000e	VT_DECIMAL	16-byte fixed point
0x0011	VT_UI1	unsigned char
0x0018	VT_VOID	C style void
0x001b	VT_SAFEARRAY	(use VT_ARRAY in VARIANT)
0x001d	VT_USERDEFINED	user-defined type

Arrays of the following types have these codes:

Numeric Code	Variant Data Type	Automation Data Type
0x2000	VT_EMPTY	nothing
0x2002	VT_I2	2-byte signed int
0x2003	VT_I4	4-byte signed int
0x2004	VT_R4	4-byte real
0x2005	VT_R8	8-byte real
0x2006	VT_CY	currency

0x2007	VT_DATE	date
0x2008	VT_BSTR	OLE Automation string
0x2009	VT_DISPATCH	IDispatch * (currently only for recordset pointer)
0x200b	VT_BOOL	True=-1, False=0
0x200c	VT_VARIANT	VARIANT *
0x200e	VT_DECIMAL	16-byte fixed point
0x2011	VT_UI1	unsigned char
0x2018	VT_VOID	C style void
0x201b	VT_SAFEARRAY	(use VT_ARRAY in VARIANT)
0x201d	VT_USERDEFINED	user-defined type

The following types are passed by reference:

Numeric Code	**Variant Data Type**	**Automation Data Type**
0x4000	VT_EMPTY	nothing
0x4002	VT_I2	2-byte signed int
0x4003	VT_I4	4-byte signed int
0x4004	VT_R4	4-byte real
0x4005	VT_R8	8-byte real
0x4006	VT_CY	currency
0x4007	VT_DATE	date
0x4008	VT_BSTR	OLE Automation string
0x4009	VT_DISPATCH	IDispatch * (currently only for recordset pointer)
0x400b	VT_BOOL	True=-1, False=0
0x400c	VT_VARIANT	VARIANT *
0x400e	VT_DECIMAL	16-byte fixed point
0x4011	VT_UI1	unsigned char
0x4018	VT_VOID	C style void
0x401b	VT_SAFEARRAY	(use VT_ARRAY in VARIANT)

0x401d	VT_USERDEFINED	user-defined type

Arrays of the following types are passed by reference:

Numeric Code	Variant Data Type	Automation Data Type
0x6000	VT_EMPTY	nothing
0x6002	VT_I2	2-byte signed int
0x6003	VT_I4	4-byte signed int
0x6004	VT_R4	4-byte real
0x6005	VT_R8	8-byte real
0x6006	VT_CY	currency
0x6007	VT_DATE	date
0x6008	VT_BSTR	OLE Automation string
0x6009	VT_DISPATCH	IDispatch * (currently only for recordset pointer)
0x600b	VT_BOOL	True=-1, False=0
0x600c	VT_VARIANT	VARIANT *
0x600e	VT_DECIMAL	16-byte fixed point
0x6011	VT_UI1	unsigned char
0x6018	VT_VOID	C style void
0x601b	VT_SAFEARRAY	(use VT_ARRAY in VARIANT)
0x601d	VT_USERDEFINED	user-defined type

Memory Leak When Using User-Defined Types in User-Defined Types

If Microsoft COM Transaction Integrator (COMTI) is configured to use a "Customer Information Control System (CICS) or Information Management System (IMS) by using TCP/IP" Remote Environment (RE), and a client application repeatedly calls the COM+ component, which in turn instantiates COMTI objects by using user-defined types, eventually the application might fail and return the following error message:

Method %1 of Object %2 failed

Note
Other REs may exhibit the same problem.

If you use Microsoft Windows System Monitor to log data for the Private Bytes and Working Set of the Process object, a memory leak occurs.

The problem is caused by having Occurs Depending On (ODO) arrays in a user-defined type. Specifically, a call is made to obtain a VarDesc structure from a type library, and a free method call is never issued to release the memory back to the operating system.

Avoiding Data Translation

In some circumstances, you may want the Transaction Integrator runtime to pass untranslated data to or from the mainframe. To do this, set up an array of PIC X Untranslated bytes.

TI supports many data types, however, you may not always want TI to translate or interpret the data.

To configure a byte array of PIC X Untranslated bytes, follow these steps:

1. Open the COMTI Component Builder.
2. Unlock the COMTI component.
3. Select the properties for the parameter that you want to change.
4. On the Automation tab, set the data type to Byte.
5. On the COBOL Definition tab, set the COBOL Definition to PIC X Untranslated.
6. On the Arrays tab, set the array to be a Single Dimension Array, and set the maximum size of the array equal to the expected number of bytes.
7. Lock the component.

After the last step is complete, TI will pass the bytes in the array to the calling program as untranslated binary data.

Because MTI passes the bytes as untranslated binary data, the interface program must take into account the newly modified parameter. You can use this procedure if, for example, the characters coming from or going to the host are outside the range of the translation table. By following the steps earlier in this section, you can implement a custom translation table in code that handles the data.

If a variable-sized array is to be transferred, follow these steps:

1. Set the array size to the maximum number of characters ever to be exchanged.
2. On the Advanced tab of the method properties, set the Data buffer options as follows:
    a. Final field from host is Bounded.
    b. Final field to host is Bounded.

Using TI User-Defined Types with the .NET Framework and Visual Studio

TI supports the use of user-defined types for parameters and return values. A few things to note about user-defined types:

- They are defined by using the TI Designer application.
- They work very well in a Visual Basic 6 development environment.
- They also work well in a Visual C++ 6 development environment.

However, by default, user-defined types do not work in an application that is based on the .NET Framework, version 1.0. For example, if a UDT is passed to TI by a .NET Framework application, the following error will be logged by TI:

(102) COM Transaction Integrator reported the following exception to the client:

Component: TestUDT.TestUDT.1

Method: Method1

Exception description:

(1205) COM Transaction Integrator detected an error on parameter 1 prior to the remote operation. COM Transaction Integrator could not convert from variant type (0x4009) to (0x401d) (0x80020008). Contact the application programmer. Install the correct component library for this component in Microsoft Transaction Server.

This call does not work because the COM Interop layer of the .NET Framework 1.0 marshals the user-defined type as a VT_DISPATCH type instead of as a VT_RECORD type or VT_USERDEFINED type.

To successfully use COMTI user-defined types with a .NET Framework 1.0 application, that application must implement a custom marshaller. This means that the application must build the VT_RECORD structure itself before handing it off to COMTI. This type of coding requires advanced knowledge of COM and .NET Framework data types and marshaling between those types.

In the .NET Framework (version 1.1), the COM Interop layer automatically marshals user-defined types as VT_RECORD types. This means that .NET Framework 1.1 applications can use COMTI and user-defined types without implementing any custom marshaling.

Visual Studio .NET 2003 uses this version of the .NET Framework. Therefore, applications that are written in Visual Studio .NET 2003 can also use COMTI and user-defined types without any extra coding.

To use TI from a .NET Framework 1.1 application:

1. Create a .NET interop assembly for the COMTI type library. To do this, you can use either the TLB Importer Utility (Tlbimp.exe) or the Add Reference dialog box in Visual Studio.
2. Register the newly created .NET Framework interop assembly by using the Register Assembly Utility (Regasm.exe). If the assembly is not registered, the calling application can pass user-defined types to COMTI but will receive an exception when COMTI tries to pass a user-defined type back to the calling application.
3. Add a reference to the .NET interop assembly in the .NET Framework 1.1 application.

How to Use Variable Length Recordsets with Transaction Integrator

When data of variable length with field type of recordset is sent to the host by way of COM Transaction Integrator (COMTI), COMTI sends the final field to the host padded with NULL characters (0x00) up to the defined maximum size of the field.

When the last parameter in the type library is a recordset that refers to an OCCURS DEPENDING ON value, the null values will be passed to the mainframe unless the option Final field from host is variably sized (Return Value) is selected.

The Final field from host is variably sized (Return Value) option is located in the method's Properties on the Advanced tab.

The following trace snippet from an SNA Server Logical Unit (LU) 6.2 message trace shows the problem when the Final field from host is variably sized (Return Value) option is not selected:

Development

This software development kit (SDK) section of Microsoft Host Integration Server Help provides information for the programmer writing applications for Host Integration Server 2009.

Using Help in a Developer Environment

Host Integration Server Help contains features that you can use to display the developer documentation in your preferred language and to link between Host Integration Server Help and Visual Studio Help.

Using Language Filtering

The Host Integration Server .NET Framework Class Reference and COM Object Reference provide signatures and code examples in multiple programming languages.

You can customize your view of the content in the reference pages to display information only in your preferred programming language. To select a custom language, use the Language Filter button in the upper-left corner of the reference page. After it is enabled, the language filtering is persisted until it is changed. When language filtering is enabled on a page, the name of the language follows the title in the blue bar at the top of the page.

Viewing Host Integration Server Help in Visual Studio

You can view Host Integration Server Help in three ways:

- In Visual Studio, select **Contents** on the **Help** menu.
- In the Visual Studio Help, select **Microsoft Visual Studio** from the **Programs** menu.
- In the stand-alone Microsoft Host Integration Server Help, select **Host Integration Server Documentation** from the **Programs, Microsoft Host Integration Server** menu.

If you are developing in Visual Studio, either of the first two methods are recommended. Using either of these methods enables integration between Host Integration Server Help and Visual Studio Help; this integration is extremely useful when navigating class relationships across the documentation sets. If you view Host Integration Server Help outside of Visual Studio, read the following tip to properly render links to Visual Studio.

Linking between Host Integration Server Help and Microsoft Visual Studio Help

When a member is inherited from the .NET Framework Base Class Library, two links are provided, as shown in the following example:

Finalize (inherited from **System.Object**)	For additional information about the System namespace, see .NET Framework Help available from Visual Studio or go to http://go.microsoft.com/fwlink/?LinkID=9677.

If you are viewing Host Integration Server Help in Visual Studio or in the Visual Studio Help, the link in the left column goes to the exact member page. If you are viewing Host Integration Server Help outside of Visual Studio, use the link in the right column to go to the System namespace page in MSDN Library. Note that the link will not go to the specific member page.

Programmer's Guide

Host Integration Server 2009 provides comprehensive bidirectional services for integrating Microsoft Windows with legacy systems.

Most of the services provided by Host Integration Server expose a programming interface, which enables you to extend the functionality of the product and integrate it more tightly in your own environment. This guide describes these interfaces and provides guidance on how to use them.

In This Section

Application Integration Programmer's Guide

This section of the Microsoft Host Integration Server 2009 Software Development Kit (SDK) provides information required to develop software to integrate COM and .NET applications with Customer Information Control System (CICS) and Information Management System (IMS) transactions on IBM mainframe and AS/400 computers.

Transaction Integrator (TI) enables developers to integrate mainframe-based transaction programs (TPs) with component-based Microsoft Windows applications. With Transaction Integrator, you can integrate existing mainframe-based TPs with Windows-based COM or distributed COM (DCOM) applications. You may not have to modify your mainframe TP if the business logic is separate from the presentation logic. The wizards available in the TI Designer and TI Manager guide you through the process, step-by-step.

Transaction Integrator is appropriate when you need a synchronous or transactional solution where both systems being integrated are running at all times. For applications only requiring an asynchronous integration solution, a messaging-based solution using the MSMQ-MQSeries Bridge is preferred over Transaction Integrator.

Applications that integrate message queuing and that use MSMQ-MQSeries Bridge in a Host Integration Server 2009 environment can be developed using several different development tools and application programming interfaces including the following:

- C or C++ applications that use the MSMQ-MQSeries Bridge Extensions to extend the MSMQ-MQSeries Bridge.
- Microsoft Visual Basic applications that use MSMQ-MQSeries Bridge Extensions to extend the MSMQ-MQSeries Bridge.

To use this guide effectively, you should be familiar with the following:

- Microsoft Host Integration Server 2009
- Microsoft Windows 2000 or later
- Message Queuing
- IBM MQSeries

Depending on the application programming interface and development tools used, you should be familiar with the following:

- Microsoft COM objects
- ASP
- ASP.NET

For API references and other technical information for the Transaction Integrator, see the Programmer's Reference section of the SDK.

For sample code using the Transaction Integrator, see Application Integration Samples in the Samples section of the SDK.

For information about how to tune your system to get the best possible performance from Transaction Integration, see the Transaction Integrator Performance Guide in the Operations section.

Application Integration Development Tools

This section contains the following topics:

In This Section

- How to Install Host Integration Server Designer
- How To Migrate from Earlier Versions of Host Integration Server
- How To Report Errors in Host Integration Server Designer

How to Install Host Integration Server Designer

Transaction Integrator (TI) Designer is installed and configured by the Host Integration Server 2009 Installation Wizard. You can install and configure TI Designer at the time you first install Host Integration Server 2009, or you can use the Host Integration Server 2009 Installation Wizard at a later time to add TI Designer. The Host Integration Server 2009 Installation Wizard installs everything you need, including program files, Help files, sample applications, and other tools. The TI Project template is automatically installed on your computer at <drive>:/Program Files/Microsoft Host Integration Server/System/Projects/.

Note
TI Designer is hosted in the Visual Studio development environment and must be registered in Visual Studio at the time of in stallation. Be sure that Visual Studio is installed on your computer before you install TI Designer.

To install Transaction Integrator Designer

1. Start Host Integration Server Setup and accept all defaults until you reach the **Custom Installation** page.
2. On the **Custom Installation** page, expand the **Application Integration** node.
3. Select **Transaction Integrator Designer** and any other options you want to install.
4. Click **Next**, and then follow the on-screen directions.

TI Designer

How To Migrate from Earlier Versions of Host Integration Server

If you used the COM Transaction Integrator (COMTI) feature of Microsoft Host Integration Server 2000 (or SNA Server 4.0) to integrate Windows-based applications with the mainframe, you have a choice of four options for migrating to Transaction Integrator (TI):

1. Do nothing. Your current type libraries and remote environments (REs) work as they are. Host Integration Server 2009 is fully backward compatible with components created with Host Integration Server 2000 (or SNA Server 4.0).

2. Upgrade all your type libraries at once by dragging them into Microsoft Visual Studio and then clicking **Save All**. Create new REs that have the same characteristics as the old REs using the TI Manager. Associate the updated type libraries with the new REs. This is the easiest upgrade path.

3. Upgrade your type libraries one-at-a-time by opening them in Visual Studio and then clicking **Save As**. Create new REs that have the same characteristics as the old REs using the TI Manager. Associate the updated type libraries with the new REs.

4. Upgrade your type libraries one-at-a-time by creating new type libraries, and then importing the property settings from the old type library. Use TI Manager to create new REs that have the same characteristics as the old REs. Associate the updated type libraries with the new REs. This is the most time-consuming option because each library is created individually.

When a type library is fully upgraded to Host Integration Server 2009, three aspects of the old type library may be updated depending on the upgrade process you used. These are:

- Remote environment class
- Library, interface, coclass, and UDT GUIDs
- Default conversion information defined at the library level. The defaults for converting data types are different in TI than in COMTI.

Depending upon your circumstances and the requirements of your applications, you might want to update one, two, or all three aspects.

User Action	**TI Actions**	**Results**	**When to use**
None. Use existing Type Libraries and REs.	No changes are made to: • RE • Type library GUID • Type library default conversions	• Type library and RE is fully functional in both Host Integration Server 2009 and Host Integration Server 2000. • The properties within the type library and RE can no longer be modified. • New Type libraries created with TI Project cannot be associated with older REs. • Existing COM client works unmodified.	• Initial upgrade to Host Integration Server 2009. • Old type libraries and old REs work and do not need to be modified.

Open and **Save**	• Updates the Remote Environment class.
	
	No changes are made to:
	  • Typelibrary GUIDs
	  • Default conversions
		• The method property **Include Context Parameter** is automatically set to **True**. Client Applications do not need to support the Client Context and work unchanged as Client Context is an optional parameter in the COM environment. In the Visual Studio TI Project, set **Include Context Parameter** to **False** on the method.
		
		• Old type libraries are updated the Host Integration Server 2009. The updated type library can only be associated with an RE created with TI Manager.
		
		• Existing COM client works unmodified.
			• When a new RE needs to be created in the Host Integration Server 2009 environment.
			
			• Using new Host Integration Server 2009 RE features.
			
			• Using new Client context features (Client Security, Persistent Connections, and so forth).
			
			• Moving to the Host Integration Server 2009 supported environment.
			
			• Programming model stays the same.

Open and **Save As**	• Updates the Remote Environment class. • Generates new type library GUIDS. Save does not. • No changes made to the type library default conversions	The method property **Include Context Parameter** is automatically set to **True**. Client Applications do not need to support the Client Context and work unchanged as Client Context is an optional parameter in the COM environment. In the Visual Studio TI Project, set **Include Context Parameter** to **False** on the method. If you migrate an old type library to a .NET assembly, TI also migrates all Visual Basic version 6.0 Automation data types to Visual Basic .NET data types, including: • Integer to Short • Long to Integer • Currency to Decimal • Recordset to datatable • UDT to Structure Client Applications using the **NewRecordSet** function to create disconnected recordsets must modify the code. The **NewRecordset** function is not supported in .NET. Existing COM Clients that use declarative binding need to be recompiled because of GUID changes.	• Creating a new instance of the application for side by side operation with Host Integration Server 2009 with the intent of extending the application. • Programming model stays the same.
Import	• Updates the Remote Environment class • Updates the GUIDs • Adds Host Integration Server 2009 defaults to the new library	• Same results as **Open** and **Save As** • All methods use new library default defined for Host Integration Server 2009 • This is the only way to migrate type libraries to Assemblies.	• Same as **Save As** • Programming model change • Target environment change (CICS, IMS, AS/400) • Initiation change (WIP, HIP) • Platform change (COM, .NET)

How To Report Errors in Host Integration Server Designer

The standard error-reporting mechanism in Visual Studio is through the **Output** window. This window has been extended to allow for error reporting. For example, if an operation could not be completed, an error message is logged in the **Output** window; the user can then double-click the error message to see its source in the Host Integration Server Designer.

Creating an Application using Host Integration Server Designer

Using the tools for Host Integration Server (HIS) Designer in Visual Studio, you can create an application that uses Transaction Integrator (TI) to communicate with a remote mainframe.

1. Create a new project for your application.

2. Add a library to your project that uses Transaction Integrator.

3. If available, import a Host File.

   A host file is a file that describes the interfaces your application will be programming towards on the remote server. Using HIS Designer, you can create a .dll that describes these interfaces.

4. If necessary, use HIS Designer to make any changes or additions to the interfaces.

5. Deploy the interface.

   Deploying the interface allows you to write code against the interfaces you create in steps three and four.

6. Write your application.

   Your application is simply a standard application that includes a reference to the deployed .dll.

7. Test and modify your code.

   If necessary, you many need to undeploy the assembly in order to update the interfaces.

One you are finished testing your application, you can move your application to a staging or production server. If you want to use the BizTalk Adapter for Host Applications, you can add your assemblies to a BizTalk Server export package.

Host Integration Server Designer UI

How to Create a New Host Integration Server Designer Project

You can create a new Transaction Integrator (TI) Designer project in the Visual Studio 2005 development environment.

To create an HIS Designer Project

1. Click **Start**, point to **Programs**, and then click **Microsoft Visual Studio**.
2. On the Visual Studio **File** menu, click **New**, and then click **Project**.
3. Under **Project Types**, select **Host Integration Projects**.
4. Under **Templates**, select **Transaction Integrator Project**.
5. After **Name**, type the name of the project.

   The name can be a maximum of 256 Unicode characters.
6. After **Location**, type or browse to the location to store the project.

Concepts
Host Integration Server Designer UI

How to Add a Library to a Transaction Integrator Project

Once you have created the Transaction Integrator (TI) project, you need to add an assembly to the project. Once you have added the assembly, you can import a host file definition.

To add a library to a TI project

1. Click **Project**, and then click **Add .NET Client Library**.
2. On the Add New Item dialog, in the Templates pane, confirm that .NET Client Library is highlighted.
3. In the **Name:** field, type the name of the assembly, and then click **Add**.
4. On the Welcome to the .NET Client Library Wizard page, click **Next**.
5. On the Remote Environment page, select the information that describes the remote environment your application will interact with, and then click **Next**.

   Visual Studio will use this information to optimize your application for the specified remote environment. In contrast, the information you entered in Transaction Manager will be used by Host Integration Server when making a connection.
6. On the Completing the .NET Client Library Wizard page, confirm that the displayed settings are correct, and then click **Create**.

Creating an Application using Host Integration Server Designer

How to Import a Host File into a Transaction Integrator Project

Once you have created a library in your Transaction Integrator (TI) project, you can import a Host Definition file. After you import the host definition file, you can modify the interfaces using Host Integration Server (HIS) Designer.

To import a Host File into a TI project

1. If you have a Host Definition file (.hcd) file available, you can use the Import COBOL Wizard or the Import RPG Wizard to define your interfaces.

   For more information, see How to Import COBOL into a TI Component or Importing RPG.

2. If you have a previous .NET client library that you want to base your new object on, you can use the Import Library tool to import the library into your project.

   For more information, see How to Import a TI Component.

How to Modify and Update a Transaction Integrator Interface

Once you have imported a host definition file, you can modify and update the interface. Optionally, if you did not start with a host definition file, you can create a new TI interface using the available tools.

Once you have modified the interface, you can deploy and write code against the interface.

To create, modify, or update a TI interface

1. Use HIS Designer to create, modify, or update the TI interface. For more information, see Host Integration Server Designer UI.

Creating an Application using Host Integration Server Designer

How to Deploy a Host File Interface

Once you have finished importing and modifying the host file interface, you can deploy the interface. Deploying the interface allows you to write and test code against the interface.

To deploy a Host File interface

1. In HIS Designer, select the tab that has the name of the assembly to deploy.
2. In the **Properties** window, confirm that you have selected the remote environment that you want your assembly to communicate with.
3. In the HIS tree node, right-click on the name of the assembly, and select **Deploy**.

Creating an Application using Host Integration Server Designer

How to Code a Transaction Integrator Application

Once you have deployed a Transaction Integrator (TI) component, you can write code against that component. Once you are finished writing your code, you can test your code, and if necessary modify the interface to the TI component.

To code a TI application

1. Create an instance of the TI object.

   The TI object contains the interfaces that you will write code against. When your application calls an interface on the TI object, TI Manager will pass the information on to your remote server.

   For more information on creating a TI component and .NET assembly, see **Introduction to COM and COM+ [HIS06]**.

2. Set up your data variables.

   As with many applications that use Host Integration Server, it is important that you use a data type that can successfully translate to and from your remote server. For more information on data types and how they map between systems, see **Data Types [HIS06]** and **Host and Automation Data [HIS06]**.

3. Make calls against any relevant parameters in the TI object.

   Perform any actions necessary to your application, which will likely include calling the interfaces described by your TI object. You may also have additional tasks necessary for your application. For more information, see **Programming Windows-Initiated Processing [HIS06]**.

4. When writing your application, be sure to consider the relevant security details of your environment.

   For more information, see the **Transaction Integrator Security Guide [HIS06]**.

Example

The following example is cut from the main program code from the Discriminated Union tutorial in the SDK sample directory. For the complete code sample, see <Installation Directory>\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration\WindowsInitiated\DiscrimiatedUnion.

```
using System;
using System.Collections.Generic;
using System.Text;
using Banking;

namespace DiscriminatedUnions
{
    class Program
    {
        static void Main(string[] args)
        {
            Console.WriteLine("Processing Output only Account Information");
            AccountInformationOutOnly();

            Console.WriteLine("\n\nProcessing Input and Output Account Information");
            AccountInformationInOut();

            Console.WriteLine("\nPress any key to continue...");
            Console.Read();

        }

        #region Output Only Discriminated Union Processing
        static void AccountInformationOutOnly()
        {
            // Define an instance of the TI Banking object
            Banking.Accounts MyBankObj = new Banking.Accounts();

            // Call the Get Account Information method on the TI Object
            // passing it the array that contains the checking and saving
            // account information
```

```
            string AccountNumber = "BNK4566112";
            string AccountType = " ";
            Object AcctInfoUnionObj = null;
            string FillerNotUsedByThisSample = " ";

            MyBankObj.GetAInfoOutOnly("111223333", AccountNumber, out AccountType, out Acct
InfoUnionObj, out FillerNotUsedByThisSample);
            switch (AcctInfoUnionObj.GetType().ToString())
            {
                // check the type of the union that was returned to determine
                // whether the array element
                // is a checking or saving account so that the correct
                // structure of the union can be used
                case "Banking.CHECKING":
                        Banking.CHECKING ChkInfo = (Banking.CHECKING)AcctInfoUnionObj;

                        Console.WriteLine("Checking account number: {0}", AccountNumber);
                        Console.WriteLine("\tOverdraft charge:\t {0,10:C2}", ChkInfo.CHK_OD
_CHG);
                        Console.WriteLine("\tOverdraft limit:\t {0,10:C2}", ChkInfo.CHK_OD_
LIMIT);
                        Console.WriteLine("\tLinked account:\t {0,18}", ChkInfo.CHK_OD_LINK
_ACCT);
                        Console.WriteLine("\tLast Statement:\t {0,18}", ChkInfo.CHK_LAST_ST
MT);
                        Console.WriteLine("\tDetail Items:\t {0,18:F0}", ChkInfo.CHK_DETAIL
_ITEMS);
                        Console.WriteLine("\tBalance:\t {0,18:C2}\n", ChkInfo.CHK_BAL);
                    break;

                case "Banking.SAVINGS":
                        Banking.SAVINGS SavInfo = (Banking.SAVINGS)AcctInfoUnionObj;

                        Console.WriteLine("Savings account number: {0}", AccountNumber);
                        Console.WriteLine("\tInterest rate:\t {0,20:P}", SavInfo.SAV_INT_RA
TE / 100);
                        Console.WriteLine("\tService charge:\t {0,18:C2}", SavInfo.SAV_SVC_
CHRG);
                        Console.WriteLine("\tLast Statement:\t {0,18}", SavInfo.SAV_LAST_ST
MT);
                        Console.WriteLine("\tDetail Items:\t {0,18:F0}", SavInfo.SAV_DETAIL
_ITEMS);
                        Console.WriteLine("\tBalance:\t {0,18:C2}\n", SavInfo.SAV_BAL);
                    break;

                default:
                    break;
            }
        }
        #endregion Output Only Discriminated Union Processing
    }
}
```

Optional comments.

How to Test and Modify a Transaction Integrator Application

Once you have finished coding your application, you may test and modify your application. During this process, you may need to undeploy and modify the host file interface.

To test and modify your TI application

1. Before compiling and executing your application, ensure that the host file interface is deployed.
2. Execute your application and test as you would any other application.
3. To undeploy a host file interface, right-click on the name of the .dll that contains the interface and select **UnDeploy**.
4. Make modifications to the interface using HIS Designer, and then save your work.
5. Once you are finished making changes, you can deploy the interface again by clicking on the name of the .dll in HIS Designer and selecting **Deploy**.

Programming Windows-Initiated Processing

This section discusses various issues you need to understand to program Windows-initiated processing components and applications.

In This Section

Creating a Windows-Initiated Application

In This Section

This section contains the following topics

- How To Confirm that COMTIIntrinsic is Set in Windows XP
- How to Update a Transaction Integrator Assembly
- How to Debug a Visual Basic Application Integration Application
- How To Handle a Host Server Exception

How To Confirm that COMTIIntrinsic is Set in Windows XP

If you use Explicit Security in your application, make sure that the property **COMTIIntrinsic** is set to **–1**. The property **COMTIIntrinsic** is set to **Off** by default for COM+ in Windows XP Professional.

You can use the following Visual Basic script to display and set the **COMTIIntrinsic** value:

```
'Get arguments  ' Set objArgs = WScript.Arguments
 '  if objArgs.Count <> 3 then
 '      WScript.Echo "ComtiSec"
 '      WScript.Echo ""
 '      WScript.Echo "Usage:"
 '      WScript.Echo "ComtiSec [appname], [progid], [value]"
 '      WScript.Echo "[appname]: Name of the application"
 '      WScript.Echo "[progid]:  ProgID of the component to change. Type 'all' for all comp
onents."
 '      WScript.Echo "[value]:   0 for False, 1 for True"
 '      WScript.Quit (0)
 '  end if
   applicationName = "COMTI Utilities"
   componentProgID = "all"
   'ComtiIntrinsics must be set to -1 for comti callback secuity to work.
   ' ComtiIntrinsics = -1 ' This will make Explicit Security work in COM+ on Win XP Pro
   ' ComtiIntrinsics = 0 ' This is the deffault value for COM+ in Win XP Pro
   Set catalog = CreateObject("COMAdmin.COMAdminCatalog.1")
   Set applications = catalog.GetCollection("Applications")
   applications.Populate
   numApplications = applications.Count
   For i = numApplications - 1 To 0 Step -1
       If applications.Item(i).Value("Name") = applicationName Then
           Set application = applications.Item(i)
           Exit For
       End If
   Next
   Set components = applications.GetCollection("Components", application.Value("ID"))
   components.Populate
   numComponents = components.Count
   For i = numComponents - 1 To 0 Step -1
       If components.Item(i).Name = componentProgID Or componentProgID = "all" Then
           Set component = components.Item(i)
           'component.Value("COMTIIntrinsics") = ComtiIntrinsics
      WScript.Echo component.Value("COMTIIntrinsics")
       End If
   Next
   components.SaveChanges
   applications.SaveChanges
   WScript.Echo "Changes All Complete"
```

Note

You must clear the **Protection** and **Disable Changes** properties for the COM+ COMTI Utility application before you run this script.

How to Update a Transaction Integrator Assembly

If you are upgrading your version of Host Integration Server, you may have Transaction Integrator (TI) assemblies that use a previous version of the .NET Framework. Host Integration Server allows you several options on how to upgrade, so that your assemblies use, so that they may be compatible with the newest version of the .NET Framework.

To update a TI Assembly

1. Do nothing.

   If you do not modify your TI assembly in any way, you do not need to upgrade the assembly: .NET Frameworks 2.0 is backwards-compatible with any TI assembly created using .NET Frameworks 1.x.

2. Open the assembly, make a change, and save the file.

   When you save the file, Host Integration Server will automatically update the TI assembly to the .NET Framework 2.0.

3. Change the name of the assembly in Visual Studio using the **Save As...** command.

   As with option 2, Host Integration Server will update the assembly when you save the name.

How to Debug a Visual Basic Application Integration Application

The following tips will help prevent frustrating debugging sessions:

- When a Transaction Integrator (TI) .NET Framework application is configured to display error numbers (err.number), the number returned is always 0 and not the TI error results. Although TI returns the correct values to COM Interop and COM Interop passes the right values to Visual Basic, Visual Basic considers any positive return code to be success and changes it to 0. To work around this problem, configure the .NET Framework application to return an error description (err.description) instead of the error number. The error description provides accurate and useful error information.

- TI Project parameter type Integer must be defined as a short within Visual Basic.

- TI Project parameter type Long must be defined as an integer within Visual Basic.

- A Visual Basic array index begins at 0, the index of TI parameters defined as arrays starts at position 1. Therefore, it is no longer possible to directly align one for one the index of TI parameters defined as arrays with those defined within Visual Basic.

- Arrays of Decimal data types must be defined as an array of objects, not an array of decimals within Visual Basic. All other arrays of data types can be defined as either an object or data type.

- A common cause of errors during development of host-initiated processing (HIP) .NET Framework components is forgetting to copy all the required assemblies, including all the dependencies, to the HIP Implementing Assemblies folder.

How To Determine Who Initiated a Transaction

It is helpful to be able to determine who initiated a specific transaction, for example, when you need to track down the history of a transaction failure. You can also use this technique to implement resource or transaction-level, per user, security.

When you select either user-level or package-level security on the **Security** tab of the Transaction Integrator (TI) remote environment (RE) properties page, TI sends security information in the session request to the host. If you deploy the Host Account Mapping database known as the Host Account Cache (HAC) and set up a mapping between each Microsoft Windows user and the corresponding host user ID, TI will send that information. Or you can use the **Allow application to override security** option on the **Security** tab, and have the application return any host user ID (and password).

Whether the host does anything with the different user IDs depends mostly on the ATTACHSEC setting for the CICS connection; this corresponds to the APPC LU that TI uses. The default ATTACHSEC setting is **local**, meaning that CICS does not validate the user ID in the session, and CICS runs the transaction in a default host credential. But if you set the ATTACHSEC setting, CICS uses Resource Access Control Facility (RACF) to validate the user ID in the session, and CICS then attaches that user ID to the trusted computing base (TCB) for the transaction as it runs through the mirror transaction into the target mainframe transaction program (TP).

How to Call a Transaction Integrator Proxy Object in a Secured Virtual Directory

One of the interactions Transaction Integrator (TI) has with the windows operating system is the Virtual Directory. In order to use TI and virtual directories together, you need to ensure that you have to correct credentials set on your application. By explicitly using the default credentials for your application, you can ensure that the user's credentials are property replicated across TI and virtual directory.

To call a TI proxy object in a secured virtual directory

1. Create an instance of the new object.
2. Set the credentials of the object to CredentialCache.DefaultCredentials.

   The default credentials of CredentialCache.DefaultCredentials are the credentials of the current user.
3. Continue with your application.

Example

The following code shows how to call a TI proxy object that is inside a secured virtual directory.

```
using System;
using System.Collections.Generic;
using System.Text;
using System.Net;

namespace ELMBankingClient2
{
    class Program

    {
        static void Main(string[] args)
        {
            GetBal.Service MyBal = new ELMBankingClient2.GetBal.Service();
            decimal Balance;
            MyBal.Credentials = CredentialCache.DefaultCredentials;
            Balance = MyBal.GetBalance("Kim Akers", "12345");
            Console.WriteLine(Balance);
        }
    }
}
```

Programming Windows-Initiated Processing

How To Impersonate Client Application Security Credentials

If you are using Windows-initiated processing (WIP) and are configuring a remote environment (RE) to use Enterprise Single Sign-On (SSO), you have a choice between using the security credentials of the client application or of the COM server program. You make this choice in Transaction Integrator (TI) Manager on the **Security** tab of the ***remote environment*** **Properties** dialog box. If you select **User credentials**, the COM server impersonates the client's security credentials to access SSO and retrieve the host account information. If you select **COM application or ASP.NET credentials**, the COM server uses its own credentials.

Before the COM server can impersonate the client, however, you must program the client to grant the COM server explicit permission to do the impersonating. You can grant the explicit permission in either of two ways:

- Program the client application to call **CoInitializeSecurity(...)** at the beginning of its lifetime, and then request the **Impersonate access level**:

```
HRESULT hr = CoInitializeSecurity(NULL, -1, NULL, NULL,
             RPC_C_AUTHN_LEVEL_CONNECT, RPC_C_IMP_LEVEL_IMPERSONATE
             NULL, NULL, NULL);
```

- Set the default COM security level on your computer to **Impersonate**.

1. Click **Start**, point to **Programs**, point to **Microsoft Host Integration Server 2009**, and then click **TI Manager**.
2. In the TI Manager navigation tree, expand **Component Services**, and then expand **Computers**.
3. Right-click **My Computer**, and then click **Properties**.
4. On the **Default Properties** tab, set the **Default Impersonation Level** to **Impersonate**.
5. Restart your computer so the settings take effect.

The first course of action, adding the **CoInitializeSecurity(...)** call to your application, is the more secure of the two alternatives because it limits the explicit permission to just that client application. The second course of action, changing the default COM security level on your computer, should be chosen only if you are not able to rebuild your client application.

Specifying a Remote Environment Programmatically

When an application uses a Transaction Integrator (TI) component, you can structure the application to explicitly specify the remote environment (RE) used by the TI run-time environment. When the application specifies the RE, the application identifies the CICS or IMS region where transaction programs (TP) are executed when they handle method calls to the component. The specific algorithm an application uses to select an RE is up to you. For example, an enterprise can use separate CICS or IMS regions to handle requests from different branches. In this case, the application should set the RE to the appropriate value that identifies the region suitable for the current branch.

In This Section

This section includes the following topics

- How To Use REOverride to Specify a Remote Environment
- Guidelines for Using REOverride

How To Use REOverride to Specify a Remote Environment

To programmatically specify an RE, an application uses the REOverride Context entry. TI Project automatically adds an optional parameter to a TI object for passing TI context data. The application sets the REOverride entry for an object representing a TI component by assigning the name of the RE.

The following Visual Basic code example (with no error checking) shows how to use REOverride to programmatically instruct the TI run-time environment to use a non-default RE named AltREName to handle the calls to Method1, Method2, and Method4. The calls to the three methods are directed to AltREName because the client program has set the context name REOverride to have the value of AltREName and include the optional context parameter ContextArray. The call to Method3 is directed to the RE assigned as default to the object because it does not include the optional ContextArray context parameter.

```
Dim Obj As Object
Dim ConObj AS Object
Dim ContextArray() As Variant

Set ConObj = CreateObject("COMTI.ContextObject")
Set Obj = CreateObject("Your.Object")

ConObj.WriteContext "REOverride", "AltREName", ContextArray

Obj.Method1 parm1, parm2, parm3, ContextArray
Obj.Method2 parm1, parm2, ContextArray
Obj.Method3 parm1, parm2, parm3, parm4, parm5
Obj.Method4 parm1, parm2, parm3, parm4, ContextArray
```

Tasks

Specifying a Remote Environment Programmatically

Guidelines for Using REOverride

Use the following guidelines for when to use REOverride to set an RE programmatically:

- Avoid hard-coding RE names into applications. Instead, load RE names from a file or database.
- Ensure that applications are structured to handle failures when they attempt to set the RE.
- Structure your application code to use a list of RE names. This practice reduces errors caused by missing REs.
- Ensure that procedures for adding and configuring REs include a mechanism to update REs referenced in the application code.

Note
Use REOverride to confirm that administrative and operational tasks do not interfere with application code that sets an RE. S pecifically, review when and how REs are deactivated and deleted.

To implement RE selection by using REOverride, you must ensure that the TI component starts out with an associated RE instance even though the application will set the RE programmatically. The RE that is currently assigned to the component is used when an application does not explicitly set the RE.

Specifying a Remote Environment Programmatically

How to Program with Discriminated Unions

A discriminated union is a data structure that can hold a data value of several different types. Host Integration Server uses discriminated unions with several providers, such as the Managed Provider for Host Files. When creating an application that uses Remoting or Web Services, you must satisfy the Web Services Description Language (WSDL) requirements for the discriminated union. WSDL generation constraints require that all structures in an object be used in a method call. Therefore, you need to ensure that all the structures in a discriminated union are also used, even if only in a piece of stub code.

To use a discriminated union with Remoting or Web Services

1. Create your schema as normal.
2. Identify any structure in the discriminated union that is not explicitly used in another method call.
3. Create a dummy method call that calls the unused structure.

Example

The following example shows a line of dummy method that uses several discriminated union structures. By having such a method, the WSDL generation requirements are satisfied.

```
void dummyroutine1 (ACCT_TYPE_SAVE acct_type_sav, ACCT_TYPE_CHK acct_type_chk)
```

How To Override Settings in the Type Library

If you need to temporarily change certain data sent from the type library to the host, you can override the type library settings without changing the original file. Use the following keywords in combination with the COMTIContext parameter to override the type library setting:

- CONNTIMEOUT
- CONNTYPE
- IMS_LTERM
- IMS_MODNAME
- LibNameOverride
- OverrideSourceTP
- PASSWORD
- PortOverride
- ProgNameOverride
- RecvTimeOut
- REOverride
- SendTimeOut
- TPNameOverride
- USERID

The override remains active until either a new override is set or the override is deleted. Use the **WriteContext** function to set the override and the **DeleteContext** function to delete the override. If you delete the override, the value defaults to the setting in the original type library.

How to Pass a Custom TRM
Concepts
Using Custom TRMs and ELMs with COMTIContext

Using a Persistent Connection

Windows-initiated processing (WIP) supports persistent connections over TCP/IP and SNA for the following programming models:

- IMS Connect
- TCP Transaction Request Message (TRM) Link
- TCP Enhanced Listener Message (ELM) Link
- TCP Transaction Request Message (TRM) User Data
- TCP Enhanced Listener Message (ELM) User Data
- OS/400 DPC
- CICS Link LU 6.2
- CICS User Data LU 6.2

Persistent connections are not supported in the following programming models:

- IMS Implicit
- IMS Explicit
- IMS LU 6.2

Windows-initiated processing (WIP) persistent connections allow you to maintain a single TCP connection or SNA conversation over multiple method calls to the host. In Host Integration Server 2000, COMTI had to open and close a connection each time a method call was made to the host. On the mainframe side, CICS had to start and stop a transaction program (TP). In Host Integration Server 2009, persistent connections allow Transaction Integrator (TI) to open a connection for the first method in a group of methods, make all the method calls, and then close the connection. On the mainframe side, CICS starts an instance of the transaction program, keeps the instance active between method calls, and then stops the program after the last call.

One of the major benefits from using persistent connections is that it allows CICS to maintain state across multiple method calls and allows for the use of local variables. Persistent connections are implemented and managed through the COMTIContext.

COMTIContext supports methods that flow to the COM+ or .NET Framework application and updates client status information (**COMTIContext** array) or closes persistent connections.

UpdateContextInfo updates the clients **COMTIContext** array with information obtained from the COM+ or .NET Framework application object, but with no server object involvement.

ClosePersistentConnection closes persistent connections by contacting the COM+ or .NET Framework application object, but with no server object involvement.

The client can obtain connection state information by calling the **GetConnectionInfo** method that is implemented by the **COMTIContext** object. In the case of a .NET Framework method failure, the client must call **UpdateContextInfo** before it calls **GetConnectionInfo**.

A time-out mechanism reclaims orphaned persistent connections. The new **COMTIContext** keyword **CONNTIMEOUT** takes an integer value specifying, in seconds, how much time elapses before a persistent connection is considered abandoned, and then automatically closed. The timing starts as the client call processing is completed by the COM+ or .NET Framework generic object.

GetConnectionInfo querys the status of a persistent connection. The following shows a COM-based method:

```
HRESULT GetConnectionInfo (
     [in, out] SAFEARRAY(VARIANT)*COMTIContextArray,
     [out] BOOL* pfConnectionIsPersistent,
     [out] BOOL* pfConnectionIsViable);
```

The following shows the .NET Framework-based equivalent:

```
GetConnectionInfo (ref object[] contextArray,
    out bool fConnectionIsPersistent,
    out bool fConnectionIsViable).
```

The **COMTIContextArray** parameter is updated to reflect the state of the connection, the **pfConnectionIsPersistent** parameter contains TRUE if the connection is persistent and active, and the **pfConnectionIsViable** parameter contains TRUE if the connection is active.

UpdateContextInfo updates the clients **COMTIContext** array. The following shows a COM-based method:

```
HRESULT UpdateContextInfo (
    [in, out] SAFEARRAY(VARIANT)*COMTIContextArray);
```

The following shows the .NET Framework-based equivalent:

```
UpdateContextInfo (ref object[] contextArray).
```

The **COMTIContextArray** parameter is updated to reflect the state of the connection. At a later time other information kept in the COM+ or .NET Framework application might also be returned in the update **COMTIContextArray**.

ClosePersistentConnection closes a persistent connection without the need for a call to the server system. The following shows a COM-based method:

```
HRESULT ClosePersistentConnection (
    [in, out] SAFEARRAY(VARIANT)*COMTIContextArray);
```

The following shows the .NET Framework-based equivalent:

```
ClosePersistentConnection (ref object[]COMTIContextArray).
```

The **COMTIContextArray** parameter is updated to reflect the state of the connection.

How To Use a Persistent Connection

The following topic describes how to use a persistent connection with Windows-Initiated Processing (WIP)

To use a persistent connection with WIP

1. Set the COMTIContext keyword CONNTYPE to OPEN.

   If a call with CONNTYPE set to OPEN completes successfully, the returned COMTIContext array CONNTYPE keyword will have a value of USE.

   After you set the COMTIContext keyword CONNTYPE to OPEN, you can choose to set CONNTYPE to USE. However, this action is not mandatory because it is set to USE by default.

2. Once you have established the connection, you can use the COMTIContext object to access the mainframe.

3. If the method call fails, use UpdateContextInfo and GetConnectionInfo on the COMTIContextLib.ContextObject to obtain updated status of the connection.

4. To make a call and terminate the persistent connection, set the CONNTYPE keyword to CLOSE.

   If the call completes successfully, the returned COMTIContext array CONNTYPE keyword will have a value of NON-PERSISTENT.

   Optionally, you can call ClosePersistentConnection at any time to close a persistent connection. The connection will be terminated and there will be no interaction with a server program.

Example

The following Visual Basic 6.0 code example shows how to use the OPEN and CLOSE method calls that might return an error. The sample also demonstrates how to determine whether a connection can still be used.

```
Public CtxCount As Long
Public COMTIContext() As Variant
Public ContextObj As COMTIContextLib.ContextObject

Dim fConIsPersistent as Boolean
Dim fConnIsViable as Boolean
Dim varConnType as Variant

Private Sub cmdBalance_Click()
  On Error GoTo ErrorHandler

OpenCall:
  varConnType = "OPEN"
  ContextObj.WriteContext "CONNTYPE", varConnType, COMTIContext
  lngReturn = objBank.cedrbank(txtName.Text, txtAccount.Text, curRetBalance, COMTIContext)

UseCall:
  lngReturn = objBank.cedrbank(txtName.Text, txtAccount.Text, curRetBalance, COMTIContext)

CloseCall:
  If (fCloseWithMethod) Then
      varConnType = "CLOSE"
      ContextObj.WriteContext "CONNTYPE", varConnType, COMTIContext
      lngReturn = objBank.cedrbank(txtName.Text, txtAccount.Text, curRetBalance, COMTIConte
xt)
  Else
      COMTIContext = objBank.ClosePersistentConnection
  End-if

  Exit Sub

ErrorHandler:
    COMTIContext  = objBank.UpdateContextInfo   Optional for COM required for .NET
    ContextObj.GetConnectionInfo (COMTIContext, fConnIsPersistent, fConnIsViable)
    If (fConnIsPersistent = True And fConnIsViable = True) Then
```

```
        Continue with the next Use or Close method call is OK
    Else
        Connection is either Non-persistent or no longer viable
        So a Use or Close call is not valid
    End-if
    Exit Sub

End Sub
```

How to Self-Host a Windows-Initiated Process

Self-Hosting is a technology that allows you the option of running a Transaction Integrator (TI) assembly in-process with an associated application. Self-Hosting improves performance of your application by not running the TI assembly through Internet Information Services (IIS).

To self-host a TI assembly

1. Create a TI assembly as you would normally.

   For more information, see Creating an Application using Host Integration Server Designer.

2. Register the TI assembly using TI Manager, using the **Self-Host** radio button selected.

   You may also set the hosting model in the Properties toolbox in Visual Studio.

   For more information, see Creating an Object.

3. In Visual Studio, use Solution Explorer to add a reference to your TI assembly.

4. Code your application, using the interfaces on the TI assembly as you would any other interface.

Programming Host-Initiated Processing

This section discusses various issues you need to understand to program host-initiated processing components and applications.

In This Section

- Connecting HIP Components to Visual Basic Applications

How To Connect a HIP Component to a Visual Basic Applications

A key link in host-initiated processing (HIP) is the connection between the HIP component in Transaction Integrator (TI) and the client application. The connection between the HIP component and the Microsoft Visual Basic server DLL is created through matching elements of the HIP type library with elements of the Visual Basic project. The following table shows the relationship between the elements.

HIP Type Library	Visual Basic Project
Type Library name	Visual Basic Project name.
Type Library Interface name	Visual Basic Class name.
Type Library Method names	Functions or subroutines within the Visual Basic Class.
Type Library method parameters	Defined one for one within the Visual Basic functions or subroutines with the Visual Basic subroutines and functions.

Note
Make sure that the Visual Basic server DLL is registered.

If you are using the **Implements** key word within a Visual Basic server, the following additional rules apply:

- The **Visual Basic Implement Compatible Interface** property must be enabled. Set the property on the component *interface* **Properties** page within the TI type library or assembly
- All parameters defined to type library methods must be **Input\Output**. The **Implements** keyword does not support parameters defined as either input or output. All parameters must be defined as input or output.
- The function or subroutine calls must be defined as public, not private, within the Visual Basic class.

Programming Host-Initiated Processing

How to Use a Persistent Connection with Host-Initiated Processing

A persistent connection is a connection that stays open past the duration of a specific call. Because your application does not need to re-create the connection on each call, you can use a persistent connection to increase the efficiency of your Host-initiated application. An application that uses a persistent connection with Host-initiated Processing (HIP) operates in many ways the same way as a Windows-Initiated Processing (WIP). The difference, of course, is that the mainframe initiates and terminates the connection, while the windows application responds to the requests of the mainframe.

Note
Host Integration Server supports many of the same programming environments for HIP as for WIP. The exceptions are IMS Connect, Distributed Program Call (DPC), and SNALink, which are not supported for HIP persistent connections.

To use a persistent connection with HIP

1. Receive a call with your Windows application from the mainframe, indicating that a connection has been created.

   It is the responsibility of the mainframe application to request the persistent connection.

2. Have your Windows application react to the request in the relevant manner.

   There is nothing specific your application must do in order to use a persistent connection: creating and terminating the connection is the responsibility of the mainframe application.

3. Optionally, you can create a new instance of the HIPServerUserContext to query the status of the connection.

   The new instance is automatically created with the context information for the relevant connection. Using HIPServerUserConext, you can determine what type of connection the mainframe has created, and react accordingly.

Example

The following code is pulled from the CICS sample application in the SDK. The sample uses the CONNTYPE of the server object to perform different actions.

```
decimal GetAccountBalance(object[] contextArray)
        {
            decimal ReturnBalance = 0.0m;
            string ConnType;
            object contextValue;

            _TIServerContext.ReadContext("CONNTYPE", out contextValue, ref contextArray);

            if (contextValue == null)
                ReturnBalance = 123.45m;
            else
            {
                ConnType = contextValue.ToString();
                ConnType.ToUpper();
                switch (ConnType)
                {
                    case "OPEN":
  // Set the initial value of the Account Balance
  // and save it in a global varaible and return it.
                        ReturnBalance = 123.45m;
                        _AccountBalance = ReturnBalance;
                        break;

                    case "USE":
  // Increase the value of the global Account Balance
  // varaible and and return its value. Save this new value
  // in the global variable for later use
                        _AccountBalance += 100;
                        ReturnBalance = _AccountBalance;
                        break;
```

```
                    case "CLOSE":
    // Increase the value of the global Account Balance
    // variable and return the new value. Set the global variable
    // to zero because the "CLOSE" call indicates that we are
    // done with it.
                        ReturnBalance = _AccountBalance + 150;
                        _AccountBalance = 0.0m;
                        break;

                    case "UNKNOWN":
                    default:
                        _AccountBalance = 0.0m;
                        ReturnBalance = 123.45m;
                        break;
                }
            }

            return ReturnBalance;
        }
```

The code sample uses a global variable to store information. It is also possible to use the context object itself to store information. Although not shown here, it is possible to use the context object to pass information back to the windows application.

This section provides information about steps you can take to safeguard Transaction Integrator, your data, and your network when you are programming client or server applications.

In This Section

Mainframe Authentication for CICS LINK

Resource-level authentication is recommended in the CICS region. Due to a restriction imposed by the IBM distributed program link (DPL) protocol, a user ID and password transmitted from the workstation by Transaction Integrator (TI) are ignored and not used for transaction-level authentication. The target CICS region expects, under such circumstances, that authentication has been completed by the application that executes the IBM DPL; for example, a TI application on the PC. (Traditionally, the application that executes an IBM DPL has been another CICS region.)

Instead, for transaction-level authentication, the target CICS region associates the default user ID for the region with the transaction ID of the CICS (Mirror transaction) task and the user ID from the sender is ignored. Unless this practice is taken into consideration, attempts to secure the Mirror transaction can cause an application malfunction because of the failure to authenticate.

Application Integration Security Guide

Using SSO with Host-Initiated Processing

When you use Single Sign-On (SSO) security with host-initiated processing (HIP), the impersonation of user credentials is handled differently depending upon whether you are calling a .NET object or a COM object. If HIP is calling a .NET object, there are no special considerations; the Transaction Integrator (TI) run-time environment impersonates the user account. If HIP is calling a COM object, however, there are special considerations.

Depending on the threading model and registration type of the components, the following actions occur when HIP calls the method of a .COM object when it is impersonating a user account (the one that the host credentials would have been mapped to via SSO):

Threading Model	Registration	Actions
Single, apartment	Server/Library/No COM+ application	• Server object methods are called under HIP Service/COM+ application configured identity. • Server object methods call **CoImpersonateClient** to start impersonating the user identity. • Optionally, methods can call **CoRevertToSelf**, although that is not necessary because COM will call it anyway after the method returns.
Free, both, neutral	Server COM+ application	• Server object methods are called under HIP Service/COM+ application configured identity. • Server object methods call **CoImpersonateClient** to start impersonating the user identity. • Optionally, methods can call **CoRevertToSelf**, although that is not necessary because COM will call it anyway after the method returns.
Free, both, neutral	Library/No COM+ application	• Server object methods are called under the user identity being impersonated. • Server object method should not call **CoImpersonateClient** or **CoRevertToSelf** because they would fail with RPC_E_CALL_COMPLETE.

If you are programming in Microsoft Visual Basic® 6.0, be sure to include the **CoImpersonateClient** and **CoRevertToSelf** declarations in your programs:

```
Private Declare Function CoImpersonateClient Lib "ole32.dll" () As Long
Private Declare Function CoRevertToSelf Lib "ole32.dll" () As Long
```

Application Integration Security Guide

Using SSO with Encrypted Passwords

If you are using Single Sign-On (SSO) security, you must determine whether the client application passes plain text passwords or encrypted passwords to the Transaction Integrator (TI) run-time environment. If the passwords are in plain text, SSO accepts the passwords when they are submitted by the TI run-time environment. If the passwords are encrypted, SSO does not accept the passwords, and the call to SSO fails. To avoid failed SSO calls, disable password validation for the SSO affiliate application.

Threat Mitigation within Visual Studio

Product security is a top priority throughout Microsoft development. Beginning with the Microsoft Windows Security Push in 2002, Microsoft has invested additional time and resources to developing more secure code and detailed instructions for deploying and securing your computing environment.

The Host Integration Server product team conducted a complete threat modeling analysis to identify and mitigate potential areas of concern. A threat model is a security-based analysis that helps you determine the highest-level security risks posed to a product or application and how attacks can manifest themselves.

Although Microsoft has mitigated all known internal security threats to Host Integration Server, you should take steps to mitigate threats from elsewhere in your network environment. Threat modeling helps you evaluate the threats to the applications you are writing or running, and thereby reduce the overall risk to your computer system. For more information about threat model analysis, see Chapter 4 Threat Modeling in Michael Howard and David LeBlanc, *Writing Secure Code 2nd Edition*, Redmond, WA: Microsoft Press. 2003.

Howard and LeBlanc summarize six categories of possible security threats to your computing environment:

- **Spoofing identity**. Spoofing threats enable an attacker to pose as another user or enable a rogue server to pose as a valid server. An example of user identity spoofing is illegally gaining access and then using another users authentication information, such as username and password.

- **Tampering with data**. Data tampering involves malicious modification of data. Examples include unauthorized changes made to persistent data, such as that held in a database, and the alteration of data as it flows between two computers over an open network, such as the Internet.

- **Repudiation**. Repudiation threats are associated with a user who denies that he performed an action without other parties having any way to prove otherwise—for example, a user performs an illegal operation in a system that lacks the ability to trace the prohibited operations.

- **Information disclosure**. Information disclosure threats involve the exposure of information to individuals who are not supposed to have access to it—for example, a users ability to read a file that she was not granted access to and an intruders ability to read data in transit between two computers.

- **Denial of service**. Denial of service (DoS) attacks deny service to valid users—for example, by making a Web server temporarily unavailable or unusable. You protect against certain types of DoS threats simply to improve system availability and reliability.

- **Elevation of privileges**. In this type of threat, an unprivileged user gains privileged access and thereby has sufficient access to compromise or destroy the entire system. Elevation of privilege threats include situations in which an attacker has effectively penetrated all system defenses and become part of the trusted system itself, a dangerous situation indeed.

Howard and LeBlanc also point out that some threat types can interrelate. For example, it is possible for information disclosure threats to lead to spoofing threats if the users credentials are not secured. Similarly, elevation of privilege threats is by far the worst because if someone can become an administrator or root on the target computer, every other threat category becomes a reality. Conversely, spoofing threats might lead to a situation where escalation is no longer needed for an attacker to achieve his goal.

To mitigate threats that originate outside Transaction Integrator (TI) but which can negatively affect TI components and your application, Microsoft recommends that you do the following:

- Protect the TI COM Type Library or .NET Assembly from Unauthorized Access

- Protect the Output from Tracing and Network Monitoring Activities

- Protect the TI Record or Playback Files from Unauthorized Access

Protecting the TI COM Type Library or .NET Assembly from Unauthorized Access

To prevent an attacker from viewing or modifying the contents of a Transaction Integrator (TI) COM type library or .NET assembly and then using that information to either create a client application which spoofs the identity of an authorized user or modify the custom properties of the component, you should:

- Place the computer running Visual Studio and TI Designer in a secure location.
- Confirm that the access permissions to Visual Studio, TI Designer, or any other tool used to modify TI type libraries and .NET assemblies are set correctly.
- Store all TI component type libraries and .NET assemblies in a secure directory.
- Confirm that the access permissions are set correctly on all type libraries and .NET assemblies.
- Confirm that the access permissions are set correctly on the directory that contains the type libraries and .NET assemblies.

Threat Mitigation within Visual Studio

Protecting the Output from Tracing and Network Monitoring Activities

To prevent an attacker from viewing the user credential information that might be stored in trace files or network monitoring files, you should:

- Confirm that only authorized users are allowed to run the SNA TRACE or Microsoft Network Monitoring programs on the computer that is running Transaction Integrator.
- Store all tracing (Tracebits) output files and network monitoring (Netmon) output files in a secure directory.
- Confirm that the access permissions are set correctly on all tracing output files and network monitoring output files.
- Confirm that the access permissions are set correctly on the directory that contains the output files.
- Delete all tracing output files and network monitoring output files as soon as you are done with them.

Protecting the TI Record or Playback Files from Unauthorized Access

To prevent an attacker from either viewing the contents of the Transaction Integrator (TI) record or playback files or replacing those files with ones that could record user data sent to or from the host, you should:

- Store all TI record and playback files in a secure directory.
- Confirm that the access permissions on all record or playback files are set correctly. A user must have administrator rights to be able to record and save a file.
- Confirm that the access permissions are set correctly on the directory that contains the record or playback files are stored.
- Store the record file in a form other than plain text.

In This Section

Data Access Library

Programming with the Data Access Library

Data Access Library

This section describes the background for the Data Access Library (DAL), how the different interfaces relate to each other, and what technologies you must be familiar with to program the DAL.

In This Section

Goals for the Data Access Library

The original goal of the Data Access Library (DAL) was to expose an interface that would enable developers to automate lengthy tasks normally performed through the Data Access Tool (DAT) user interface. As development progressed, the Data Access Library grew to include the most common functionality of the DAT.

When Microsoft developers originally created the Data Access Tool, they realized that some tasks were relatively time-consuming. For example, creating a DB2 data package takes several steps through the DAT user interface. The developers determined that the best way to reduce the time to perform such tasks was to expose a programming interface to the DAT. They determined that in exposing the interface that is required to automate a lengthy procedure, they could expose essentially the entire functionality of the Data Access Tool.

Therefore, the purpose of the Data Access Library interface is to provide a programmatic interface for the Data Access Tool and Data Source Wizard. This is done through a straightforward interface that correlates almost entirely to actions that you can take using the appropriate user interface. Although the Data Access Library provides a subset of the capabilities the user interface exposes, you can automate most of the common tasks for which you would typically use the UI.

See Also
Other Resources
Data Access Library

Data Access Library Interface

The Data Access Library is based around four objects that represent the core functionality of the Data Access Tool (DAT) and Data Source Wizard. The following table describes the core objects for the Data Access Library.

Object	Description
DataAccessControl	Provides access to the options listed on the DAT Action menu: testing connections and queries, creating packages, and converting data.
DataAccessSettings	Provides access to the functionality of the Data Source Wizard: describing where information is stored, and controlling the Wizard dialog boxes and warnings.
IConnectionString	Base class for describing the different types of connection strings that the DAT uses.
IHCDItem	Base class for describing the objects that make up a host column description (HCD) file.

In addition to the above objects, the Data Access Library interface has an exception object, possible data types, a callback function triggered when creating packages, and a collection of IHCD items. For more information, see the Data Access Library Programmer's Reference.

Data Access Library

What You Should Know Before Programming the Data Access Library

The Data Access Library (DAL) is a .NET Framework interface for creating universal data link (.udl) files for Host Integration Server. Therefore, you should be familiar with the following concepts and technologies:

- Host Integration Server 2009

  The purpose of the DAL is make it easier to create .udl files, which Host Integration Server then uses to access remote servers through a variety of technologies. Therefore, you should be familiar with the general framework that you will be working with when you use the DAL.

- Data Access Tool (DAT) and Data Access Wizard

  The DAT and the Data Access Wizard are the technologies that enable you to create .udl files and ODBC DSNs through a user interface. Therefore, you should be familiar with the standard way in which the technology performs a task before you try to perform that task programmatically.

- .NET Framework 2.0

  The Data Access Library was written using Microsoft Visual Studio 2005 and the .NET Framework 2.0. Therefore, in order to successfully use the DAL, you should be familiar with the technologies that went into constructing it.

Other Resources

Programming with the Data Access Library

How to Create a Connection String for a .udl File

A universal data link (.udl) file is essentially a text file that contains the connection string for an OLE DB data source. You can create a .udl file by using the appropriate **DB2OleDbConnectionString** or **FileSysOleDbConnectionString** constructor, and then save the string to secondary storage with a call to **Save**. The Data Access Library automatically creates the appropriate .udl file to store the string in, and save the file to disk.

To create a .udl file and associated connection string

1. Create an empty connection string by calling a connection string constructor.

   Calling the constructor creates a connection string with default settings. These default settings can be set only through the Data Access Tool user interface.

   If you use a file path for a file that currently exists, the system loads the connection string information in that file instead.

   You can determine the default path your system uses for storing .udl files with a call to **DataAccessSettings.MakeUDLPath**. **DataAccessSettings** also stores the default paths for DSN and HCD files.

2. Add in the relevant connection information to the connection string by calling the various connection string properties, such as **DataSourceName**, **UserName**, or **Password**.

   You can also retrieve the full connection string as a text string with a call to **GetString**, and then save the modified string with **SetString**.

3. Save the string by calling the relevant **Save** method, such as **DB2OleDbConnectionString.Save**.

   The system saves the connection string in a .udl file. The system creates the .udl file using the file path passed in the *name* parameter of the constructor. If the file does not contain the full path, the system uses the default path as described in **DataAccessSettings.UDLpath**.

The following code example demonstrates how to create a .udl file using a new file name, user name, and password.

```
static DB2OleDbConnectionString CreateUDLFile(string FileName, string NameOfUser, string Pa
ssWord, ref System.Exception myException)
{
   try
   {
      DB2OleDbConnectionString myConnection = new DB2OleDbConnectionString(FileName, false)
;
      myConnection.UserName = NameOfUser;
      myConnection.Password = PassWord;
      myConnection.Save();
      System.Exception MyEx= new System.Exception(@"Successful Creation", null);
      myException = MyEx;
      return myConnection;

   }
   catch (Exception ex)
   {
      myException = ex;
      return null;
   }
}
```

Programming with the Data Access Library

How to Create a Connection String for an ODBC System, User or File DSN

The other type of data that you can create by using the Data Access Library is a data source name (DSN). Like a universal data link (UDL) file, a DSN contains the connection information necessary to access a remote database. However, where a .udl file is generally used for an OLE DB database connection, most systems use DSN files for ODBC connections. Further, a DSN does not necessarily have to be a file: a DSN can be a file, a registry-based system DSN, or a registry-based user DSN.

To create a DSN file and associated connection string

1. Call the constructor for **DB2OdbcFileConnectionString**, **DB2OdbcSysConnectionString**, or **DB2OdbcUserConnectionString**.

   Calling the constructor creates a connection string with default settings. These default settings can be set only through the Data Access Tool user interface.

   If you use a file path for a file that currently exists, the system loads the connection string information in that file instead.

2. Fill in the relevant connection string properties by calling the properties of the object created.

   You can also fill in the connection string with **GetString**, which returns the connection string as a text string. After you finish modifying the relevant values, you can return the connection string to the object with a call to **SetString**.

3. Save the connection string information back into storage with a call to **Save**.

The following code example demonstrates how to create a DSN file and associated connection string.

```
static DB2OdbcFileConnectionString CreateUDLFile2(string FileName, string NameOfUser, strin
g PassWord, ref System.Exception myException)
{
   try
   {
      DB2OdbcFileConnectionString myConnection = new DB2OdbcFileConnectionString(FileName,
false);
      myConnection.UserName = NameOfUser;
      myConnection.Password = PassWord;
      myConnection.Save();
      System.Exception MyEx= new System.Exception(@"Successful Creation", null);
      myException = MyEx;
      return myConnection;

   }
   catch (Exception ex)
   {
      myException = ex;
      return null;

   }
}
```

Creating a Connection String

How to Retrieve Data

Creating connection string information requires that you create an object that is derived from the **IConnectionString** class, such as **DB2OdbcConnectionString** or **DB2OleDbConnectionString**. After you create the string, you can save, modify, or retrieve information from it by using the associated properties.

To retrieve and modify connection string information

1. Create a new connection string by calling the specific type of connection string constructor, using the file path of the .udl file that contains the specified connection string.

   Or, you can call **ReadUDL** for the specified **ConnectionString** type. Many of the **ConnectionString** classes also have a **Clone** method that you may want to use. Note that **Clone** does not load the current instance into active memory, but instead makes a copy that you can later modify and save to disk.

   If you are attempting to retrieve data from a connection string that you currently have an instance of, you can call **Load**. For example, if you recently created a new connection string and called **Save**, you can retrieve the object from storage and into active memory by calling **Load** on the object again.

   If you use a path that describes a file that does not exist, the system creates a .udl new file using the path described.

2. Retrieve the connection data from your current instance by using **GetString** or by accessing the relevant property.

   Using **GetString** enables you to manipulate the connection string as though it were a standard text string. In contrast, accessing the value as a property is usually simpler and safer.

3. When you are finished viewing or manipulating the relevant value, return the value to the object by calling **SetString** or by setting the appropriate property.

4. When you are finished, save your changes to secondary storage by calling **Save**.

The following code example demonstrates how to retrieve, change, and save connection string data.

```
static System.Exception ChangeCommentInUDL(string connString, string newComment)
{
   try
   {
      IConnectionString udl = DB2OleDbConnectionString.ReadUDL(connString);
      udl.Comment = newComment;
      udl.Save();
      System.Exception noException = null;
      return noException;

   }
   catch (System.Exception ex)
   {
      return ex;
   }
}
```

Performing Administrative Tasks

The administrative tasks for the Data Access Library are the tasks you can perform using the **DataAccessControl** interface. In general, these tasks are those that require you go beyond creating universal data link (UDL) or host column description (HCD) files, and start interacting with the actual data sources.

In This Section

How to Convert Data Source Information

Converting a data source enables you to convert DB2 data source information from one provider type to another. Note that this does not change the data source itself, but rather reformats the data source information stored on your system.

To convert data source information

1. Retrieve the connection string for the relevant database using the appropriate call to **ReadUDL**.
2. Create a connection string to the converted database by calling **DataAccessControl.ConvertTo**, describing the data types of the original data and translated data.
3. Save the data in the new connection string by calling **IConnectionString.Save**.

The following example demonstrates how to convert data source information between OLE DB UDLs and ODBC DSNs.

```
IConnectionString ConvertUDLtoODBC(string originalUDL)
{
   try
   {
      IConnectionString udl = DB2OleDbConnectionString.ReadUDL(originalUDL);
      IConnectionString odbcDsn = DataAccessControl.ConvertTo(udl, typeof(DB2OdbcSysConnect
ionString));
      odbcDsn.Save();
      return odbcDsn;
   }
   catch
   {
      return null;
   }
}
```

How to Create a DB2 Package

A DB2 package is a collection of data used by a provider implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester. The provider uses packages to issue SQL statements and call DB2 stored procedures. You can use CreatePackages to create these packages.

The create package command creates a Host Integration Server package on a DB2 system.

To create a DB2 package

1. Create a connection string to the targeted database with a call to ReadUDL.
2. Create the package with **CreatePackages**.

The following example describes how to create a package.

```
static void CreatePackage(string myUDL, System.Exception myException)
{
try
   {
      IConnectionString connString = DB2OleDbConnectionString.ReadUDL(myUDL);
      DataAccessControl.CreatePackages(connString, null);
      myException = null;
   }
catch (System.Exception Caught)
   {
      myException = Caught;
   }
}
```

How to Test a Connection

After you create the appropriate connection string and store it in a file, you can programmatically test the validity of your connection with a call to TestConnection.

To test a connection

1. Create or retrieve the connection string on which you run the sample query.

   For more information about creating and retrieving connection strings, see Creating a Connection String and How to Retrieve Data.

2. Test the connection with a call to **TestConnection**.

   If successful, **TestConnection** returns the class and version number of the server. Otherwise, the method returns null. Note that you may be required to enter the user name and password. In this case, the **Password** dialog box appears.

How to Run a Sample Query

One of the final checks you can perform on a created connection string is a simple query that fetches a list of available files and data sources in the target database. Once you create the connection string, you can run this query using DataAccessControl.Microsoft.HostIntegration.DataAccessLibrary.DataAccessControl.SampleQuery(Microsoft.HostIntegration.DataAccessLibrary.IConnectionString).

To run a sample query

1. Create or retrieve the connection string on which you run the sample query.

   For more information on creating and retrieving connection strings, see Creating a Connection String and How to Retrieve Data.

2. Run the sample query with a call to **SampleQuery**.

   If successful, **SampleQuery** returns a data table with the relevant values. Otherwise, the method returns null.

Managed Provider Programmer's Guide

A Managed Provider is a .NET Framework data provider that is used for connecting Host Integration Server 2009 applications to a database, executing commands, and retrieving results. Those results are processed directly, placed in an ADO.NET DataSet to be exposed to the user, combined with data from multiple sources, or accessed remotely between tiers. A Host Integration Server Managed Provider is designed to be lightweight, creating a minimal layer between the data source and your code, and increasing performance without sacrificing functionality.

In This Section

Managed Provider for DB2 Programmer's Guide

This section describes the general architecture and implementation details of the Managed Provider for DB2. The Managed Provider for DB2 enables a client to connect to a DB2 data source in order to retrieve and modify data. The Managed Provider for DB2 implements a subset of the **System.Data** interfaces to enable connection management and query execution.

In This Section

Managed Provider for DB2

Host Integration Server 2009 includes a Managed Provider to access data from a loosely coupled data source: in this case, a DB2 database. The Managed Provider for DB2 uses two central .NET Framework components to implement this capability: the ADO.NET **DataSet** object and the Managed Provider for DB2 itself.

A **DataSet** object is designed for data access independent of any data source. As a result, it can be used with multiple and different data sources, with XML data, or to manage data local to the application. A **DataSet** contains a collection of one or more **DataTable** objects consisting of rows and columns of data, and also primary key, foreign key, constraint, and relation information about the data in the **DataTable** objects.

In contrast, the Managed Provider for DB2 provides data manipulation and fast, forward-only, read-only access to data. Therefore, the Managed Provider for DB2 exposes a specific set of objects. The MSDb2Command object enables access to DB2 commands to return data, modify data, run stored procedures, and send or retrieve parameter information. The MsDb2DataReader provides a high-performance stream of data from the DB2 database. Finally, the MsDb2DataAdapter provides the bridge between the **DataSet** object and the DB2 database. MsDb2DataAdapter uses MsDb2Command objects to execute SQL commands at the data source to both load the **DataSet** with data, and reconcile changes that were made to the data in the **DataSet** back to the data source.

In This Section

Managed Provider for DB2 Goals

The main goal of the Managed Provider for DB2 is to enable access to loosely coupled data sources using the technologies offered by ADO.NET and the .NET Framework. To implement this goal, the Managed Provider for DB2 was designed as an incremental improvement over the traditional COM-based OLE DB providers. In addition, the Managed Provider for DB2 is optimized for DB2 over the currently available OLE DB .NET Framework data provider.

ODBC and OLE DB Solutions

Microsoft has offered programming models and tools for developing enterprise data integration solutions for several years. These include the industry-standard ODBC and the COM-based OLE DB. However, developing and deploying ADO-based Web solutions presents a number of issues, including insufficient design tools, decreased performance, limited scalability, and little XML interoperability.

Additionally, the ADO- and OLE DB-based data architecture is based on solutions that require tightly coupled, live connections between application and data tiers. However, the vast majority of Web solutions today require a loosely coupled association between application components and tiers. Also, most modern Web application requirements include the use of XML as the universal Web message and data medium. Remote Data Services (RDS) offered a disconnected recordset between application and presentation tiers. ADO also offered the ability to persist recordsets as XML. However, there was no uniform way to provide asynchronous execution between tiers. In addition, XML recordset persistence was extremely limited.

ADO.NET and the .NET Framework

To make implementation easier and to improve performance, scalability, and XML support, Microsoft offered the .NET Framework and ADO.NET. The .NET Framework offered developers a number of advantages over COM, such as cross-language inheritance, object lifetime management, and multilanguage class libraries as supported by the common language runtime (CLR). The CLR offers developers a predictable, managed environment in which to execute their programs. The ADO.NET programming model was designed to provide better performance and scalability than the older ADO. ADO.NET is a set of common classes for exposing data services that are implemented by .NET Framework data providers.

Microsoft Visual Studio has shipped two .NET Framework data provider implementations: the first provider accesses Microsoft SQL Server through an application-level protocol called Tabular Data Stream (TDS), and is called the SQL Server .NET Framework Data Provider. The second provider accesses the underlying OLE DB providers, and is called the OLE DB .NET Framework Data Provider.

However, just as the OLE DB Provider for ODBC offers less optimal performance and scalability than a direct OLE DB provider solution, so too does the OLE DB .NET Framework Data Provider offer a less optimal solution than a specific .NET Framework data provider implementation would. In addition, the OLE DB .NET Framework Data Provider adds complexity and compatibility issues with an extra layer of indirection. Therefore, Host Integration Server has implemented a .NET Framework data provider for a key enterprise data source: DB2.

Managed Provider for DB2 Programmer's Guide

Relationships between the .NET Provider for DB2 Interfaces

The Managed Provider for DB2 interfaces interact in different ways—with the exception of MsDb2DataAdapter, the remaining classes adhere to a rigid parent/child relationship:

- An MsDb2Connection can have one MsDb2Transaction running, although it can have multiple MsDb2Commands.
- An MsDb2Transaction can have one or more MsDb2Commands running.
- An MsDb2Command owns one MsDb2ParameterCollection, which stores multiple MsDb2Parameters.

  An MsDb2Command can also create a single MsDb2DataReader for parsing one or more resultsets.

The MsDb2DataAdapter takes advantage of all the other Managed Provider interfaces. The MsDb2DataAdapter serves as the gateway between a host DB2 system and a client-side ADO.NET DataSet. The DataSet is an important piece of the .NET data framework because it provides a mechanism for caching data in a managed environment and inferring XML schema information, basically providing a gateway between DB2 data and Microsoft Web services.

Using the Managed Provider for DB2

The Managed Provider for DB2 operates in most ways as a normal data provider: you can connect to a DB2 database, execute commands, retrieve data, and use stored procedures.

In This Section

Using the Managed Provider for DB2 with Visual Studio

You can create a project that uses the managed provider for DB2 with Visual Studio as you would any other project. The following topics describe any issues that are unique to this provider.

Data Design Tools

The Make Table option in the Visual Studio 2005 Query Designer is not supported for the Managed Provider for DB2 in conjunction with IBM DB2 databases. Therefore, the syntax generated by the SELECT INTO statement in Visual Studio is not supported by DB2 when executed using dynamic SQL. There is no solution for this problem.

Using the Managed Provider for DB2

Connecting to and Disconnecting from a DB2 Database

There are two ways to connect and disconnect to a DB2 database. The first and most common way is using an MsDb2Connection to open and close the connection. The second method is to access a connection pool.

In This Section

How to Connect with an MsDb2Connection

The first step in accessing a remote DB2 database is to connect to the database. You must use MsDb2Connection to access an IBM DB2 data source. After you have connected, you can retrieve, modify, and update any information that you want. Note that connections are not implicitly released when the MsDb2Connection falls out of scope or is reclaimed by garbage collection. Therefore, you must close the connection when you are finished using it. You can close a connection by using either **MsDb2Connection.Close** or **MsDb2Connection.Dispose**.

Example

The following example demonstrates how to connect to a DB2 database.

```
Public void SampleConnect()
{
   MsDb2Connection myConnection = null;
   Try
   {
      myConnection = new MsDb2Connection(@"file name=HOST.udl ");
      myConnection.Open();
      // Perform any necessary tasks here.
      myConnection.Close();
   }
finally
   {
      if(myConnection!= null)
         myConnection.Dispose();
   }
}
```

Tasks

How to Connect to and Disconnect from a Host File System

Other Resources

Using the Managed Provider for DB2

How to Connect to a DB2 Connection Pool

Another way to connect to a DB2 database is through a *connection pool*. Although implemented differently on the server, a connection pool is identical to a traditional connection from the perspective of a client application.

A connection pool is a set of one or more connections that the server keeps open to service requests from one or more clients. When the client is finished with a connection, the server does not terminate the connection. Instead, the connection is released back into the pool, and can then service another client. Connection pooling is frequently used in situations where clients connect, query, and terminate a connection to the server multiple times over the course of a session, such as a database server that is accessed through the Internet.

To connect and disconnect to a DB2 connection pool Using Host Integration Server

1. Connect to the DB2 server with MsDb2Connection, with the Microsoft.HostIntegration.MsDb2Client.MsDb2Connection.ConnectionPooling set to **true**.
2. Perform your queries as you would with a traditional DB2 connection.
3. Use **MsDb2Connection.Close** or **MsDb2Connection.Dispose** to end your session.

Note
Calling **Close** or **Dispose** on a connection from a connection pool does not actually close or dispose the connection. In stead, the server returns the connection to the pool.

The following code example shows how to connect to a DB2 database using a connection pool.

```
int GetNumberOfOrders()
{
    MsDb2Connection conn = new MsDb2Connection(@"File Name=C:\MyConn.UDL");
    sDb2Command cmd;
    int numOrders = 0;
    conn.ConnectionPooling = true;
    conn.Open();
    cmd = new MsDb2Command("select count(*) from orders", conn);
    numOrders = (int)cmd.ExecuteScalar();
    conn.Close();
    return numOrders;
}
```

Using the Managed Provider for DB2

Connecting to and Disconnecting from a DB2 Database

Working with Connection Strings and the Managed Provider for DB2

A connection string contains initialization information passed as a parameter from a data provider to a data source, which is then parsed immediately after being set. Syntax errors generate a run-time exception, but other errors can be found only after the data source has validated the information in the connection string. After the information is validated, the data source sets various connection string options that enable the connection and allow it to be opened.

The .NET Framework 2.0 provides new capabilities for working with connection strings, such as the **MsDb2ConnectionStringBuilder** class, which facilitates building valid connection strings at run time based on user input.

In This Section

Building Connection Strings

The Managed Provider for DB2 provides a strongly typed connection string builder class that inherits from **DbConnectionStringBuilder**. The connection string builders let developers programmatically create syntactically correct connection strings that are based on user input, and also parse and rebuild existing connection strings by using methods of the class. The MsDb2ConnectionStringBuilder class provides strongly typed properties that correspond to the known key/values pairs allowed by the Managed Provider for DB2.

In earlier versions of ADO.NET, there was no compile-time checking of connection strings that consisted of concatenated string values. At run time, an incorrect keyword would generate an invalid ArgumentException. Because values received from a user were not checked or quoted appropriately, it was possible for an attacker to bypass expected settings.

The **MsDb2ConnectionStringBuilder** class performs checks for valid key/value pairs. An invalid pair throws an exception and injected values are handled in a safe manner. Each class maintains a fixed collection of synonyms and can translate from a synonym to the corresponding well-known key name.

Example
See Also
Other Resources
Working with Connection Strings and the Managed Provider for DB2

Using Connection String Keywords

The format of a connection string is a semicolon-delimited list of key/value parameter pairs:

keyword1=value; keyword2=value

When the connection string is validated by the data source, spaces are ignored and keywords are not case sensitive. However, values may be case sensitive, depending on the case sensitivity of the data source. To include values that contain a semicolon, single-quote character, or double-quote character, the value must be enclosed in double quotation marks.

To avoid misspellings, the Managed Provider for DB2 exposes the keywords and values of the connection string as properties.

Example
See Also
Other Resources
Working with Connection Strings and the Managed Provider for DB2

Storing and Retrieving Connection Strings

We recommend that you not embed connection strings in your code. If the location of the server ever changes, your application must be recompiled. In addition, unencrypted connection strings that are compiled into an application's source code can be viewed using the MSIL Disassembler (ildasm.exe).

To avoid storing connection strings in your code, you can store them in the web.config file for an ASP.NET application and in the app.config file for a Windows application. Although configuration files are mainly used in ASP.NET applications, where they are protected from being browsed to, you can also use them in a Windows application. The syntax and format of the app.config and web.config files is identical for both ASP.NET and Windows applications.

The connection string can be stored in the configuration file in the **<connectionStrings>** element. Connection strings are stored as key/value pairs, where the name key can be used to look up the value stored in the **connectionString** attribute at run time.

You can work with configuration files programmatically by using the **MsDb2Configuration** class. The methods of the **WebConfigurationManager** object also enable you to obtain a configuration section, each of which has its own object type. In addition, the **System.Configuration** namespace provides classes for working with configuration information stored in configuration files.

Example

Other Resources
Working with Connection Strings and the Managed Provider for DB2

Executing Commands in a DB2 Database

The MsDb2Command object exposes several **Execute** methods that you can use to perform the intended action. When you are returning results as a stream of data, use ExecuteReader to return a **DataReader** object. Use ExecuteScalar to return a singleton value. Use ExecuteNonQuery to execute commands that do not return rows.

Using MsDb2Command with Stored Procedures

When you use the **MsDb2Command** object with a stored procedure, you can set the **CommandType** property of the **MsDb2Command** object to **StoredProcedure**. With a **CommandType** of **StoredProcedure**, you can use the **Parameters** property of the **Command** to access input and output parameters and return values. The **Parameters** property can be accessed regardless of the **Execute** method called. However, when you call **ExecuteReader**, return values and output parameters cannot be accessed until the **DataReader** is closed.

Note that SQL statements that modify data (such as **INSERT**, **UPDATE**, or **DELETE**) do not return rows. Similarly, many stored procedures perform an action but do not return rows. To execute commands that do not return rows, create an **MsDb2Command** object with the appropriate SQL command and an MsDb2Connection, including any required MsDb2Parameter**s**. Execute the command by using the **ExecuteNonQuery** method of the **MsDb2Command** object. The **ExecuteNonQuery** method returns an integer that represents the number of rows affected by the statement or stored procedure that was executed. If multiple statements are executed, the value returned is the sum of the records affected by all the statements executed.

Modifying Databases and Catalogs

To execute a command to modify a database or catalog, such as the **CREATE TABLE** or **CREATE PROCEDURE** statement, create an **MsDb2Command** object by using the appropriate SQL statements and an **MsDb2Connection** object. Execute the command by using the **ExecuteNonQuery** method of the **MsDb2Command** object.

Reading Data from a DB2 Database

In addition to executing commands on a remote database, you can also retrieve information from the database to view locally.

In This Section

Reading Data from a Database

You can use MsDb2DataReader to retrieve a read-only, forward-only stream of data from a database. Using **MsDb2DataReader** can increase application performance and reduce system overhead because only one row at a time is ever in memory.

After you create an instance of the MsDb2Command object, you can create an **MsDb2DataReader** by calling ExecuteReader to retrieve rows from a data source.

You can use Microsoft.HostIntegration.MsDb2Client.MsDb2DataReader.Read to obtain a row from the results of the query. You access each column of the returned row by passing the name or ordinal reference of the column to **MsDb2DataReader**. However, for best performance, **MsDb2DataReader** provides a series of methods that enable you to access column values in their native data types. Using the typed accessor methods when the underlying data type is known reduces the amount of type conversion required when retrieving the column value.

MsDb2DataReader also provides a nonbuffered stream of data that enables procedural logic to efficiently process results from a data source sequentially. **MsDb2DataReader** is a good choice when you are retrieving large amounts of data because the data is not cached in memory.

After you are finished with **MsDb2DataReader**, be sure to call the **Close** method. In addition, output parameters and return values from an **MsDb2Command** are not available until **MsDb2DataReader** is closed.

Note

The Distributed Relational Data Architecture (DRDA) uses a "." as a decimal point and a "," to separate numerical values. If yo u are working in a language, such as German, that uses a "," as a decimal point, you might receive an error when you are retri eving data from your database. To avoid this error, use **System.Globalization.CultureInfo.InvariantCulture** when you call the **ToString** and **Parse** methods.

Example

The following example shows how to read data from a DB2 database by reading a row from a **SELECT** statement:

```
Public void ReadMyData(string myConnString)
{
   string mySelectQuery = "SELECT OrderID, CustomerID FROM Orders";
   MsDb2Connection myConnection = new MsDb2Connection(myConnString);
   MsDb2Command myCommand = new MsDb2Command(mySelectQuery,myConnection);
   myConnection.Open();
   MsDb2DataReader myReader;
   myReader = myCommand.ExecuteReader();
   // Always call Read before accessing data.
   While (myReader.Read())
   {
       Console.WriteLine(myReader.GetInt32(0) + ", "
       + myReader.GetString(1));
   }
   // Always close when done reading.
   myReader.Close();
   // Close the connection when done.
   myConnection.Close();
}
```

How to Retrieve Multiple Result Sets

MsDb2DataReader provides the NextResult method to iterate through multiple returned results.

Example

The following example shows how to retrieve multiple result sets.

```
Public void ReadMyData(string myConnString)
{
   string myCallQuery = "CALL MyReports()";
   MsDb2Connection myConnection = new MsDb2Connection(myConnString);
   MsDb2Command myCommand = new MsDb2Command(myCallQuery,myConnection);
   myConnection.Open();
   MsDb2DataReader myReader;
   myReader = myCommand.ExecuteReader();
   do
      {
      // Always call Read before accessing data.
      While (myReader.Read())
         {
         Console.WriteLine(myReader.GetString(0) + " , ", "
                 + myReader.GetString(1));
         }
       }
   while(myReader.NextResult());
   // Always call Close when done reading.
   myReader.Close();
   // Close the connection when done with it.
   myConenction.Close();
}
```

Managed Provider for DB2 Programmer's Guide

Managed Provider for DB2 Programmer's Reference

Retrieving Schema Information

While an MsDb2DataReader is open, you can retrieve schema information about the current result set by using **MsDb2DataReader.**GetSchemaTable. **GetSchemaTable** returns a data table that is populated with rows and columns that contain the schema information for the current result set. The data table contains one row for each column of the result set. Each column of the schema table row maps to a property of the column returned in the result set, where the **ColumnName** is the name of the property and the value of the column is the value of the property.

Using Stored Procedures in a DB2 Database

Stored procedures offer many advantages in data-driven applications. By using stored procedures, you can encapsulate database operations in a single command, optimized for best performance, and enhanced with additional security. Although you can call a stored procedure by passing the stored procedure name followed by parameter arguments as an SQL statement, using the Parameters collection of MsDb2Command object enables you to more explicitly define stored procedure parameters, and also to access output parameters and return values.

To call a stored procedure, set the CommandType of the **MsDb2Command** object to **StoredProcedure**. After the **CommandType** is set to **StoredProcedure**, you can use the **Parameters** collection to define parameters.

You can create an MsDb2Parameter object by using the **MsDb2Parameter** constructor, or by calling the **Add** method of the **Parameters** collection of an **MsDb2Command**. **MsDb2Parameters.Add** takes as input either constructor arguments or an existing **MsDb2Parameter object**. When setting the Value of an **MsDb2Parameter** to a null reference, use **DBNull.Value**.

For parameters other than Input parameters, you must set the **ParameterDirection** property to specify whether the parameter type is **InputOutput**, **Output**, or **ReturnValue**.

How to Obtain a Single Value from a DB2 Database

You might need to return database information that is just a single value rather than in the form of a table or data stream. For example, you might want to return the result of an aggregate function such as Count(*), Sum(Price), or Avg(Quantity). The **Command** object enables you to return single values by using the **ExecuteScalar** method. The **ExecuteScalar** method returns as a scalar value the value of the first column of the first row of the result set.

Example

The following code example demonstrates how to retrieve a single value from a DB2 database.

```
static void SingleValueConnection()
{
    MsDb2Connection myConnection = null;
    try
    {
// Obtaining a single value as a database.
        myConnection = new MsDb2Connection(@"file name=HOST.udl ");
        myConnection.Open();
        MsDb2Command myCommand = new MsDb2Command("SELECT Count(*) FROM Orders", myConnecti
on);
       Int32 count = (Int32)myCommand.ExecuteScalar();
        myConnection.Close();
    }
        catch (Exception exc)
    {
        Console.WriteLine(exc);
        Console.ReadLine();
    }

    finally
    {
        if(myConnection!= null)
            myConnection.Dispose();
    }
} // End SingleValueConnection.
```

Using the Managed Provider for DB2

Working with the DataAdapter and the DataSet for a DB2 Database

The MsDb2DataAdapter is the main interface for retrieving and updating the **DataSet**.

In This Section

Populating a Managed Provider Dataset from a Data Adapter

The dataset is a memory-resident representation of data that provides a consistent relational programming model independent of the data source. The dataset represents a complete set of data including tables, constraints, and relationships among the tables. Because the dataset is independent of the data source, a dataset can include data that is local to the application, and also data from multiple data sources. Interaction with existing data sources is controlled through an **MsDb2DataAdapter** object.

The Microsoft.HostIntegration.MsDb2Client.MsDb2DataAdapter.SelectCommand is a **Command** object that retrieves data from the data source. The **InsertCommand**, **UpdateCommand**, and **DeleteCommand** properties of MsDb2DataAdapter are also **Command** objects that manage updates to the data in the data source according to modifications made to the data in the dataset.

Fill Method

The **MsDb2DataAdapter.Fill** method is used to populate a dataset with the results of **Microsoft.HostIntegration.MsDb2Client.MsDb2DataAdapter.SelectCommand**. **Fill** takes as its arguments a **DataSet** object to be populated, and a **DataTable** object, or the name of the **DataTable** object to be filled with the rows returned from **SelectCommand**.

The **Fill** method uses MsDb2DataReader implicitly to return the column names and types that are used to create the tables in the dataset, and also the data to populate the rows of the tables in the dataset. Tables and columns are only created if they do not already exist; otherwise **Fill** uses the existing dataset schema. Column types are created as .NET Framework types. Primary keys are not created unless they are located in the data source, and **DataAdapter.MissingSchemaAction** is set to **MissingSchemaAction.AddWithKey**. If **Fill** finds that a primary key exists for a table, it overwrites data in the **DataSet** with data from the data source for rows where the primary key column values match those of the row returned from the data source. If no primary key is found, the data is appended to the tables in the **DataSet. Fill** uses any mappings that may exist when populating the **DataSet** object.

Note
If **SelectCommand** returns the results of an OUTER JOIN, the **MsDb2DataAdapter** does not set a PrimaryKey value for the resulting **DataTable**. You must define the PrimaryKey yourself to ensure that duplicate rows are resolved correctly

Multiple Result Sets

If **MsDb2DataAdapter** encounters multiple result sets, it creates multiple tables in the dataset. The tables are given an incremental default name of TableN, starting with "Table" for Table0. If a table name is passed as an argument to the **Fill** method, the tables are given an incremental default name of TableNameN, starting with "TableName" for TableName0.

Any number of **MsDb2DataAdapter** objects can be used with a dataset. Each **MsDb2DataAdapter** can be used to fill one or more **DataTable** objects and resolve updates back to the relevant data source. You can add **DataRelation** and **Constraint** objects to the dataset locally, enabling you to relate data from dissimilar data sources.

Using the Managed Provider for DB2

Working with DataAdapter Events

MsDb2DataAdapter exposes two events you can use to respond to changes made to data at the data source. The following table shows the **MsDb2DataAdapter** events.

Event	Description
RowUpdating	An UPDATE, INSERT, or DELETE operation on a row (by a call to one of the **Update** methods) is about to begin.
RowUpdated	An UPDATE, INSERT, or DELETE operation on a row (by a call to one of the **Update** methods) is complete.

RowUpdating is raised before any update to a row from the dataset has been processed at the data source. **RowUpdated** is raised after any update to a row from the dataset has been processed at the data source. As a result, you can use **RowUpdating** to modify update behavior before it occurs, to provide additional handling when an update occurs, to retain a reference to an updated row, to cancel the current update and schedule it for a batch process to be processed later, and so on. **RowUpdated** is useful for responding to errors and exceptions that occur during the update. You can add error information, retry logic, and so on, to the dataset.

Arguments

The *MsDb2RowUpdatingEventArgs* and *MsDb2RowUpdatedEventArgs* arguments that are passed to the **RowUpdating** and **RowUpdated** events include the following:

- A **Command** property that references the **Command** object that is used to perform the update.
- A **Row** property that references the **DataRow** object containing the updated information.
- A **StatementType** property for what type of update is being performed.
- The **TableMapping**, if applicable.
- The **Status** of the operation.

You can use the **Status** property to determine whether an error has occurred during the operation and, if you want, to control the actions against the current and resulting rows. When the event occurs, the **Status** property equals either **Continue** or **ErrorsOccurred**.

Status Property Values

The following table shows the values to which you can set the **Status** property in order to control subsequent actions during the update.

Status	Description
Continue	Continue the update operation.
ErrorsOccurred	Abort the update operation and throw an exception.
SkipCurrentRow	Ignore the current row and continue the update operation.
SkipAllRemainingRows	Abort the update operation, but do not throw an exception.

Setting the **Status** property to **ErrorsOccurred** causes an exception to be thrown. You can control which exception is thrown by setting the **Errors** property to the desired exception. Using one of the other values for **Status** prevents an exception from being thrown.

Using the Managed Provider for DB2

Updating the DB2 Database with a Data Adapter and the Dataset

The **Update** method of **MsDb2DataAdapter** is called to resolve changes from a dataset back to the data source. The **Update** method, like the **Fill** method, takes as arguments an instance of **DataSet**, and an optional **DataTable** object or **DataTable** name. The **DataSet** instance is the **DataSet** object that contains the changes that have been made, and the **DataTable** object identifies the table from which to retrieve the changes.

Calling the Update Method

When you call the **Update** method, **MsDb2DataAdapter** analyzes the changes that have been made and executes the appropriate command (INSERT, UPDATE, or DELETE). When the **MsDb2DataAdapter** encounters a change to a data row, it uses **InsertCommand**, **UpdateCommand**, or **DeleteCommand** to process the change. This enables you to maximize the performance of your ADO.NET application by specifying command syntax at design time and, where possible, with stored procedures. You must explicitly set the commands before calling **Update**. If **Update** is called, and the appropriate command does not exist for a particular update (for example, no **DeleteCommand** for deleted rows), an exception is thrown. You can use command parameters to specify input and output values for an SQL statement or stored procedure for each modified row in a dataset.

If your **DataTable** object maps to or is generated from a single database table, you can take advantage of the **MsDb2CommandBuilder** object to automatically generate the **DeleteCommand**, **InsertCommand**, and **UpdateCommand** properties of the **MsDb2DataAdapter** object.

Updating Datasets

The **Update** method resolves your changes back to the data source; however other clients might have modified data at the data source since the last time you filled the dataset. To update your dataset with current data, use the **MsDb2DataAdapter** and **Fill** method. New rows are added to the table, and updated information is incorporated into existing rows. The **Fill** method determines whether a new row will be added or an existing row will be updated by examining the primary key values of the rows in the dataset and the rows returned by **SelectCommand**. If the **Fill** method encounters a primary key value for a row in the dataset that matches a primary key value from a row in the results returned by **SelectCommand**, it updates the existing row with the information from the row returned by **SelectCommand** and sets the **RowState** property of the existing row to **Unchanged**. If a row returned by **SelectCommand** has a primary key value that does not match any of the primary key values of the rows in the dataset, the **Fill** method adds a new row with a **RowState** of **Unchanged**.

Note
If **SelectCommand** returns the results of an OUTER JOIN, the **DataAdapter** object does not set a PrimaryKey value for the r esulting **DataTable** object. You must define the PrimaryKey yourself to ensure that duplicate rows are resolved correctly.

To handle exceptions that might occur when you call the **Update** method, you can use the **RowUpdated** event to respond to row update errors as they occur, or you can set **DataAdapter.ContinueUpdateOnError** to **true** before calling **Update**, and respond to the error information stored in the **RowError** property of a particular row when the update is complete.

Note
Calling **AcceptChanges** on the **DataSet**, **DataTable**, or **DataRow** objects causes all Original values for a data row to be ove rwritten with the Current values for the data row. If the field values that identify the row as unique have been modified, after you call **AcceptChanges**, the Original values no longer match the values in the data source.

Working with Auto-Incrementing Columns

If the tables from your data source have auto-incrementing columns, you can fill the columns in your dataset either by returning the auto-increment value as an output parameter of a stored procedure and mapping that to a column in a table, or by using the **RowUpdated** event of the **MsDb2DataAdapter**.

However, the values in your dataset can become out of sync with the values at the data source and result in unexpected behavior. For example, consider a table that has an auto-incrementing primary key column of CustomerID. If you add two new customers within the dataset, they receive auto-incremented CustomerId values of 1 and 2. When the second customer row is passed to the **Update** method of **MsDb2DataAdapter**, the newly added row receives an auto-incremented CustomerID value of 1 at the data source, which does not match the value, 2, in the dataset. When the **MsDb2DataAdapter** fills the row in the dataset with the returned value, a constraint violation occurs because the first customer row already has a CustomerID of 1.

To avoid this behavior, we recommend that, when you are working with auto-incrementing columns at a data source and auto-incrementing columns in a dataset, you create the column in the dataset with an AutoIncrementStep of -1 and an AutoIncrementSeed of 0, and also ensure that your data source generates auto-incrementing Identity values starting at 1 and incrementing with a positive step value. As a result, the dataset will generate negative numbers for auto-incremented values that do not conflict with the positive auto-increment values generated by the data source. Another option is to use columns of type **Guid** instead of auto-incrementing columns. The algorithm that generates **Guid** values should never generate the same **Guid** in the dataset as is generated by the data source.

In many circumstances, the order in which changes that are made through the dataset are sent to the data source is important. For example, if a primary key value for an existing row is updated, and a new row has been added with the new primary key value, it is important to process the update before the insert.

You can use the **Select** method of the **DataTable** object to return a **DataRow** array that only references rows with a particular **RowState**. You can then pass the returned **DataRow** array to the **Update** method of the **MsDb2DataAdapter** to process the modified rows. By specifying a subset of rows to be updated, you can control the order in which inserts, updates, and deletes are processed.

Working with the DataAdapter and the DataSet for a DB2 Database

Using Parameters with the DB2 DataAdapter

The **DataAdapter** class has four properties that are used to retrieve data from and update data to the data source: the **SelectCommand** property returns data from the data source; the **InsertCommand**, **UpdateCommand**, and **DeleteCommand** properties are used to manage changes at the data source. You must set the **SelectCommand** property before calling the **Fill** method of the **DataAdapter** object. The **InsertCommand**, **UpdateCommand**, or **DeleteCommand** properties must be set before the **Update** method of the **DataAdapter** is called, depending on what changes were made to the data in the **DataSet**. For example, if rows have been added, you must set the **InsertCommand** property before calling the **Update** method. When **Update** is processing an inserted, updated, or deleted row, the **DataAdapter** object uses the respective **Command** property to process the action. Current information about the modified row is passed to the **Command** object through the **Parameters** collection.

When you are updating a row at the data source, you call the UPDATE statement, which uses a unique identifier to identify the row in the table to be updated. The unique identifier is commonly the value of a primary key field. The UPDATE statement uses parameters that contain both the unique identifier, and the columns and values to be updated.

Specifying the **Parameter** type converts the value of the Parameter to the Managed Provider for DB2 before passing the value to the data source. You may also specify the type of a **Parameter** in a generic fashion by setting the **DbType** property of the **Parameter** object to a particular **DbType**.

ParameterDirection Enumeration Values

The following table shows the values you can use with the **ParameterDirection** enumeration to set the **Direction** of the **Parameter**.

Member name	Description
Input	The parameter is an input parameter. This is the default.
InputOutput	The parameter is capable of both input and output.
Output	The parameter is an output parameter.
ReturnValue	The parameter represents a return value.

SourceColumn and **SourceVersion** may be passed as arguments to the **Parameter** constructor, or set as properties of an existing **Parameter**. The **SourceColumn** is the name of the **DataColumn** from the **DataRow** where the value of the **Parameter** is retrieved. The **SourceVersion** specifies which **DataRow** version the **DataAdapter** uses to retrieve the value.

DataRowVersion Enumeration Values

The following table shows the **DataRowVersion** enumeration values available for use with **SourceVersion**.

Member name	Description
Current	The parameter uses the current value of the column. This is the default.
Default	The parameter uses the DefaultValue of the column.
Original	The parameter uses the original value of the column.
Proposed	The parameter uses a proposed value.

You can control how the values returned from the data source are mapped back to the **DataSet** object by using the **UpdatedRowSource** property of the **Command** object. By setting the **UpdatedRowSource** property to one of the **UpdateRowSource** enumeration values, you can control whether parameters returned by the **DataAdapter** command are ignored or applied to the changed row in the **DataSet** object. You can also specify whether the first returned row (if it exists) is applied to the changed row in the **DataSet** object.

UpdateRowSource Enumeration Values

The following table describes the different values of the **UpdateRowSource** enumeration and how they affect the behavior of a command used with a **DataAdapter** object.

Member name	Description
Both	Both the output parameters and the first row of a returned result set can be mapped to the changed row in the **DataSet**.
ReturnedFirstRecord	Only the data in the first row of a returned result set can be mapped to the changed row in the **DataSet**.
None	Any output parameters or rows of a returned result set are ignored.
OutputParameters	Only output parameters may be mapped to the changed row in the **DataSet**.

Working with the DataAdapter and the DataSet for a DB2 Database

Adding Constraints to a DB2 DataSet

The **Fill** method of the **MsDb2DataAdapter** fills a dataset only with table columns and rows from a data source; though constraints are commonly set by the data source, the **Fill** method does not add this schema information to the dataset by default. To populate a dataset with existing primary key constraint information from a data source, you can either call the **FillSchema** method of the **MsDb2DataAdapter**, or set the **MissingSchemaAction** property of the **MsDb2DataAdapter** to **AddWithKey** before calling **Fill**. This ensures that primary key constraints in the dataset reflect those at the data source. Foreign key constraint information is not included and must be created explicitly.

Adding schema information to a **DataSet** object before filling it with data ensures that primary key constraints are included with the **DataTable** objects in the **DataSet** object. As a result, when additional calls to fill the **DataSet** are made, the primary key column information is used to match new rows from the data source with current rows in each **DataTable** object, and current data in the tables is overwritten with data from the data source. Without the schema information, the new rows from the data source are appended to the **DataSet**, resulting in duplicate rows.

Note

If a column in a data source is identified as auto-incrementing, the **FillSchema** method, or the **Fill** method with a **MissingSchemaAction** of **AddWithKey**, creates a **DataColumn** with an **AutoIncrement** property set to **true**. However, you must set the **AutoIncrementStep** and **AutoIncrementSeed** values yourself.

Using the **FillSchema** method or setting the **MissingSchemaAction** to **AddWithKey** requires extra processing at the data source to determine primary key column information. This additional processing can hinder performance. If you know the primary key information at design time, we recommend that you explicitly specify the primary key column or columns in order to achieve optimal performance.

If the **MsDb2DataAdapter** encounters multiple result sets returned from the **SelectCommand** property, it creates multiple tables in the dataset. The tables are given a zero-based incremental default name of TableN, starting with Table instead of "Table0". If a table name is passed as an argument to the **FillSchema** method, the tables are given a zero-based incremental name of TableNameN, starting with TableName instead of "TableName0".

Setting up DataTable and DataColumn Mappings for a DB2 Database

An **MsDb2DataAdapter** contains a collection of zero or more **DataTableMapping** objects in its **TableMappings** property. A **DataTableMapping** object provides a master mapping between the data returned from a query against a data source, and a **DataTable** object. The **DataTableMapping** name can be passed instead of the **DataTable** name to the **Fill** method of the **MsDb2DataAdapter**.

A **DataTableMapping** object enables you to use column names in a **DataTable** object that are different from those in the database. The **MsDb2DataAdapter** uses the mapping to match the columns when the table is updated.

If you do not specify a **TableName** or a **DataTableMapping** name when calling the **Fill** or **Update** method of the **MsDb2DataAdapter**, the **MsDb2DataAdapter** looks for a **DataTableMapping** named "Table". If that **DataTableMapping** does not exist, the **TableName** of the **DataTable** object is "Table". You can specify a default **DataTableMapping** by creating a **DataTableMapping** with the name of "Table".

When the **Fill** method is passed an instance of a **DataSet** and a **DataTableMapping** name, and if a mapping with that name exists, it is used; otherwise, a **DataTable** object with that name is used.

Note

If a source column name is not supplied for a column mapping, or a source table name is not supplied for a table mapping, d efault names are automatically generated. If no source column is supplied for a column mapping, the column mapping is giv en an incremental default name of SourceColumnN, starting with SourceColumn1. If no source table name is supplied for a t able mapping, the table mapping is given an incremental default name of SourceTableN, starting with SourceTable1.

Note

We recommend that you avoid the naming convention of SourceColumnN for a column mapping, or SourceTableN for a tabl e mapping, because the name you supply may conflict with an existing default column mapping name in the **ColumnMappi ngCollection** or table mapping name in the **DataTableMappingCollection**. If the supplied name already exists, an excepti on is thrown.

If **SelectCommand** returns multiple tables, **Fill** automatically generates table names with incremental values for the tables in the dataset, starting with the specified table name and continuing on in the form TableNameN, starting with TableName1. You can use table mappings to map the automatically generated table name to a name you want specified for the table in the dataset.

Using the Managed Provider for DB2

How to Perform Transactions with a DB2 Database

Transactions are a group of database operations combined into a logical unit of work, and are used to control and maintain the consistency and integrity of each database despite errors that might occur in the system. A transaction consists of a series of SQL SELECT, INSERT, UPDATE, or DELETE statements. If no errors occur during a transaction, all modifications in the transaction become a permanent part of the database. If errors occur, none of the modifications are made to the database.

A transaction is considered to be a local transaction when it is a single-phase transaction and is handled by the database directly. Transactions are considered to be distributed transactions when they are coordinated by a transaction monitor and use fail-safe mechanisms (such as two-phase commit) for transaction resolution.

Note
Transactions are most efficient when they are performed on the server. If you are working with a SQL Server database that m akes extensive use of explicit transactions, you should consider writing them as stored procedures using the Transact-SQL BE GIN TRANSACTION statement.

You control transactions with the **MsDb2Connection** object. You can initiate a local transaction with the **BeginTransaction** method. Once you have begun a transaction, you can enlist a command in that transaction with the **Transaction** property of an **MsDb2Command** object. You can then commit or roll back modifications made at the data source based on the success or failure of the components of the transaction.

There are three basic commands for transactions: BEGIN, COMMIT, and ROLLBACK. The BEGIN statement marks the beginning of a transaction. All procedures attempted after the BEGIN statement are considered part of the transaction, which is completed by the COMMIT statement, or canceled by the ROLLBACK statement.

To perform a transaction

1. Call **MsDb2Connection.BeginTransaction** to mark the start of the transaction.

   BeginTransaction returns a reference to the transaction. Retain this reference so that you can assign it to commands that are enlisted in the transaction.

2. Assign the transaction to the **MsDb2Command.Transaction** to be executed.

   If a command is executed on a connection with an active transaction and the **Transaction** object has not been assigned to the **Transaction** property of the **Command**, an **MsDb2Exception** is thrown.

3. Execute the required commands.

4. Call **MsDb2Transaction.Commit** to complete the transaction, or call **MsDb2Transaction.Rollback** to cancel the transaction.

   If the connection is closed or disposed before either the **Commit** or **Rollback** methods have been executed, the transaction is rolled back.

The following code example demonstrates how to perform a transaction.

```
static void TransactionConnection()
{
    MsDb2Connection myConnection new MsDb2Connection(@"file name=HOST.udl ");
    myConnection.Open();
    // Start a local transaction.
    MsDb2Transaction myTrans = myConnection.BeginTransaction();
    // Enlist the command in the current transaction.
    MsDb2Command myCommand = myConnection.CreateCommand();
    myCommand.Transaction = myTrans;
    try
    {
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (1
00, 'Description')";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (1
01, 'Description')";
        myCommand.ExecuteNonQuery();
```

```
            myTrans.Commit();
            Console.WriteLine("Both records are written to database.");
        }
        catch(Exception e)
        {
            try
            {
               myTrans.Rollback();
            }
            catch (MsDb2Exception ex)
            {
                if (myTrans.Connection != null)
                {
                    Console.WriteLine("An exception of type " + ex.GetType() +
                        " was encountered while attempting to roll back the transaction.");
                }
            }

            Console.WriteLine("An exception of type " + e.GetType() +
                "was encountered while inserting the data.");
            Console.WriteLine("Neither record was written to database.");
        }
        finally
        {
            Console.ReadLine();
            myConnection.Close();
        }
    }
    // End TransactionConnection
```

Using the Managed Provider for DB2

How to Perform a Two-Phase Commit Transaction over TCP/IP

Two-phase commit (2PC) is a host server-installed protocol that ensures that updates to multiple instances of a database on a network either succeed or fail in their entirety. Host Integration Server 2009 supports 2PC over TCP/IP, enabling you to gain the security of a 2PC connection over the Internet.

Host Integration Server supports 2PC works using three components: the Microsoft Distributed Transaction Coordinator (DTC), the Resync service, and the transaction log. The DTC governs the normal DTC transaction flow: enlist, prepare, commit, and abort. The Resync service coordinates transaction recovery in case of any failure or disconnection, while the transaction log maintains a log of information that is needed in case of recovery.

You can perform a 2PC transaction with ADO.NET and the Managed Provider for DB2 by using the **System.EnterpriseServices** namespace. Using a 2PC transaction is automatic. However, you may need to configure your 2PC connection by using tools such as the Data Access Tool.

Example

The following code example demonstrates how to use 2PC in a DB2 transaction.

```
Public class CentralBank : ServicedComponent
{
   public CentralBank()
   {
   }

   public void Transfer(string connString, int fromId, int toId, double amount)
   {
      MsDb2Connection conn = null;
      MsDb2Command cmd = null;
      int rowsAffected = 0;
      try
      {
         conn = new MsDb2Connection(connString);
         conn.Open();

         cmd = new MsDb2Command();
         cmd.Connection = conn;
         cmd.CommandText = "UPDATE ACCOUNTS SET BALANCE = BALANCE + ?
WHERE ID = ?";
         cmd.Parameters.Add("balance", amount);
         cmd.Parameters.Add("toId", toId);
         rowsAffected = cmd.ExecuteNonQuery();
         cmd.Parameters.Clear();
         cmd.CommandText = "UPDATE ACCOUNTS SET BALANCE = BALANCE - ?
WHERE ID = ?";
         cmd.Parameters.Add("balance", amount);
         cmd.Parameters.Add("fromId", fromId);
         rowsAffected = cmd.ExecuteNonQuery();
         ContextUtil.SetComplete();
      }
      catch(MsDb2Exceptionsqlca)
      {
         Console.WriteLine(sqlca.Message);
         ContextUtil.SetAbort();
      }
      finally
      {
         if(cmd != null)
            cmd.Dispose();
         if(conn != null)
         {
            if(conn.State == ConnectionState.Open)
               conn.Close();
            conn.Dispose();
         }
      }
```

```
        }
    }
```

Using the Managed Provider for DB2

Obtaining Schema Information from the Managed Provider for DB2

You can obtain schema information from a database by using *schema discovery*. Schema discovery enables applications to request that managed providers find and return information about the database schema, also known as *metadata*, of a given database. Different database schema elements such as tables, columns, and stored-procedures are exposed through schema collections. Each schema collection contains a variety of schema information specific to the provider that is being used.

The Managed Provider for DB2 implements **MsDb2Connection.GetSchema**. The schema information returned from **GetSchema** comes in the form of a **DataTable** object. **GetSchema** provides optional parameters for specifying the schema collection to return, and restricting the amount of information returned.

In This Section

Working with the Managed Provider for DB2 GetSchema Methods

Understanding the Schema Collections for the Managed Provider for DB2

Working with the Managed Provider for DB2 GetSchema Methods

The **Connection** classes in the Managed Provider for DB2 implement a **GetSchema** method, which is used to retrieve schema information about the database that is currently connected, and the schema information returned from the **GetSchema** method comes in the form of a **DataTable** object. The **GetSchema** method is an overloaded method that provides optional parameters for specifying the schema collection to return, and restricting the amount of information that is returned.

Specifying the DB2 Schema Collections

The first optional parameter of the **GetSchema** method is the collection name, which is specified as a string. There are two types of schema collections: common schema collections that are common to all providers, and specific schema collections, which are specific to each provider.

To determine the list of supported schema collections

1. Call **GetSchema** to determine a list of supported schema collections.

   You can call **GetSchema** with no arguments, or with the schema collection name "MetaDataCollections. This returns a **DataTable** object with a list of the supported schema collections, the number of restrictions that they each support, and the number of identifier parts that they use.

Specifying the Restriction Values for a DB2 Schema Collection

The second optional parameter of the **GetSchema** method is the restrictions that are used to limit the amount of schema information returned, and it is passed to the **GetSchema** method as an array of strings. The position in the array determines the values that you can pass, and this is equivalent to the restriction number.

Note
The number of elements in the array must be less than or equal to the number of restrictions supported for the specified sch ema collection, or an **ArgumentException** is thrown. There can be fewer than the maximum number of restrictions. The mis sing restrictions are assumed to be null (unrestricted).

To determine the list of supported restrictions

1. Call the **GetSchema** method with the name of the restrictions schema collection, which is "Restrictions".

   This returns a **DataTable** object with a list of the collection names, restriction names, default restriction values, and restriction numbers.

Obtaining Schema Information from the Managed Provider for DB2

Understanding the Schema Collections for the Managed Provider for DB2

The following tables describe the schema collections that are implemented by the Managed Providers for DB2. You can query the Managed Provider for DB2 to determine the list of supported schema collections by calling the **GetSchema** method with no arguments, or with the schema collection name "MetaDataCollections". This returns a **DataTable** object with a list of the supported schema collections, the number of restrictions that they each support, and the number of identifier parts that they use. These collections describe all of the required columns. If a provider cannot determine the value of a required column, it returns **null**.

Common Schema Collections

- MetaDataCollections
- DataSourceInformation
- DataTypes
- Restrictions
- ReservedWords

Provider-Specific Collections

- Tables
- Columns
- Procedures
- ProcedureParameters
- Incexes
- PrimaryKeys
- ForeignKeys
- TablePrivileges
- Statistics

Getting Started with the Managed Provider for DB2 Tutorial

Before you start the Managed Provider for DB2 tutorial, make sure to perform the following actions:

1. Install Visual Studio 2005
2. Ensure IIS is installed and ASP.NET 2.0 is configured.
3. Install Host Integration Server.
4. Ensure you have access to a DB2 instance with permissions to query and modify data.

Tasks

Step 1: Configuring a Connection to DB2

Other Resources

Managed Provider for DB2 Tutorial

Step 1: Configuring a Connection to DB2

The first step you need to perform is to create and configure a connection string to your DB2 data source. Once you are finished creating the string, you will use the string to create an XML web service.

To create the connection string

1. Start the Data Access Tool by clicking on **Start**, then **Programs**, then **Microsoft Host Integration Server 2009**, and then click **Data Access Tool**.
2. On the Data Access Tool, click **File**, select **New**, click **Data Source...**, and then click **Next**.
3. On the Data Source page, select your data source platform and network type, and then click **Next**.

   For the purpose of this tutorial, we will select DB2/MVS from **Data source platform**, and TCP/IP as a **Network type**.
4. On the TCP/IP Network Connection page, enter the IP address or alias of your DB2 source into the **Address or alias** field, and enter the port number of your DB2 source into the **Port** field.
5. Ensure the **Distributed Transactions** box is unchecked, and then click **Next**.
6. On the DB2 Database page, fill in the **Initial Catalog**, **Package collection**, **Default schema**, and **Default qualifier** fields with the information relevant to your database, and then click **Next**.
7. On the Locale page, confirm that the locales are correct for your system, and then click **Next**.
8. On the Security page, select Interactive Sign-On from the **Security Method** drop-down box, enter your user name and password in the **Properties** fields, and then click **Next**.
9. On the Advanced Options page, confirm that no options are checked, and then click **Next**.
10. On the Validation page, click **Connect** to connect to your database using the information you provided, and click **Sample Query** to send a sample query to your DB2 database.

    Once you confirm that your information is correct, click **Next**.
11. On the Saving Information page, check the **Initialization string file** box, enter a data source name in the **Data source name** field, and then click **Next**.
12. On the Completing the Data Source Wizard, click **Finish**.

To view the connection string

1. Click **Start**, and then click **Run...**.
2. In the **Run** dialog, type **Notepad** in the **Open:** field, and then click **OK**.
3. In Notepad, click **File**, and then click **Open...**.
4. Use the Open dialog to browse to the .txt file that contains the connection string information for the data source.

   For this tutorial, the file name is HIS_TRAINING.txt, and is located in c:\Documents and Settings\username\My Documents\Host Integration Projects\Data Sources.

Tasks

Step 2: Creating an XML Web Service

Other Resources

Managed Provider for DB2 Tutorial

Step 2: Creating an XML Web Service

Once you have created the connection string to your DB2 database, you can create the XML web service. Once you have created the service, you can add the service to the project.

To create the XML web service

1. In Visual Studio, click File, select New, and then click Project...
2. In the New Project dialog, in the **Project types:** pane, click on Other Project Types, and then select Visual Studio Solutions.
3. In the **Templates** pane, confirm that Blank Solution is selected.
4. Type **HISTraining** in the **Name** field, and then click **OK**.

To add code to the web service

1. In Solution Explorer, right-click HISTraining, select **Add...**, and then click **New Project**.
2. In the Add New Project dialog, in the **Project types:** pane, click **Other Languages**, and then select **Visual Basic**.
3. In the **Templates:** pane, select **Class Library**.
4. In the **Name** field, type **DB2DAL**, and then click **OK**.
5. In Solution Explorer, right-click DB2DAL, select **Add...**, and then click **Add Reference...**.
6. In the Add Reference dialog, on the **.NET** tab, select Microsoft.HostIntegration.MsDb2Client, and then click **OK**.
7. Add the following code to your Class1.vb file:

```
Imports Microsoft.HostIntegration.MsDb2Client
Public Class DB2DAL
    Public Function executeSQL(ByVal sqlQuery As String, ByVal connString As String) A
s DataSet
        Dim db2Conn As New MsDb2Connection(connString)
        Dim db2Cmd As New MsDb2Command(sqlQuery, db2Conn)
        Dim db2DA As New MsDb2DataAdapter(db2Cmd)
        Dim returnDS As New DataSet
        db2Conn.Close()
        db2DA.Fill(returnDs)
        db2Conn.Close()
        Return returnDS
    End Function
End Class
```

8. On the **Build** menu, click **Build Solution**.
9. On the **File** menu, click **Save All**.

Tasks

Step 3: Adding a Web Service to the Project

Other Resources

Managed Provider for DB2 Tutorial

Step 3: Adding a Web Service to the Project

Once you have created the XML web service, you can add the web service to your project. Once you have added the web service, you can start the application.

To add a web service to the project

1. In the Solution Explorer, right-click HISTraining, select **Add...**, and then click **New Web Site**.
2. In the Add New Web Site dialog, select ASP.NET Web Service.
3. In the Location drop-down box, select HTTP, and enter **http://localhost/DB2WebService** to the field, and then click OK
4. In Solution Explorer, right-click **http://localhost/DB2WebService**, and then click **Add Reference...**.
5. In the Add Reference dialog, on the **Projects** tab, select DB2DAL, and then click OK.
6. In Solution Explorer, expand **http://localhost/DB2WebService**, expand App_Code, and double-click Service.vb.
7. Add the following code to Service.vb

```
Imports System.Web
Imports System.Web.Services
Imports System.Web.Services.Protocols

<WebService(Namespace:="http://tempuri.org/")> _
<WebServiceBinding(ConformsTo:=WsiProfiles.BasicProfile1_1)> _
<Global.Microsoft.VisualBasic.CompilerServices.DesignerGenerated()> _
Public Class Service
     Inherits System.Web.Services.WebService

    <WebMethod()> _
    Public Function executeSQLQuery(ByVal connstring As String, ByVal sqlStatement As
String) As Data.DataSet
        Dim dal As New DB2DAL.DB2DAL
        Return dal.executeSQL(sqlStatement, connstring)
    End Function

End Class
```

8. On the **Build** menu, click **Build Solution**.
9. On the File menu, click **Save All**.

Managed Data Provider for Host Files Programmer's Guide

This section describes the general architecture and implementation details of the Managed Provider for Host Files. The Managed Provider for Host Files enables a client to connect to a remote host file system, read and write data from the host file system using a managed framework, exposes bulk file transfer, and enables remote commands to the host.

In This Section

Managed Data Provider for Host Files

This section contains a discussion about the background and general design principles surrounding the Managed Data Provider for Host Files.

In This Section

Goals for the Managed Data Provider for Host Files

The primary purpose of the Managed Data Provider for Host Files is to enable developers to access files and data structures on mid-range and mainframe systems using the Microsoft .NET Framework. This differs from the Managed Provider for DB2, which enables developers to access host DB2 recordsets.

The Managed Data Provider for Host files was designed with the following capabilities in mind:

- Granting developers access to the file system commands of mid-range and mainframe systems. By exposing the file system commands, a developer can perform such activities as setting record attributes, locking files and records, navigating between records, and modifying file contents. Such activities are exposed primarily through the Managed Provider for Host Files interface.

- Granting access to the file commands of the most popular mid-range and mainframe file server systems. In doing so, developers familiar with AS/400 input and output commands can use their knowledge to access mid-range file systems. This differs from the Managed Provider for DB2, which allows developers familiar with SQL to use that knowledge to access DB2/400 tables.

- Improving the bulk transfer rate between systems.

Using the Managed Data Provider For Host Files

How to Create a Project in Visual Studio for the Managed Provider for Host Files

Host Integration Server 2009 provides a specific way to create a project that uses the Managed Provider for Host files.

To create a project in Visual Studio using the Managed Provider for Host Files

1. In Visual Studio, on the **File** menu, point to **New**, and then click **Project**.
2. In the **New Project** dialog box, in the **Project Types** pane, click **Host Integration Projects**.
3. In the **Templates** pane, click **Host File Project**.
4. In the **Name** field, type the name of the file.
5. In the **Location** field, type the location to save the project.
6. Click **OK** to create the project.

How to Create an Assembly for the Managed Data Provider for Host Files

Once you have finished defining a remote environment for your application, you can use Visual Studio to create the application assembly. Host Integration Server provides a variety of wizards and tools to help you in this process:

1. Create a Host File project.
2. Add one or more .NET client libraries to the project that will contain your application.
3. Create the interfaces for your application using Host Integration Server Designer.

   HIS Designer enables you to create interfaces that represent data and methods native to your host environment. By programming towards these interfaces, you can pass information and commands through Host Integration Server and onto the mainframe.

After you create the assembly, you can deploy your assembly to your local computer and test the interfaces against your code.

To create an application assembly that uses the Managed Provider for Host Files

1. Start Visual Studio.
2. Click **File**, then **New**, and then click **Project**.
3. In the **New Project** dialog box, in the **Project types:** pane, click on Host Integration Projects.
4. In the **Templates** pane, click **Host File Project**.
5. In the **Name** field, type the name of your project.
6. In the **Location** field, type the location to save your project, and then click **OK**.

To add an assembly to your project

1. Click **Project**, and then click **Add .NET Client Library**.

   The Managed Provider for Host Files supports .NET only.
2. On the **Add New Item** dialog box, in the **Templates** pane, confirm that .NET Client Library is highlighted.
3. In the **Name:** field, type the name of the assembly, and then click **Add**.
4. On the **Welcome to the .NET Client Library Wizard** page, click **Next**.
5. On the **Completing the .NET Client Library Wizard** page, confirm that the displayed settings are correct, and then click **Create**.

To define interfaces using the HIS Designer

1. If you do not have a Host Definition file (.hcd) file available, you can use the **Import COBOL Wizard** or the **Import RPG Wizard** to define your interfaces.

   For more information, see How to Import COBOL into a TI Component.
2. If you have a previous .NET client library that you want to base your new object on, you can use the Import Library tool to import the library into your project.

   For more information, see How to Import a TI Component.
3. If you want to manually create or modify the interface definitions, you can do so using the console tree of HIS Designer.

Creating an Application for the BizTalk Adapter for Host Applications

How to Deploy an Assembly for the Managed Data Provider for Host Files

Once you have created the assembly that contains your code, you can deploy the assembly to your local computer. Deploying the assembly registers the assembly with Host Integration Server and Transaction Integrator, and loads the assembly into the appropriate location to be used. After you deploy the assembly, you can test the interfaces and the code that you wrote. You can then undeploy the assembly, modify the code, and redeploy as necessary.

To deploy and undeploy an assembly to your local machine

1. In HIS Designer, select the tab that has the name of the assembly to deploy.
2. In the **Properties** window, confirm that you have selected the remote environment that you want your assembly to communicate with.
3. In the HIS tree node, right-click the name of the assembly, and select **Deploy**.
4. Test your application as necessary.
5. When you are finished, you may undeploy your assembly by right-clicking the assembly name in HIS Designer, and selecting **UnDeploy**.

Creating an Application for the BizTalk Adapter for Host Applications

How to Connect to and Disconnect from a Host File System

The first step in accessing a host file system is to connect to the file system. You must use **HostFileConnection** to access the host file system. After you have connected, you can retrieve, modify, and update the information that you want.

Procedure
To connect and disconnect to a Host File System

1. Create a **HostFileConnection** object, using the connection string that describes the Host system.
2. Open a connection with a call to **HostFileConnection.Open**.
3. Interact with the host file system as necessary.
4. When you are finished, release the **HostFileConnection** object with a call to **HostfileConnection.Close** and **HostFileConnection.Dispose**.

   Connections are not implicitly released when a **HostFileConnection** falls out of scope. Therefore, you need to release the object when you are finished using it.

Example

The following very simple code example shows how to use **HostFileConnection** to open and close a connection.

```
try
   {
      HostFileConnection cn = new HostFileConnection();
      cn.ConnectionString = cnstring;
      cn.Open();
      // Perform tasks here.
      cn.Close();
      cn.Dispose();
   }
```

Using the Managed Data Provider For Host Files
BizTalk Adapter for Host Files

How to Execute Commands in the Host File System

After establishing a connection to a data source, you can execute commands and return results from the data source using **HostFileCommand**.

Important
The Managed Provider for Host Files does not support any type of transaction. Therefore, you should try to avoid using INSERT, UPDATE, or DELETE commands on mission-critical data.

Procedure
To execute a command on the host file system

1. Establish a connection using **HostFileConnection**.

   For more information, see How to Connect to and Disconnect from a Host File System.

2. Once connected, create a **HostFileCommand** object by using **HostfileConnection.CreateCommand**.

3. Use the **HostFileCommand** object to execute commands on the Host File system.

   HostFileCommand exposes several Execute methods that you can use:

   - When returning results as a stream of data, use **ExecuteDbDataReader** to return a **DataReader** object.
   - Use **ExecuteScalar** to return a singleton value.
   - Use **ExecuteNonQuery** to execute commands that do not return rows.
   - Use **ExecuteRecordSet** to execute commands on a recordset.

Note
When modifying an Alternate Index File (AIX), you may receive an "Invalid record length" error when the Index is defined not to accept duplicate keys. This error may occur because the INDEX of the Alternate Index VSAM file is not large enough to hold multiple key values for the same index record .

Using the Managed Data Provider For Host Files

BizTalk Adapter for Host Files

How to Retrieve Data from the Host File System

Just as you can do with other managed data providers, you can access host data with an implementation of a **DataReader** object through **HostfileCommand**.

To retrieve data using a data reader

1. Create an instance of **HostFileCommand**.
2. Create a **DataReader** object through a call to **HostFileCommand.ExecuteDBDataReader**.

   Calling **ExecuteDBDataReader** retrieves data rows from the data source.
3. Use **DBDataReader.Read** to obtain a row from the results of the query.

   You can access each column of the returned row by passing the name or ordinal reference of the column to the **DBDataReader** object. However, for best performance, the **DBDataReader** object provides a series of methods that enable you to access column values in their native data types (**GetDateTime**, **GetDouble**, **GetGuid**, **GetInt32**, and so on).
4. Once you are finished with the **DBDataReader** object, call **DBDataReader.Close**.

   If your **HostFileCommand** object contains output parameters or return values, they will not be available until the **DBDataReader** is closed.

   Note that while **DBDataReader** is open, the **HostFileConnection** is in use exclusively by that **DBDataReader**. You cannot execute any commands for the **HostFileConnection**, including creating another **DBDataReader**, until the original **DBDataReader** is closed.

Retrieving Information from the Host File System
BizTalk Adapter for Host Files

How to Retrieve Schema Sets from the Host File System

When a **HostFileConnection** is open, you can retrieve schema information about the target data by using the **GetSchema** method. **GetSchema** returns a **DataTable** object populated with the rows and columns that contain the schema information of the target of the current connection.

In addition, while a **DBDataReader** is open, you can retrieve schema information about the current result set by using the **GetSchemaTable** method. **GetSchemaTable** returns a **DataTable** object populated with rows and columns that contain the schema information for the current result set. The **DataTable** object contains one row for each column of the result set. Each column of the schema table row maps to a property of the column returned in the result set, where the **ColumnName** is the name of the property and the value of the column is the value of the property.

To retrieve schema sets from the host file system

1. Open a connection to the host file system with a call to **HostFileConnection**.
2. Call **HostfileConnection.GetSchema** to retrieve the schema data.

Example

The following code example demonstrates how to retrieve the schema sets from a connection object. Note that the ETCMLogging and HostFileUtils objects are developer-created objects that provide logging and utility functionality.

```
public void CNGetSchema(ETCMLogging.Logging logging, string host, string ccsid, string cnst
ring, HostFileUtils.Utils.HostFileType hostfiletype)
        {
            HostFileUtils.Oledb oledb = new HostFileUtils.Oledb();
            HostFileUtils.Utils u = new HostFileUtils.Utils();
            logging.LogInfo(host);
            try
            {
                // Create connection.
                HostFileConnection cn = oledb.CreateConnection(logging);
                cn.ConnectionString = cnstring;
                DataTable dt = cn.GetSchema();
                if (dt.HasErrors)
                {
                    logging.LogFail("returned datatable has errors");
                }
                // Open the connection.
                logging.LogInfo("Open Connection");
                cn.Open();
                DataTable dt2 = cn.GetSchema();
                if (dt2.HasErrors)
                {
                    logging.LogFail("returned datatable has errors");
                }
                int rowcnt = dt.Rows.Count;
                for (int i = 0; i < rowcnt; i++)
                {
                    int colcnt = dt.Rows[i].ItemArray.Length;
                    for (int o = 0; o < colcnt; o++)
                    {
                        u.CompareValues(dt.Rows[i][o].ToString(), dt2.Rows[i][o].ToString()
, logging);
                    }
                }
                // Close the open connection.
                cn.Close();
            }
            catch (Exception e)
            {
                logging.LogInfo(e.Message);
                logging.LogFail(e.StackTrace);
            }
        }
```

How to Obtain a Single Value from a Host File System

You might need to return database information that is just a single value rather than in the form of a table or data stream. For example, you might want to return the result of an aggregate function such as COUNT(*), SUM(Price), or AVG(Quantity).

To obtain a single value from the Host File System

1. Make a call to **HostFileCommand.ExecuteScalar**.

   ExecuteScalar returns a scalar value: the value of the first column of the first row of the result set.

Working with the Host File Adapter and Dataset

A **HostFileDataAdapter** is used to retrieve data from a data source and populate tables within a dataset. The **HostFileDataAdapter** also resolves changes made to the dataset back to the data source. The **HostFileDataAdapter** uses the **HostFileConnection** object to connect to a data source, and it uses **HostFileCommand** objects to retrieve data from and resolve changes to the data source.

In This Section

Using the Managed Data Provider For Host Files

BizTalk Adapter for Host Files

How to Populate a Host File Dataset from the Data Adapter

The dataset is a memory-resident representation of data that provides a consistent relational programming model independent of the data source. The dataset represents a complete set of data including tables, constraints, and relationships among the tables. Because the dataset is independent of the data source, a dataset can include data local to the application, and also data from multiple data sources. Interaction with existing data sources is controlled through the **DataAdapter** object.

The **HostfileDataAdapter.SelectCommand** property is a **HostFileCommand** object that retrieves data from the data source. The **HostFileDataAdapter.Fill** method is used to populate a dataset with the results of the **SelectCommand**. **Fill** takes as its arguments a **DataSet** object to be populated, and a **DataTable** object, or the name of the **DataTable** to be filled with the rows returned from the **SelectCommand**.

The **Fill** method uses the **HostFileDataReader** object implicitly to return the column names and types used to create the tables in the **DataSet** object, and also the data to populate the rows of the tables in the **DataSet** object. Tables and columns are only created if they do not already exist; otherwise **Fill** uses the existing **DataSet** schema. Primary keys are not created unless they are in the data source, and **HostFileDataAdapter.MissingSchemaAction** is set to **MissingSchemaAction.AddWithKey**. If **Fill** finds that a primary key exists for a table, it overwrites data in the **DataSet** object with data from the data source for rows where the primary key column values match those of the row returned from the data source. If no primary key is found, the data is appended to the tables in the **DataSet** object. **Fill** uses any mappings that might exist when populating the **DataSet** object.

If the **HostFileDataAdapter** encounters multiple result sets, it creates multiple tables in the **DataSet** object. The tables are given an incremental default name of TableN, starting with "Table" for Table0. If a table name is passed as an argument to the **Fill** method, the tables are given an incremental default name of TableNameN, starting with "TableName" for TableName0.

You can use any number of **HostFileDataAdapter** objects with a **DataSet** object. Each **DataAdapter** object can be used to fill one or more **DataTable** objects and resolve updates back to the relevant data source. You can add **DataRelation** and **Constraint** objects to the **DataSet** locally, enabling you to relate data from dissimilar data sources. One or more **DataAdapter** objects can handle communication to each data source.

To populate a host file dataset from the data adapter

1. Create a new connection to your data source by using **HostFileConnection**.
2. Open the connection by using **HostFileConnection.Open**.
3. Create a SELECT command that describes the data to retrieve with **HostFileCommand**.
4. Create a **HostFileDataAdapter** using **HostFileConnection** to interact with the stored data.
5. Create a **DataSet** object to store the data locally.
6. Retrieve the data through the **HostFileDataAdapter** using the **DataSet** object and the **Fill** command.

Example

The following code example shows how to fill a dataset through a **HostFileDataAdapter**. In this example, the ETCMLogging and HostFileUtils objects supply logging and utility functionality, respectively.

```
public void HFDAdapterCommandConstructor(ETCMLogging.Logging logging, string host, string c
csid, string cnstring, HostFileUtils.Utils.HostFileType hostfiletype)
        {
            HostFileUtils.Utils u = new HostFileUtils.Utils();
            logging.LogInfo(host + "::" + hostfiletype.ToString());
            HostFileUtils.Utils.MytestsVals[] Datavals = u.InitMytestsVals();

            try
            {
                HostFileConnection cn = new HostFileConnection(cnstring);
                cn.Open();
                String SELECT = u.CreateSQLCommand(host, hostfiletype, cnstring, "SELECT",
"MYTEST");
                HostFileCommand hfc = new HostFileCommand(SELECT, cn);
                HostFileDataAdapter hfda = new HostFileDataAdapter(hfc);
                DataSet ds = new DataSet();
                hfda.Fill(ds);
                int[] cp = u.CheckColumns(SELECT, cn, logging);
```

```
                u.ValidateDataSet(ds, logging, Datavals, cp);

                cn.Close();
            }
            catch (Exception e)
            {
                logging.LogInfo(e.Message);
                logging.LogFail(e.StackTrace);
            }
        }
```

In this code example, the **HostFileUtils** object and the *cnstring* and *ccsid* parameters enable you to quickly create a test SQL command with the relevant information.

How to Update the Host File System with the Data Adapter

HostFileDataAdapter.Update is called to resolve changes from a **DataSet** object back to the data source. The **Update** method, like the **Fill** method, takes an instance of a **DataSet** as an argument.

To update the host file system with the data adapter

1. Create a **DataSet** object that contains the information that you want to update.

   Or, you can overwrite the data of an existing **DataSet** object with a call to **DataSet.AcceptChanges**.

   Note that calling **AcceptChanges** on the **DataSet**, **DataTable**, or **DataRow** object causes all Original values for a **DataRow** object to be overwritten with the Current values for the **DataRow**. If the field values that identify the row as unique have been modified, after you call **AcceptChanges**, the Original values no longer match the values in the data source.

   In addition, you can use **HostFileCommand** parameters to specify input and output values for a SQL statement for each modified row in a **DataSet** object.

2. Call **HostFileDataAdapter.Update**, with the DataSet object that you want to update.

   When you call the **Update** method, the **HostFileDataAdapter** analyzes the changes that have been made and executes the appropriate command. If **Update** is called and the appropriate command does not exist for a particular update (for example, no **DeleteCommand** for deleted rows), an exception is thrown.

3. If you want to update your dataset with data, call **HostFileDataAdapter.Fill** on your **DataSet** object.

   The **Update** method resolves your changes back to the data source; however other clients may have modified data at the data source since the last time you filled the DataSet. New rows are added to the table, and updated information is incorporated into existing rows.

Example

The following code example demonstrates how to updating a dataset with the **Fill** and **Update** commands. Note that the ETCMLogging and HostFileUtils objects provide logging and utility functionality, respectively.

```
public void BVTHFDataAdapterInsert(ETCMLogging.Logging logging, string host, string ccsid,
string cnstring, HostFileUtils.Utils.HostFileType hostfiletype)
        {
            HostFileUtils.Utils u = new HostFileUtils.Utils();
            logging.LogInfo(host + "::" + hostfiletype.ToString());
            HostFileUtils.Utils.BvttestsVals[] Datavals = u.InitBvttestsVals();

            try
            {
                HostFileConnection cn = new HostFileConnection(cnstring);
                cn.Open();
                String SELECT = u.CreateSQLCommand(host, hostfiletype, cnstring, "SELECT",
"BVTTESTS");
                HostFileDataAdapter hfda = new HostFileDataAdapter(SELECT, cn);
                DataSet ds = new DataSet();
                DataSet dsold = new DataSet();
                hfda.Fill(ds);
                hfda.Fill(dsold);
                int[] cp = u.CheckColumns(SELECT, cn, logging);
                u.ValidateDataSet(ds, logging, Datavals, cp);
                object[] newrow = new object[5];
                // ('REC129-1','REC129-2',129,1290,'129.645')
                newrow[cp[0]] = "REC129-1";
                newrow[cp[1]] = "REC129-2";
                newrow[cp[2]] = 129;
                newrow[cp[3]] = 1290;
                newrow[cp[4]] = 129.645M;
                ds.Tables[0].Rows.Add(newrow);
                int z = hfda.Update(ds);
                if (z != 1)
                {
```

```
                    logging.LogFail("a unexpected number of updates::"+z.ToString());
                }
                DataSet ds1 = new DataSet();
                hfda.Fill(ds1);
                int j = 0;
                int i = 0;
                foreach (DataRow row in ds1.Tables[0].Rows)
                {
                    string rec = (string)ds1.Tables[0].Rows[j][cp[0]];
                    if (!rec.Equals("REC129-1"))
                    {
                        u.CompareValues((string)ds1.Tables[0].Rows[j][cp[0]], Datavals[i].O
UT1_CHAR1, logging);
                        u.CompareValues((string)ds1.Tables[0].Rows[j][cp[1]], Datavals[i].O
UT1_CHAR2, logging);
                        u.CompareValues((short)ds1.Tables[0].Rows[j][cp[2]], Datavals[i].OU
T1_SMALLINT, logging);
                        u.CompareValues((int)ds1.Tables[0].Rows[j][cp[3]], Datavals[i].OUT1
_INTEGER, logging);
                        u.CompareValues((decimal)ds1.Tables[0].Rows[j][cp[4]], Datavals[i].
OUT1_DECIMAL, logging);
                        j++;
                        i++;
                    }
                    else
                    {
                        u.CompareValues((string)ds1.Tables[0].Rows[j][cp[0]], "REC129-1", l
ogging);
                        u.CompareValues((string)ds1.Tables[0].Rows[j][cp[1]], "REC129-2", l
ogging);
                        u.CompareValues((short)ds1.Tables[0].Rows[j][cp[2]], 129, logging);
                        u.CompareValues((int)ds1.Tables[0].Rows[j][cp[3]], 1290, logging);
                        u.CompareValues((decimal)ds1.Tables[0].Rows[j][cp[4]], 129.645M, lo
gging);
                        j++;
                    }
                }
                if (j == 0)
                {
                    logging.LogFail("No Rows on DataTable!");
                }
                z = 0;
                z = hfda.Update(dsold);
                if (z != 1)
                {
                    logging.LogFail("a unexpected number of updates::" + z.ToString());
                }
                DataSet ds2 = new DataSet();
                hfda.Fill(ds2);
                u.ValidateDataSet(ds2, logging, Datavals, cp);

                cn.Close();
            }
            catch (Exception e)
            {
                logging.LogInfo(e.Message);
                logging.LogFail(e.StackTrace);
            }
        }
```

How to Add Constraints to the Host File Dataset

The **HostFileDataAdapter.Fill method** fills a **DataSet** object with table columns and rows from a data source; though constraints are commonly set by the data source, the **Fill** method does not add this schema information to the **DataSet** object by default. To populate a **DataSet** object with existing primary key constraint information from a data source, you can call **HostFileDataAdapter.FillSchema**.

Note
If a **column** in a data source is identified as auto-incrementing, the **FillSchema** method, or the **Fill** method with a **MissingSchemaAction** of **AddWithKey**, creates a **DataColumn** that has an **AutoIncrement** property set to **true**. However, you must set the **AutoIncrementStep** and **AutoIncrementSeed** values yourself.

To populate a dataset with additional key constraints

1. Call **HostFileDataAdapter.FillSchema**, using the targeted **DataSet** and Schema that contains the specified key constraints.

   Adding schema information to a **DataSet** before filling it with data ensures that primary key constraints are included with the **DataTable** objects in the **DataSet** object. As a result, when additional calls to fill the **DataSet** are made, the primary key column information is used to match new rows from the data source with current rows in each **DataTable** object, and current data in the tables is overwritten with data from the data source. Without the schema information, the new rows from the data source are appended to the **DataSet** object, resulting in duplicate rows.

How to Close a Connection with the Host File Adapter

If you create a HostFileDataAdapter object with a connection string, the object will automatically create a connection object. Once you are finished using a host file adapter, you need to dispose of the implicit connection you made. You can use the Dispose and Close commands to do so.

To close the connection created implicitly through a HostFileDataAdapter object

1. Once you are finished with the connection, call HostFileDataAdapter.Dispose() to dispose of the connection.
2. Alternately, you may also call HostFileDataAdapter.SelectCommand.Connection.Close() to close the connection as well.

Example

The following code sample shows how to create a connection through a HostFileDataAdapter object, and how to properly dispose of the connection.

```
try
{
    HostFileDataAdapter hfda = new HostFileDataAdapter(SELECT,"valid connection string");
    DataSet ds = new DataSet();
    hfda.Fill(ds);
    string xml = ds.GetXml();
    Console.WriteLine(xml);
    hfda.Dispose();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}
```

Obtaining Schema Information from the Host File System

You can obtain schema information from a database by using *schema discovery*. Schema discovery enables applications to request that managed providers find and return information about the database schema, also known as *metadata*, of a given database. Different database schema elements such as tables, columns, and stored procedures are exposed through schema collections. Each schema collection contains a variety of schema information specific to the provider that is being used.

The Managed Provider for Host Files implements **HostFileConnection.GetSchema** class, and the schema information that is returned from **GetSchema** comes in the form of a **DataTable** object. **GetSchema** also provides optional parameters for specifying the schema collection to return, and restricting the amount of information returned.

Using the Managed Data Provider For Host Files

BizTalk Adapter for Host Files

Working with the Host File GetSchema Methods

The Managed Provider for Host File **HostFileConnection** class implements a **GetSchema** method, which is used to retrieve schema information about the file system that is currently connected. The schema information that is returned from the **GetSchema** method comes in the form of a **DataTable** object. The **GetSchema** method is an overloaded method that provides optional parameters for specifying the schema collection to return, and restricting the amount of information that is returned.

To retrieve file system schema information

1. Create a **HostFileConnection** object that represents the connection to the host file system.
2. Retrieve the schema information by calling **HostFileConnection.GetSchema**.
    a. The first optional parameter of the **GetSchema** method is the collection name, which is specified as a string. There are two types of schema collections: common schema collections that are common to all providers, and specific schema collections, which are specific to each provider. You can call **GetSchema** either with no parameters, or else with the schema collection name "MetaDataCollections". This returns a DataTable object with a list of the supported schema collections, the number of restrictions that they each support, and the number of identifier parts that they use.

    b. The second optional parameter of the **GetSchema** method is the restrictions that are used to limit the amount of schema information returned, and it is passed to the **GetSchema** method as an array of strings. The position in the array determines the values that you can pass, and this is equivalent to the restriction number.

3. If you want to put a restriction on the Tables schema collection, consider the following:
    a. Create an array of strings with four elements.

    b. Put a value in the element that matches the restriction number.

        For example, to restrict the tables returned by the **GetSchema** method to only those tables that are owned by the "dbo" role, set the second element of the array to "dbo".

    c. Pass the value into your **GetSchema** call.

To determine a list of supported restrictions on a Schema

1. Call **GetSchema** with the first parameter set to "Restrictions".

    This returns a DataTable object with a list of the collection names, the restriction names, the default restriction values, and the restriction numbers.

BizTalk Adapter for Host Files

Common Schema Collections for the Host File System

The common schema collection is the schema collection that is implemented by the Managed Provider for Host Files. You can query the managed provider to determine the list of supported schema collections by calling the **GetSchema** method with no arguments, or with the schema collection name "MetaDataCollections". This returns a **DataTable** object with a list of the supported schema collections, the number of restrictions that they each support, and the number of identifier parts that they use.

The following tables describe the common schema collections for the Host File System.

Columns

Column Name	Data Type	Description
table_catalog	String	Catalog of the table.
table_schema	String	Schema that contains the table.
table_name	String	Table name.
column_name	String	Column name.
ordinal_position	Int16	Column identification number.
column_default	String	Default value of the column
is_nullable	String	Nullability of the column. If this column allows NULL, this column returns YES. Otherwise, No is returned.
data_type	String	System-supplied data type.
character_maximum_length	Int32 – Sql8, Int16 – Sql7	Maximum length, in characters, for binary data, character data, or text and image data. Otherwise, NULL is returned.
character_octet_length	Int32 – SQL8, Int16 – Sql7	Maximum length, in bytes, for binary data, character data, or text and image data. Otherwise, NULL is returned.
numeric_precision	Unsigned Byte	Precision of approximate numeric data, exact numeric data, integer data, or monetary data. Otherwise, NULL is returned.
numeric_precision_radix	Int16	Precision radix of approximate numeric data, exact numeric data, integer data, or monetary data. Otherwise, NULL is returned.
numeric_scale	Int32	Scale of approximate numeric data, exact numeric data, integer data, or monetary data. Otherwise, NULL is returned.
datetime_precision	Int16	Subtype code for datetime and SQL-92 interval data types. For other data types, NULL is returned.
character_set_catalog	String	Returns master, indicating the database in which the character set is located, if the column is character data or text data type. Otherwise, NULL is returned.
character_set_schema	String	Always returns NULL.
character_set_name	String	Returns the unique name for the character set if this column is character data or text data type. Otherwise, NULL is returned.

collation_catalog	String	Returns master, indicating the database in which the collation is defined, if the column is character data or text data type. Otherwise, this column is NULL.

DataSourceInformation

CompositeIdentifierSeparatorPattern	string	The regular expression to match the composite separators in a composite identifier. For example, "\." (for SQL Server) or "@|\." (for Oracle).
		A composite identifier is typically what is used for a database object name, for example: pubs.dbo.authors or pubs@dbo.authors.
		For SQL Server, use the regular expression "\.". For OracleClient, use "@|\.".
		For ODBC use the Catalog_name_seperator.
		For OLE DB use DBLITERAL_CATALOG_SEPARATOR or DBLITERAL_SCHEMA_SEPARATOR.
DataSourceProductName	string	The name of the product accessed by the provider, such as "Oracle" or "SQLServer".
DataSourceProductVersion	string	The version of the product accessed by the provider, in the data sources native format and not in Microsoft format.
		In some cases DataSourceProductVersion and DataSourceProductVersionNormalized are the same value. With OLE DB and ODBC, these are always be the same because they are mapped to the same function call in the underlying native API.
DataSourceProductVersionNormalized	string	A normalized version for the data source, such that it can be compared with **String.Compare()**. The format of this is consistent for all versions of the provider to prevent version 10 from sorting between version 1 and version 2.
		For example, the Oracle provider uses a format of "nn.nn.nn.nn.nn" for its normalized version, which causes an Oracle 8i data source to return "08.01.07.04.01". SQL Server uses the typical Microsoft "n.nn.nnnn" format.
		In some cases, DataSourceProductVersion and DataSourceProductVersionNormalized will be the same value. In the case of OLE DB and ODBC these will always be the same as they are mapped to the same function call in the underlying native API.
GroupByBehavior	GroupBy Behavior	Specifies the relationship between the columns in a GROUP BY clause and the non-aggregated columns in the select list.
IdentifierPattern	String	A regular expression that matches an identifier and has a match value of the identifier. For example "[A-Za-z0-9_#$]".
IdentifierCase	Identifier Case	Indicates whether non-quoted identifiers are treated as case sensitive.
OrderByColumnsInSelect	bool	Specifies whether columns in an ORDER BY clause must be in the select list. A value of true indicates that they are required to be in the select list, a value of false indicates that they are not required to be in the select list.

ParameterMarkerFormat	string	A format string that represents how to format a parameter.
		If named parameters are supported by the data source, the first placeholder in this string should be where the parameter name should be formatted.
		For example, if the data source expects parameters to be named and prefixed with an ':' this would be ":{0}". When formatting this with a parameter name of "p1" the resulting string is ":p1".
		If the data source expects parameters to be prefixed with the '@', but the names already include them, this would be '{0}', and the result of formatting a parameter named "@p1" would just be "@p1".
		For data sources that do not expect named parameters and expect the use of the '?' character, the format string can be specified as just '?', which would ignore the parameter name. For OLE DB we return '?'.
ParameterMarkerPattern	string	A regular expression that matches a parameter marker. It has a match value of the parameter name, if any.
		For example, if named parameters are supported with an '@' lead-in character that will be included in the parameter name, this would be: "(@[A-Za-z0-9_$#]*)".
		However, if named parameters are supported with a ':' as the lead-in character and it is not part of the parameter name, this would be: ":([A-Za-z0-9_$#]*)".
		Of course, if the data source does not support named parameters, this would just be "?".
ParameterNameMaxLength	int	The maximum length of a parameter name in characters. Visual Studio expects that if parameter names are supported, the minimum value for the maximum length is 30 characters.
		If the data source does not support named parameters, this property returns zero.
ParameterNamePattern	string	A regular expression that matches the valid parameter names. Different data sources have different rules regarding the characters that may be used for parameter names.
		Visual Studio expects that if parameter names are supported, the characters "\p{Lu}\p{Ll}\p{Lt}\p{Lm}\p{Lo}\p{Nl}\p{Nd}" are the minimum supported set of characters that are valid for parameter names.
QuotedIdentifierPattern	string	A regular expression that matches a quoted identifier and has a match value of the identifier itself without the quotes. For example, if the data source uses double-quotes to identify quoted identifiers, this would be: "(([^\"]|\"\")*)".
QuotedIdentifierCase	IdentifierCase	Indicates whether quoted identifiers are treated as case sensitive.
StatementSeparatorPattern	string	A regular expression that matches the statement separator.
StringLiteralPattern	string	A regular expression that matches a string literal and has a match value of the literal itself. For example, if the data source used single-quotes to identify strings, this would be: "('([^']|'')*')"'
SupportedJoinOperators	SupportedJoinOperators	Specifies what types of SQL join statements are supported by the data source.

DataTypes

Column Name	Data Type	Description
TypeName	string	The provider-specific data type name.
ProviderDbType	int	The provider-specific type value that should be used when specifying a parameter's type. For example, **SqlDbType.Money** or **OracleType.Blob**.
ColumnSize	long	The length of a non-numeric column or parameter refers to either the maximum or the length defined for this type by the provider.
		For character data, this is the maximum or defined length in units, defined by the data source. Oracle has the concept of specifying a length and then specifying the actual storage size for some character data types. This defines only the length in units for Oracle.
		For date-time data types, this is the length of the string representation (assuming the maximum allowed precision of the fractional seconds component).
		If the data type is numeric, this is the upper bound on the maximum precision of the data type.
CreateFormat	string	Format string that represents how to add this column to a data definition statement, such as CREATE TABLE. Each element in the **CreateParameter** array should be represented by a "parameter marker" in the format string.
		For example, the SQL data type DECIMAL needs a precision and a scale. In this case, the format string would be "DECIMAL({0},{1})".
CreateParameters	string	The creation parameters that must be specified when creating a column of this data type. Each creation parameter is listed in the string, separated by a comma in the order they are to be supplied.
		For example, the SQL data type DECIMAL needs a precision and a scale. In this case, the creation parameters should contain the string "precision, scale".
		In a text command to create a DECIMAL column with a precision of 10 and a scale of 2, the value of the CreateFormat column might be DECIMAL({0},{1})" and the complete type specification would be DECIMAL(10,2).
DataType	string	The name of the .NET Framework type of the data type.
IsAutoincrementable	bool	**true**—Values of this data type may be auto-incrementing.
		false—Values of this data type may not be auto-incrementing.
		Note that this merely indicates whether a column of this data type may be auto-incrementing, not that all columns of this type are auto-incrementing.
IsBestMatch	Bool	**true**—The data type is the best match between all data types in the data store and the .NET Framework data type indicated by the value in the DataType column.
		false—The data type is not the best match.

		For each set of rows in which the value of the DataType column is the same, the IsBestMatch column is set to true in only one row.
IsCaseSensitive	bool	**true**—The data type is a character type and is case sensitive. **false**—The data type is not a character type or is not case sensitive.
IsFixedLength	bool	**true**—Columns of this data type created by the data definition language (DDL) are of fixed length. **false**—Columns of this data type created by the DDL are of variable length. **DBNull.Value**—It is not known whether the provider will map this field with a fixed-length or variable-length column.
IsFixedPrecisionScale	bool	**true**—The data type has a fixed precision and scale. **false**—The data type does not have a fixed precision and scale.
IsLong	bool	**true**—The data type contains very long data; the definition of very long data is provider-specific. **false**—The data type does not contain very long data.
IsNullable	bool	**true**—The data type is nullable. **false**—The data type is not nullable. **DBNull.Value**—It is not known whether the data type is nullable.
IsSearchable	bool	**true**—The data type can be used in a WHERE clause with any operator except the LIKE predicate. **false**—The data type cannot be used in a WHERE clause with any operator except the LIKE predicate.
IsSearchableWithLike	bool	**true**—The data type can be used with the LIKE predicate. **false**—The data type cannot be used with the LIKE predicate.
IsUnsigned	bool	**true**—The data type is unsigned. **false**—The data type is signed. **DBNull.Value**—Not applicable to data type.
MaximumScale	short	If the type indicator is a numeric type, this is the maximum number of digits allowed to the right of the decimal point. Otherwise, this is **DBNull.Value**.
MinimumScale	short	If the type indicator is a numeric type, this is the minimum number of digits allowed to the right of the decimal point. Otherwise, this is **DBNull.Value**.
IsConcurrencyType	bool	**true**–The data type is updated by the database every time the row is changed and the value of the column is different from all previous values **false**–The data type is note updated by the database every time the row is changed **DBNull.Value**–The database does not support this data type.
IsLiteralsSupported	bool	**true**–The data type can be expressed as a literal. **false**–The data type cannot be expressed as a literal.
LiteralPrefix	string	The prefix applied to a given literal.

LitteralSuffix	string	The suffix applied to a given literal.
NativeDataType	String	An OLE DB-specific column for exposing the OLE DB type of the data type .

MetaDataCollections

Column Name	Data Type	Description
CollectionName	string	The name of the collection to pass to the **GetSchema** method to return the collection.
NumberOfRestriction	int	The number of restrictions that can be specified for the collection.
NumberOfIdentifierParts	int	The number of parts in the composite identifier/database object name. For example, in SQL Server, this would be 3 for tables and 4 for columns. In Oracle, it would be 2 for tables and 3 for columns.

ReservedWords

Column Name	Data Type	Description

Restrictions

Column Name	Data Type	Description
CollectionName	string	The name of the collection that these restrictions apply to.
RestrictionName	string	The name of the restriction in the collection.
RestrictionDefault	string	Ignored.
RestrictionNumber	int	The actual location in the collections restrictions that this particular restriction falls in.

Tables

Column Name	Data Type	Description
table_catalog	String	Catalog of the table.
table_schema	String	Schema that contains the table.
table_name	String	Table name.
table_type	String	Type of table. Can be VIEW or BASE TABLE.

BizTalk Adapter for Host Files

Managed Provider for Host Files Tutorial

This tutorial shows how to access host file data by using the Managed Provider for Host Files. After completing the tutorial, you will be able to do the following:

- Configure a connection to a host file dataset
- Build a simple XML Web service to expose host file data using ASP.NET
- Retrieve a recordset of information from a host file and return that information as a .NET dataset through an XML Web service.

Getting Started with the Managed Provider for Host Files Tutorial

Before you start the Managed Provider for Host Files tutorial, make sure to perform the following actions:

1. Install Microsoft® Visual Studio® 2005.
2. Ensure that Internet Information Services (IIS) is installed and ASP.NET 2.0 is configured.
3. Install Microsoft Host Integration Server 2009.
4. Ensure that you have access to a host dataset with permissions to query and modify data. For more information about the dataset used in this tutorial, see the Appendix.

Running the Managed Data Provider for Host Files Tutorial

To access host file data, you must first define the metadata associated with the dataset. Then you can use the Data Access Tool to configure a connection to the host file. After that, you can create the XML Web service and launch your application.

Step 1: Define the Structure of the Host File

To access the host dataset, you need to define the metadata associated with the dataset. After you have finished defining the various structures used to access the host file system, you can define the connection string you will use to connect to the file system.

To create the host file project

1. In Visual Studio, click **File**, point to **New**, and then click **Project**.
2. In the **New Project** dialog box, in the **Project types** pane, click **Other Project Types**.
3. In the **Templates** pane, click **Blank Solution**.
4. In the **Name** field, enter **Data Integration Samples**, and then click **OK**.
5. In Solution Explorer, right-click **Data Integration Samples**, point to **Add**, and then click **New Project**.
6. In the **Add New Project** dialog box, in the **Project types** pane, click **Host Integration Projects**.
7. In the **Templates** pane, click **Host File Project**.
8. In the **Name** field, type **NorthwindHostFiles**, and then click **OK**.

To add a host file library to the host file project.

1. In Solution Explorer, right-click **NorthwindHostFiles**, point to **Add**, and then click **Add Host File Library**.
2. In the **Add New Item - NorthwindHostFiles** dialog box, in the **Name** field, type **NorthwindHostFiles_OS390**, and then click **Add**.
3. On the **Welcome to the Host Files Library Wizard** page, click **Next**.
4. On the **Host Environment** page, confirm that **Host Files for OS390** is selected in the **Host environment** drop-down

box, click **Next**, and then click **Create**.

To import the host file definition

1. In Solution Explorer, double-click **NorthwindHostFiles_OS390.DLL** to bring up the Host File Designer.
2. In the Host File Designer, right-click **NorthwindHostFiles_OS390**, point to **Import**, and then click **Host Definition**.
3. On the **Welcome to the COBOL Import Wizard** page, click **Next**.
4. On the **Import COBOL Source File** page, click **Browse** to locate the COBOL file that defines the data structures on your host file system, and then click **Next**.
5. On the **Structures member** page, select the COBOL group that represents the structure members, click **Next**, and then click **Modify**.

To map the host file schema to a table

1. In Host File Designer, expand **NorthwindHostFiles_OS390**, right-click **Tables**, and then click **Add Table**.
2. Right-click the newly created **table1**, and then click **Properties**.
3. In the Properties toolbox, enter an alias in the **Alias** field, the host file name in the **Host File Name** field, and a schema name in the **Schema** field.

To provide a strong key name to sign the host file project

1. In Host File Designer, right-click **NorthwindHostFiles_OS390**, and then click **Properties**.
2. In the **Properties** toolbox, expand **Assembly Information**, and then provide the path and file name to a key file.

To save and register the assembly

1. In Visual Studio, on the **File** menu, click **Save**.
2. Use the gacutil utility and the regasm tool to register the host file assembly.

Step 2: Create the Data Access String

After you have finished defining the structure of the host file, you can use the Data Access Tool to create a data access string. After you confirm the creation of the string, you can then create the XML Web service.

To start the Data Access Tool and run the Data Source Wizard

1. Click **Start**, point to **Programs**, point to **Microsoft Host Integration Server 2009**, and then click **Data Access Tool**.

   This starts the Data Access Tool, which you can use to configure connections in both DB2 and host file systems.
2. In the Data Access Tool, click **File**, point to **New**, and then click **Data Source**.
3. On the **Welcome to the Data Source Wizard** page, click **Next**.
4. On the **Data Source** page, in the **Data Source Platform** field, select **Mainframe or AS/36 file system**.
5. Confirm that the **SNA LU6.2 (APPC)** check box is selected, and then click **Next**.
6. On the **APPC Network Connection** page, enter the connection information for your mainframe, and then click **Next**.
7. On the **Mainframe or AS/36** page, enter the default information into the **Default library information** field.
8. Enter the path of the host file assembly created in the preceding section into the **Host File assembly** field, and then click **Next**.
9. On the **Locale** page, accept the default values, and then click **Next**.
10. On the **Security** page, in the **Security Method** field, confirm that **Interactive sign-on** is selected in the drop-down box.
11. Enter the connection information for your mainframe in the **Properties** fields, and then click **Next**.
12. On the **Advanced Options** page, click **Next**.
13. On the **Validation** page, click **Connect** to test your connection string, and then click **Next**.

14. On the **Saving Information** page, in the **Data source name** field, type **HIS_TRAINING_HF**.
15. Select the **Initialization string file** check box, and then click **Next**.
16. On the **Completing the Data Source Wizard** page, click **Finish**.

To view the data source string

1. Open Notepad and navigate to the directory the data source string is saved in.

   By default, the data source string file is located in C:\Documents and Settings\<USERNAME>\My Documents\Host Integration Projects\Data Sources.

2. Use Notepad to view the HIS_STRAINIGN_HF.txt file.

   You should see the connection string created by the Data Access Tool. It should look something like the following:

```
User ID=myname;Password=mypassword;APPC Remote LU Alias=DFM; APPC Local LU Alias=L3888888;APPC Mode
Name=PA62KNU; Network Transport Library=SNA; Host CCSID=37;PC Code Page=1252;Network Port=446;Default
Library=MyLibrary;Metadata='C:\Work\DataIntegrationSamples\NortwindHost
Files\NortwindHostFiles_OS390.DLL'
```

Step 3: Create the XML Web Service

After you have created the data string, you can create the XML Web service and associated code. Then you can test your code on a live Web site.

To start Visual Studio and create a new project

1. Click **Start**, point to **All Programs**, point to **Microsoft Visual Studio 2005**, and then click **Microsoft Visual Studio 2005**.
2. In Visual Studio, on the **File** menu, point to **New**, and then click **Project**.
3. In the **New Project** dialog box, in the **Project types** pane, expand **Other Project Types**, and then click **Visual Studio Solutions**.
4. In the **Templates** pane, confirm that **Blank Solution** is selected, enter **HISTraining** in the **Name** field, and then click **Next**.

To add a class to hold the DB2 access logic

1. In Solution Explorer, right-click **HISTraining**, point to **Add**, and then click **New Project**.
2. In the **Add New Project** dialog box, in the **Project types** pane, expand **Other Languages**, and then click **Visual Basic**.
3. In the **Templates** pane, click **Class Library**.
4. In the **Name** field, type **HFDAL**, and then click **OK**.

To add a reference to the HostFileProvider

1. In Solution Explorer, right-click **HFDAL**, and then click **Add Reference**.
2. In the **Add Reference** dialog box, click the **.NET** tab, click the **Microsoft.HostIntegration.HostFileProvider** component, and then click **OK**.

To write the code for the Data Access class

1. In Solution Explorer, click **Class1.vb**.
2. Enter the following code into the text editor window:

```
Public Class HFDAL
    Public Function executeSQL(ByVal sqlQuery As String, ByVal connString As String) A
s DataSet
        Dim hfConn As New HostFileConnection(connString)
        Dim hfCmd As New HostFileCommand(sqlQuery, hfConn)
        Dim hfDA As New HostFileDataAdapter(hfCmd)
        Dim returnDS As New DataSet
```

```
        hfConn.Open()
        hfDA.Fill(returnDS)
        hfConn.Close()
        Return returnDS
    End Function

End Class
```

3. On the **File** menu, click **Save All**.
4. On the **Build** menu, click **Rebuild Solution**.

To create a Web service for the solution

1. In Solution Explorer, right-click **HISTraining**, point to **Add**, and then click **New Web Site**.
2. In the **Add New Web Site** dialog box, click **ASP.NET Web Service**.
3. In the **Location** combo box, confirm that **HTTP** is selected, type **http://localhost/HFWebService** in the associated text box, and then click **OK**.
4. In Solution Explorer, right-click **http://localhostHFWebService**, and then click **Add Reference**.
5. On the **Add Reference** dialog box, click the **Projects** tab, click **HFDAL**, and then click **OK**.
6. In Solution Explorer, expand **http://localhostHFWebService**, expand **App_Code**, and then double-click **Service.vb**.
7. Add the following code to Service.vb:

```
Imports System.Web
Imports System.Web.Services
Imports System.Web.Services.Protocols

<WebService(Namespace:="http://tempuri.org/")> _
<WebServiceBinding(ConformsTo:=WsiProfiles.BasicProfile1_1)> _
<Global.Microsoft.VisualBasic.CompilerServices.DesignerGenerated()> _
Public Class Service
     Inherits System.Web.Services.WebService

    <WebMethod()> _
    Public Function executeSQLQuery(ByVal connString As String, ByVal sqlStatement As
String) As Data.DataSet
        Dim dal As New HFDAL.HFDAL

        Return dal.executeSQL(sqlStatement, connString)

    End Function

End Class
```

8. On the **File** menu, click **Save All**.

Step 4: Launch the XML Web Service

After you are finished creating the XML Web service, you can launch the service and observe the resulting behavior.

To execute the Web service

1. In Solution Explorer, right-click **Service.asmx**, and then click **View in Browser**.
2. In the Web browser view of Service.asmx, click the hyperlink to **executeSQLQuery**.
3. On the **executeSQLQuery** page, copy the connection string from HIS_TRAINIGN_HF.TXT into the **connString** field.

4. In the **sqlStatement** field, type **SELECT* FROM CUSTOMERS**, and then click **Invoke**.

Appendix

The following COBOL copybook is used in this tutorial as the host file dataset.

```
01 CUSTOMER
     05 CUSTIDPIC S9(9)COMP.
     05 COMPANYPIC X(40).
     O5 CONTACT PIC X(30).
     05 TITLE PIC X(30).
     05 ADDRESS PIC X(60).
     05 CITY PIC X(20).
     05 REGION PIC X(15).
     05 ZIP PIC X(10).
     05 COUNTRY PIC X(10).
     05 PHONE PIC X(15).
     05 FAX PIC X(24).
     05 WEBPINPIC X(5).
```

Managed Data Provider for Host Files Programmer's Guide

.NET Framework Data Providers for Host Integration Server

In concept, a .NET Framework data provider is similar to an OLE DB provider: the provider runs as an interface between your application and the data source. However, the .NET Framework data provider exposes only a single set of ADO.NET interfaces.

In This Section

Examining the Core Interface for a Managed Provider

Managed Provider Programmer's Guide

Examining the Core Interface for a Managed Provider

A data provider in the .NET Framework serves as a bridge between an application and a data source. The data provider is used to retrieve data from a data source and to reconcile changes to that data back to the data source.

ADO.NET exposes a common model for .NET Framework data provider objects so that a single set of code can be written to work regardless of the .NET Framework data provider. The **Connection**, **Command**, **DataReader**, and **DataAdapter** objects represent the core elements of the .NET Framework data provider model. The following table describes the purpose of these objects, and how they are implemented in the Managed Provider for DB2 and Managed Provider for Host Files.

Common model	**Managed Provider for Host Integration Server**	**Description**
Connection	MsDb2Connection HostFileConnection	Responsible for opening, closing, and maintaining a connection to a DB2 host.
Command	MsDb2Command HostFileCommand	Manages all parameters that a query may include, which includes both SQL parameters and stored procedure parameters.
DataReader	MsDb2DataReader	A server-side forward-only cursor implementation that inherits form the **IDataReader** and **IDataRecord** interfaces.
DataAdapter	MsDb2DataAdapter HostFileDataAdapter	Acts as the gateway between the host data and a .NET Framework data set.

In addition, each provider has several interfaces specific to this implementation. These interfaces deal with exception and event handling, setting up connections to a DB2 host over different types of networks, and passing parameters.

ADO.NET DataSet for Host Integration Server

The ADO.NET **DataSet** is the object that contains the data that a managed provider retrieves from a remote data source. Specifically, the ADO.NET **DataSet** is a local cache of tables, similar to a collection of ADO disconnected recordsets, described in the **System.Data** namespace. In addition, the **DataSet** records the relationships between the tables using keys and constraints. The **DataSet** is central to supporting disconnected, distributed data scenarios with ADO.NET.

In This Section

DataTableCollection

DataRelationCollection

ExtendedProperties

XML Support

DataTableCollection

An ADO.NET **DataSet** contains a collection of zero or more tables represented by **DataTable** objects. The **DataTableCollection** contains all the **DataTable** objects in a **DataSet**.

A **DataTable** is defined in the **System.Data** namespace and represents a single table of memory-resident data. It contains a collection of columns represented by a **DataColumnCollection**, and constraints represented by a **ConstraintCollection**, which together define the schema of the table. A **DataTable** object also contains a collection of rows represented by the **DataRowCollection**, which contains the data in the table. Along with its current state, a **DataRow** object retains both its current and original versions to identify changes to the values stored in the row.

Concepts

ADO.NET DataSet for Host Integration Server

Other Resources

Managed Provider Programmer's Guide

DataRelationCollection

A **DataSet** object contains relationships in its **DataRelationCollection** object. A relationship, represented by the **DataRelation** object, associates rows in one **DataTable** with rows in another **DataTable**. It is analogous to a join path that might exist between primary and foreign key columns in a relational database. A **DataRelation** identifies matching columns in two tables of a **DataSet**.

Relationships enable navigation from one table to another within a **DataSet**. The essential elements of a **DataRelation** are the name of the relationship, the name of the tables being related, and the related columns in each table. Relationships can be built with more than one column per table by specifying an array of **DataColumn** objects as the key columns. When a relationship is added to the **DataRelationCollection**, it may optionally add a **UniqueKeyConstraint** and a **ForeignKeyConstraint** to enforce integrity constraints when changes are made to related column values.

Managed Provider Programmer's Guide

ExtendedProperties

A **DataSet** object (like **DataTable** and **DataColumn**) has an **ExtendedProperties** property. **ExtendedProperties** is a **PropertyCollection** where you can add customized information, such as the SELECT statement that was used to generate the result set or a date/time stamp of when the data was generated. The **ExtendedProperties** collection is persisted with the schema information for the **DataSet** (and also the **DataTable** and **DataColumn**).

Concepts

ADO.NET DataSet for Host Integration Server

Other Resources

Managed Provider Programmer's Guide

XML Support

A **DataSet** object can persist and reload its contents as XML and its schema as XSD. The **DataSet** has direct support for reading (shredding) and writing data using XML using the .NET Framework **XmlReader** and **XmlWriter** classes. When you are writing XML, the output conforms to the W3C XSD schema. XML is a good method of moving data between application tiers. The **XMLDataDocument** can use the XML services, such as XSL/T and XPath.

Managed Provider Programmer's Guide

OLE DB Providers Programmer's Guides

This section of the Host Integration Server 2009 software development kit (SDK) provides information about using the OLE DB providers for AS/400, VSAM, and DB2.

For more information about OLE DB providers, see the Data Access section of the Operations guide.

This section contains:

- OLE DB Provider for AS/400 and VSAM Programmer's Guide
- OLE DB Provider for DB2 Programmer's Guide
- ADO Object, Method, Property, and Collection Support for AS/400, VSAM and DB2

OLE DB Provider for AS/400 and VSAM Programmer's Guide

The Microsoft® OLE DB Provider for AS/400 and VSAM enables you to directly access record-level data in mainframe VSAM, partitioned data sets (PDSs), and midrange OS/400 files from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provide heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for AS/400 and VSAM combines the universal data access of OLE DB with the Record-Level Input/Output (RLIO) protocol of the IBM distributed data management (DDM) architecture.

DDM is a set of rules for distributing or extending the data management from one computer to another, such as from a mainframe to an AS/400 computer, or from one of these host computers to a server computer. By combining the OLE DB and DDM architectures, Microsoft enables organizations to preserve their investments in an existing data management infrastructure, while extending universal data access to all enterprise-wide data sources.

For API references and other technical information about the OLE DB provider, see the OLE DB Providers Programmer's Reference section of the SDK.

For more information about using the OLE DB Provider for AS/400 and VASM, see OLE DB Provider for AS/400 and VSAM in the Operations guide.

Data Integration Programmer's Guide

Goals of the OLE DB Provider for AS/400 and VSAM

For the majority of enterprises today, much mission-critical information resides on IBM mainframe and AS/400 computers. This information is stored in records on the OS/400 and VSAM file systems. This information is created, owned, and often accessible by only host-based applications. In the mainframe environment, these applications include CICS and DB2; other commercial applications; and a large number of custom applications written in COBOL, PL/I, and other languages. In the AS/400 environment, these applications include primarily DB2 and commercial applications, plus a large number of custom report program generator (RPG) applications. Not all of these data sources are SQL-accessible. Many of the host data stores contain non-SQL-accessible data that is owned by something other than a traditional relational database management system (RDBMS).

These same enterprises rely on vast networks of personal computers to enable their users to achieve business goals. End users invariably rely on network e-mail, Microsoft Windows productivity applications such as Microsoft Office, and personal database programs such as Microsoft Access, to accomplish their daily tasks. It is essential for these same users to incorporate data stored on host systems into their regular correspondence, analysis, and reports.

Available methods of accessing host data do not provide the granular, record-level access required for cost-effective, more secure, and meaningful integration of host and personal computer systems. In many cases, end users employ antiquated means of data integration. These methods include copying and pasting data from a terminal emulation screen, retyping information from host application reports, and importing text files containing comma-delimited values that use host EBCDIC-to-computer ASCII file transfer. These methods are not efficient although widely used and are not supported by products from independent software vendors (ISVs).

The challenge is how to provide direct record-level access to this valuable data without going through the host application. Much of the renewed interest in improved access to host data sources is a result of the growth of local intranets, the use of the Internet, and Web technology as a mechanism for delivering information. Fast and inexpensive methods of record-level access are needed to deliver modern, three-tiered information systems during this era of cost-cutting and budget tightening. Additional uses of this direct data access are specific queries and Web-based reporting.

It is common for corporate management to rethink host data storage and the appropriate software used to provide data access. For many organizations, the answer to these issues is in rewriting the arguably outdated host-based business rules with server-based, or even client-based, business logic.

The goal of the Microsoft OLE DB Provider for AS/400 and VSAM is to provide customers and solution providers with the means to integrate desktop applications with this wealth of data residing on host computers.

OLE DB Environment

Three main roles are performed by software applications in an OLE DB environment:

- **OLE DB Consumer.** The end-user or server-based program that uses (consumes) the OLE DB interfaces. An example is a Web-based component that makes OLE DB calls to integrate host records with a Web-based report.

- **OLE DB Data Provider.** A driver or other program that exposes OLE DB interfaces for use by consumer applications. Data providers translate OLE DB interfaces to a language or commands that the target data source understands. An example is the Microsoft® OLE DB Provider for AS/400 and VSAM, which translates OLE DB interfaces to distributed data management (DDM) commands.

- **OLE DB Service Provider.** An application that both uses (consumes) and exposes OLE DB interfaces. Service providers typically act as proxies for the consumer, retrieving the data through the data provider and offering services to the consumer by manipulating the target data. An example is a query-processing engine.

DDM Record-Level Access

The Microsoft® OLE DB Provider for AS/400 and VSAM provides record-oriented access to host files. There is no need to perform bandwidth-intensive file transfers of entire host files to access data on the host.

The OLE DB interface provided by the OLE DB Provider for AS/400 and VSAM supports the following features:

- Set attributes and a record description of a host file (column information).
- Lock files and records.
- Position to the first record or the last record in a file.
- Navigate to the previous or next record in a file.
- Seek to a record, based on an index.
- Change records in a file.
- Insert new records and delete records in a file.
- Preserve file and record attributes.

The OLE DB Provider for AS/400 and VSAM is a source distributed data management (DDM) requester implementation that can initiate DDM commands to be serviced by a remote host-based target DDM server. On the Microsoft® Windows Server™ 2003 or Windows® 2000 operating system, the Microsoft DDM requester can run as a Windows service. This enables the DDM service to integrate with other host applications using the IBM DDM protocol and DDM servers that are resident on the host. Microsoft-based host software is not required. For more information, see Platforms Supported by the OLE DB Provider for AS/400 and VSAM. IBM offers DDM servers for the most popular host environments.

Providing users with direct record-level access reduces the development time to build and deploy new data integration solutions. Accessing only the target records, as opposed to entire host files, helps ensure data integrity.

Platforms Supported by the OLE DB Provider for AS/400 and VSAM

On the mainframe platform, IBM offers a target distributed data management (DDM) server implementation in IBM Distributed File Manager (DFM), a component of IBM Data Facility Storage Management Subsystem (DFSMS). The Microsoft OLE DB Provider for AS/400 and VSAM requires DFSMS version 1 release 2 or later for MVS/ESA and OS/390 to support an SNA LU 6.2 connection.

On midrange AS/400 computers, IBM has implemented target DDM servers directly in OS/400. The OLE DB Provider for AS/400 and VSAM requires OS/400 Version 3 Release 2 or later to support an SNA LU 6.2 connection. The OLE DB Provider for AS/400 and VSAM requires OS/400 Version 4 Release 2 or later to support a TCP/IP connection.

On the AS/400 platform, the OLE DB Provider for AS/400 and VSAM supports physical and logical files with an associated external record description file. For specific limitations, see the *AS/400 DDM User's Guide*.

On the mainframe platform, the OLE DB Provider for AS/400 and VSAM supports the following data set types:

Sequential Access Method (SAM) data sets

- Basic Sequential Access Method data sets (BSAM)
- Queued Sequential Access Method data sets (QSAM)

Virtual Storage Access Method (VSAM) data sets

- Entry-Sequenced Data Sets (ESDS)
- Key-Sequenced Data Sets (KSDS)
- Fixed-Length Relative Record Data Sets (RRDS)
- Variable-Length Relative Record Data Sets (VRRDS)
- Relative Record Data Set (RRDS)
- VSAM Alternate Indexes for ESDS and KSDS data sets

Basic Partitioned Access Method (PDS) data sets

- Partitioned Data Set Extended members (PDSE)
- Partitioned data set (PDS) members
- Read-only support for PDSE directories
- Read-only support for PDS directories

The preceding data set types are supported by IBM DFM/MVS.

The following data set types are not supported by DFM/MVS and cannot be accessed using the OLE DB Provider for AS/400 and VSAM:

- VSAM Linear Data Sets (LDS)
- Generation Data Groups (GDG)
- Generation Data Sets (GDS)

- Basic Direct Access Method data sets (BDAM)
- Indexed Sequential Access Method data sets (ISAM)
- Sequential Data Striping data sets
- OpenEdition MVS Hierarchical File System (HFS) files
- Tape Media

All mainframe data sets accessible through IBM Distributed File Manager must be cataloged in an Intersystem communications function (ICF) catalog and reside on direct access storage devices (DASD).

The OLE DB Provider for AS/400 and VSAM supplied with Host Integration Server 2009 supports the following OLE DB and ADO versions:

- **OLE DB version 2.5.** The Host Integration Server 2009 data access features require the run-time libraries for OLE DB version 2.5. On Windows Server 2003 or Windows 2000, these OLE DB libraries are installed as part of the operating system.
- **ADO version 2.5.** The Host Integration Server data access features require the run-time libraries for ADO version 2.5. On Windows Server 2003 or Windows 2000, these ADO libraries are installed as part of the operating system.

OLE DB version 2.0 or later and ADO version 2.0 or later are required to support indexed record access from an ADO consumer application using the OLE DB Provider for AS/400 and VSAM. Indexed support through OLE DB is supported with OLE DB versions 2.0 and later.

Indexed File Access

The Microsoft® OLE DB Provider for AS/400 and VSAM provides both sequential and indexed file access. Sequential file access is provided for all supported file types on the Platforms Supported by the OLE DB Provider for AS/400 and VSAM.

Indexed file access is provided for the following host file types only:

- Mainframe Virtual Storage Access Method (VSAM) data sets.
    - Key-Sequenced Data Sets (KSDS) only when the keys are unique.
    - Fixed-length Relative Record Data Sets (RRDS) only when the keys are unique.
    - Variable-length Relative Record Data Sets (VRRDS) only when the keys are unique.
- AS/400 files.
    - Logical files.
    - Keyed physical files (externally described to the system).

OLE DB and ADO offer several interfaces that enable indexed file access.

The OLE DB Provider for AS/400 and VSAM supports integrated indexes based on the underlying rowset. OLE DB support for indexed file access using the OLE DB Provider for AS/400 and VSAM is available using the **IRowsetIndex**, **IViewFilter**, and **IViewRowset** interfaces.

For more information about indexes, see Chapter 8, "Indexes" and Chapter 16, "Integrated Indexes" in the *OLE DB Programmer's Reference*. To obtain a list of available indexes in a target AS/400 library, a program can call the OLE DB **IDBSchemaRowset::GetRowset** function of the **Session** object requesting a query type of DBSCHEMA_INDEXES.

ADO support for indexed file access using the OLE DB Provider for AS/400 and VSAM is available using the Find method, Filter property, and Sort property on the ADO **Recordset** object. To obtain a list of available indexes in a target AS/400 library using ADO, a program can call the OpenSchema method on the **Connection** object specifying a *QueryType* of **adSchemaIndexes**.

By default, the OLE DB Provider for AS/400 and VSAM uses a server-based cursor. This means that all indexed file access is based on the cursor located over the host file and not a local computer copy of the host file. If you want to use the many client-based cursor service providers available with the Microsoft® Data Access Components (MDAC), you must configure the provider to use a client-based cursor. For example, a client-based cursor is required when using Remote Data Service (RDS) and the Microsoft® Visual Studio® ADO data-bound controls. However, using these controls, an application can access the host files for read-only purposes. If your application needs to access host files with an intent of both reading and writing, and you require indexed file access, your application should use the OLE DB Provider for AS/400 and VSAM server-based cursor.

File and Record Attributes

By definition, the record description is not part of the record I/O architecture in distributed data management (DDM). Traditionally, applications must embed the record format as part of the application program. This creates a burden on the application and is inconsistent with the existing computer-based data access standards, such as OLE DB and ODBC.

To solve this problem, the Microsoft® OLE DB Provider for AS/400 and VSAM uses an external host column description (HCD) file stored on the computer that enables administrators to describe the host record format. At run time, the OLE DB Provider for AS/400 and VSAM transparently converts the host data to computer data using the local HCD information. Before a user program can view or open a VSAM file using the OLE DB Provider for AS/400 and VSAM, the user program must create a valid record description file or entry for the target VSAM file.

The OLE DB Provider for AS/400 and VSAM includes a Microsoft Management Console (MMC) application designed to enable administrators and developers to easily create these local record description files and the necessary registry settings for data sources. The OLE DB DDM Management application makes it relatively easy to create HCD files without knowing the HCD file format. The Host Column Description file format is documented in the Data Integration Programmer's Reference.

The conversion process occurs in two steps. The host data is converted from host EBCDIC to ASCII data by the DDM dynamic-link library (DLL). The HCD file is used during this step to convert host data types to C data types, which are defined in ODBC and based on the SQL data types defined in the ANSI/ISO SQL-92 standard. The second phase of this conversion occurs in the SNAOLEDB DLL where these SQL C data types are converted to the defined OLE DB data types.

The use of an HCD file is not necessary to describe the record format for data stored in the AS/400 computer because the OLE DB Provider for AS/400 and VSAM automatically detects that the target host system is an AS/400 and uses the appropriate DDM commands to retrieve the record description. If the system administrator or the OLE DB application developer wants to use an HCD file instead of retrieving the AS/400 record description, this behavior can be forced by setting the configuration of the **Host Column Description File** property using Data Links.

Configuring the OLE DB Provider for AS/400 and VSAM

Microsoft® Data Access Components (MDAC) includes Data Links, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Links provide a uniform method of creating persistent OLE DB data source object definitions stored in the form of universal data link (.udl) files. The Microsoft® OLE DB Provider for AS/400 and VSAM normally uses Data Links and .udl files for loading and configuring data sources.

Data Links provide a flexible method for finding and saving connection information to OLE DB data sources.

The Data Source Wizard in the new Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft® SQL Server™ can then use the .udl file to connect to IBM data sources, such as DB2 and the mainframe file system.

To use Microsoft OLE DB Provider for AS/400 and VSAM with an OLE DB consumer application, the user must either create a Microsoft data link (.udl) file and call this from the application, or call the OLE DB provider from within the application using a connection string that includes the provider name and other necessary parameters. If an application accesses VSAM data sets, after configuring a data link, a host data description must also be configured using the Data Descriptions tool.

This section contains:

Creating Data Links for the OLE DB Provider for AS/400 and VSAM

Data source information must be configured for each AS/400 or mainframe system data source object that is to be accessed using the OLE DB provider. The default parameters for the OLE DB provider are used as the default values for data sources when these parameters are not configured for each data source.

Microsoft Data Links, a core element of Microsoft Data Access Components (MDAC), provide a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files.

The Data Source Wizard in the new Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can then use the .udl file to connect to IBM data sources, such as DB2 and the mainframe file system.

Applications, such as the RowsetViewer sample included with the Microsoft Data Access SDK and the MSDN Platform SDK, can open created .udl files and pass the stored initialization string to the OLE DB Provider for AS/400 and VSAM at run time.

Creating New Data Links for the OLE DB Provider for AS/400 and VSAM

You create new Data Links using the Data Source Wizard from the Data Access Tool.

Browsing Data Links for the OLE DB Provider for AS/400 and VSAM

You can browse data sources using the Data Source Browser window in the Data Access Tool.

To find the physical location of the .udl file associated with a data source, right-click the data source and select **Locate** from the context menu. Windows Explorer appears which will display the location of the file.

Configuring Data Links for the OLE DB Provider for AS/400 and VSAM

To edit the properties of a Data Link file, browse to that file in Windows Explorer, and right-click the file and then click **Data Link Properties**. The **Data Link Properties** dialog box appears with several property tabs:

- **General**
- **Security**
- **Summary**
- **Provider**
- **Connection**
- **Advanced**
- **All**

The **General**, **Security**, and **Summary** tabs provide access to general file information for the .udl file that is available for other files and is not related to the Data Link properties. This information includes file location, file type, file size, file dates, file security permissions for access, and descriptive summary information (description and origin properties and values such as title, subject, and author) for the .udl file. The **General** tab has a text box with the name of the Data Link. This file name must end with the .udl extension if the file is to be recognized as a Data Link file. Note that the **Security** and **Summary** tabs are available on NTFS files systems, and not on the older FAT file systems.

This section contains:

Provider

The **Provider** tab enables you to select the OLE DB provider (the provider name string) to be used in this .udl file from a list of possible OLE DB providers. Select the Microsoft OLE DB Provider for AS/400 and VSAM. The parameters and fields displayed by the remaining tabs (**Connection**, **Advanced**, and **All**) are determined by the OLE DB provider that is selected.

Connection

The **Connection** tab enables you to configure the basic properties required to connect to a data source. For the Microsoft OLE DB Provider for AS/400 and VSAM, the connection properties include the following values.

Property	Description
Data Source	This is an optional parameter that can be used to describe the data source.
Network	This drop-down list box enables you to select the type of network connection to be used. The allowable options are **TCP/IP Connection** or **SNA Connection**. If **TCP/IP Connection** is selected, click **More Options**, to open a dialog box for configuring TCP/IP network settings. The parameters you can configure include the IP address of the remote host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **SNA Connection** is selected (using LU 6.2), click **More Options** to open a dialog box for configuring SNA network settings. The parameters you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode used for communication with the host. The default value for the APPC mode normally defaults to **QPCSUPP**. The local and remote LU alias fields do not have default values.
	This button enables using the Host Integration Security features providing a to access this OLE DB data source. When this button is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The user name and password fields are set based on the Windows Server 2003 or Windows 2000 logon values. When this button is not selected, the **User name** and **Password** fields must normally contain appropriate values to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The user must click the button that requires a specific user name and password to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The **Blank password** check box is only applicable for a Test Connection. To enter a password, the user needs to clear the **Blank password** check box if it is selected. If **Blank password** is selected, a Test Connection with a blank password does not cause the OLE DB provider to prompt for a password. Optionally, the user can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file.
Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems.

It is possible to connect using a specific user name and password defined on the host system or use the feature (often referred to as Windows integrated security). If a specific user name and password is to be used, this information may need to be saved into the .udl file. The user name and password are saved in plain text in the .udl file. For security reasons in these cases, it is imperative that the .udl file be protected with an access control list (ACL) that restricts access to only authorized users. Saving the user name and password in the data link also forces this .udl file to be updated whenever the password associated with the username is changed. So for a variety of reasons, specifying a user name and password is not the preferred authentication option. Using the Windows integrated security option is the preferred method for authentication.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection parameters. The connection can only be tested after all of the required parameters are entered. When you click this button, an APPC session or a TCP/IP session attempts to be established to the host using the OLE DB Provider for AS/400 and VSAM.

Advanced

The **Advanced** tab enables you to set the network protection level and access permissions. You can set the protection level from the list box of allowable values. Access permissions are set by selecting the appropriate check boxes. For the Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the values listed in the following table.

Property	Description
Host CCSID	The character code set identifier (CCSID) matching the column data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the column CCSID and default ANSI code page. This parameter defaults to **U.S./Canada (37)**. This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
PC Code Page	The PC Code Page parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the Process Binary as Character check box is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows. This parameter defaults to **Latin 1 (1252)**. This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Read only	When the Read-only parameter is selected in the **Advanced** tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the **Mode** parameter to **Read** (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.

All

The **All** tab allows users to configure essentially all of the properties for the data source except for the OLE DB provider. The properties available in the **All** tab include properties that can be configured using the **Connection** and **Advanced** tabs as well as optional detailed properties used to connect to a data source. Some of the properties in the **All** tab are required.

These properties on the **All** tab may be edited by selecting a property from the list displayed and selecting **Edit Value**. This button invokes a dialog box for the specific property containing a Property Description describing the property and a Property Value box for making changes.

For the Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the following values.

Property	Description
Affiliate Application	This property is only used when is enabled. It provides the application name to use when retrieving host credentials from the database.
APPC Local LU Alias	The name of the local LU alias configured on the Host Integration Server 2009 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server computer configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to **QPCSUPP**. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the Host Integration Server computer. This parameter is equivalent to the DBPROP_SNAOLEDB_REMOTELU OLE DB property ID.
Cache Authentication	This parameter determines whether the OLE DB provider caches authentication information such as a password in an internal cache. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter is not currently supported by the OLE DB provider and defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_CACHE_AUTHINFO OLE DB property ID.
Connect Timeout	The amount of time (in seconds) to wait for initialization to complete. This parameter is not currently supported by the OLE DB provider and defaults to **0**. This parameter is equivalent to the DBPROP_INIT_TIMEOUT OLE DB property ID.
Data Source	The data source is an optional parameter that can be used to describe the data source. This parameter is equivalent to the DBPROP_INIT_DATASOURCE OLE DB property ID.

Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
Encrypt Password	This parameter determines whether special security mechanisms are used to ensure password privacy. The value of this property (true or false) is selected from the drop-down list box. This parameter is not currently supported by the OLE DB provider and defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_ENCRYPT_PASSWORD OLE DB property ID.
Extended Properties	This parameter is a string containing provider-specific, extended connection information. Properties passed through this parameter should be delimited by semicolons and will be interpreted by the provider's underlying network client. The use of this property implies that the OLE DB consumer knows how this string is interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property parameters. This parameter is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the data as represented on the host. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the host column CCSID and default ANSI code page. This parameter defaults to **U.S./Canada (37)**. This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Host Column Description File	The fully qualified file name of the distributed data management (DDM) Host Column Description (HCD) file. This parameter can be a UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory below where the Host Integration Server or Client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
Impersonation Level	The level of impersonation that the server is allowed to use when impersonating the client. This property applies only to network connections other than Remote Procedure Call (RPC) connections. These impersonation levels are similar to those provided by RPC. The values of this property correspond directly to the levels of impersonation that can be specified for authenticated RPC connections, but can be applied to connections other than authenticated RPC. This parameter can be set to one of the following values: **Anonymous**—The client is anonymous to the server. The server process cannot obtain identification information about the client and cannot impersonate the client. **Delegate**—The process can impersonate the client's security context while acting on behalf of the client. The server process can also make outgoing calls to other servers while acting on behalf of the client. **Identity**—The server can obtain the client's identity. The server can impersonate the client for access control list (ACL) checking, but cannot access system objects as the client. **Impersonate**—The server process can impersonate the client's security context while acting on behalf of the client. This information is obtained when the connection is established, and not on every call. The value of this property is selected from the drop-down list box. This parameter defaults to **Impersonate**. This parameter is equivalent to the DBPROP_INIT_IMPERSONATION_LEVEL OLE DB property ID.

Integrated Security	This parameter is a string containing the name of the authentication service used by the server to identify the user using the identity provided by an authentication domain. For example, for Microsoft Windows Server 2003 or Windows 2000 Integrated Security, this is "SSPI" (for Security Support Provider Interface). If this parameter is a null pointer, the default authentication service should be used. When this property is used, no other DBPROP_AUTH* properties are needed and, if provided, their values are ignored. This parameter is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Locale Identifier	This parameter specifies the locale to be used. OLE DB Provider for AS/400 and VSAM does not support this parameter and defaults to **437**. This parameter is equivalent to the DBPROP_INIT_LCID OLE DB property ID.
Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems. This parameter is equivalent to the DBPROP_INIT_LOCATION OLE DB property ID.
Mask Password	This parameter indicates whether the password should be sent to the data source or enumerator in a masked form. The value of this property (**true** or **false**) is selected from the drop-down list box. The OLE DB provider does not support this parameter and defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_MASK_PASSWORD OLE DB property ID.
Mode	After a connection is established, this parameter represents a bitmask of the access permissions that will be applied to the data file. As implemented by the OLE DB Provider for AS/400 and VSAM, access permissions apply to host file locks and do not apply to record locks. The allowable values include the following: Read, ReadWrite, Share Deny None, Share Deny Read, Share Deny Write, Share Exclusive, and Write. This parameter can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_WRITE—Write-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target DDM service access port when connecting through TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.

Network Transport Library	This parameter, which represents the dynamic-link library used for transport, designates whether the provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are **TCPIP** or **SNA**. If TCPIP is selected, values for Network Address and Network Port are required. The OLE DB Provider for AS/400 and VSAM does not support TCP/IP connectivity to the mainframe. If SNA is selected, values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. The value of this property (SNA or TCPIP) is selected from the drop-down list box. This value defaults to **SNA**. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is shown as asterisks in this dialog box for security purposes. Optionally, you can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
PC Code Page	Indicates the code page used for character code conversion. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in the Windows operating system. If this parameter is set to **Binary** or **65535**, no character code conversions takes place. This parameter defaults to **Latin 1 (1252)**. This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Persist Security Info	This parameter indicates whether the data source object is allowed to persist sensitive authentication information such as a password along with other authentication information. Optionally, a user can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter defaults to **false**. This parameter is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	This parameter indicates whether to process binary fields (CCSID of 65535) as character data type fields on a per data source basis. The **Host CCSID** and **PC Code Page** values are required input parameters when this parameter is true. The value of this property (true or false) is selected from the drop-down list box. The default for this parameter is **false**; do not process binary fields as character fields. This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.

Protection Level	The level of protection of data sent between client and server. The values of this property correspond directly to the levels of protection that can be specified for authenticated RPC connections. This parameter can be set to one of the following values: DB_PROT_LEVEL_NONE—Performs no authentication of data sent to the server. DB_PROT_LEVEL_CONNECT—Authenticates only when the client establishes the connection with the server. DB_PROT_LEVEL_CALL—Authenticates the source of the data at the beginning of each request from the client to the server. DB_PROT_LEVEL_PKT—Authenticates that all data received is from the client. DB_PROT_LEVEL_PKT_INTEGRITY—Authenticates all data received is from the client and that it has not been changed in transit. DB_PROT_LEVEL_PKT_PRIVACY—Authenticates all data received is from the client, that it has not been changed in transit, and protects the privacy of the data by encrypting it. The value of this property is selected from the drop-down list box. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to the connect level of protection. This parameter is equivalent to the DBPROP_INIT_PROTECTION_LEVEL OLE DB property ID.
Read only	When the Read only parameter is selected in the **Advanced** tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the **Mode** parameter to **Read** (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
Strict Validation	This parameter indicates whether strict validation should be used and defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.
User ID	A valid user name is normally required to access data sources on hosts. This value is case-sensitive. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

Configuring Data Descriptions

You use the Data Access Tool to describe the host data file format for mainframe access. Use of the host column description (HCD) files is not required for AS/400 files because by default, the data file format is retrieved automatically from the host.

The data descriptions are stored in a local Host Column Description (HCD) file for each data source.

The following table provides the general parameters or attributes that can be configured describing each column in a data description on the **General** property page.

General parameters	Description
Name	The character string that represents the name of the column. This parameter may be null.
Alias	An optional character string that represents an alias label for the column string name. This parameter may be null.
Comment	An optional character string that represents a comment about the column. This attribute may be null.

The following table provides the data type parameters or attributes that can be configured describing each column in a data description in the **Host** property page.

Host parameters	Description
Type	The data type on the host. The allowed data values for host data type are selected from a drop-down list box. (For allowed values, see Host Data Types.)
Length	Length of the field in bytes. Depending on the selected host type, this parameter may not be editable.
Precision	Total number of decimal digits in the column containing numeric data on the host. Depending on the selected host type, this parameter may not be editable. The only numeric data types that require this information are the PACKED and ZONED data types. For these types, this field cannot be null. It must contain a valid numeric value. For all other host types, this parameter is not editable.
Scale	Number of decimal digits to the right of any decimal point for numeric data on the host. Depending on the selected host type, this parameter may not be editable. The only numeric data types that require this information are the PACKED and ZONED host data types. For these types, this field cannot be null. It must contain a valid numeric value. For all other host types, this parameter is not editable.
CCSID	The character code set identifier (CCSID) used on the host. The allowed data values for host CCSID are selected from a drop-down list box. This parameter defaults to the host CCSID configured for the OLE DB provider and is typically U.S./Canada (37).

The following table describes the parameters contained in the **Local** property page.

Local parameters	Description
Type	Indicates the OLE DB data type on the local computer. The allowed data values for the local data type are selected from a drop-down list box. (For allowed values, see Local OLE DB Data Types.)

The OLE DB provider limits the maximum length character field that can be accessed on an AS/400 computer to 32,745. On mainframes, a limitation of the IBM DFM is that SAM data sets and PDSE members are inaccessible if the fixed record length is greater than 32,760 or variable record lengths are greater than 32,756. DFM also limits all VSAM data sets on a mainframe to have a maximum record length no greater than 32,760. If you attempt to access a character field greater than these lengths on

an AS/400 or a mainframe, the attempt will fail and can have unpredictable results.

The CCSID setting used by the OLE DB provider must be set to match the CCSID actually used on the host—otherwise, data loss will occur. Some AS/400 systems default to a CCSID of 937 for enabling double-byte character sets (DBCS).

This section contains:

- Host Data Types
- Local OLE DB Data Types

Host Data Types

The **Host Type** parameter represents the data type used for this column on the host. The allowed values for **Host Type** that can be selected from the drop-down list box are listed in the following table.

Host Type	Description
Binary	Fixed-length binary data (no character conversion). The length must be specified for this data type.
Character	Fixed-length character data. The length must be specified for this data type.
Date	The date represented as character data in the format yyyy-mm-dd that fits into 10 bytes.
DBCS	Fixed-length character data that can contain only DBCS data. The length must be specified for this data type.
DCBS – Mixed Either	Fixed-length character data that can contain either DBCS or alphanumeric data. The length must be specified for this data type.
DCBS – Mixed Open	Fixed-length character data that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters. The length must be specified for this data type.
DBCS – Variable	Variable-length character data with a prefix of 2 bytes for length that contains only DBCS data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Either	Variable-length character data with a prefix of 2 bytes for length that can contain either DBCS or alphanumeric data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Open	Variable-length character data with a prefix of 2 bytes for length that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters. The maximum possible length for the column containing this data type must be specified.
Double	Floating-point data that fits in 8 bytes (64 bits).
Long	Integer data that fits in 4 bytes (32 bits).
Packed	Packed decimal numeric data where the precision and scale are exactly as specified.
Short	Integer data that fits in 2 bytes (16 bits).
Single	Floating-point data that fits in 4 bytes (32 bits).
Time	The time represented as character data in the format hh:mm:ss that fits into 8 bytes.
Time Stamp	Time stamp represented as characters in the format yyyy-mm-dd hh:mm:ss.ffffff that fits into 19 bytes.
Variable Binary	Variable-length binary data represented as an unsigned character array with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Variable Character	Variable-length character data with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Zoned	Zoned decimal numeric data where the precision and scale are exactly as specified.

Note

The floating-point data format assumed by the OLE DB Provider for AS/400 and VSAM depends on the host. For AS/400, the host floating-point data format is assumed to be IEEE. On mainframe hosts, floating-point data types are assumed to be in IBM floating-point formats. Because OLE DB supports the IEEE floating-point format, data conversion errors can occur when converting the extreme values of VSAM floating-point data in IBM format to IEEE floating-point data by the OLE DB provider. These conversion errors occur because the default IBM floating-point formats and the IEEE floating-point format use a different number of bits for the mantissa and exponent when representing a floating-point number.

Local OLE DB Data Types

The **Local Type** represents the OLE DB data type used for this column on the computer. The OLE DB data types are defined in the OLE DB specifications and **#defines** can be found in the Oledb.h file. The allowed values for **Local Type** that can be selected from the drop-down list box are listed in the following table.

Host Type	Description
DBTYPE_BYTES	Fixed-length binary data represented as an unsigned char array.
DBTYPE_DBDATE	The OLE DB DBDATE typedef struct as defined in the Oledb.h file.
DBTYPE_DBTIME	The OLE DB DBTIME typedef as defined in the Oledb.h file.
DBTYPE_DBTIMESTAMP	The OLE DB DBTIMESTAMP typedef struct as defined in the Oledb.h file.
DBTYPE_DECIMAL	The OLE DB DECIMAL typedef struct as defined in the Oledb.h file.
DBTYPE_I2	Integer data stored in 2 bytes (16 bits).
DBTYPE_I4	Integer data stored in 4 bytes (32 bits).
DBTYPE_NUMERIC	The OLE DB NUMERIC typedef struct as defined in the Oledb.h file.
DBTYPE_R4	Single precision IEEE floating-point data stored in 4 bytes (32 bits).
DBTYPE_R8	Double precision floating-point data stored in 8 bytes (64 bits).
DBTYPE_STR	Fixed and variable length character data.

Converting Existing Data Sources

The OLE DB management console that was previously used in SNA Server 4.0 and SNA Server 4.0 with Service Pack 1 (SP1) for configuring OLE DB Provider for AS/400 and VSAM data sources has been removed and replaced by Microsoft Data Links and the Data Access Tool. Microsoft Data Links is a component of Microsoft Data Access Components (MDAC) 2.5. On Windows Server 2003 or Windows 2000, MDAC 2.5 is installed as part of the operating system.

Existing registry-based OLE DB Provider for AS/400 and VSAM data sources that were created in SNA Server 4.0 and SNA Server 4.0 SP1 can be converted to .udl files using the Reg2udl tool supplied with Host Integration Server. The Reg2Udl tool is not installed as part of Host Integration Server, but is located on the Host Integration Server 2009 CD in the \Options\Maintenance folder.

When a duplicate .udl file is present in the destination folder, the Reg2udl tool will increment the file name by 1 (Data.udl will become Datat1.udl, for example). This may cause existing applications to fail because the OLE DB Provider for AS/400 and VSAM is looking for the existing name (Data.udl).

Manual conversion of registry-based data sources to .udl files may be necessary in some cases when Setup for Host Integration Server 2009 is used. A version of the Reg2udl tool (for Intel) can be found in the \Support\Utilities folder on the Host Integration Server 2009 CD.

Programming Considerations When Using the OLE DB Provider for AS/400 and VSAM

All the Microsoft® OLE DB objects exposed by the Microsoft® OLE DB Provider for AS/400 and VSAM support aggregation. Each OLE DB object has two classes, one that delegates its **IUnknown** calls and one that controls the object as a whole.

The apartment-threading model is supported, allowing multiple threads to access the objects safely. This is the only threading model supported.

When working with the Data Environment (DE) commands within Microsoft® Visual Studio® 6.0, you must use a period (.) as a delimiter when specifying the AS/400 Library or File path. For example, the following is valid syntax when opening the AUTHORS physical file in the PUBS library on an AS/400:

```
EXEC OPEN PUBS.AUTHORS
```

To use the ADO Recordset Findmethod or the ADO Filter property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this method is used on an AS/400 nonkeyed physical file or any other mainframe file type, this method fails.

When using RRDS files, the **Find** method fails when a search is executed using a column name. For example, the following Microsoft® Visual Basic® code will fail on an RRDS file with a column called Area:

```
RecordSet.Find "Area > '1111'", 0, adSearchForward, adBookmarkFirst
```

The error description indicates that a bookmark is invalid.

RRDS files do not have an index based on a column name and the value of the column data, so the syntax to the preceding ADO **Find** method call does not work for RRDS files. In a COBOL program designed to dynamically find a record in an RRDS file, the record position would be passed. For example, for the 75th record in the file, a COBOL program would pass a value of 75. The COBOL program would then use the returned record number and the record length to calculate the position of the first byte of the record in the file.

The SQL command parser of the Data Environment does not accept the forward slash (/) character. The OLE DB Provider for AS/400 and VSAM automatically substitutes a forward slash in place of the period and passes the correctly formatted path to your AS/400 computer.

When using the Data Environment with Microsoft Visual Basic 6.0, it is possible to get the following error when accessing the OLE DB Provider for AS/400 and VSAM:

```
"File is in use by another process. Unspecified error"
```

This error can occur after a data source has been configured for the OLE DB Provider for AS/400 and VSAM using the Data Links property page and a command is added using the Data Environment where the command added is the following:

```
"EXEC OPEN filename"
```

Using the Data Environment and selecting **Run** for this command can result in the preceding error. The Data Environment is opening the file and then trying to open it a second time based on the command to execute without closing the first copy. Depending upon the share options of the data set and the DBPROP_INIT_MODE property set for this data source, this error can occur and the user can be locked out of the AS/400 or VSAM file.

The OLE DB Provider for AS/400 and VSAM does not support the following Microsoft® SQL Server™ features:

- Replication
- Distributed queries as a linked server

However, the provider does support Data Transformation Services (DTS), with the following limitations:

1. Only bulk table copy (Import/Export) is available.

2. Only one data conversion layout (HCD map) per dataset.

   Specifically, there is no support for converting nested records, such as COBOL OCCURS or REDEFINE.

3. DTS can connect to DFM (a component of IMB SMS and Tivoli), but only over a SNA LU6.2 network connection.

4. Due to the architecture of the OLE DB provider, the SNAOLEDB connection is slower than Host File Transfer ActiveX control.

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

The syntax supported by the OLE DB Provider for AS/400 and VSAM for command text is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 using a 5250 terminal session. For a detailed list of possible commands, see the *OS/400 CL Reference* for your platform.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a rowset (table) using command text is as follows:

```
EXEC OPEN FileName
```

where *FileName* represents one of the following host file naming conventions listed in the following table.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned data sets (PDSs)	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILENAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY.FILENAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

The distributed queries feature of SQL Server is sometimes referred to as the Distributed Query Processor (DQP).

The AS/400 BIGINT data type is not supported in this release.

This section contains:

- Record Access and Data Conversion

- Record Locking
- Client Cursor Engines Using the OLE DB Provider for AS/400 and VSAM
- Error Codes Returned by the OLE DB Provider for AS/400 and VSAM

Record Access and Data Conversion

The design of the OLE DB APIs is similar to the APIs provided by ODBC and other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default C data types as defined in ODBC, as illustrated in the following table.

Host data type	Default C data type
Binary	unsigned char binary[]
Character	char string[]
Date (in character format)	date struct
Double	Double
Long	Int
Packed	unsigned char number[]
Short	Short
Single	Float
Time (in character format)	time struct
Time Stamp (in character format)	timestamp struct
Variable Binary	unsigned char binary[]
Variable Character	char string[]
Zoned	unsigned char number[]

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example). However, truncation and conversion errors can occur that will not be reported by the OLE DB Provider for AS/400 and VSAM.

The OLE DB Provider for AS/400 and VSAM has a number of other limitations:

- Positive signed floating-point values cannot be read from ZONED DECIMAL fields.
- No floating point values can be inserted into ZONED DECIMAL fields.
- No values can be inserted into single-precision FLOATING POINT fields.
- Positive signed floating-point values cannot be inserted into PACKED DECIMAL fields.
- The ADO **Find** method fails to locate the first record when the key is multiple columns and the first column is a VARCHAR or TIME data type.

You can use the OLE DB Provider for AS/400 and VSAM to access a System/36 computer. However, the automatic mapping from host to client does not occur correctly when you attempt to access the System/36 host. Instead, you must manually map the data types using a host column description (HCD) file. The following table indicates the data types you must map to when accessing a System/36 computer.

Host data type	OLE DB data type	Comments
Character	DBTYPE_STR	Null-terminated ASCII character string.

Zoned	DBTYPE_STR	The NUMERIC typedef structure defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.

Record Locking

Distributed data management (DDM) supports record locks so that a requester can perform intended operations on a record without interference from concurrent users. Record locks are used only when the requester opens a file with intent to update the file and specifies that the file is to be shared with another user. Two types of record locks are supported. Record locks are handled automatically by the Microsoft OLE DB Provider for AS/400 and VSAM whenever users call **IRowsetChange::SetData** (in immediate mode) or **IRowsetUpdate** (in the delayed mode). The OLE DB Provider for AS/400 and VSAM locks the record, updates the record, and then releases the lock.

Client Cursor Engines Using the OLE DB Provider for AS/400 and VSAM

The Microsoft Data Access Components (MDAC) supports the option of a client cursor engine. This feature is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the **CursorLocation** property on the recordset to **adUseClient**.

The OLE DB Provider for AS/400 and VSAM does not support any updating capabilities when used with a client cursor engine. If a client cursor engine is enabled using RDS or ADO, the OLE DB provider cannot be used to update data on the host. The ADO recordset is treated as if it were read-only.

Error Codes Returned by the OLE DB Provider for AS/400 and VSAM

The Microsoft OLE DB Provider for AS/400 and VSAM supports ranges of error codes, as listed in the following table.

Error code range	Source	Definition
1–100	Ddmapi.dll	OLE DB error codes (see OLE DB Provider for AS/400 and VSAM).
256–511	Ddm.dll	IBM DDM documentation.
512–higher	Ddmwappc.dll	Errors specific to the OLE DB Provider for AS/400 and VSAM.

An invalid local LU alias at connect time yields "Network Error" instead of "Invalid Local LU Alias" error. No error is reported when connecting using a nonexistent default library value.

Host Column Description

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a host column description (HCD) file to specify how data on the host is converted by the OLE DB provider. These HCD files are not necessary when used with IBM AS/400 computers because the host data format is automatically determined by the OLE DB provider. When used with AS/400 computers, the OLE DB provider uses default conversions from host data type to OLE DB data types. However, HCD files can be used with AS/400 computers to override the host data format and specify a particular local OLE DB data type to which the data is to be converted.

The following topics describe the host column description file format in detail and provide an example of an HCD file for illustration.

This section contains:

Host Column Description File Format

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a host column description (HCD) file to describe the format of data files on IBM mainframes and dictate how the data in columns or fields in these files is to be converted by the OLE DB provider. Host column description files can also be used for data on AS/400 computers to override the data format description maintained by the AS/400 host.

The default naming convention for the HCD file is <*data source*>.hcd, where <*data source*> is the remote LU alias, and .hcd is the file extension of the record description file. For example, if the remote LU alias configured on Host Integration Server is named ABC01234, the host column description file would be named ABC01234.hcd as the default. Any name may be used for an HCD file as long as the file extension is .hcd.

All the Virtual Storage Access Method (VSAM) files that have local record descriptions are listed in the [Files] section of the record description file. Each file that is listed in the [Files] section has a record description section, and that section name is the same as the file name. For example, a VSAM file named PUBS/AUTHORS has its record description saved in the [PUBS/AUTHORS] section.

The first key of a record description section is the number of the columns for the file. The syntax is as follows:

```
numcol=<number of columns>
```

Where <*number of columns*> is the actual number of columns described in the section. Each column of a file is described by one key. The naming convention for the key name is as follows:

```
col<column number>
```

For example the ninth columns key is **col9**. Each key has an attribute list that contains eleven concatenated attributes that describe the column. Attributes are separated by semicolons.

Host Column Description Attributes

Attributes are shown in the following table.

Attribute	Field number	Description
Reserved	1	Always zero
Column Name	2	Character string
Alias	3	Character string
Precision	4	Numeric value
Scale	5	Numeric value
Length	6	Numeric value
Host Type	7	Keyword representing the host data type
OLE DB Type	8	Keyword representing the local OLE DB data type
Nullable	9	Y or N
CCSID	10	Numeric value
Title	11	Character string

Column Name

The Column Name attribute is the character string that represents the name of the column. This attribute may be null.

Alias

The Alias attribute is an optional character string that represents an alias label for the column string name. This attribute may be null.

Precision

The Precision attribute is the total number of decimal digits in the column containing numeric data on the host. The only two fixed-point numeric data types that require this information are the NUMERIC and DECIMAL keyword data types, and for these types this field cannot be null and must contain a valid numeric value.

The precision must be set the same as the length attribute for CHAR and BINARY keyword data types, and set to zero for the other types. (Note that under ODBC, the precision was also used to indicate the length of nonnumeric data types including character, date, time, and binary data types.) Precision has no default value and must not be left null.

Scale

The Scale attribute is the number of decimal digits to the right of any decimal point for numeric data on the host. The only two numeric data types that require this information are the NUMERIC and DECIMAL keyword data types, and for these types this field cannot be null and must contain a valid numeric value. For other numeric (the SINGLE and DOUBLE keywords, for example) and nonnumeric data types (binary, character, date, time, and timestamp), the scale should be set to zero. This field must not be left null and must contain a numeric value.

Length

The Length attribute is the total length of the data on the host. This field must not be left empty and must contain a numeric value.

Host Type

The Host Type attribute is a keyword value that represents the data type of the host data. This keyword value is based on standard data types used on AS/400 and VSAM files. If no keyword is entered, this attribute defaults to the BINARY keyword. The following table describes the allowable types for AS/400 and VSAM.

Host type name	Keyword	Comment
Binary	BINARY	Fixed-length binary data (no character code conversions). The length must be specified.

Character	CHAR	Fixed-length character data. The length must be specified.
Date	DATE	The date represented as character data in the format yyyy-mm-dd that fits in 10 bytes.
DBCS	DBCS	Fixed-length character data that can contain only DBCS data.
DCBS – Mixed Either	MIXED_EITHER	Fixed-length character data that can contain either DBCS or alphanumeric data.
DCBS – Mixed Open	MIXED_OPEN	Fixed-length character data that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters.
DBCS – Variable	VARDBCS	Variable-length character data with a prefix of 2 bytes for length that contains only DBCS data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Either	VARMIXED_EITHER	Variable-length character data with a prefix of 2 bytes for length that can contain either DBCS or alphanumeric data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Open	VARMIXED_OPEN	Variable-length character data with a prefix of 2 bytes for length that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with SHIFT+CTRL characters. The maximum possible length for the column containing this data type must be specified.
Double	DOUBLE	Floating-point data that fits in 8 bytes (64 bits).
Long	LONG	Integer data that fits in 4 bytes (32 bits).
Long Variable Binary	LONGVARBINARY	Variable-length binary data represented as an unsigned character array with prefix 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Long Variable Character	LONGVARCHAR	Variable-length character data with a prefix of 2 bytes for the length. The maximum possible length for the column containing this data type must be specified.
Packed	PACKED	Packed decimal numeric data where the precision and scale are exactly as specified.
Short	SHORT	Integer data that fits in 2 bytes (16 bits).
Single	SINGLE	Floating-point data that fits in 4 bytes (32 bits).
Time	TIME	The time represented as character data in the format hh:mm:ss that fits in 8 bytes.
Time Stamp	TIMESTAMP	Timestamp represented as characters in the format yyyy-mm-dd hh:mm:ss.ffffff that fits in 19 bytes.
Variable Binary	VARBINARY	Variable-length binary data represented as an unsigned character array with prefix 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Variable Character	VARCHAR	Variable-length character data with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Zoned	ZONED	Zoned decimal numeric data where the precision and scale are exactly as specified.

Note that the OLE DB provider limits the maximum length character field that can be accessed on an AS/400 computer to 32,745. Attempting to access a character field greater than this length on an AS/400 computer can have unpredictable results and can cause the OLE DB provider to stop responding.

Note that the floating-point data format assumed by the OLE DB Provider for AS/400 and VSAM depends on the host. For AS/400, the host floating-point data format is assumed to be IEEE. On mainframe hosts, floating-point data types are assumed to be in IBM floating-point formats. Because OLE DB supports the IEEE floating-point format, data conversion errors can occur when converting the extreme values of VSAM floating-point data in IBM format to IEEE floating-point data by the OLE DB provider.

Note that the DECIMAL, FLOAT, INTEGER, NUMERIC, REAL, and SMALLINT keywords should not be used in HCD files and should be replaced with the newer keywords as follows:

- The DOUBLE keyword replaces the FLOAT keyword.
- The LONG keyword replaces the INTEGER keyword.
- The PACKED keyword replaces the NUMERIC keyword.
- The SHORT keyword replaces the SMALLINT keyword.
- The SINGLE replaces the REAL keyword.
- The ZONED keyword replaces the DECIMAL keyword.

The Data Descriptions management console snap-in provided with Host Integration Server does not work properly with HCD files containing these older keywords and will give unpredictable results.

OLE DB Type

The OLE DB Type attribute is a keyword that represents the data type of the local personal computer data. This keyword value is based on the standard OLE DB data types as defined in the OLEDB.H header file included with the OLE DB SDK version 1.5 and later. The data structures for the date, time, and timestamp C data types are defined as typedefs in the OLEDB.H header file included with the OLE DB SDK. Similar data types are also used by ODBC. If no keyword is entered, this attribute defaults to the BINARY keyword.

For the decimal and numeric host data types, the OLE DB Type attribute must be set to DBTYPE_STR. These two fixed-point numeric types are currently converted to character data strings by the DDM layer of the Microsoft OLE DB Provider for AS/400 and VSAM. If these host types are converted to any of the defined OLE DB numeric C types, numeric accuracy can be lost.

The allowable types are listed in the following table.

OLE DB type name	Keyword	Comment
DBTYPE_BYTES	BINARY	Fixed-length binary data represented as an unsigned char array.
DBTYPE_DBDATE	DATE	The OLE DB DBDATE typedef struct as defined in the OLEDB.H header file.
DBTYPE_DBTIME	TIME	The OLE DB DBTIME typedef as defined in the OLEDB.H header file.
DBTYPE_DBTIMESTAMP	TIMESTAMP	The OLE DB DBTIMESTAMP typedef struct as defined in the OLEDB.H header file.
DBTYPE_DECIMAL	DECIMAL	The OLE DB DECIMAL typedef struct as defined in the OLEDB.H header file.
DBTYPE_I2	SHORT	Integer data stored in 2 bytes (16 bits).
DBTYPE_I4	LONG	Integer data stored in 4 bytes (32 bits).
DBTYPE_NUMERIC	NUMERIC	The OLE DB NUMERIC typedef struct as defined in the OLEDB.H header file.
DBTYPE_R4	FLOAT	Floating-point data stored in 4 bytes (32 bits).
DBTYPE_R8	DOUBLE	Floating-point data stored in 8 bytes (64 bits).
DBTYPE_STR	CHAR	Character data.
DBTYPE_I1	Not applicable	Not supported (signed tiny integer stored in one byte, 8 bits).

DBTYPE_I8	Not applicable	Not supported (signed long integer stored in eight bytes, 64 bits).
DBTYPE_UI1	Not applicable	Not supported (unsigned tiny integer stored in one byte, 8 bits).
DBTYPE_UI2	Not applicable	Not supported (unsigned short integer stored in two bytes, 16 bits).
DBTYPE_UI4	Not applicable	Not supported (unsigned long integer stored in four bytes, 32 bits).
DBTYPE_UI8	Not applicable	Not supported (unsigned long integer stored in eight bytes, 64 bits).

Nullable

The Nullable attribute indicates whether this field can be a null value. Legal values for this field are Y or N. If this field is empty, the default value for nullable is N. The current version of the OLE DB Provider for AS/400 and VSAM does support nullable fields, so this value must be set to N.

CCSID

The character code set identifier (CCSID) attribute indicates the character set used on the host. If this field is empty, the default value for CCSID is set to EBCDIC US English (37). The CCSID setting used by the OLE DB provider must be set to match the CCSID actually used on the host, otherwise data loss will occur. Note that some AS/400 systems default to a CCSID of 937, rather than 37, for enabling double-byte character sets (DBCS).

If the CCSID is set to 0 or 65535, no character translation will take place when converting character data from the host to the personal computer by the OLE DB provider. The allowable values for CCSID when used with OLE DB Provider for AS/400 and VSAM are listed in the following table.

EBCDIC character set	CCSID value
U.S./Canada	37
Germany	273
Denmark/Norway	277
Finland/Sweden	278
Italy	280
Latin America/Spain	284
United Kingdom	285
France	297
International	500

Note that this value needs to correspond to the CCSID used on the host.

Title

The Title attribute is an optional character string that represents a comment describing the column. This attribute may be null.

Host Column Description Example File

The following is an example for a host column description (HCD) file containing two sample database file descriptions—SAMPLE/ACCOUNTS and PUBS/AUTHORS. The first sample file (SAMPLE/ACCOUNTS) has four columns of data while the second example (PUBS/AUTHORS) has nine columns that must be described.

```
[files]
SAMPLE/ACCOUNTS=1
PUBS/AUTHORS=1

[SAMPLE/ACCOUNTS]
numcol=4
col1=0;CUST_NO;CUST_NO;8;0;0;ZONED;LONG;N;37;;
col2=0;CUST_NAME;CUST_NAME;0;0;40;CHAR;CHAR;N;37;;
col3=0;BALANCE;BALANCE;10;2;0;ZONED;FLOAT;N;37;;
col4=0;LAST_ACC;LAST_ACC;0;0;26;TIMESTAMP;TIMESTAMP;N;37;;

[PUBS/AUTHORS]
NumCol=9
Col1=0;AU_ID;AU_ID;11;0;11;CHAR;CHAR;N;37;;
Col2=0;AU_LNAME;AU_LNAME;0;0;40;VARCHAR;CHAR;N;37;;
Col3=0;AU_FNAME;AU_FNAME;0;0;20;VARCHAR;CHAR;N;37;;
Col4=0;PHONE;PHONE;0;0;12;CHAR;CHAR;N;37;;
Col5=0;ADDRESS;ADDRESS;0;0;40;VARCHAR;CHAR;N;37;;
Col6=0;CITY;CITY;0;0;20;VARCHAR;CHAR;N;37;;
Col7=0;STATE;STATE;2;0;2;CHAR;CHAR;N;37;;
Col8=0;ZIP;ZIP;0;0;5;CHAR;SHORT;N;37;;
Col9=0;CONTRACT;CONTRACT;0;0;9;BINARY;BINARY;N;37;;
```

Conversion from Host to OLE DB Data Types

The external record description for data files residing on mainframes is configured in a host column description (HCD) file using the SNA OLE DB management snap-in. This HCD file is used to convert from host EBCDIC data types to ASCII C data types for the computer in the Distributed Data Management (DDM) dynamic-link library (DLL). These C data types are then mapped to OLE DB data types by the SNAOLEDB DLL.

This section contains:

Default OLE DB Data Types

The following table indicates the default OLE DB data types that result from the mapping of the host data types by the Microsoft OLE DB Provider for AS/400 and VSAM.

Host data type	OLE DB data type	Comments
Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char).
Character	DBTYPE_STR	Null-terminated ASCII character string.
Date	DBTYPE_DBDATE	The DBDATE typedef struct defined in OLEDB.H header file.
DBCS	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Mixed Either	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Mixed Open	DBTYPE_STR	Null-terminated ASCII character string.
DBCS – Variable	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Variable Mixed Either	DBTYPE_STR	Null-terminated ASCII character string.
DCBS – Variable Mixed Open	DBTYPE_STR	Null-terminated ASCII character string.
Double	DBTYPE_R8	8-byte floating-point data.
Float	DBTYPE_R8	8-byte floating-point data.
Long Integer	DBTYPE_I4	4-byte signed integer.
Long Variable Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char).
Long Variable Character	DBTYPE_STR	Null-terminated ASCII character string.
Packed	DBTYPE_DECIMAL	The DECIMAL structure typedef defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.
Real	DBTYPE_R4	4-byte floating-point data.
Short	DBTYPE_I2	2-byte signed integer.
Single	DBTYPE_R4	4-byte floating-point data.
Time	DBTYPE_DBTIME	The DBTIME typedef defined in OLEDB.H header file.
Time Stamp	DBTYPE_DBTIMESTAMP	The DBTIMESTAMP typedef defined in OLEDB.H header file.
Variable Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char).
Variable Character	DBTYPE_STR	Null-terminated ASCII character string.
Zoned	DBTYPE_NUMERIC	The NUMERIC typedef structure defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.

The host Binary, VarBinary, and Long VarBinary data types are converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_BYTES data type by the SNAOLEDB DLL. The host Zoned data type is converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_NUMERIC data type by the SNAOLEDB DLL. The host Packed data type is converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_DECIMAL data type by the SNAOLEDB DLL.

DBDATE

The **DBDATE** structure typedef is defined as follows:

Syntax

```
typedef struct tagDBDATE {
    SHORT  year;
    USHORT month;
    USHORT day
} DBDATE;
```

Members

year

The year (0 to 9999) is measured from 0 A.D.

month

The month ranges from 1 to 12 representing January through December.

day

The day ranges from 1 to a maximum of 31, depending on the number of days in the month.

DBTIME

The **DBTIME** structure typedef is defined as follows:

Syntax

```
typedef struct tagDBTIME {
    USHORT hour;
    USHORT minute;
    USHORT second
} DBTIME;
```

Members

hour

The hour ranges from 0 to 23.

minute

The minute ranges from 0 to 59.

second

The second ranges from 0 to 59.

DBTIMESTAMP

The **DBTIMESTAMP** structure typedef is defined as follows:

Syntax

```
typedef struct tagDBTIMESTAMP {
    SHORT  year;
    USHORT month;
    USHORT day;
    USHORT hour;
    USHORT minute;
    USHORT second;
    ULONG  fraction
} DBTIMESTAMP;
```

Members

year

The year (0 to 9999) is measured from 0 A.D.

month

The month ranges from 1 to 12 representing January through December.

day

The day ranges from 1 to a maximum of 31, depending on the number of days in the month.

hour

The hour ranges from 0 to 23.

minute

The minute ranges from 0 to 59.

second

The second ranges from 0 to 59.

fraction

The fraction represents billionths of a second ranging from 0 to 999,999,999.

DECIMAL

The **DECIMAL** typedef structure is an exact numeric value with a fixed precision and fixed scale, stored in the same way as in OLE Automation. The **DECIMAL** typedef structure is defined as follows:

Syntax

```
typedef struct tagDECIMAL {
    USHORT wReserved;
    union {
        struct {
            BYTE scale;
            BYTE sign;
         };
        USHORT signscale;
    };
    ULONG Hi32;
    union {
        struct {
             ULONG Lo32;
             ULONG Mid32;
          };
         ULONGLONG Lo64;
    };
} DECIMAL;
```

Members

wReserved

This member is reserved and should be 0.

scale

Specifies the number of digits to the right of the decimal point and ranges from 0 to 28.

sign

The sign is 0 if positive, 0x80 if negative.

Hi32

The high part of the integer (32-bit aligned).

Mid32

The middle part of the integer (32-bit aligned).

Lo32

The low part of the integer (32-bit aligned).

For example, to specify the number 12.345, the scale is 3, the sign is 0, and the number stored in the 12-byte integer is 12345.

NUMERIC

The **NUMERIC** typedef structure is an exact numeric value with a fixed precision and fixed scale. The **NUMERIC** typedef structure is defined as follows:

Syntax

```
typedef struct tagNUMERIC {
    BYTE precision;
    BYTE scale;
    BYTE sign;
    BYTE val[16];
} DB_NUMERIC;
```

Members

precision

The maximum number of digits in base 10.

scale

The number of digits to the right of the decimal point.

sign

The sign is 1 for positive numbers, and 0 for negative numbers.

val

A number stored as a 16-byte scaled integer, with the least significant byte on the left.

For example, to specify the base 10 number 20.003 with a scale of 4, the number is scaled to an integer of 200030 (20.003 shifted by four tens digits), which is 186AA in hexadecimal. The value stored in the 16-byte integer is 5E 0D 03 00 00 00 00 00 00 00 00 00 00 00 00 00, the precision is the maximum precision, the scale is 4, and the sign is 1.

Character Code Conversions

Character code conversions under the OLE DB Provider for AS/400 and VSAM are controlled by a hierarchy of parameters. When connecting to mainframes all of these parameters are controlled on the personal computer. However, when connecting to data sources on the AS/400, parameter settings on the AS/400 as well as parameter settings on the personal computer can be involved.

The character code set identifier (CCSID) used by the host for a data source can be specified in several locations. The Host CCSID setting used by the OLE DB provider must be set to match the CCSID actually used on the host; otherwise data loss will occur. Note that some AS/400 systems default to a CCSID of 937 rather than 37 for enabling double-byte character sets (DBCS).

The following table illustrates the separate hierarchy controlling the Host CCSID parameter on the SNA client, AS/400 host, and mainframe host.

SNA client	**AS/400 host**	**Mainframe host**
SNA OLE DB provider (defaults to U.S./Canada 37)	System (DSPSYSVAL, QCCSID)	None. Determined by the Data Description (HCD file) on the SNA Client.
Data Source (the Host CCSID parameter in the Data Links file describing the Data Source)	User identifier (wrk usrprf)	
Data Description (HCD file)	Job (dspjob, crtjobd)	
	File (dspfd, crtpf)	
	Column (dspffd)	

Note

Only those fields in a Data Source that contain character data are affected by the Host CCSID parameters and character conversions. This section contains:

- Host CCSID and SNA OLE DB Provider
- Host CCSID and Data Source
- Host CCSID and Data Description
- Host CCSID and the Process Binary As Character Parameter

Host CCSID and SNA OLE DB Provider

The Host CCSID setting at the OLE DB provider level defaults to U.S./Canada (37).

Host CCSID and Data Source

The Host CCSID setting at the Data Source level is configured using Data Links for each Data Source. The **Host CCSID** parameter is configured under the **All** tab of the **Data Links** dialog box.

Valid values for the Host CCSID registry setting are any CCSID, including 65535. If the Host CCSID attribute is set to 65535, no character conversion occurs (the data is treated as binary). If the Host CCSID setting at the Data Source level does not exist, the value for Host CCSID defaults to the value at the SNA OLE DB provider level.

Host CCSID and Data Description

A Host CCSID attribute can be applied at the Data Description level. Each column in a host column description (HCD) file can have a Host CCSID attribute that determines how the character data in the column is to be converted. These attributes in the HCD file at the Data Description level should be configured using the SNA OLE DB management console snap-in. (For more information, see Configuring Data Descriptions) Valid values are any CCSID including 65535.

The Host CCSID attribute at the column Data Description level can be any value and may be empty. A Host CCSID value at the Data Description level overrides the value specified at the Data Source and OLE DB provider levels. If the Host CCSID is blank, the value for Host CCSID defaults to the value at the Data Source level. If the Host CCSID attribute is set to 65535, no character conversion occurs (the data is treated as binary).

Host CCSID and the Process Binary As Character Parameter

There is a Data Source parameter configurable using Data Links that affects whether binary data is considered as character data and is converted based on the Host CCSID setting. This **Process Binary As Character** parameter defaults to *false*. If this parameter is *false*, binary data is not treated as character (binary data is not affected by the Host CCSID setting). If this parameter is set to *true*, binary data is converted based on the Host CCSID setting.

This parameter is configured for each Data Source using Data Links under the **All** tab of the **Data Links** dialog box.

Using Package Designer with the OLE DB Provider for AS/400 and VASM

When using SQL Server Integration Services with the Microsoft OLE DB Provider for AS/400 and VSAM within the Package Designer in Visual Studio 2005, SSIS may raise the following warning dialog:

```
Warning at {9C6AC00C-13CF-4EF8-B44A-72055CC508C2} [OLE DB Source [262]]: Cannot retrieve the column code page info from the OLE DB provider. If the component supports the "DefaultCodePage" property, the code page from that property will be used. Change the value of the property if the current string code page values are incorrect. If the component does not support the property, the code page from the component's locale ID will be used.
```

Server Integration Services supports the option of specifying a per-column Locale Identifier for string data types, such as CHARACTER. However, the Microsoft OLE DB Provider for AS/400 and VSAM does not support this option. You can work around this limitation by modifying the settings in the Advanced Editor.

To allow the OLE DB Provider for AS/400 and VASM to use the default code page

1. In the Data Flow Task Design surface, add a new OLE DB Source or OLE DB Destination for use with the Microsoft OLE DB Provider for AS/400 and VSAM.
2. Right-click the OLE DB source or destination object, and then click **Show Advanced Editor...**.
3. On the Advanced Editor screen, click the Component Properties page.
4. Set **AlwaysUseDefaultCodePage** to True.
5. Click **OK**.

   Clicking OK saves the settings for use with the current OLE DB source or destination object within the SSIS package.

OLE DB Provider for AS/400 and VSAM Programmer's Guide

OLE DB Provider for DB2 Programmer's Guide

Microsoft® OLE DB Provider for DB2 enables users to access IBM DB2 from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for DB2 combines the universal data access of OLE DB with the IBM Distributed Relational Database Architecture (DRDA).

Organizations have invested in secure, robust, enterprise-wide data storage and management systems. DRDA is a set of rules for distributing or extending relational data from one computer to another, such as from a personal computer server to an IBM DB2 database server running on a mainframe or an AS/400 computer. By combining the OLE DB and DRDA architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal data access to all enterprise-wide data sources.

For application programming interface (API) references and other technical information about OLE DB providers, see theOLE DB Providers Programmer's Reference section of the software development kit (SDK).

For more information on using the OLE DB Provider for DB2, seethe OLE DB Provider for DB2 section of the Operations guide.

In This Section

- OLE DB Provider for DB2 Requirements
- Configuring the OLE DB Provider for DB2

Goals of the OLE DB Provider for DB2

Relational database management systems (RDBMS) are one of the major sources of mission-critical information in today's enterprise organizations. Relational database technology enables departments and individual users to save their information in centrally managed database stores that can be easily maintained by the organization's information systems group. Specific query tools designed for accessing relational database systems have added greater flexibility and ease of access to this information.

These same enterprises rely on vast networks of personal computers to enable their users to achieve business goals. End users invariably rely on network e-mail; Microsoft® Windows® productivity applications, such as Microsoft Office; and personal database programs, such as Microsoft Access, to accomplish their daily tasks. It is essential for these same users to incorporate data stored in relational database systems into their regular correspondence, analysis, and reports.

The challenge you have is how to provide access to this valuable data without the effort involved in developing traditional database applications. Much of the renewed interest in improved access to data sources is a result of the growth in the use of Internet and Web technology as mechanisms for delivering information. Fast and inexpensive methods of accessing data stored in RDBMS systems are necessary to deliver modern, three-tiered information systems during this era of cost cutting and budget tightening. Additional uses of this relational database access include specific queries and Web-based reporting.

IBM DB2 is a popular RDBMS for a significant number of enterprise customers. Customers need a cost-effective and manageable means to integrate DB2 with Microsoft SQL Server™, Microsoft Internet Information Services (IIS), and Microsoft Office applications. The goal of the OLE DB Provider for DB2 is to provide customers and solution providers with the means to integrate desktop applications with this wealth of data residing on DB2 database systems.

Distributed Relational Database Architecture

Database technology has enabled departments and individual users to save their information locally—as opposed to centrally managed stores owned by the organization's information systems group. Along with local storage and database query tools comes greater flexibility and ease of access to information. As more databases became distributed, a need emerged for users to access data stored remotely. IBM devised the Distributed Relational Database Architecture (DRDA) to enable their customers to access remote, distributed database systems across hardware platforms.

DRDA supports most dialects of the Structured Query Language (SQL) for access to relational database management systems (RDBMS). SQL is an international standard that defines a standardized language for accessing database management systems (DBMS). DRDA implementations generally support SQL in two ways: static (embedded) SQL, where the SQL commands are embedded directly in the application program and prepared as an extra step in the process of compiling the application; and dynamic or interactive (callable) SQL, where the user passes SQL commands as function calls at run time. One popular IBM implementation of dynamic SQL is the Call Level Interface (CLI). With dynamic SQL or CLI, SQL preparation is not required.

Clients that comply with DRDA are referred to as application requesters (AR) because they request data from the DRDA server. Servers that comply with DRDA are referred to as application servers (AS). Typically, application servers are implemented as the link to the RDBMS. In some cases, products are implemented as both application requesters and application servers.

DRDA supports access to stored procedures on DB2. SQL applications can invoke stored procedures or user-written programs on DB2 using the SQL **CALL** statement.

The OLE DB Provider for DB2 is an application requester implementation that can initiate DRDA commands to be serviced by a remote target DRDA application server represented by IBM DB2. On the Microsoft® Windows Server™ 2003 and Windows® 2000 Server operating systems, the Microsoft DRDA application requester can run as a service. This enables the integration of the DRDA service with other host applications using the IBM DRDA protocols and DRDA servers resident on the host. Microsoft host software is not required. (For more information, see Platforms Supported by the OLE DB Provider for DB2). IBM offers DB2 servers for most popular environments.

Platforms Supported by the OLE DB Provider for DB2

IBM and other software vendors have implemented Distributed Relational Database Architecture (DRDA) support into database systems, such as IBM DB2, and database tools on a wide range of operating systems. DRDA is an open, published, and widely supported protocol, which requires no additional license for development. This makes DRDA appealing to independent software vendors (ISVs), solution providers, large corporate development groups, as well as their customers.

The Microsoft® OLE DB Provider for DB2 is implemented as an IBM DRDA application requester, which means it connects to popular DRDA-compliant DB2 systems.

The Microsoft OLE DB Provider for DB2 can access DB2 systems through SNA LU 6.2 using Microsoft Host Integration Server, and can access DB2 systems directly using TCP/IP.

OLE DB Provider for DB2 Requirements

When connecting over SNA using LU 6.2, the OLE DB Provider for DB2 requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2009
- Microsoft Host Integration Server Client

When connecting to a host system using TCP/IP, the OLE DB Provider for DB2 does not require any special host connectivity software.

The OLE DB Provider for DB2 supports the following OLE DB and ADO versions:

- OLE DB version 2.5. The Host Integration Server data access features require the run-time libraries for OLE DB version 2.5. These OLE DB libraries are installed as part of the Windows Server 2003 and Windows 2000 operating systems.
- ADO version 2.5. The Host Integration Server data access features require the run-time libraries for ADO version 2.5. On Windows Server 2003 and Windows 2000, these ADO libraries are installed as part of the Windows Server 2003 and Windows 2000 operating systems.

Configuring the OLE DB Provider for DB2

Microsoft® Data Access Components (MDAC) include Data Links, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Links provides a uniform method of creating persistent OLE DB data source object definitions stored in the form of universal data link (.udl) files. The OLE DB Provider for DB2 normally uses Data Links and .udl files for loading and configuring data sources.

The Data Source Wizard in the Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server™ can use the .udl files to connect to IBM data sources, such as DB2 and the mainframe file system.

To use Microsoft OLE DB Provider for DB2 with an OLE DB consumer application, the user must either create a Microsoft universal data link (.udl) file and call this from the application, or call the OLE DB provider from within the application using a connection string that includes the provider name and any other needed parameters.

This section contains:

Creating Data Links for the OLE DB Provider for DB2

Data source information must be configured for each DB2 system data source object that is to be accessed using the Microsoft® OLE DB Provider for DB2. The default parameters for the OLE DB Provider for DB2 are used as the default values for data sources when these parameters are not configured for each data source.

The Microsoft Data Links, a core element of the Microsoft Data Access Components, provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files.

The Data Source Wizard in the Microsoft Data Access Tool can help to define .udl files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can use the .udl files to connect to IBM data sources, such as DB2 and the mainframe file system.

Creating New Data Links for the OLE DB Provider for DB2

You create new Data Links using the Data Source Wizard from the Data Access Tool.

Browsing Data Sources for the OLE DB Provider for DB2

You can browse data sources using the Data Source Browser window in the Data Access Tool.

To find the physical location of the .udl file associated with a data source, right-click the **DB2 OLE DB UDLs** folder, and then click **Locate** on the context menu. Windows Explorer opens which displays the location of the file.

Configuring Data Links for the OLE DB Provider for DB2

To edit the properties of a universal data link (.udl) file, right-click the file using Windows Explorer and click **Properties**. The **Properties** dialog box appears with property tabs:

- **General**
- **Security**
- **Summary**
- **Provider**
- **Connection**
- **Advanced**
- **All**

The **General**, **Security**, and **Summary** tabs provide access to general file information for the .udl file that is available for other files and is not related to the Data Link properties. This information includes file location, file type, file size, file dates, file security permissions for access, and descriptive summary information (description and origin properties and values such title, subject, and author) for the .udl file. The **General** tab has a text box with the name of the Data Link. This filename must end with the .udl extension if the file is to be recognized as a Data Link file. Note that the **Security** and **Summary** tabs are available on NTFS files systems, and not on the older FAT file systems.

The **Provider**, **Connection**, **Advanced**, and **All** tabs provide access to the Data Link properties that need to be configured to connect to the DB2 system.

The NewSnaDS tool can also be used to open and modify an existing .udl file. The **Data Link Properties** dialog box appears with property tabs.

This section contains:

Provider

The **Provider** tab enables you to select the OLE DB provider (the provider name string) to use in the universal data link (.udl) file from a list of possible OLE DB providers. Select **the Microsoft OLE DB Provider for DB2**. The parameters and fields displayed in the remaining tabs (**Connection**, **Advanced**, and **All**) are determined by the OLE DB provider that is selected.

Connection

The **Connection** tab enables you to configure the basic properties required to connect to a data source. The **Connection** tab dialog box contains several sections:

- Data source and Network connectivity
- Authentication
- Database Properties

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for Data source and Network connectivity values.

Property	Description
Data source	The data source is an optional property that can be used to describe the data source.
Network	This drop-down list box allows selecting the type of network connection to be used. The allowable options are **TCP/IP Connection** or **APPC Connection**. If **TCP/IP Connection** is selected, click **More Options** () to open a dialog box for configuring TCP/IP network settings. The properties you can configure include the IP address of the DB2 host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **APPC Connection** is selected (using SNA LU 6.2), click **More Options** () to open a dialog box for configuring APPC network settings. The properties you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode name used for communication with the host. The default value for the APPC mode normally defaults to QPCSUPP. The local and remote LU alias fields do not have default values. The default value for the APPC mode name normally defaults to QPCSUPP. The APPC mode name can be selected from the drop-down list box.

The **Data source** in OLE DB is similar to a Data Source Name (DSN) in ODBC. The data source information is stored in a Microsoft Data Links file and contains the connection information required for the OLE DB Provider for DB2 to access IBM DB2.

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for authentication information:

Property	Description
Single sign-on	Click this check box to enable using the Host Integration Server security features providing a Single Sign-On to access this OLE DB data source. When this check box is selected, the **User** name and **Password** fields are dimmed and inaccessible. The user name and password fields are set based on the logon name used for the Windows Server 2003 or Windows 2000 domain logon. When this check box is not selected, the **User** name and **Password** fields must normally contain appropriate values to access data sources on hosts.

User name	A valid user name and password are normally required to access data sources on a host. These values are case-sensitive. Users must not check the **Single sign-on** option if a specific user name and password are to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The **Blank password** check box is only applicable for a test connection. To enter a password, the user will need to clear the **Blank password** check box if it is selected. If **Blank password** is selected, a test connection with a blank password does not cause the OLE DB provider to prompt for a password. Optionally, users can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file.

The AS/400 computer requires that the **User name** and **Password** properties be in uppercase. When connecting to DB2/400, these parameters must be passed as uppercase strings. When connecting to DB2 on IBM mainframes, the **User name** and **Password** parameters can be in mixed case.

It is possible to connect using a specific user name and password defined in DB2 on the host system or use the Single Sign-On (SSO) feature (often referred to as integrated Windows security). If a specific DB2 user name and password is to be used, this information may need to be saved into the .udl file. The user name and password are saved in plain text in the .udl file. For security reasons in these cases, it is imperative that the .udl file be protected with an access control list (ACL) that restricts access to only authorized users. Saving the user name and password in the data link also forces this .udl file to be updated whenever the password associated with the user name is changed. So for a variety of reasons, specifying a user name and password is not the preferred authentication option. Using the **Single Sign-On** option is the preferred method for authentication.

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for database property values.

Property	Description
Initial catalog	This field is the first entry in the Database section of the **Connection** properties. This OLE DB property is used as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, one can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required property. This property is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.

Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be uppercase, lowercase, or mixed case. The OLE DB provider creates packages dynamically in the location to which the user points using the Package Collection property. By default, the OLE DB provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level specified when calling the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as when setting the ADO **IsolationLevel** property on the **Connection** object. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users. (For more information, see Creating Packages for Use with the OLE DB Provider for DB2). The OLE DB Provider for DB2 ships with a tool program for use by administrators to create packages. The Data Access Tool is used to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool creates a set of packages and grants **EXECUTE** privilege on these packages to the PUBLIC group representing all users on the DB2 system. The packages (for more information, see descriptions under the isoLevel parameter of the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as the ADO IsolationLevel property) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server CrtPkg tool to make them compatible with Host Integration Server 2009. The package names changed from SNA Server 4.0. This property is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Default schema	The name of the collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the SCHEMA name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the OLE DB provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Because this default is inappropriate in many cases, it is essential that the Default Schema value in the data source be defined. This property is equivalent to the DBPROP_DB2OLEDB_CATALOGCOL OLE DB property ID.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection properties. The connection can only be tested after all of the required parameters are entered. When this button is pressed, an APPC session or a TCP/IP session attempts to be established with the host using the OLE DB Provider for DB2.

Advanced

The **Advanced** tab enables users to select the character code set identifier used by the host, the personal C code page used on the client, and some specific options when using the OLE DB Provider for DB2.

For the Microsoft OLE DB Provider for DB2, these properties include the following values.

Property	Description
DBMS Platform	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute enables the user to access database objects without fully qualifying the objects using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no **SET** statement is issued by the OLE DB Provider. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to **true**, character data is converted based on the DB2 column CCSID and default ANSI code page. This property defaults to U.S./Canada (37). This property is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.
PC code page	The PC code page property indicates the code page to be used on the computer for character code conversion. This property is required when processing binary data as character data. Unless the **Process binary as character** check box is selected (value is set to **true**), character data is converted based on the default ANSI code page configured in Windows. This property defaults to Latin 1 (1252). This property is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Read only	When this option is selected, the OLE DB Provider for DB2 creates a read-only data source by setting the Mode property to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (**INSERT**, **UPDATE**, or **DELETE**, for example). This property defaults to a **Mode** property of Read/Write (DB_MODE_READ/WRITE). This property is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Process binary as character	When this option is selected (property is set to **true**), the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This property defaults to **false**. This property is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Distributed transactions	When this option is selected, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and a Host Integration Server 2009 Resync Service. This option requires that an **APPC Connection** is selected as the network transport in the **Connection** tab and Microsoft Transaction Server (MTS) is installed. Note that Host Integration Server supports 2PC over TCP/IP as well as SNA LU 6.2. This property is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.

All

The **All** tab enables users to configure essentially all of the properties for the data source except for the OLE DB provider. The properties available in the **All** tab include properties that can be configured using the **Connection** and **Advanced** tabs as well as optional detailed properties used to connect to a data source.

For the Microsoft OLE DB Provider for DB2, these properties include the following values.

Property	Description
Affiliate Application	This property is only used when Single Sign-On is enabled. It contains the application name to use when retrieving host credentials from the Single Sign-On database. This property is equivalent to the DBPROP_DB2OLEDB_AFFILIATEAPP OLE DB property ID.
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS), which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2009 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, the Alternative TP Name is set to 0X07F9F9F9. This property is equivalent to the DBPROP_DB2OLEDB_TPNAME OLE DB property ID.
APPC Local LU Alias	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the name of the local LU alias configured in SNA services. This property is equivalent to the DBPROP_DB2OLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and SNA services configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property normally defaults to QPCSUPP. This property is equivalent to the DBPROP_DB2OLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the name of the remote LU alias configured in SNA services. This property is equivalent to the DBPROP_DB2OLEDB_REMOTELU OLE DB property ID.

APPC Security Type	When an **APPC Connection** using SNA LU 6.2 is selected for the Network Transport Library, this field is the security type that is used when allocating an SNA connection. The allowable values are: **Program** (default) and **Same**. This property is equivalent to the DBPROP_DB2OLEDB_APPCSEC OLE DB property ID.
Cache Authentication	This property determines whether the OLE DB provider caches authentication information. This property defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This property is equivalent to the DBPROP_AUTH_CACHE_AUTHINFO OLE DB property ID.
Client Application Name	Use this property to specify a custom application name that the DB2 Network Client (DRDA AR) will pass to the DB2 Server when connecting. When troubleshooting issues, you can use this value to help identify relevant portions within DB2 or system logs. This property is equivalent to the DBPROP_DB2OLEDB_CLIENTAPPNAME OLE DB property ID.
Connection Pooling	This property determines whether connection pooling is used. Connection pooling keeps a connection active after it is closed in case another connection is opened with the same properties. The default value is **False**. This property is equivalent to the DBPROP_DB2OLEDB_CONNPOOLING OLE DB property ID.
Data Source	The data source is an optional property that can be used to describe the data source. This property does not have a default value.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute enables the user to access database objects without fully qualifying the objects using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no **SET** statement is issued by the OLE DB Provider. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Default Schema	The name of the collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the SCHEMA name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the OLE DB Provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Because this default is inappropriate in many cases, it is essential that the Default Schema value in the data source be defined. This property is equivalent to the DBPROP_DB2OLEDB_CATALOGCOL OLE DB property ID.

Extended Properties	This property is a string containing provider-specific, extended connection information. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property values. This property is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. This property defaults to U.S./Canada (37). This property is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.
Initial Catalog	This OLE DB property is used as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, one can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required property. This property is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.
Integrated Security	This property determines whether the OLE DB provider uses Host Security Integration (Single Sign-On). When this property is set to SSPI, Single Sign-On is enabled and separate user ID and password parameters are not required. The user name and password fields are set based on the logon name used for the Windows Server 2003 or Windows 2000 domain logon. When this property is null, this Single Sign-On feature is disabled. This property defaults to null (host security integration is disabled) and a user ID and password are required. This property is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.

Mode	A Mode property is a bitmask specifying access permissions. This bitmask can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_WRITE—Write-only. The following values for mode are supported by the OLE DB Provider for DB2: Read (DB_MODE_READ) and Read/Write (DB_MODE_READ/WRITE). This property defaults to Read/Write. When the **Read Only** property is selected in the **Advanced** tab, the OLE DB Provider for DB2 creates a read-only data source by setting the **Mode** property to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (**INSERT**, **UPDATE**, or **DELETE**, for example). This property is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this property indicates the IP address of the DB2 host or a hostname alias for this computer. This property is equivalent to the DBPROP_DB2OLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this property is the TCP/IP port used for communication with the DB2 host. The default value is TCP/IP port 446. This property is equivalent to the DBPROP_DB2OLEDB_NETPORT OLE DB property ID.
Network Transport Library	The network transport dynamic-link library property designates whether the OLE DB Provider for DB2 connects through an APPC connection using SNA LU 6.2 or a TCP/IP connection. The possible values for this property are TCPIP or SNA. The default value for this property is **SNA**. If the default SNA is selected, values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. If TCPIP is selected, values for Network Address and Network Port are required. This property is equivalent to the DBPROP_DB2OLEDB_NETTYPE OLE DB property ID.
New Password	This property allows an OLE DB connection to change the host password for the user account used for the connection. If this property is set, the account password will be changed to the property value. This property is equivalent to the DBPROP_DB2OLEDB_NEWPWD OLE DB property ID.

Package Collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be uppercase, lowercase, or mixed case. The OLE DB provider creates packages dynamically in the location to which the user points using the Package Collection property. By default, the OLE DB provider automatically creates one package in the target collection, if one does not exist, at the time the user issues the first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level specified when calling the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as when setting the ADO **IsolationLevel** property on the **Connection** object. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users. (For more information, see **Creating Packages for Use with the OLE DB Provider for DB2**.) The OLE DB Provider for DB2 ships with a tool program for administrators to create packages. You use the **Data Access Tool** to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool creates a set of packages and grants EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system . The packages (for more information, see descriptions under the isoLevel parameter of the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as the ADO **IsolationLevel** property) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server **Data Access Tool** to make them compatible with Host Integration Server 2009. The package names changed from SNA Server 4.0. This property is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is displayed as asterisks in this dialog box for security purposes. This property is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
PC Code Page	The PC Code Page property indicates the code page to be used on the personal computer for character code conversion. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set to **true**, character data is converted based on the default ANSI code page configured in Windows. This property defaults to Latin 1 (1252). This property is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Persist Security Info	This property indicates whether the data source object is allowed to persist sensitive authentication information, such as a password along with other authentication information. This property defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This property is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	When this property is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This property defaults to **false**. The value of this property (**true** or **false**) is selected from the drop-down list box. This property is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Units of Work	This property indicates whether two-phase commit (distributed unit of work) used for transactions is supported for this data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the Host Integration Server Resync Service. The following values for this property are supported by the OLE DB Provider for DB2: RUW (remote unit of work) DUW (distributed unit of work) This property defaults to RUW. Distributed unit of work (two-phase commit) requires an APPC Connection using SNA LU 6.2 or 2PC over TCP/IP as the network transport. Microsoft Transaction Server (MTS) should also be installed. This property is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.
User ID	A valid user name is normally required to access data sources on hosts. This value is case-sensitive. This property is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

These properties on the **All** tab may be edited by selecting a property from the list displayed and selecting **Edit Value**. This button invokes a dialog box for the specific property containing a property description describing the property and a property value box for making changes.

Creating Packages for Use with the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2, which is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester, uses packages to issue SQL statements and call DB2 stored procedures. There is a provider-specific property that the OLE DB Provider for DB2 uses to identify a location in which to create and store DB2 packages. The OLE DB Provider for DB2 creates packages dynamically in the location to which the user points using the Package Collection property corresponding to the DBPROP_DB2OLEDB_PACKAGECOL property ID of OLE DB. This location may be configured using the **Connection** and **Advanced** tabs using Microsoft Data Links or can be passed as part of the connection string as an attribute keyword and argument. This attribute keyword can be either pkgcol or the long form of this attribute, Package Collection.

There are two package creation options:

1. The OLE DB Provider for DB2 autocreates one package for the currently used isolation level at run time if no package already exists. This autocreate process may fail if the user account does not have authority to create packages.

2. An administrator or user can manually creates all four packages (five packages on DB2/400) for use with all isolation levels and for use by all users (the PUBLIC group on DB2 representing all users) or a specific set of users. The OLE DB Provider for DB2 includes a program for use by users with appropriate administrative privilege that will create these packages and grant access to the PUBLIC group for this purpose.

However, some users may not have the security level when manually creating packages to GRANT authority to the packages to other users (grant authority to the DB2 PUBLIC group representing all users, for example). This can be a problem if two or more users with different user IDs try to access a single collection of packages. The first user that created the packages will have access to the packages, but the second user likely will not. The Host Integration Server 2009 CD includes a program for use by an administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. You use the Data Access Tool to create packages for use with DB2.

A shortcut for this tool is added to the **Programs** menu off the **Start** button on the Windows taskbar under the **Host Integration Server\Data Integration** folder with a name of **Data Access Tool**. This shortcut is created when the Microsoft Host Integration Server or the Host Integration Client is first installed and support for Data Access is checked.

This tool creates a set of packages and grants EXECUTE privileges on these packages to the PUBLIC group. The PUBLIC group on DB2 systems is a default group that represents all DB2 users. The following packages are created:

- AUTOCOMMITTED package (MSNC001) is only applicable on DB2/400)
- READ UNCOMMITTED package (MSUR001)
- READ COMMITTED package (MSCS001)
- REPEATABLE READ package (MSRS001)
- SERIALIZABLE package (MSRR001)

Note that the AUTOCOMMITTED package (MSNNC001) is only created on DB2 for OS/400.

The descriptive process name used by the Data Access Tool corresponds with the isolation levels defined in the ANSI SQL standard. The following table indicates how these packages correspond with the terms used by IBM for isolation levels in DB2 documentation.

Package description	**Package name**	**IBM documentation**
AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level)	MSNC001	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 autocommit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.

READ UNCOMMITTED	MSUR001	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.
READ COMMITTED	MSCS001	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
REPEATABLE READ	MSRS001	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.
SERIALIZABLE	MSRR001	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2009. The package names used by the OLE DB Provider for DB2 on SNA Server 4.0 are not compatible with the OLE DB Provider for DB2 included with Host Integration Server. On SNA Server 4.0, these packages used different names as follows:

```
AUTOCOMMITTED package (SNANC001) only applicable on DB2/400
READ UNCOMMITTED package (SNACH001)
READ COMMITTED package, (SNACS001)
REPEATABLE READ package, (SNARR001)
SERIALIZABLE package (SNAAL001)
```

These isolation levels are described in detail in Support for Isolation Levels Using the OLE DB Provider for DB2. These isolation levels are also described under the OLE DB isoLevel parameter and ADO IsolationLevel property. Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

Note that the Data Access Tool creates this set of packages and grants EXECUTE privileges to the PUBLIC group. There may be cases for security reasons where EXECUTE privileges to this set of packages on the DB2 system should be restricted to a different group of users or specific users. In these cases, execution privileges on these created packages need to be modified on the host system.

The Data Access Tool creates all of these packages inside the Collection that is specified in the Package Collection property in the data link file, or in the connection string. If the user does not have the appropriate authority to create packages in the specified Collection, or if the specified Collection does not exist, the OLE DB Provider for DB2 will return an error.

In the case of DB2 on MVS or OS/390, the normal error text returned if the user does not have the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version fo
r a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -56
7.
```

In the case of DB2/400, the normal error text returned if the user does not have the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version fo
r a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -80
5.
```

In the case of DB2/400, the normal error returned if the collection does not exist would be as follows:

```
Failed to create AUTOCOMMITTED (NC) package.  RETCODE=-99.
SQL Error: Code=-204, State=42704, Error Text= A SQL error has occurred.  Please consult th
e documentation for your specific DB2 version for a description of the associated Native Er
```

```
ror and SQL State. SQLSTATE: 42704, SQLCODE: -204
```

There are two authorities required to execute the create package process on MVS using the Data Access Tool:

```
GRANT BINDADD TO <authorization ID>
GRANT CREATE IN COLLECTION <collection ID> TO <authorization ID>
```

The "authorization ID" is the user who needs the permission to create the packages. The "collection ID" is the name of the collection, which the user specifies in the data link file for the Package Collection property. This collection should be a valid collection within the DB2. If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can then run the CrtPkg tool. Once run, the CrtPkg process creates four sets of packages (one for each of the four isolation levels supported on DB2 for MVS or OS/390) for use by all (PUBLIC) users of the Microsoft data access features.

The following example illustrates this process on DB2 for MVS or DB2 for OS/390.

Grant rights to run the CrtPkg tool to authorization ID WNW999

```
GRANT BINDADD TO WNW999
GRANT CREATE IN COLLECTION MSPKG TO WNW999
```

Run the Data Access Tool using authorization ID WNW999.

To execute the Data Access Tool on DB2/400, a user ID must have one of the following authorities:

- *CHANGE authority on the DB2 collection
- *ALL authority on the DB2 collection

If the user has *USE authority or if the user has *EXCLUDE authority, the Create Package process will fail.

There are several steps required to change user authority on a DB2/400 collection (AS/400 library): From interactive SQL (STRSQL command) while logged on as user with administrative privileges, create a new collection. This command can also be issued using ADO, OLE DB, and ODBC. However, most administrators typically create collections from the AS/400 console because the administrator must be logged on at the console to issue the Command Language (CL) command with which to change the user authority on the collection.

```
CREATE COLLECTION <collection ID>
```

From the AS/400 command console, type the CL WRKOBJ command with the <collection ID> as a parameter.

```
WRKOBJ <collection ID>
```

The "collection ID" is the name of the collection, which the user specifies in the data link file for the Package Collection property. This collection should be a valid collection within DB2. The **Work with objects** dialog box appears. Place the cursor on the *PUBLIC Object Authority line and change the authority from *USE to *ALL.

If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can then run the CrtPkg tool. Once run, the CrtPkg process creates five sets of packages (one for each of the five isolation levels supported on DB2/400) for use by all (PUBLIC) users of the Microsoft data access features. On DB2/400, five packages are created including the AUTOCOMMITTED packages.

The following example illustrates this process on DB2/400.

Grant rights to run the Data Access Tool to authorization ID WNW999

```
CREATE COLLECTION MSPKG
```

```
WRKOBJ MSPKG
```

Run the Data Access Tool.

When using the Data Access Tool, if the package collection specified does not exist, DB2 returns SQLCODE -805.

When using auto-create packages, if a package collection is not specified or the package collection does not exist, during the auto-create package process, the consumer application receives SQLSTATE HY000 and SQLCODE -385. The SQLSTATE HY000 is defined as a provider-specific error. The -385 Error Return Code is not a SQLCODE but rather a DDM DRDA AR (DB2 client) return code. This error code is defined as DDM_VALNSPRM with the following associated text string:

```
"The parameter value is not supported by the target system."
```

The OLE DB Provider for DB2 client error codes are defined in the Db2oledb.h file located on the Host Integration Server CD.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server.

ADO Object, Method, Property, and Collection Support for AS/400, VSAM and DB2

Microsoft® ActiveX® Data Objects (ADO) version 2.0 defines a number of objects, methods, properties, and collections.

Microsoft OLE DB Provider for AS/400 and VSAM supports the ADO objects, methods, properties, and collections that are appropriate for an OLE DB data provider accessing a non-SQL host file system.

Microsoft OLE DB Provider for DB2 supports the ADO objects, methods, properties, and collections that are appropriate for an OLE DB data provider accessing an SQL database.

Similar support for ODBC can be found in the topic ADO Object Support in the ODBC Driver for DB2.

This section contains:

- ADO Object Support in the OLE DB Provider for AS/400 and VSAM
- ADO Object Support in the OLE DB Provider for DB2

ADO Object Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 objects that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Support
Collection	Yes, most methods
Command Object	Yes, some methods, some properties, and all collections
Connection Object	Yes, some methods, some properties, and all collections
Error Object	Yes, some properties
Field Object	Yes, all methods, properties, and collections
Parameter Object	No
Recordset Object	Yes, most methods, most properties, and all collections

This section contains:

- ADO Method Support in the OLE DB Provider for AS/400 and VSAM
- ADO Property Support in the OLE DB Provider for AS/400 and VSAM
- ADO Collection Support in the OLE DB Provider for AS/400 and VSAM
- Command Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Connection Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Error Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Field Object in the OLE DB Provider for AS/400 and VSAM (ADO)
- Recordset Object in the OLE DB Provider for AS/400 and VSAM (ADO)

ADO Method Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ActiveX® Data Objects (ADO) version 2.0 object methods that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Method	Support
Collection object	**Append** Method	No
	Clear Method	Yes
	Delete Method	Yes
	Item Method	Yes
	Refresh Method	Yes
Command Object	**CreateParameter** Method	No
	Cancel Method	No
	Execute Method	Yes, but options must be **adCmdText**
Connection Object	**BeginTrans** Method	No
	Cancel Method	No
	Close Method	Yes
	CommitTrans Method	No
	Execute Method	Yes, but options must be **adCmdText**
	Open Method	Yes
	OpenSchema Method	Yes
	RollbackTrans Method	No
Field Object	AppendChunk Method	Yes
	GetChunkMethod	Yes
	ReadFromFile Method	No
	WriteToFile Method	No
Parameter Method	**AppendChunk** Method	No
Recordset Object	AddNew Method	Yes
	Cancel Method	No
	CancelBatch Method	Yes
	CancelUpdate Method	Yes
	Clone Method	Yes
	Close Method	Yes
	Delete Method	Yes

	Find Method	Yes
	GetRows Method	Yes
	Move Method	Yes
	MoveFirst Method	Yes
	MoveLast Method	Yes
	MoveNext Method	Yes
	MovePrevious Method	Yes
	NextRecordset Method	No
	Open Method	Yes
	Requery Method	Yes
	Resync Method	No
	Save Method	Yes
	Seek Method	No
	Supports Method	Yes
	Update Method	Yes
	UpdateBatch Method	Yes

Note

The **Collection** object is a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection
- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the OLE DB provider

ADO Property Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ActiveX® Data Objects (ADO) version 2.0 object properties that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Property	Support
Command Object	ActiveConnection Property	Yes
	CommandText Property	Yes
	CommandTimeout Property	No
	CommandType Property	Yes
	Prepared Property	No
	State Property	Yes
Connection Object	Attributes Property	Yes
	CommandTimeout Property	No
	ConnectionString Property	Yes
	ConnectionTimeout Property	No
	CursorLocation Property	Yes
	DefaultDatabase Property	No
	IsolationLevel Property	No
	Mode Property	Yes
	Provider Property	Yes
	State Property	Yes
	Version Property	Yes
Error Object	Description Property	Yes
	HelpContext Property	No
	HelpFile Property	No
	NativeError Property	Yes
	Number Property	Yes
	Source Property	Yes
	SQLState Property	No
Field Object	ActualSize Property	Yes
	Attributes Property	Yes
	DataFormat Property	No
	DefinedSize Property	Yes

	Name Property	Yes
	NumericScale Property	Yes
	OriginalValue Property	Yes
	Precision Property	Yes
	Type Property	Yes
	UnderlyingValue Property	Yes
	Value Property	Yes
Parameter Object	**Attributes** Property	No
	Direction Property	No
	Name Property	No
	NumericScale Property	No
	Precision Property	No
	Size Property	No
	Type Property	No
	Value Property	No
Recordset Object	**AbsolutePage** Property	No
	AbsolutePosition Property	No
	ActiveCommand Property	Yes
	ActiveConnection Property	Yes
	BOF Property	Yes
	Bookmark Property	Yes
	CacheSize Property	Yes
	CursorLocation Property	Yes
	CursorType Property	Yes
	DataMember Property	No
	DataSource Property	No
	EditMode Property	Yes
	EOF Property	Yes
	Filter Property	Yes
	Index Property	No
	LockType Property	Yes
	MarshalOptions Property	No
	MaxRecords Property	No

	PageCount Property	No
	PageSize Property	No
	RecordCount Property	No
	Sort Property	Yes
	Source Property	Yes
	State Property	Yes
	Status Property	Yes
	StayInSync Property	No

ADO Collection Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ActiveX® Data Objects (ADO) version 2.0 object collections that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

ADO object	Collection	Support
Command Object	**Parameters**	No
	Properties	Yes
Connection Object	**Errors**	Yes
	Properties	Yes
Field Object	**Properties**	Yes
Parameter	**Properties**	No
Recordset Object	**Fields**	Yes
	Properties	Yes

Command Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX® Data Objects (ADO) **Command** object is a definition of a specific command that is executed against an OLE DB data source.

You use **Command** objects to create a **Recordset** object and obtain records, execute a bulk operation, or manipulate the structure of a database. When using Microsoft OLE DB Provider for AS/400 and VSAM, some collections, methods, or properties of a **Command** object may generate an error when called.

The primary purpose of the **Command** object in the context of OLE DB Provider for AS/400 and VSAM is to issue AS/400 command language (CL) commands for execution by the remote OS/400 DDM target server. For a listing of legal distributed data management (DDM) command-line strings, see *AS/400 DDM User's Guide* published by IBM.

The following table lists the **Command** object methods, properties, and collections that the current version of OLE DB Provider for AS/400 and VSAM supports.

Name	Comment
Execute Method	Evaluates command text as a text string. (The only supported *Options* parameter for this method is **adCmdText**, which indicates that this is not an SQL command.)
ActiveConnection Property	Sets or returns the information used to establish a connection to a data source. (For more information, see the notes that follow.)
CommandText Property	Sets or returns the command text to be executed.
CommandType Property	Sets or returns the type of command in a **CommandText** property.
State Property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. You can use the **Command** object to open tables or execute DDM commands on a remote DDM server. If errors occur, they can be examined with the **Errors** collection on the **Connection** object.

A **Command** object can be created independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the Command object to a valid connection string. ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object needs to be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command. The syntax for the string in the **CommandText** property when used with OLE DB Provider for AS/400 and VSAM is as follows:

```
EXEC COMMAND DDMCmd
```

Where **DDMCmd** represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands enable you to request functions from the OS/400 operating system. Some examples are the **DLTF** (Delete File) or **DSPFFD** (Display File Description) commands. These are the same commands that you could type at the command prompt if you were connected to an AS/400 computer through a 5250 terminal session. For a detailed list of possible commands, see the OS/400 CL Reference for your platform.

The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with OLE DB Provider for AS/400 and VSAM.

You can also use the **Command** object to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open (an **EXEC OPEN *DataSetName***statement, for example, where *DataSetName* represents a valid data file or library member on the host). You must set the **CommandType** property to **adCmdText** for use with OLE DB Provider for AS/400 and VSAM. If you open a host data file from a **Command** object, the data file is opened as read-only. This results from the limitation that no argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updateable.

Connection Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Connection** object represents an open connection to an OLE DB data source. The **Provider** property sets the OLE DB provider. You can configure the connection before opening the data source by setting the **ConnectionString** properties. The **Version** property determines the version of the ADO implementation in use.

The **Open** method establishes the physical connection to the data source and the **Close** method terminates the connection. If errors occur, you can examine them with the **Errors** collection.

The following table lists the methods, properties, and collections for the **Connection** object that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Name	Comment
Close Method	Closes a connection to a data source.
Execute Method	Evaluates command text as a table name. (The only supported *Options* parameter for this method is **adCmd Table**.)
Open Method	Opens a connection to a data source and may optionally pass **ConnectionString** parameters with this meth od. (The only supported *Options* parameter for this method is **adCmdText**.)
OpenSchema Me thod	Obtains database schema information from the OLE DB provider.
Attributes Metho d	Indicates one or more characteristics supported for a given **Connection** object.
ConnectionString Property	Contains the information used to establish a connection to a data source. (For more information, see the not e that follows.)
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
Mode Property	Indicates the available permissions for modifying data in a connection.
Provider Propert y	Sets or returns the name of the provider for a connection.
State Property	Describes the current state of an object.
Version Property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collec tion	Collections of properties on the connection.

Note that the information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with OLE DB Provider for AS/400 and VSAM or OLE DB Provider for DB2. This information is either a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons.

ADO supports several standard ADO-defined arguments for the **ConnectionString** property, as listed in the following table.

Argu ment	Description
Data Sourc e	Name of the data source for the connection. This argument is optional when using OLE DB Provider for AS/400 and VS AM.

File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed and is not supported by OLE DB Provider for AS/400 and VSAM.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password to use when opening the connection. Host Integration Server 2009 uses this password to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	Name of the provider to use for the connection. To use OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB." To use OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB."
User ID	Valid mainframe or AS/400 user name to use when opening the connection. Host Integration Server 2009 uses this user name to validate that the user can log on to the target host system and has appropriate access rights to the file.

OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which default to values in the registry. The following table lists these arguments.

Argument	**Description**
BinAsChar	This parameter indicates whether to process binary fields as character fields. (The default is 0; do not process binary fields as character fields.) This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If you omit this argument, the default value is U.S./Canada (37). This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
HCDFileName	The fully qualified file name of the distributed data management (DDM) Host Column Description (HCD) file. This parameter can be a UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the Host Integration Server system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
LocalLU	The name of the local logical unit (LU) alias configured in the SNA server. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
ModeName	The Advanced Program-to-Program Communications (APPC) mode must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
NetAddr	When you select TCP/IP for the Network Transport Library (NTL), this parameter indicates the IP address of the host. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
NetPort	When you select TCP/IP for the NTL, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.

NetLib	This parameter determines whether you use TCP/IP or SNA APPC for network communication. The possible values for this parameter are TCPIP or SNA. The default value is SNA. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
PCCodePage	The character code page to use on the computer. If you omit this argument, the default value is set to Latin 1 (1252). This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
RDB	The remote database name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in the SNA server.
RepairHostKeys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry, The default is **false**. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
RemoteLU	The name of the remote logical unit (LU) alias configured in the Host Integration Server computer. This parameter is equivalent to the DBPROP_SNAOLEDB_REMOTELU OLE DB property ID.
StrictVal	This parameter indicates whether strict validation should be used. The default is **false**. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.

A sample **ConnectionString** for use with OLE DB Provider for AS/400 and VSAM is as follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic®.

When opening a connection object in ADO 2.0, you must specify the **Prompt** connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and prompts the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters is as follows:

```
RS.Open "library/member",Conn,2,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (for example, the **adOpenDynamic** enum is 2), *LockType* (for example, the **adLockReadOnly** enum is 1), and *Options* (**adCmdText** is 1, which indicates that the source name should be evaluated as a table name). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with OLE DB Provider for AS/400 and VSAM.

The allowable values for CCSID when using SNA National Language Support (SNANLS) for character code conversions (the default) are listed in the following table.

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535

Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278
France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870

Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

Note

SNANLS conversion uses the locale configured for the data sources using data links. For more information on SNANLS, see SNA National Language Support Programmer's Guide.

Error Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections. However, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). OLE DB Provider automatically appends **Error** objects to the **Errors** collection when they occur.

The following table lists the **Error** object properties that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Property Name	**Comment**
Description Property	The text of the error alert that is returned based on the minor error code (specific to OLE DB Provider for AS/400 and VSAM) contained in the **Error** object resulting from an error.
NativeError Property	A **Long** integer value of the error code returned by OLE DB Provider for AS/400 and VSAM.
Number Property	The **Long** integer value of the error constant.
Source Property	A **string** that indicates the name of the object or application that originally generated an error.

Field Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following table lists the **Field** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Name	Comment
AppendChunk Method	Appends data to a large text or binary data **Field** object.
GetChunk Method	Returns all or portions of the contents of a large text or binary data **Field** object.
ActualSize Property	Actual length of the value of a field.
Attributes Property	One or more characteristics supported for a given **Field** object.
DefinedSize Property	Defined size of a **Field** object.
Name Property	Name of the **Field** object.
NumericScale Property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue Property	Value of a **Field** object that existed in the record before changes were made.
Precision Property	Degree of precision for numeric values in a **Field** object for numeric data.
Type Property	Operational type or data type for a **Field** object.
UnderlyingValue Property	Current value of a **Field** object.
Value Property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

Recordset Object in the OLE DB Provider for AS/400 and VSAM (ADO)

The ActiveX Data Objects (ADO) **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following table lists the **Recordset** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for AS/400 and VSAM supports.

Name	Comment
AddNew Method	Creates a new record for an updateable **Recordset** object.
CancelBatch Method	Cancels a pending batch update.
CancelUpdate Method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone Method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close Method	Closes an open object and any dependent objects.
Delete Method	Deletes the current record in an open **Recordset** object or an object from a collection.
Find Method	Finds the next record to match a condition (ADO 1.5 and later).
GetRows Method	Retrieves multiple records of a **Recordset** into an array.
Move Method	Moves the position of the current record in a **Recordset** object.
MoveFirst Method	Moves to the first record in a specified **Recordset**.
MoveLast Method	Moves to the last record in a specified **Recordset**.
MoveNext Method	Moves to the next record in a specified **Recordset**.
MovePrevious Method	Moves to the previous record in a specified **Recordset**.
Open Method	Opens a cursor on a **Recordset**.
Requery Method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save Method	Saves a **Recordset** in a file or **Stream** object.
Seek method	
Supports Method	Determines whether a specified **Recordset** object supports a particular type of function.
Update Method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch Method	Writes all pending batch updates to disk.
ActiveCommand Property	Returns the **Command** object that created the specified **Recordset**.

ActiveConnection Property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF Property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark Property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize Property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType Property	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenDynamic CursorType** is supported by the current version of OLE DB Provider for AS/400 and VSAM.
EditMode Property	Indicates the editing status of the current record type.
EOF Property	Indicates whether the current record position is after the last record in a **Recordset** object.
Filter Property	Indicates a filter for data in a **Recordset** (revised in ADO 1.5 and later).
LockType Property	Sets or returns the types of locks placed on records during editing. All four lock types (**adLockReadOnly**, **adLockOptimistic**, **adLockPessimistic**,and **adLockBatchOptimistic**) are supported by the OLE DB Provider for AS/400 and VSAM. Note that the OLE DB provider internally maps **adLockPessimistic** to a LockType of **adLockBatchOptimistic**.
Sort Property	Indicates the column names and order to sort data in a **Recordset** object (new property in ADO 1.5 and later).
Source Property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State Property	Describes the current state of an object.
Status Property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a recordset (table) using the **Recordset.Open** method is as follows:

```
EXEC OPEN TableName
```

where *TableName* represents one of the host file naming conventions listed in the following table.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILE.NAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY/FILE.NAME(MEMBER)

Note that if a member of a library contains a dot in the member name, you must surround the member name with double

quotes. For example, if the member name is NAMES.DAT, the proper syntax for command text used for the **Recordset.Open** method is:

```
RecordSet.Open "EXEC OPEN LIBRARY/FILE(""NAMES.DAT"")",...
```

You must specify the full path to the mainframe data set. In the preceding example, there are two path elements (LIBRARY/FILE) and one name element (NAMES.DAT).

Whenever a data set is allocated, it is given a unique name composed of one or more segments. Each segment of the data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully qualified data set name (three path elements and one name element):

```
SAMPLES.DEMO.KSDS.TITLES
```

The high-level qualifier is SAMPLES. The low-level qualifier is TITLES. Each segment can be from 1 through 8 characters in length. (The first character must be alphabetical, and the remainder can be alphanumeric or hyphens.) The full data set name must be no more than 44 characters in length and contain no more than 22 segments.

The Recordset **Bookmark** method is supported for all AS/400 physical and logical files, as well as the following mainframe file types:

- KSDS if the file has a unique key
- RRDS if the file has a unique key

You can use the Recordset **AddNew** method on Entry-Sequenced Data Sets (ESDS) files on the AS/400 only when you are positioned at the end of the **Recordset** object (file). With Alternate Index files on the AS/400, you can use the **AddNew** method to add records when at the end of the **Recordset** object or by key. With Key-Sequenced Data Sets (KSDS) or Fixed-Length Relative Record Data Sets (RRDS) files on the mainframe, the **AddNew** method adds new records by key.

To use the Recordset **Find** method or the **Filter** property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If you use these methods or properties on an AS/400 non-keyed physical file or any other mainframe file type, the method fails.

The Recordset **Sort** property is used with an open **Recordset** object based on an AS/400 physical file. The **Sort** property enables the user to indicate which logical view to apply to an AS/400 physical file. The logical view must be a valid index specified in the description of the AS/400 physical file. The AS/400 logical file provides the logical view. OLE DB Provider for AS/400 and VSAM responds to the **Sort** property request by first closing the open physical file, and then opening the logical file that points back to the data in the physical file.

The **Recordset Sort** property is only supported on AS/400 hosts. If the user opens a **Recordset** object based on an AS/400 logical file, there is probably no need to use **Recordset**.**Sort**. For performance reasons, applications should be written to open the AS/400 logical file first, because the overhead is so much greater when opening a physical file first.

ADO Object Support in the OLE DB Provider for DB2

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 objects that the current version of Microsoft OLE DB Provider for DB2 supports.

ADO object	Support
Collection	Yes, most methods
Command Object	Yes, some methods, some properties, and all collections
Connection Object	Yes, some methods, some properties, and all collections
Error Object	Yes, some properties
Field Object	Yes, no methods, most properties, and all collections
Parameter Object	Yes, most methods, most properties, and all collections
Recordset Object	Yes, most methods, most properties, and all collections

This section contains:

- ADO Method Support in the OLE DB Provider for DB2
- ADO Property Support in the OLE DB Provider for DB2
- ADO Collection Support in the OLE DB Provider for DB2
- Command Object in the OLE DB Provider for DB2 (ADO)
- Connection Object in the OLE DB Provider for DB2 (ADO)
- Error Object in the OLE DB Provider for DB2 (ADO)
- Field Object in the OLE DB Provider for DB2 (ADO)
- Recordset Object in the OLE DB Provider for DB2 (ADO)

ADO Method Support in the OLE DB Provider for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object methods that the current version of Microsoft OLE DB Provider for DB2 supports.

ADO object	Method	Support
Collection	**Append**	No
	Clear Method	Yes
	Delete Method	Yes
	Item Method	Yes
	Refresh Method	Yes
Command Object	**CreateParameter** Method	Yes
	Cancel Method	No
	Execute Method	Yes
Connection Object	**BeginTrans** Method	Yes
	Cancel Method	No
	Close Method	Yes
	CommitTrans Method	Yes
	Execute Method	Yes
	Open Method	Yes
	OpenSchema Method	Yes
	RollbackTrans Method	Yes
Field Object	**AppendChunk** Method	No
	GetChunk Method	No
	ReadFromFile Method	No
	WriteToFile Method	No
Parameter Object	**AppendChunk** Method	No
Recordset Object	AddNew Method	Yes
	Cancel Method	No
	CancelBatch Method	Yes
	CancelUpdate Method	Yes
	Clone Method	Yes
	Close Method	Yes
	Delete Method	Yes
	Find Method	No

	GetRows Method	Yes
	Move Method	Yes
	MoveFirst Method	Yes
	MoveLast Method	No
	MoveNext Method	Yes
	MovePrevious Method	No
	NextRecordset Method	No
	Open Method	Yes
	Requery Method	Yes
	Resync Method	No
	Save Method	Yes
	Seek Method	No
	Supports Method	Yes
	Update Method	Yes
	UpdateBatch Method	Yes

Note

The **Collection** object is a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection
- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the OLE DB provider

ADO Property Support in the OLE DB Provider for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object properties that the current version of Microsoft OLE DB Provider for DB2 supports.

ADO object	Property	Support
Command Object	ActiveConnection Property	Yes
	CommandText Property	Yes
	CommandTimeout Property	No
	CommandType Property	Yes
	Prepared Property	Yes
	State Property	Yes
Connection Object	Attributes Property	Yes
	CommandTimeout Property	No
	ConnectionString Property	Yes
	ConnectionTimeout Property	No
	CursorLocation Property	Yes
	DefaultDatabase Property	No
	IsolationLevel Property	Yes
	Mode Property	Yes
	Provider Property	Yes
	State Property	Yes
	Version Property	Yes
Error Object	Description Property	Yes
	HelpContext Property	No
	HelpFile Property	No
	NativeError Property	Yes
	Number Property	Yes
	Source Property	Yes
	SQLState Property	Yes
Field Object	ActualSize Property	Yes
	Attributes Property	Yes
	DataFormat Property	No
	DefinedSize Property	Yes
	Name Property	Yes

	NumericScale Property	Yes
	OriginalValue Property	Yes
	Precision Property	Yes
	Type Property	Yes
	UnderlyingValue Property	Yes
	Value Property	Yes
Parameter Object	**Attributes** Property	Yes
	Direction Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	Precision Property	Yes
	Size Property	Yes
	Type Property	Yes
	Value Property	Yes
Recordset Object	**AbsolutePage** Property	No
	AbsolutePosition Property	No
	ActiveCommand Property	Yes
	ActiveConnection Property	Yes
	BOF Property	Yes
	Bookmark Property	Yes
	CacheSize Property	Yes
	CursorLocation Property	Yes
	CursorType Property	Yes
	DataMember Property	No
	DataSource Property	No
	EditMode Property	Yes
	EOF Property	Yes
	Filter Property	No
	Index Property	No
	LockType Property	Yes
	MarshalOptions Property	No
	MaxRecords Property	Yes
	PageCount Property	No

	PageSize Property	No
	RecordCount Property	No
	Sort Property	No
	Source Property	Yes
	State Property	Yes
	Status Property	Yes
	StayInSync Property	No

ADO Collection Support in the OLE DB Provider for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object collections that Microsoft OLE DB Provider for DB2 supports.

ADO object	Collection	Support
Command Object	**Parameters** Collection	Yes
	Properties Collection	Yes
Connection Object	**Errors** Collection	Yes
	Properties Collection	Yes
Field Object	**Properties** Collection	Yes
Parameter Object	**Properties** Collection	Yes
Recordset Object	**Fields** Collection	Yes
	Properties Collection	Yes

Command Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Command** object is a definition of a specific command that is to be executed against an OLE DB data source.

You can use **Command** objects to create a **Recordset** object and obtain records, to execute a bulk operation, or to manipulate the structure of a database. When using Microsoft OLE DB Provider for DB2, some collections, methods, or properties of a **Command** object may generate an error when called.

The primary purpose of the **Command** object in the context of OLE DB Provider for DB2 is to issue SQL commands for execution by the remote DB2 target server. Legal SQL commands are documented for the target DB2 platforms in SQL Reference Guides published by IBM.

The following table lists the **Command** object methods, properties, and collections that the current version of OLE DB Provider for DB2 supports.

Name	Comment
Execute Method	Evaluates command text (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is an SQL text command).
ActiveConnection Property	Sets or returns the information used to establish a connection to a data source. (For more information, see the notes that follow.)
CommandText Property	Sets or returns the command text to be executed.
CommandType Property	Sets or returns the type of command in a **CommandText** property.
State Property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. You can use the **Command** object to open tables or execute SQL commands on a remote DB2 server. If errors occur, you can examine these with the **Errors** collection on the **Connection** object.

You can create a **Command** object independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string. (For the proper syntax, see the **ConnectionString** property of the **Connection** object.) ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object needs to be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command (for example, **SELECT ALL FROM TABLE**). The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with OLE DB Provider for DB2.

Connection Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Connection** object represents an open connection to an OLE DB data source. The **Provider** property sets the OLE DB provider to use. The connection can be configured before opening the data source by setting the **ConnectionString** properties. The version of the ADO implementation in use can be determined from the **Version** property.

The physical connection to the data source is established using the **Open** method and terminated with the **Close** method. If errors occur, these can be examined with the **Errors** collection.

The following table lists the **Connection** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for DB2 supports.

Name	Comment
Close Method	Closes a connection to a data source.
Execute Method	Evaluates command text.
Open Method	Opens a connection to a data source and may optionally pass **ConnectionString** parameters with this method.
OpenSchema Method	Obtains database schema information from the OLE DB provider.
Attributes Property	One or more characteristics supported for a given **Connection** object.
ConnectionString Property	Contains the information used to establish a connection to a data source. (For more information, see the notes that follow.)
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
IsolationLevel Property	Sets or returns the level of isolation for a **Connection** object.
Mode Property	Indicates the available permissions for modifying data in a connection.
Provider Property	Sets or returns the name of the provider for a connection.
State Property	Describes the current state of an object.
Version Property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

You can set the information needed to establish a connection to a data source in the **ConnectionString** property or pass it as part of the **Open** method. In either case, this information must be in a specific format for use with OLE DB Provider for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property as listed in the following table.

Argument	Description
Data Source	Name of the data source for the connection. This argument is optional when using OLE DB Provider for DB2.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.

Password	Valid mainframe or AS/400 password to use when opening the connection. This password is used to verify that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
Provider	Name of the provider to use for the connection. To use OLE DB Provider for DB2, you must set the Provider string to "DB2OLEDB."
User ID	Valid mainframe or AS/400 user name to use when opening the connection. This user name validates that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the following tables.

The following table lists the arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2009.

Argument	**Description**
BinAsChar	When this parameter is set to **true**, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to **false**.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If you omit this argument, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2, SYSIBM, SYSTEM, CURLIB, or USERID depending on platform. This parameter does not have a default value.
InitCat	You use this parameter as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the **WRKRDBDIRE** command from the console to the OS/400 system. If there is no RDBNAM value, you can create one using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local logical unit (LU) alias configured in Host Integration Server.
ModeName	The Advanced Program-to-Program Communications (APPC) mode must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.

NetAddr	When you select TCP/IP for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When you select TCP/IP for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether you use TCP/IP or SNA APPC for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the computer. If you omit this argument, the default value is set to Latin 1 (1252).
PkgCol	The name of the Distributed Relational Database Architecture (DRDA) target collection (AS/400 library) where Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB provider creates packages dynamically in the location to which the user points using the Package Collection parameter.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The transaction program name when used with SQL/DS.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are distributed unit of work (DUW) or remote unit of work (RUW). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using OLE DB Provider for DB2 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
```

```
    "ModeName=QPCSUPP;CCSID=37;PcCodePage=437"
  Conn.Properties("PROMPT")=adPromptNever
  Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic®.

When opening a connection object in ADO 2.0, you must specify the **Prompt** connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=DB2OLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters is as follows:

```
RS.Open "Accounting",Conn,0,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (for example, the **adOpenForwardOnly** enum is 0), *LockType* (for example, the **adLockReadOnly** enum is 1), and *Options* (**adCmdText** is 1, which indicates that the source name should be evaluated as SQL text). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with OLE DB Provider for DB2.

The allowable values for the Character Code Set Identifier (CCSID) when using SNA National Language Support (SNANLS) for character code conversions (the default) are listed in the following table.

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278
France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423

Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

Note that the SNA National Language Support (SNANLS) conversion uses the locale configured for the data sources using data links. For more information, see the SDK documentation under the SNA National Language Support Programmer's Guide.

The allowable values for CCSID when using ANSI/OEM for character code conversions are listed in the following table.

ANSI/OEM character set	**CCSID value**
ANSI - Arabic	1256
ANSI - Baltic	1257
ANSI - Cyrillic	1251
ANSI - Eastern Europe	1250

ANSI - Greek	1253
ANSI - Hebrew	1255
ANSI - Latin I	1252
ANSI - Turkish	1254
ANSI/OEM - Korean (Extended Wansung)	949
ANSI/OEM - Japanese Shift-JIS	932
ANSI/OEM - Simplified Chinese GBK	936
ANSI/OEM - Traditional Chinese Big5	950
ANSI/OEM - Thai	874
ANSI/OEM - Vietnam	1258

Error Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections. However, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). The OLE DB provider automatically appends **Error** objects to the **Errors** collection when they occur.

The following table lists the **Error** object properties that the current version of Microsoft OLE DB Provider for DB2 supports.

Property Name	**Comment**
Description Property	The text of the error alert that is returned based on the minor error code (specific to the OLE DB Provider for DB2) contained in the **Error** object resulting from an error.
NativeError Property	A **Long** integer value of the error code returned by the OLE DB Provider for DB2.
Number Property	The **Long** integer value of the OLE DB error constant.
Source Property	A string that indicates the name of the object or application that originally generated an error.

Field Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following table lists the **Field** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for DB2 supports.

Name	Comment
ActualSize Property	Actual length of a field's value.
Attributes Property	One or more characteristics supported for a given **Field** object.
DefinedSize Property	Defined size of a **Field** object.
Name Property	Name of the **Field** object.
NumericScale Property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue Property	Value of a **Field** object that existed in the record before changes were made.
Precision Property	Degree of precision for numeric values in a **Field** object for numeric data.
Type Property	Operational type or data type for a **Field** object.
UnderlyingValue Property	Current value of a **Field** object.
Value Property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

Recordset Object in the OLE DB Provider for DB2 (ADO)

The ActiveX Data Objects (ADO) **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following table lists the **Recordset** object methods, properties, and collections that the current version of Microsoft OLE DB Provider for DB2 supports.

Name	Comment
AddNew Method	Creates a new record for an updateable **Recordset** object.
CancelBatch Method	Cancels a pending batch update.
CancelUpdate Method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone Method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close Method	Closes an open object and any dependent objects.
Delete Method	Deletes the current record in an open **Recordset** object or an object from a collection.
GetRows Method	Retrieves multiple records of a **Recordset** into an array.
Move Method	Moves the position of the current record in a **Recordset** object.
MoveFirst Method	Moves to the first record in a specified **Recordset**.
MoveNext Method	Moves to the next record in a specified **Recordset**.
Open Method	Opens a cursor on a **Recordset**.
Requery Method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save Method	Saves a **Recordset** in a file or **Stream** object.
Supports Method	Determines whether a specified **Recordset** object supports a particular type of function.
Update Method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch Method	Writes all pending batch updates to disk.
ActiveCommand Property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection Property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF Property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark Property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize Property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).

CursorType Property	Sets or returns the type of cursor used in a **Recordset** object. The current version of OLE DB Provider for DB2 supports only the **adOpenForwardOnly CursorType**.
EditMode Property	Indicates the editing status of the current record type.
EOF Property	Indicates whether the current record position is after the last record in a **Recordset** object.
LockType Property	Sets or returns the types of locks placed on records during editing. OLE DB Provider for DB2 supports locks of type **adLockReadOnly** and **adLockPessimistic**.
MaxRecords Property	Sets or returns the maximum number of records to return to a **Recordset** from a query.
Source Property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State Property	Describes the current state of an object.
Status Property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

ODBC Driver for DB2 Programmer's Guide

The Microsoft ODBC Driver for DB2 enables users to access IBM DB2 DB2 from within an ODBC-aware application. ODBC defines a standard set of interfaces that provide access to disparate databases. The ODBC Driver for DB2 combines the data access of ODBC with the underlying Microsoft Distributed Relational Database Architecture (DRDA) application requester also used by the Microsoft OLE DB Provider for DB2. Using this combination of technologies, the ODBC Driver for DB2 can provide database access to IBM's Distributed Relational Database Architecture and IBM DB2.

Organizations have invested in secure, robust, enterprise-wide data storage and management systems. DRDA is a set of rules for distributing or extending relational data from one computer to another, such as a server computer to an IBM DB2 database server running on a mainframe or an AS/400 computer. By combining the ODBC and DRDA architectures, Microsoft allows organizations to preserve their investments in an existing data management infrastructure, while extending data access to all enterprise-wide DB2 data sources.

The ODBC Driver for DB2 can be used interactively or from an application program to issue SQL statements and execute DB2 stored procedures. From Microsoft Excel, users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. From Microsoft Access, users can import from and export to DB2. With Microsoft Internet Information Services (IIS), developers can publish DB2-stored information to users through a Web browser.

For API reference and other technical information about the ODBC Driver for DB2, see the ODBC Driver for DB2 Programmer's Reference section of the SDK.

For more information about how to use the ODBC Driver for DB2, see the ODBC Driver for DB2 section in the Operations guide.

In This Section

Goals of the ODBC Driver for DB2

Relational database management systems (RDBMS) are one of the major sources of mission-critical information in today's enterprise organizations. Relational database technology enables departments and individual users to save their information in centrally managed database stores that can be maintained by the organization's information systems group.

IBM DB2 is a popular RDBMS for a significant number of enterprise customers. Customers need a cost-effective and manageable means to integrate DB2 with Microsoft® SQL Server™, Microsoft Internet Information Services (IIS), and Microsoft Office applications. The goal of Microsoft ODBC Driver for DB2 is to provide customers and solution providers with the means to integrate desktop database applications with this wealth of data residing on IBM DB2 database systems.

ODBC Driver for DB2 Architecture

The Microsoft ODBC Driver for DB2 is an ODBC-compliant database driver for Microsoft Windows Server 2003 and Windows 2000 that enables your existing ODBC applications access data residing in IBM DB2 database servers without changing any code. The ODBC Driver for DB2 can connect ODBC-compliant applications with DB2 data sources using the underlying Microsoft Distributed Relational Database Architecture (DRDA) application requester. The ODBC application connects to the ODBC Driver for DB2. These ODBC requests are processed by the underlying Microsoft DRDA application requester. The data is then passed by an SQL interface to the DB2 data store.

The ODBC Driver for DB2 shares the same DRDA application requester that is used by the Microsoft OLE DB Provider for DB2. The DRDA application requester is the network client that provides remote database access to DB2 across an SNA LU 6.2 and TCP/IP network.

The ODBC Driver for DB2 is compliant with the Microsoft Open Database Connectivity (ODBC) specification. ODBC is a specification for an application program interface (API) that enables applications to access multiple database systems using SQL.

Platforms Supported by the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 supports popular DB2 platforms supported by the Microsoft OLE DB Provider for DB2 because both use the same underlying Distributed Relational Database Architecture (DRDA) application requester.

The ODBC Driver for DB2 offers network connectivity using SNA APPC LU 6.2 connectivity, as well as native TCP/IP (not reliant on any special IBM or third-party routers).

ODBC Driver for DB2 Requirements

Information about hardware and software requirements for ODBC Driver for DB2 can be found in Host Integration Server 2009.

When connecting over SNA using LU 6.2, the ODBC Driver for DB2 requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2009
- Microsoft Host Integration Server Client

Note that the ODBC Driver for DB2 does not require any special host connectivity software when connecting directly to a host system using TCP/IP.

The ODBC Driver for DB2 supports the following OLE DB and ADO versions:

The ODBC Driver for DB2 supplied with Host Integration Server supports the following ADO version:

- ADO version 2.5. The Host Integration Server data access features require the runtime libraries for ADO version 2.5. On Windows Server 2003 and Windows 2000, these ADO libraries are installed as part of the Windows Server 2003 operating systems or Windows 2000.

Configuring ODBC Data Sources

A data source associates a particular ODBC driver with the data to be accessed through that driver. Data source information must be configured for each DB2 system that is to be accessed using the ODBC Driver for DB2. The default parameters for the ODBC Driver for DB2 are used for the data source only when these parameters are not configured for each data source.

An ODBC data source name (DSN) can be one of the following types:

- User. A data source local to a computer and accessible only by the current user that created the data source.
- System. A data source local to a computer but not dedicated to a specific user, so any user with appropriate privileges can access a system DSN. A System data source is visible to all users on a computer, including Windows NT services.
- File. A data source stored in a file that can be shared among all users who have the same ODBC drivers installed. These data sources need not be dedicated to a specific user or local to a computer.

User and System data sources are stored in the registry. File data sources are stored as files with a file extension of .dsn. File DSNs can be stored in any location on the file system including remotely mounted shares. By default, File DSNs are stored in the following location:

C:\Program Files\Common Files\ODBC\Data Sources

ODBC data sources can be configured using the **ODBC Data Source Administrator**. On Microsoft Windows Server 2003 and Windows 2000, a shortcut to the **ODBC Data Source Administrator** is located in the Control Panel under **Administrative Tools** as **Data Sources (ODBC)**. The Data Access Tool provided as part of the ODBC Driver for DB2 enables users to create and modify ODBC data sources. This tool makes calls to the ODBC Data Source Administrator application to provide these functions.

- Using the Microsoft ODBC Driver for DB2 Configuration Dialog Box
- Configuration Property Mappings Between the ODBC Driver for DB2 and the OLE DB Provider for DB2
- ODBC Connection String Attributes

Using the Microsoft ODBC Driver for DB2 Configuration Dialog Box

The **Microsoft ODBC Driver for DB2 Configuration** dialog box contains five tabs, which are described in the following topics.

This section contains:

- General
- Connection
- Security
- Target Database
- Locale

General

The **General** tab enables the user to configure the data source name required to connect to DB2. For the Microsoft ODBC Driver for DB2 supplied with Host Integration Server 2009, the **General** tab contains the following fields.

Parameter	Comments
Data Source Name	A blank field for specifying the name of the data source. Enter a string that identifies this ODBC data source. The data source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For file data sources, this field is used to name the DSN file, which is stored in C:\Program Files\Common Files\ODBC\Data Sources.
Description	A blank field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

Connection

The **Connection** tab enables the user to configure the basic attributes required to connect to a data source. For the Microsoft® ODBC Driver for DB2, the **Connection** tab has the following fields.

Parameter	Comments
Network transport	An option button is used to select the network transport. Valid options are **APPC Connection (SNA LU 6.2)** or **TCP/IP Connection**. For the default, **APPC Connection**, the values for APPC local LU alias, APPC remote LU alias, and APPC mode name are required. For **TCP/IP Connection**, the values for IP address and Network port are required.
APPC local LU alias	When **APPC Connection** is selected, this field is the name of the local LU alias configured in Host Integration Server.
APPC remote LU alias	When **APPC Connection** is selected, this field is the name of the remote LU alias configured in Host Integration Server.
APPC mode name	When **APPC Connection** is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA service configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). The default is QPCSUPP.
IP address	When **TCP/IP Connection** is selected as the network transport, this field indicates the IP address of the host DB2 server.
Network port	When **TCP/IP Connection** is selected as the network transport, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is IP port 446.

The **Connection** tab also includes a **Test connection** button that may be used to test the connection parameters. A connection can only be tested after all of the required parameters for the **Connection** tab and other ODBC data source parameters are configured properly. When this button is clicked, a session is established with the remote DB2 system using ODBC Driver for DB2

Security

The **Security** tab enables the user to configure optional attributes used to restrict connections to a data source.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2009, the **Security** tab has the following fields.

Parameter	**Comments**
Authentication	An option button is used to select the type of authentication. Valid options are **Use this username or Use single signon**. For the default **Use this username** option, the value for the user name is required.
Use this username	When this option is selected, authentication is based on the user name entered in the text box. A valid user name is normally required to access data on DB2. A user name can remain optionally in the DSN. The ODBC Driver for DB2 prompts the user at run time to enter a valid password. Additionally, the prompt dialog box enables the user to override the user name that is stored in the DSN.
Use Single Sign-On	An option button to select whether Single Sign-On (SSO) or a specific user name should be used. SSO is an optional Host Security feature. SSO enables the administrator to create data source definitions that isolate the logon process from the end user.

The AS/400 computer is case-sensitive with regard to user IDs and passwords. When connecting to DB2 for OS/400, user names and passwords must be in uppercase. The AS/400 only accepts a DB2 for OS/400 user ID and password in uppercase. If a DB2 for OS/400 connection fails due to incorrect authentication, the ODBC driver resends the authentication, forcing the user ID and password into uppercase.

When connecting to DB2 on IBM mainframes, user names and passwords can be of mixed case. The mainframe is not case-sensitive. The ODBC driver sends these values in uppercase.

DB2 Universal Database (UDB) for Windows Server 2003 or for Windows 2000 is case-sensitive. The user ID is stored in uppercase. The password is stored in mixed case and users must enter the password in the correct case. The ODBC driver sends the password exactly in the case entered by the user. The user ID should contain only the user name, not a combination of the Windows NT® domain name and user name.

It is possible to connect using a specific user name and password defined in DB2 on the host system or use the Single Sign-On feature (often referred to as integrated Windows security). If a specific DB2 user name and password are to be used, this information may need to be saved to a data source name (DSN) file. The user name and password are saved in plain text in the DSN file or to registry keys if a System or User DSN is selected. For security reasons when using File DSNs, it is imperative that the DSN file be protected with an access control list (ACL) that restricts access to only authorized users. System and User DSNs are preferred for security reasons if the locations where these ODBC DSNs are stored in the registry have appropriate security protections. Saving the user name and password in the DSN also forces this DSN to be updated whenever the password associated with the user name is changed. So for a variety of reasons, specifying a user name and password is not the preferred authentication option. Using the **Single Sign-On** option is the preferred method for authentication.

Target Database

The **Target Database** tab enables the user to configure required, as well as optional, attributes used to define the target DB2 system.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2009, the **Target Database** tab has the following fields.

Parameter	Comments
Initial catalog	This parameter is used as the first part of a three-part fully qualified DB2 table name. It is referred to by different names depending on the DB2 platform. In DB2 for OS/390 and DB2 for MVS, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 that you need to connect to on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 Installation Manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.
Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This can be the same as the default schema. The ODBC Driver for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. The ODBC driver creates packages dynamically in the location that the user points to using the Package Collection parameter. By default, the ODBC Driver for DB2 automatically creates one package in the target collection, if one does not exist, at the time the user issues the first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the user ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value specified in the connection. Problems can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), the package is created only for use by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users. (For more information, see Creating Packages for Use with the ODBC Driver for DB2.) The ODBC Driver for DB2 supplied with Host Integration Server 2009 includes the Data Access Tool for use by administrators to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This tool will create a set of packages and grant EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system. The packages (see descriptions under the SQL_ATTR_TXN_ISOLATION connection attribute) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package (MSCS001) REPEATABLE READ package (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA Server 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2009. The package names changed from SNA Server 4.0.

Default Schema	The name of the collection where the ODBC Driver for DB2 looks for catalog information. Default schema is the SCHEMA name for the target collection of tables and views. The ODBC driver uses the Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the ODBC driver uses the USER_ID provided at log on. For DB2/400, the driver uses QSYS2 if no collection is found matching the USER_ID value. This default is inappropriate in many cases so it is essential that the Default Schema value in the data source be defined.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the ODBC driver when executing operations such as data conversion. The default value is DB2/MVS.
Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute enables the user to access database objects without fully qualifying the objects using a collection (schema) qualifier. The ODBC driver sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for the default qualifier, no **SET** statement is issued by the ODBC driver. This ODBC connection attribute is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS), which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2009 uses the Alternate TP Name in the offline demo configuration (DRDADEMO.UDL). In that case, the Alternative TP Name is set to 0X07F9F9F9.
Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the Host Integration Server 2009 Resync Service.
Process binary as character	When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. For more information, see the Locale tab.

Locale

The **Locale** tab enables the user to configure the parameters used for character conversion between the client and the DB2 server.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2009, the **Locale** tab has the following fields.

Parameter	**Comments**
Host CCSID	The coded character set identifier (CCSID) matching the DB2 data as represented on the remote computer. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the DB2 column CCSID and configured ANSI code page. This parameter defaults to U.S./Canada (37).
PC code page	This parameter indicates the personal computer code page to use. It is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

Configuration Property Mappings Between the ODBC Driver for DB2 and the OLE DB Provider for DB2

This table compares the configuration parameters used by the ODBC Driver for DB2 and the OLE DB Provider for DB2.

Microsoft ODBC Driver for DB2	Microsoft OLE DB Provider for DB2
General	**General**
Data Source Name	Data Source
Data Source Description	None
Connection	**Connection**
Connection	Network Transport Library
APPC Connection	SNA
TCP/IP Connection	TCPIP
APPC local LU Alias	APPC Local LU Alias
APPC remote LU Alias	APPC Remote LU Alias
APPC mode name	APPC Mode Name
IP address	Network Address
Network port	Network Port
Security	**Security**
Use this username	None
User Name	User ID
Use Single Sign-on	Integrated Security
Affiliate Application	Affiliate Application
Target Database	**Target Database**
Initial catalog	Initial Catalog
Package collection	Package Collection
Default schema	Default Schema
Default qualifier	Default qualifier
DBMS Platform	DBMS Platform
Alternate TP name	Alternate TP Name
Distributed transactions	Distributed transactions
Process binary as character	Process binary as character
Locale	**Locale**
Host CCSID	Host CCSID
PC code page	PC Code Page

Extended	**Extended**
Client Application Name	None
Connection Pooling	None

ODBC Connection String Attributes

The ODBC **SQLBrowseConnect** and **SQLDriverConnect** functions allow passing in a connection string containing a series of attribute/value pairs to the ODBC Driver Manager to establish a connection with a data source. An example of a connection string is as follows:

```
"DSN=MYDATA;NTL=SNA;LLU=Local;RMU=Remote;RDB=BigData;PC=QSYS2;
DS=QSYS2;RO=false;UID=myname;PWD=Secret"
```

Some ODBC attributes are required as part of the connection string when used with the ODBC Driver for DB2.

The following tables compare the configuration parameters used by the ODBC Driver for DB2 and the ODBC attribute keywords that are supported by the OLE DB Driver for DB2 as part of the passed-in connection string.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2009, these attribute keywords compare as follows.

Microsoft ODBC Driver for DB2	**ODBC attribute keyword**	**Comments**
General	**General**	**General**
Data Source Name	DSN	Required parameter.
Data Source Description	DESC	None.
Connection	**Connection**	**Connection**
Connection	NTL	Required parameter.
APPC connection	NTL=SNA	None.
TCP/IP connection	NTL=TCPIP	None.
APPC local LU alias	LLU	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC remote LU alias	RLU	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC mode name	MN	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC Security Type	AST	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA). Valid values are PROGRAM (the default), or SAME.
IP address	NA	Applicable only if TCPIP (a TCP/IP connection) is used for the network transport library (NTL=TCPIP).
Network port	NP	Applicable only if TCPIP (a TCP/IP connection) is used for the network transport library (NTL=TCPIP).
Security	**Security**	**Security**
Use this username	None	None.
User Name	UID	None.

	PWD	The Password parameter is not on the Security tab and is not configurable from the ODBC Administrat or tool used to configure ODBC data sources. This parameter can only be preset using the ODBC conne ction string. Most applications prompt the user for this parameter.
Use Single S ign-On	None	Not applicable.
Affiliate app lication	AAP	Applicable only if using Single Sign-On.
Target Dat abase	**Target D atabase**	**Target Database**
Initial Catalo g	RDB	Required parameter.
Package Col lection	PC	Required parameter.
Default Sch ema	DS	Required parameter.
Default Qua lifier	DQ	None.
DBMS Platf orm	DP	Can be one of the following values: DB2/AS400, DB2/MVS (the default), DB2/6000, or DB2/NT.
Alternate TP Name	TPN	None.
Distributed t ransactions	RUW	None.
Process bin ary as chara cter	BAC	None.
Locale	**Locale**	**Locale**
Host CCSID	CCSID	Required parameter.
PC code pag e	CP	Required parameter.

Creating Packages for Use with the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2, which is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester, uses packages to issue SQL statements and call DB2 stored procedures. There is a configuration parameter that the ODBC Driver for DB2 uses to identify a location in which to create and store DB2 packages. The ODBC Driver for DB2 creates packages dynamically in the location to which the user points using the *Package Collection* parameter. This location may be configured using the **Target Database** tab from the Microsoft ODBC Data Source Administrator tool or can be passed as part of the ODBC connection string as an attribute keyword and argument. The attribute keyword for *Package Collection* is PC.

There are two package creation options:

- The ODBC Driver for DB2 autocreates one package for the currently used isolation level at run time if no package already exists. This auto-create process may fail if the user account does not have authority to create packages.

- An administrator or user can manually create all four packages (five packages on DB2/400) for use with all isolation levels and for use by all users (the PUBLIC group on DB2 representing all users) or a specific set of users. The ODBC Driver for DB2 includes a utility program for use by users with appropriate administrative privilege that will create these packages and grant access to the PUBLIC group for this purpose.

However, some users may not have the security level when manually creating packages to GRANT authority to the packages to other users (grant authority to the DB2 PUBLIC group representing all users, for example). This can be a problem if two or more users with different user IDs try to access a single collection of packages. The first user that created the packages will have access to the packages, but the second user likely will not. The Host Integration Server 2009 CD includes a program for use by an administrator or a user with appropriate privileges to create packages. This tool can be run using a privileged user ID to create packages in collections accessed by multiple users. The Data Access Tool can be used to create packages for use with DB2.

This tool creates a set of packages and grants EXECUTE privileges on these packages to the PUBLIC group. The PUBLIC group on DB2 systems is a default group that represents all DB2 users. The following packages are created:

- AUTOCOMMITTED package (MSNC001), only applicable on DB2/400

- READ UNCOMMITTED package (MSUR001)

- READ COMMITTED package (MSCS001)

- REPEATABLE READ package (MSRS001)

- SERIALIZABLE package (MSRR001)

Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

The descriptive process name used by the Data Access Tool corresponds with the isolation levels defined in the ANSI SQL standard. The following table indicates how these packages correspond with the terms used by IBM for isolation levels in DB2 documentation.

Package description	**Package name**	**IBM documentation**
AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level)	MSNC001	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 autocommit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.

READ UNCOMMITTED	MSUR001	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.
READ COMMITTED	MSCS001	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
REPEATABLE READ	MSRS001	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.
SERIALIZABLE	MSRR001	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

Note that when upgrading from SNA Server 4.0, any existing SNA Server 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2009. The package names used by the ODBC Driver for DB2 on SNA Server 4.0 are not compatible with the ODBC Driver for DB2 included with Host Integration Server. On SNA Server 4.0, these packages used different names as follows:

```
AUTOCOMMITTED package (SNANC001) only applicable on DB2/400
READ UNCOMMITTED package (SNACH001)
READ COMMITTED package, (SNACS001)
REPEATABLE READ package, (SNARR001)
SERIALIZABLE package (SNAAL001)
```

These isolation levels are described in detail in Support for Isolation Levels Using the ODBC Driver for DB2. These isolation levels are also described in IsolationLevel Property (ADO). Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

Note that the Data Access Tool tool creates this set of packages and grants EXECUTE privileges to PUBLIC. There may be cases for security reasons where EXECUTE privileges to this set of packages should be restricted to a certain group of users or specific users. In these cases, execution privileges on these created packages will need to be modified on the host system.

The Data Access Tool creates all of these packages inside the collection that is specified in the **Package Collection** property in the datalink file, or in the connection string. If the user does not have the appropriate authority to create packages in the specified collection, or if the specified collection does not exist, the ODBC Driver for DB2 returns an error.

In the case of DB2 on MVS or OS/390, the normal error text returned if the user does not have the appropriate authority is as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version fo
r a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -56
7.
```

In the case of DB2/400, the normal error text returned if the user does not the appropriate authority is as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version fo
r a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -80
5.
```

In the case of DB2/400, the normal error returned if the collection does not exist is as follows:

```
Failed to create AUTOCOMMITTED (NC) package.  RETCODE=-99.
SQL Error: Code=-204, State=42704, Error Text= A SQL error has occurred.  Please consult th
```

```
e documentation for your specific DB2 version for a description of the associated Native Er
ror and SQL State. SQLSTATE: 42704, SQLCODE: -204
```

There are two authorities required to execute the create package process on OS/390 or MVS using the Data Access Tool:

```
GRANT BINDADD TO <authorization ID>
GRANT CREATE IN COLLECTION <collection ID> TO <authorization ID>
```

The authorization ID is the user who needs the permission to create the packages. The collection ID is the name of the collection, which the user specifies in the datalink file for the **Package Collection** property. This collection should be a valid collection within the DB2.

If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can then run the Data Access Tool. Once run, the process creates four sets of packages (one for each of the four isolation levels supported on DB2 for MVS or OS/390) for use by all (PUBLIC) users of the Microsoft data access features.

The following example illustrates this process on DB2 for MVS or DB2 for OS/390:

Grant rights to run the Data Access Tool to authorization ID WNW999:

```
GRANT BINDADD TO WNW999
GRANT CREATE IN COLLECTION MSPKG TO WNW999
```

Run the Data Access tool using authorization ID WNW999 .

To execute the Data Access Tool on DB2/400, a user ID must have one of the following authorities:

- *CHANGE authority on the DB2 collection
- *ALL authority on the DB2 collection

If the user only has *USE authority or if the user has *EXCLUDE authority, the Create Package process will fail.

There are several steps required to change user authority on a DB2/400 collection (AS/400 library). From interactive SQL (STRSQL command) while logged in as user with administrative privileges, create a new collection. This command can also be issued using ADO, OLE DB, and ODBC. However, most administrators typically create collections from the AS/400 console because the administrator must be logged in at the console to issue the Command Language (CL) command with which to change the user authority on the collection:

```
CREATE COLLECTION <collection ID>
```

From the AS/400 command console, issue the CL WRKOBJ command with the <collection ID> as a parameter:

```
WRKOBJ <collection ID>
```

The collection ID is the name of the collection, which the user specifies in the datalink file for the Package Collection property. This collection should be a valid collection within DB2. The Work with objects window appears. Place the cursor on the *PUBLIC Object Authority line and change the authority from *USE to *ALL.

If an administrator executes the preceding statements on behalf of a nonprivileged user, this nonprivileged user can run the Data Access Tool. Once run, the process creates five sets of packages (one for each of the five isolation levels supported on DB2/400) for use by all (PUBLIC) users of the Microsoft data access features. On DB2/400, five packages are created including the AUTOCOMMITTED packages.

The following example illustrates this process on DB2/400:

Grant rights to run the Data Access Tool to authorization ID WNW999:

```
CREATE COLLECTION MSPKG
WRKOBJ MSPKG
```

Run the Data Access tool.

When using the create package tool, if the package collection specified does not exist, DB2 returns SQLCODE -805.

When using autocreate packages, if a package collection is not specified or the package collection does not exist, during the autocreate package process, the consumer application receives SQLSTATE HY000 and SQLCODE -385. The SQLSTATE HY000 is defined as a driver-specific error. The -385 Error Return Code is not a SQLCODE but rather a DDM DRDA AR (DB2 client) return code. This error code is defined as DDM_VALNSPRM with the following associated text string:

```
"The parameter value is not supported by the target system."
```

Note that when upgrading from SNA Server 4.0, any existing SNA Server 4.0 packages must be re-created using the Host Integration Server Data Access Tool to make them compatible with Host Integration Server 2009.

ActiveX Controls Programmer's Guide

This section provides information about how to integrate your applications using the Data Queue and Host File Transfer ActiveX® controls.

For API references and other technical information about ActiveX controls, see the ActiveX Controls Programmer's Reference section in the SDK.

For sample code using ActiveX controls, see the Data Integration Samples section in the SDK.

This section contains:

- Host File Transfer ActiveX Control Programmer's Guide
- Data Queue ActiveX Control Programmer's Guide

Host File Transfer ActiveX Control Programmer's Guide

The Microsoft Host File Transfer ActiveX control provides the ability to transfer files between a local computer and an MVS, OS/390, AS/400, or AS/36 host system. Host Integration Server 2009 provides this service via a single ActiveX control that depends on other core Host Integration Server DLLs. This extends the ability for a client application to perform file transfer operations from a large number of client development environments.

The Microsoft Host File Transfer ActiveX control uses the record-level input/output (RLIO) protocol of IBM's Distributed Data Management (DDM) architecture to transfer files. The Host File Transfer ActiveX control is implemented as a Distributed Data Management (DDM) source requester, which communicates through APPC LU 6.2 or TCP/IP to a DDM target server.

DDM is a set of rules for distributing or extending data management from one computer to another, such as from a mainframe to an AS/400 computer or from one of these host computers to a server computer. By combining the Microsoft File Transfer ActiveX control and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal file transfer to all enterprise-wide data sources.

The information in this section is required to develop applications with Host Integration Server that use ActiveX or COM objects to transfer files from local machines to hosts in a Systems Network Architecture (SNA) environment or over TCP/IP using RLIO and DDM.

In This Section

Platforms Supported by the Host File Transfer ActiveX Control

On the mainframe platform, IBM offers a target DDM server implementation in IBM Distributed File Manager (DFM), a component of IBM Data Facility Storage Management Subsystem (DFSMS).

On the mainframe platform, the Host File Transfer ActiveX control supports the following data set types:

Sequential Access Method (SAM) data sets

- Basic Sequential Access Method data sets (BSAM)
- Queued Sequential Access Method data sets (QSAM)

Basic Partitioned Access Method (PDS) data sets

- Partitioned Data Set Extended members (PDSE)
- Partitioned Data Set members (PDS)

Virtual Storage Access Method (VSAM) data sets

- Entry-Sequenced Data Sets (ESDS)
- Key-Sequenced Data Sets (KSDS)
- Fixed-Length Relative Record Data Sets (RRDS)
- Variable-Length Relative Record Data Sets (VRRDS)
- Relative Record Data Set (RRDS)
- VSAM Alternate Indexes for ESDS and KSDS data sets

The preceding data set types are supported by IBM DFM/MVS. The following data set types are not supported by DFM/MVS and cannot be accessed using the Host File Transfer ActiveX control.

- VSAM Linear Data Sets (LDS)
- Generation Data Groups (GDG)
- Generation Data Sets (GDS)
- Basic Direct Access Method data sets (BDAM)
- Indexed Sequential Access Method data sets (ISAM)
- Sequential Data Striping data sets
- OpenEdition MVS Hierarchical File System (HFS) files
- Tape Media

All mainframe data sets accessible through IBM Distributed File Manager must be cataloged in an Intersystem communications function (ICF) catalog and reside on direct access storage devices (DASD).

Configuring Data Descriptions for Host File Transfer

In order to use the Microsoft® Host File Transfer ActiveX® control to transfer files, a user or client application must describe the data format of the host file to transfer. A host data description is normally configured using the Data Access Tool.

The Data Access Tool contains one high-level object for configuring Host Column Description files:

- **Host Column Descriptions**—Stored in Host Column Description (HCD) files that contain the information required to convert host data types to PC computer data types.

When creating a Data Description for use with the Host File Transfer ActiveX control, the **Use Table for File Transfer** check box must be selected and values must be entered for the following additional parameters:

Parameter	Comment
FieldDelimiter	This value represents the delimiter used to mark the end of one field and the beginning of another within a single record. The position of the field elements within a record is assumed to be absolute as configured and variable-length fields are not supported. This element is used in order to inform the conversion routine to remove this character if it is found at the position within the record as indicated by the Data Description. This parameter is required and has no default value. The comma character "," or tab character "\t" is commonly used with desktop applications as a field separator.
RecordDelimiter	This value represents the character or characters that appear at the ending of a record. This element is used in order to inform the conversion routine to remove this character if it is found in the last position of the record as indicated by the Data Description. This parameter is required and has no default value. The end-of-line character sequence is commonly used as a record delimiter. The carriage return and linefeed character sequence "\n\r" is commonly used with desktop applications. The newline character "\n" is standard for use on UNIX systems and with some desktop applications.
TextQualifier	This value is used in order to allow elements that may contain the **FieldDelimiter** character to be properly parsed by the parsing engine. If this element is enabled on a particular field, then the inclusion of this character at the beginning of the field is an indication to the parsing engine that all characters up to the next instance of the **TextQualifier** should be treated as part of the current field being processed. This parameter has no default value. The single quote or double quote character is sometimes used as a text qualifier to protect a comma character included in a field from being misinterpreted as a field delimiter.

Registry Settings Used By Host File Transfer

The Microsoft® Host File Transfer ActiveX® control uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup key. These registry settings include the following subkey:

Subkey	Comment
RootDir	Stores the path to root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the Host File Transfer ActiveX control DLL and other support DLLs are installed.

Object Support Using Host File Transfer

The Microsoft® Host File Transfer ActiveX® control supports a number of standard COM interfaces as well some custom objects and interfaces.

This section contains:

- COM Interface Support Using Host File Transfer
- IEIGFileTransferCtl Object
- IEIGFileTransferCtlEvents Notification

COM Interface Support Using Host File Transfer

The Microsoft Host File Transfer ActiveX control supports a number of standard COM interfaces as well as a single custom interface, **IEIGFileTransferCtl**. The ActiveX control object has the ability to register and de-register itself via standard control mechanisms. Support for a number of standard COM interfaces makes it easy to develop applications using the Host File Transfer ActiveX control with Visual Basic and Visual C++ as well as from Internet Explorer and Access. Supporting a variety of standard COM interfaces also provides different ways for a client to save information.

The following table summarizes the standard COM interfaces supported by the Host File Transfer ActiveX control.

COM interface	Comments
ICategorizeProperties	This interface divides up the properties into an intelligent presentation to the client.
IConnectionPointContainer	None.
IDispatch	A dual interface deriving from **IDispatch** is exposed to provide support and flexibility to clients. Clients that provide support for automation interfaces will utilize the **IDispatch** interface, while more robust clients may use the custom interface. Using the custom interface provides for the greatest execution speed.
IOleControl	None.
IOleInPlaceActiveObject	None.
IOleInPlaceObject	None.
IOleInPlaceObjectWindowless	None.
IOleObject	None.
IOleWindow	None.
IPerPropertyBrowsing	This interface provides support for client browsing of properties in an intelligent manner. This interface exposes to the client property lists used in the population of a dropdown list. This interface is required for the control to be hosted by Microsoft Access.
IPropertyNotifySink	The interface is implemented by a sink object to receive notifications about property changes from an object that supports **IPropertyNotifySink** as an outgoing interface. The client that needs to receive the notifications in this interface (from a supporting connectable object) creates a sink with this interface and connects it to the connectable object through the connection point mechanism.
IPersist	None.

IPersistPropertyBag	This interface is the preferred method of property persisting for Internet Explorer and Visual Basic. Using this interface, persisted properties are stored as a set of name/VARIANT value pairs.
IPersistStorage	This interface stores persistent properties into a structured storage object.
IPersistStreamInit	This interface is responsible for saving the persisted properties in binary form using a stream interface. This is the method used by the Microsoft Visual C/C++ compiler to persist properties.
IProvideClassInfo	None.
IProvideClassInfo2	None.
IQuickActivate	None.
ISupportErrorInfo	This interface is the preferred method to return error indications to scripting clients. Using this interface, error codes and explanation text are returned to the client. This information may be used in order to provide diagnostic information to the user and in cases of failure.
IViewObject	None.
IViewObject2	None.
IViewObjectEx	None.

IEIGFileTransferCtl Object

The Microsoft Host File Transfer ActiveX control supports a number of standard COM interfaces as well as a single custom interface. The **IEIGFileTransferCtl** object supports a number or properties and methods that provide the ability to transfer files to and from MVS, OS/390, AS/400, or AS/36 hosts. The Host File Transfer ActiveX control also supports a set of events notifying a client application of connection status, file transfer status, and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the IConnectionPointContainer.

The following IEIGFileTransferCtl object methods are supported by the Microsoft Host File Transfer ActiveX control:

Method name	Comment
Cancel method	Terminates a file transfer operation that is already in progress.
Connect method	Establishes a connection to the configured host and reports to the user an indication of the success or failure of the action.
Disconnect method	Terminates an existing connection to a host machine.
GetFile method	Copies a file from host storage to local storage. This method requires the two file names as parameters.
PutFile method	Copies a file from local storage to host storage. This method requires the two file names as parameters.

The following **IEIGFileTransferCtl** object properties are supported by the Microsoft Host File Transfer ActiveX control:

Property name	Comment
AppendToEnd property	Sets or returns whether a file transfer should append to the end of a file (eigAnswerYes) if the file exists, or should it overwrite the existing contents replacing the data with the new information (eigAnswerNo). This property defaults to eigAnswerYes (0).
CCSID property	Sets or returns the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer. This property defaults to U.S./Canada (37).
ConnectionState property	Returns the current state of the connection. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting.
ConnectionType property	Sets or returns the network transport used for this connection. The **ConnectionType** property designates whether the Host File Transfer ActiveX control connects through APPC (SNA LU 6.2) or TCP/IP. The possible values for this parameter are a TCP/IP or an APPC connection using an enumerated value. The default value for this parameter is an APPC (SNA) connection type. If APPC is selected, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required. If TCP/IP is selected, then values for the **NetAddr** and **NetPort** properties are required.
CreateIfNonExisting property	Sets or returns whether a file operation should create a new destination file if one does not already exist (eigAnswerYes). This property defaults to eigAnswerNo (1)
LocalLU property	Sets or returns the Local LU Alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager. This property defaults to the string value of "LOCAL" represented as a BSTR.

ModeName property	Sets or returns the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property defaults to the string value of "QPCSUPP" represented as a BSTR.
NetAddr property	Sets or returns the IP address of the host computer. When TCP/IP has been selected for the **ConnectionType** property, this property indicates the IP address of the host. This property can be an IP address or the name representing the host IP address using the Domain Name System (sna.microsoft.com, for example). This property is a string (BSTR) and has no default value.
NetPort property	Sets or returns the TCP/IP port used for communication with the host. When TCP/IP has been selected for the ConnectionType property, this parameter is the TCP/IP port used for communication with the host. The default value for this property is the string (BSTR) "446" representing TCP/IP port 446.
OverwriteHostFile property	Sets or returns whether a file operation request to copy a file that will write over an existing file will fail. When this property is set to eigAnswerNo, a request to write a file over an existing file will fail. This property defaults to eigAnswerNo (1)
Password property	Sets or returns the password used for authentication. A valid user name and password are normally required to access files on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes. This property is a string (BSTR) and has no default value.
PCCodePage property	Sets or returns the PC codepage The **PCCodePage** property indicates the codepage to be used on the PC for character code conversion. This property defaults to Latin 1 (1252).
RDBName property	Sets or returns the name of the remote database name and the host column description (HCD) file that describes the data types and data conversions used to transfer this file. The HCD file describing the data should be located in the system subdirectory below the root directory where Host Integration Server was installed. Setup defaults to the following location: C:\Program Files\Host Integration Server When TCP/IP is selected for the **ConnectionType** property, the **RDBName** must also match the name of the remote database system.
RemoteLU property	Sets or returns the Remote LU Alias. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this property is the name of the local LU alias configured using SNA Manager. This property is a string (BSTR) has no default value.
UserID property	Sets or returns the user name used for authentication. A valid user name and password are normally required to access files on a host computer. This value is case sensitive. This property is a string (BSTR) and has no default value.

IEIGFileTransferCtlEvents Notification

The Microsoft Host File Transfer ActiveX control also supports a set of events notifying a client application of connection status, file transfer status, and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following IEIGFileTransferCtlEvents notification interface methods are supported by the Microsoft Host File Transfer ActiveX control:

Event notifications	Comment
ConnectionStateChange	This event is fired when the state of a connection has changed. A *ConnectionState* parameter is passed to the client callback function that receives this event method call. This parameter is an eigConnectionStateEnum value representing the new state of the ConnectionState property.
ReportError	This event is used in order to return error conditions that occur during the synchronous processing of methods. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.
TransferComplete	This event is an indication to the client that the requested transfer operation has completed.
TransferProgress	This event will be fired periodically in order to inform the client of the progress of an unattended file transfer. A *PercentageDone* parameter is passed to the client callback function that receives this event method call. This parameter is a short value representing the percentage complete of the requested operation ranging from 0 to 100. A client application has the option to terminate a file transfer when this event is fired.

Programming Considerations When Using Host File Transfer

The Microsoft® Host File Transfer ActiveX® control exposes a dual interface deriving from **IDispatch**. This provides support and flexibility to clients wishing to use the object. Clients that provide support automation interfaces can use the **IDispatch** interface while more robust clients may use the custom interface. Using the custom interface offers the greatest execution speed.

The single-threading model is supported, allowing only single threads to access the objects safely.

The Host File Transfer ActiveX control does not support uploading Direct Relative Record Data Set (RRDS) files on System/36. An error (381) will occur and the following error message will be received.

```
"Target Not Supported"
```

The Host File Transfer ActiveX control also does not support uploading RRDS files with the CreateIfNonExisting property option set to yes on System/36. An error will occur (381) and the following message will be received.

```
"Target Not Supported"
```

If there is existing data in a file on OS/390, setting the OverwriteHostFile and AppendToEnd properties to "no" should cause an error (58) to occur and the following error message should be received.

```
"File contains existing data. Upload not configured to append data - upload aborted"
```

On OS/390, this error is not triggered for sequential or KSDS files. Instead the data is appended to the existing data in the file for sequential files and duplicate records are not appended to KSDS files.

The **AppendToEnd** property and the **OverwriteHostFile** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd** defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order in which these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until the **AppendToEnd** property is set to no (disabled).

Using the Data Descriptions tool, setting the Ascending/Descending option on an OS/390 or MVS/ESA key sequenced file has no effect. Using the Host File Transfer ActiveX control, data is always uploaded and downloaded in the ascending key order.

If the **Cancel** method is executed while uploading a file with the **AppendToEnd** property set to yes, this will result in no change to the host file. However, if the **Cancel** method is executed while uploading a file with the **OverwriteHostFile** property set to yes, this will result in an empty host file. The **Cancel** method implies the transfer has been stopped and all the files are at their original values, but this is not really the case when the **OverwriteHostFile** property is set to yes.

- Troubleshooting the Host File Transfer ActiveX Control

Code Page Support Using Host File Transfer

When using the Host File Transfer ActiveX control, the Host CCSID (character code set identifier) property should be configured to match the data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the Host File Transfer ActiveX control.

This section contains:

- ISO Code Page Support Using Host File Transfer
- DBCS Code Page Support Using Host File Transfer

ISO Code Page Support Using Host File Transfer

Host Integration Server 2009 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the Host File Transfer ActiveX control. These ISO code pages can be used when accessing host files containing ISO code pages.

Depending on the version of Windows being used, to support ISO-to-UNICODE-to-ANSI (Windows), ANSI-to-UNCODE-to-ISO, and ISO-to-UNICODE-to-ISO code page conversions, you may need to install the appropriate ISO National Language Support (NLS) file for your locale.

On Microsoft Windows 2000, the appropriate ISO NLS file for your locale is installed automatically when you install a localized version of Windows 2000. On Windows Server 2003, the appropriate ISO NLS file for your locale is installed automatically when you install the US-English version.

The following table shows the ISO character code set identifiers (CCSIDs) supported by Host File Transfer ActiveX control in Host Integration Server 2009.

Microsoft display name	Microsoft NLS code page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	
ISO 8859-2 Central europe	28592	912	
ISO 8859-5 Cyrillic	28595	915	
ISO 8859-6 Arabic	28596	1089	
ISO 8859-7 Greek	28597	813	
ISO 8859-8 Hebrew	28598	916	
ISO 8859-9 Turkish	28599	920	
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the OLE DB Provider for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (euro)	20865	923	NLS Code Page 819 with support for the euro.

The Microsoft display name is the name found in the Windows 2000 definitions for these NLS files.

The Microsoft NLS code page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when using the Host File Transfer ActiveX control. When setting the Host CCSID or PC Code Page property, use the Microsoft NLS number for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The Host File Transfer ActiveX control does not recognize or display the IBM CCSID values.

The Host File Transfer ActiveX control maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The Host File Transfer ActiveX control passes the corresponding IBM CCSID to the host system at run time even though you configure this property using the Microsoft NLS number.

Note

The IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269.

Note

The ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the Host File Transfer ActiveX control.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000.

The Host File Transfer ActiveX control has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2009. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

DBCS Code Page Support Using Host File Transfer

Support for Double-Byte Character String (DBCS) data is limited using the Host File Transfer ActiveX control. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported.

Data Conversion Using Host File Transfer

Using the Host File Transfer ActiveX control, host data is converted to default C data types as defined in ODBC and OLE DB and illustrated in the following table:

Host data type (description in HCD file)	Default C data type	Comments
BINARY		A free-form binary data type of specified length. This data type is transferred without being converted.
CHAR	char string[]	A fixed-length string. This data type is converted to a DBTYPE_BSTR for use by Host File Transfer ActiveX control.
DATE	date struct	A 10-byte date string. This data type is converted to a DBTYPE_DATE for use by OLE DB.
DOUBLE	double	An 8-byte double-precision floating-point number. This data type is converted to a DBTYPE_R8 for use by OLE DB.
FLOAT	double	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE. This data type is converted to a DBTYPE_R8 for use by OLE DB.
LONG	int	A 4-byte integer ranging in value from -2,147,463,648 to +2,147,483,647. This data type is converted to a DBTYPE_I4 for use by OLE DB.
LONG VARBINARY	char string[]	A varying-length binary string up to 32,740 bytes in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARCHAR	char string[]	A varying-length character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
PACKED	unsigned char number[]	A packed decimal number. This data type is converted to a DBTYPE_DECIMAL for use by OLE DB
REAL	float	A 4-byte single-precision floating-point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
SHORT	short	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767. This data type is converted to a DBTYPE_I2 for use by OLE DB.
SINGLE	float	A 4-byte single-precision floating-point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
TIME	time struct	An 8-byte time string. This data type is converted to a DBTYPE_TIME for use by OLE DB. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.

TIMESTAMP	timestamp struct	A 26-byte string representing the date, time, and microseconds. This data type is converted to a DBTYPE_DBTIMESTAMP for use by OLE DB.
VARBINARY	char string[]	A varying-length binary field. The maximum length of the binary is dependent on the version and the host platform. This data type is transferred without being converted. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the host platform. This data type is converted to a DBTYPE_STR for use by OLE DB.
ZONED	unsigned char number[]	A zoned numeric number. This data type is converted to a DBTYPE_NUMERIC for use by OLE DB

Note

The maximum length of fixed-length BINARY, fixed-length CHAR, VARBINARY, and VARCHAR data types is dependent on the version of the host software that is being accessed. For example, the maximum length of the CHAR data type on OS/390 is 254 characters, while the maximum length of this same host data type is 32,765 on OS/400.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the Host File Transfer ActiveX control.

Using the Host File Transfer ActiveX control, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The Host File Transfer ActiveX control translates all such undefined characters to the question mark character ("?"). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters will be replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The ANSI to EBCDIC character conversions affected include the following:

Character value (decimal)	Character value (hexadecimal)	ANSI code page 1252	EBCDIC character after conversion to CCSID 37
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?

142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Usernames and Passwords Using Host File Transfer

When connecting to host systems, most users must be authenticated by the remote system by passing a valid user ID and password.

The AS/400 computer is case-sensitive with regard to user ID and password. The AS/400 only accepts a user ID and password in uppercase. The Microsoft Host File Transfer ActiveX control forces the User ID and Password into uppercase when it knows that it is connecting to an AS/400 system.

The mainframe is not case-sensitive. This means that on mainframe computers, one can enter the user ID and password in any case.

Troubleshooting the Host File Transfer ActiveX Control

The Microsoft Host File Transfer ActiveX control supplied with Host Integration Server 2009 has the ability to trace DRDA data flows when used over TCP/IP.

This tracing capability is accessible from the SNADDM Service tracing inside the Trace tool. This facility will show the same data as an APPC trace but without the control indicators (For example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Platform SDK.

The Host File Transfer ActiveX control can return the following types of errors:

- Errors from the remote hosts
- Microsoft Host File Transfer-specific errors
- Errors from the underlying DDM application requester network client

Data Queue ActiveX Control Programmer's Guide

A data queue is an AS/400 system object that is used for inter-process communications between multiple programs or jobs. Data queues allow multiple programs to send and receive shared messages via a central repository without first writing the message data to a physical database file. Typically, when a data record is read from the queue, the record is erased from the queue. The advantage of using data queues to share data in comparison with using database files is that data queues require much less file I/O and therefore improve overall system performance.

The Microsoft Data Queue ActiveX control provides the ability to access AS/400 data queues. Microsoft Host Integration Server 2009 provides this service via a single ActiveX control that depends on other core Host Integration Server DLLs. Developers can move part or all of their AS/400 applications from an AS/400 computer to a PC platform, while retaining access in the program running on the PC to a remote data queue on the AS/400.

The Data Queue ActiveX control is implemented as a Distributed Data Management (DDM) Application Requester. The Data Queue ActiveX control uses the Data Queue interfaces in the DDM Level 4 architecture, which are extensions to the record-level input/output (RLIO) protocol of IBM's Distributed Data Management architecture.

DDM is a set of rules for distributing or extending data management from one computer to another, such as from a mainframe to an AS/400 computer or from one of these host computers to a server computer. By combining the Microsoft Data Queue ActiveX control and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal file and data transfer to all enterprise-wide data sources.

The information in this section is required to develop applications with Host Integration Server that use ActiveX or COM objects to transfer data from local machines to AS/400 Data Queues in a Systems Network Architecture (SNA) environment.

In This Section

Advantages of Data Queues

Data queues provide a fast means of inter-process communication, requiring low system overhead and minimal setup. AS/400 Data Queues are designed to provide a flexible, highly efficient, yet temporary means of inter-process communication. Data queues are familiar to most AS/400 programmers as a simple method of passing information to another program.

Data queues provide considerable flexibility to the application programmer. The data queues interfaces require no communications programming and can be used either for connected or disconnected communication. AS/400 and PC applications can be developed using any supported language, yet still communicate with each other. PC programs can communicate with AS/400 programs through a common AS/400 data queue. The use of data queues requires little knowledge of communication and no knowledge of APPC if the programmer utilizes the Microsoft® Data Queue ActiveX® control. The data queue messages are merely described at the record level, allowing the application programmer to define the field-level structure as required.

By default, when one program reads an entry in the queue, the entry is then deleted. Pointers to the queue entries are then updated to reflect the change in the record stack. A data queue can exist with no entries, a single entry, or multiple entries. Multiple concurrent jobs and programs can access data queues.

When receiving data, the requesting application can set a time-out value to wait for data to arrive in the queue. Waits can be applied based on entry of the data record or for a time period (zero seconds to many days in length). A program that reads from a queue need not be running when the queue is created or when records are inserted. A single data queue can support many separate interactive jobs. At regular intervals or at the end of the day, records in the data queue can be persisted to a file by a single automated batch process.

Object Support Using Data Queues

The Microsoft® Data Queue ActiveX® control supports a number of standard COM interfaces as well some custom objects and interfaces.

This section contains:

- COM Interface Support Using Data Queues
- IEIGDataQueueCtl Object
- IEIGDataQueue Object
- IEIGDataQueueItem Object
- IEIGDataQueueCtlEvents Notifications
- IEIGDataQueueEvents Notifications

COM Interface Support Using Data Queues

The Microsoft Data Queue ActiveX control supports a number of standard COM interfaces as well as several custom interfaces, **IEIGDataQueueCtl**, **IEIGDataQueue**, and **IEIGDataQueueItem**. The ActiveX control object has the ability to register and de-register itself via standard control mechanisms. Support for a number of standard COM interfaces makes it easy to develop applications using the Data Queue ActiveX control with Visual Basicand Visual C++ as well as from Internet Explorer and Access. Supporting a variety of standard COM interfaces also provides different ways for a client to save information.

The following table summarizes the standard COM interfaces supported by the Data Queue ActiveX control.

COM interface	Comments
ICategorizeProperties	This interface divides up the properties into an intelligent presentation to the client.
IConnectionPointContainer	
IDispatch	A dual interface deriving from **IDispatch** is exposed to provide support and flexibility to clients. Clients that provide support for automation interfaces will utilize the **IDispatch** interface, while more robust clients may use the custom interface. Using the custom interface provides for the greatest execution speed.
IPerPropertyBrowsing	This interface provides support for client browsing of properties in an intelligent manner. This interface exposes to the client property lists used in the population of a drop-down list. This interface is required for the control to be hosted by Microsoft Access.
IPropertyNotifySink	The interface is implemented by a sink object to receive notifications about property changes from an object that supports **IPropertyNotifySink** as an outgoing interface. The client that needs to receive the notifications in this interface (from a supporting connectable object) creates a sink with this interface and connects it to the connectable object through the connection point mechanism.
IPersist	
IPersistPropertyBag	This interface is the preferred method of property persisting for Internet Explorer and Visual Basic. Using this interface persisted properties are stored as a set of name/VARIANT value pairs.
IPersistStorage	This interface stores persistent properties into a structured storage object.
IPersistStreamInit	This interface is responsible for saving the persisted properties in binary form using a stream interface. This is the method used by the Microsoft Visual C/C++ compiler to persist properties.
ISupportErrorInfo	This interface is the preferred method to return error indications to scripting clients. Using this interface, error codes and explanation text are returned to the client. This information may be used in order to provide diagnostic information to the user and in cases of failure.

Object Support Using Data Queues

IEIGDataQueueCtl Object

The **IEIGDataQueueCtl** object supports a number of properties and methods that provide the ability to connect with a host and communicate with OS/400 Data Queues. The **IEIGDataQueueCtl** also supports a set of events notifying a client application of connection status and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the **IConnectionPointContainer**.

The following **IEIGDataQueueCtl** object methods are supported by the Microsoft Data Queue ActiveX control.

Method name	Comment
Connect	Establishes a connection to the configured host and reports to the user an indication of the success or failure of the action.
CreateQueueContainer	Creates an instance of an IEIGDataQueue container object and optionally initializes the QueueName property. The created queue object is assumed to be associated with the connection object that created it for the life of the connection or the life of the queue object.
Disconnect	Terminates an existing connection to a host machine.

The following **IEIGDataQueueCtl** object properties are supported by the Microsoft Data Queue ActiveX control.

Property name	Comment
CCSID	Sets or returns the character code set identifier (CCSID) that must match the data in the AS/400 data queue as represented on the remote host computer. This property defaults to U.S./Canada (37).
ConnectionState	Returns the current state of the connection. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting.
ConnectionType	Sets or returns the network transport used for this connection. The default value for this parameter is SNA. Note that TCP/IP is not supported. If APPC is selected, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required.
LocalLU	Sets or returns the Local LU Alias. When APPC (SNA LU 6.2) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager. This property defaults to the string value of "LOCAL" represented as a BSTR.
ModeName	Sets or returns the APPC mode. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this field must be set to the APPC mode that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property defaults to the string value of "QPCSUPP" represented as a BSTR.
Password	Sets or returns the password used for authentication. A valid user name and password are normally required to access data on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes. This property is a string (BSTR) and has no default value.
PCCodePage	Sets or returns the PC code page The PC Code Page property indicates the code page to be used on the PC for character code conversion. This property defaults to Latin 1 (1252).

RemoteLU	Sets or returns the Remote LU Alias. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this property is the name of the remote LU alias configured using SNA Manager. This property is a string (BSTR) and has no default value.
UserID	Sets or returns the user name used for authentication. A valid user name and password are normally required to access data on a host computer. This value is case sensitive. This property is a string (BSTR) and has no default value.

Object Support Using Data Queues

IEIGDataQueue Object

The **IEIGDataQueue** object represents a logical queue and supports a number of properties and methods that provide the ability to communicate with a specific data queue. The QueueName property is the name of the physical queue. All methods and events are related to the queue that is represented by the individual instance of the object. The Data Queue ActiveX control also supports a set of events notifying a client application of connection status, data transfer status, and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the **IConnectionPointContainer**.

The following **IEIGDataQueue** object methods are supported by the Microsoft Data Queue ActiveX control.

Method name	**Comment**
AddQueueItem	Adds a record to the current queue.
Cancel	Terminates a request to receive information from the queue that is already in progress.
CancelQueue	Indicates that an application no longer wants to be notified of an incoming queue data item. This can be used to stop pending notifications that were queued as a result of calling **GetQueueItem**.
ClearAll	Removes all items from the queue.
CreateQueue	Creates a data queue.
DeleteQueue	Clears all messages from the queue and then deletes the queue.
GetQueueItem	Retrieves an item from the queue.
QueryAttribute	Requests information on one of the queue's attributes
SetAttribute	Changes the attributes associated with a data queue.
StopQueue	Stops the queue from responding to client requests.

The following **IEIGDataQueue** object property is supported by the Microsoft Data Queue ActiveX control.

Property name	**Comment**
QueueName	This is the name of the data queue this object is associated with.

Other Resources

Object Support Using Data Queues

IEIGDataQueueItem Object

The **IEIGDataQueueItem** object represents a specific queue item and supports a number of properties and methods.

The following **IEIGDataQueueItem** object method is supported by the Microsoft Data Queue ActiveX control.

Method name	Comment
Reset	Resets the queue item properties to default values.

The following **IEIGDataQueueItem** object properties are supported by the Microsoft Data Queue ActiveX control.

Property name	Comment
ExtUser	The external job user name.
ExtJobName	The external job name.
ExtJobNumber	The external job number.
InactiveRec	Indicates an Inactive record.
Keyval	The key value.
Message	The queue message.
QItemType	The type of queue item this represents.
Record	The entire queue data.
RecordAttribute	The list of record attributes.
RecCount	The record count.
RecNumber	The record number.
ReplyRequest	Indicates if the reply message should be returned.
UsrProf	The user profile.

Object Support Using Data Queues

IEIGDataQueueCtlEvents Notifications

The **IEIGDataQueueCtl** object of the Microsoft Data Queue ActiveX control also supports a set of events notifying a client application of connection status and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGDataQueueCtlEvents** notification interface methods are supported by the Data Queue ActiveX control:

Event notifications	Comment
ConnectionStateChange	This event is fired when the state of a connection has changed. A ConnectionState parameter is passed to the client callback function that receives this event method call. This parameter is an **eigConnectionStateEnum** value representing the new state of the ConnectionState property.
Report Error	This event is fired when an error condition needs to be reported during non-blocking (asynchronous) functions. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.

Object Support Using Data Queues

IEIGDataQueueEvents Notifications

The **IEIGDataQueue** object of the Microsoft Data Queue ActiveX control also supports a set of events notifying a client application of when transfers are completed, requests are received, and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGDataQueueEvents** notification interface methods are supported by the Data Queue ActiveX control:

Event notifications	**Comment**
ReportError2	This event is fired when an error condition needs to be reported during non-blocking (asynchronous) functions. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.
RequestReceived	This event is fired when a request is received.
SendComplete	This event is fired as an indication to the client that the requested transfer operation has completed.

Object Support Using Data Queues

Programming Considerations When Using the Data Queue ActiveX Control

The Microsoft® Data Queue ActiveX® control exposes a dual interface deriving from **IDispatch**. This provides support and flexibility to clients wishing to use the object. Clients that provide support for automation interfaces can use the **IDispatch** interface while more robust clients may use the custom interface. Using the custom interface offers the greatest execution speed.

The single-threading model is supported, allowing only single threads to access the objects safely.

Asynchronous read operations are not currently supported. The *BlockComplete* parameter of the GetQueueItem method must be set to a value of 0 (eigAnswerYes), indicating that the **GetQueueItem** operation should block until the completion status is known.

This section contains:

- Code Page Support Using Data Queues
- User Names and Passwords Using Data Queues
- Troubleshooting the Data Queue ActiveX Control

Code Page Support Using Data Queues

When using the Data Queue ActiveX control, the Host CCSID (character code set identifier) property should be configured to match the data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the Data Queue ActiveX control.

This section contains:

DBCS Code Page Support Using Data Queues

Support for Double-Byte Character String (DBCS) data is limited using the Data Queue ActiveX control. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are not supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

See Also

Other Resources

Code Page Support Using Data Queues

User Names and Passwords Using Data Queues

When connecting to host systems, most users must be authenticated by the remote system by passing a valid User ID and Password.

The AS/400 computer is case-sensitive with regard to user ID and password. The AS/400 only accepts a user ID and password in uppercase. The Microsoft Data Queue ActiveX control forces the user ID and password into uppercase when it knows that it is connecting to an AS/400 system.

Programming Considerations When Using the Data Queue ActiveX Control

Troubleshooting the Data Queue ActiveX Control

The Microsoft Data Queue ActiveX control supplied with Host Integration Server 2009 has the ability to trace DRDA data flows.

This tracing capability is accessible from the DB2 Network Librarytracing inside the Trace tool. This facility shows the same data as an APPC trace but without the control indicators (for example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Platform SDK.

The Data Queue ActiveX control can return the following types of errors:

- Errors from the remote hosts
- Microsoft Data Queue-specific errors
- Errors from the underlying DDM application requester network client

Programming Considerations When Using the Data Queue ActiveX Control

Using Data Design Tools

The Data Design Tools are a set of technologies exposed in Visual Studio that enable you to visually create database connections and queries, browse tables, view data, execute stored procedures, and access other database features. The following table describes the level of support the Server Explorer for Visual Studio provides for Host Integration Server 2009.

Provider	**Visual Studio Data Design Support**
ODBC Driver for DB2	None
OLE DB Provider for DB2	High
Managed Provider for DB2	Low
OLE DB Provider for AS/400 and VSAM	Low
Data Queues	None
File Transfer ActiveX controls	None

In This Section

Using Data Design Tools for the OLE DB Provider for DB2

Using Data Design Tools for the Managed Provider for DB2

Using Data Design Tools for the Microsoft OLE DB Provider for AS/400 and VSAM

Using Data Design Tools for the OLE DB Provider for DB2

The OLE DB Provider for DB2 is the provider that the Microsoft Visual Studio Data Design Tools most heavily support. The following list describes the different Data Design Tools available in Visual Studio, and how they interact with the OLE DB Provider for DB2.

- Database Designer

  With this visual tool, you can design and visualize a DB2 database to which you are connected. When designing a database, you can use the Database Designer to create, edit, or delete tables, columns, keys, indexes, relationships, and constraints. To visualize a database, you can create one or more diagrams illustrating some or all of the tables, columns, keys, and relationships.

- Table Designer

  With this visual tool, you can design and visualize a single table in a DB2 database to which you are connected.

- Query and View Designer

  With this visual tool, you can design a query, view, in-line function, or single-statement stored procedure.

- SQL Editor

  This integrated tool provides a variety of SQL text-editing features.

- Server Explorer

  With this Visual Explorer window, you can view and manipulate data links, database connections, and system resources on any server to which you have network access. Features include the ability to open data connections, log onto servers and display system resources, make database connections, and create data components that describe remote resources for your Visual Studio projects.

- Solution Explorer

  Provides an organized view of your projects and their files as well as ready access to the commands that pertain to them.

Using Data Design Tools

Using Data Design Tools for the Managed Provider for DB2

The Data Design Tools included in Microsoft® Visual Studio® .NET 2003 do not currently support the Managed Provider for DB2. However, you can partially prototype and design your data connections with System.Data and ADO.NET using the available tools.

To use the Data Design Tools for the Managed Provider for DB2

1. Use the Data Design Tools for the OLE DB Provider for DB2 to outline your data connection.

   The OLE DB Provider for DB2 and the Managed Provider for DB2 are similar enough that the generated scripts and objects can provide a starting point for your Managed Provider for DB2 connection.

2. Manually alter the autogenerated files for use with the Managed Provider for DB2.

Managed Provider for DB2 Programmer's Guide

Using Data Design Tools for the Microsoft OLE DB Provider for AS/400 and VSAM

The Microsoft OLE DB Provider for AS/400 and VASM is a non-SQL command provider. As such, this provider does not integrate well with the Microsoft Visual Studio Data Design Tools. While you can create a data connection from the supplied menus in Visual Studio, very few of the generated scripts and objects are useful for a Host Integration Server 2009 application. Instead, it is recommended that you manually create the connections using the standard programming technologies.

Data Integration Security Guide

This section covers security issues that programmers working with the data integration features of Host Integration Server 2009 should understand.

In This Section

Managed Provider Security

The following topics discuss security as it applies to the Managed Provider for DB2 section of the Host Integration Server 2009 SDK.

About Managed Provider security for developers

A Managed Provider is a .NET Framework data provider used for connecting Host Integration Server 2009 applications to a database, executing commands, and retrieving results. Those results are either processed directly, or placed in an ADO.NET **DataSet**.

The Managed Provider for DB2 is built on the .NET Framework, and because of this it can take advantage of many of the security features that a managed environment provides. This section discusses security features and issues that you should be aware of when using the Managed Provider.

Threats and mitigations for the Managed Provider

Programmers who use the Managed Provider for DB2 should be aware of the following security practices and issues.

Protect Components Store Connection Information in Plain Text

Generic data access components, such as the Data Tools and Data Bound controls in Microsoft Visual Studio store sensitive DB2 connection data in plain text. This is done to grant third parties easy access to host data when using the control.

Storing connection data in plain text is a security concern because there is the potential for another application or user to read the active memory belonging to the control, and retrieve sensitive information from the plain text stored in the control. You can improve the security of your Host Integration Server application using one or more of the following techniques:

- Store any file known to contain connection information, such as a .UDL file, in a secure location.
- Design your applications so that you release and destroy any components known to store data in plain text as soon as the user is finished with the component.

OLE DB Provider for DB 2, AS/400, and VSAM Security

The following topics discuss security as it applies to the following sections of Host Integration Server 2009 SDK.

- OLE DB Provider for DB2
- OLE DB Provider for AS/400 and VASM

About OLE DB Provider Security for Developers

These Microsoft OLE DB providers enable users to access IBM DB2 from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for DB2 combines the universal data access of OLE DB with the IBM Distributed Relational Database Architecture (DRDA).

This section discusses security features and issues that you should be aware of before programming the OLE DB Provider for DB2.

Single Sign-On

Enterprise Single Sign-On provides services that request and verify your credentials after you log on to the network, and use your credentials to determine the actions that you can perform based on your user rights. Single Sign-On is supported for the OLE DB provider for DB2.

For information on how you can configure Single Sign-On for the OLE DB Providers, see Connection.

Threats and mitigations for the OLE DB Provider

Programmers who use these features should be aware of the following security practices and issues.

The OLE DB Provider for DB2 stores host configuration data in OLE DB properties collection

The OLE DB Provider for DB2 stores host and PC configuration data in an OLE DB property collection, and then returns this data to the calling program. Your program should not pass this sensitive information on to the end user.

The OLE DB Provider for DB2 DTS and DQP consumers persist configuration data

Generic consumers such as DTS, DQP, Replication, and OLAP persist sensitive host configuration information in the following insecure ways:

- Most SQL Server consumers use the SQL Server Repository to store data source information.
- DTS can persist DTS packages (which include data source configuration info) as files and Visual Basic programs (plain text).

To minimize the risks mentioned above, generic consumers should encrypt sensitive OLE DB connection information using the crypto API (DP, data protection API).

The OLE DB Provider for AS/400 and VSAM stores host configuration data in an OLE DB properties collection

The OLE DB Provider for AS/400 and VSAM stores host and computer configuration data in an OLE DB property collection, and then returns this data to the calling program. Your program should not pass this sensitive information on to the end user.

Use provider-specific connection pooling

It is a best practice to use the provider-specific connection pooling in Host Integration Server rather than the system provided resource pooling provided by the OLE DB Provider for DB2. This avoids possible security risks in the OLE DB Provider for DB2.

The OLE DB Provider for DB2 DTS and DQP consumers persist configuration data

Generic consumers such as DTS, DQP, Replication and OLAP stores sensitive host configuration information in the following insecure ways:

- Most SQL Server consumers utilize the SQL Server Repository to store data source information.
- DTS can store DTS packages (which include data-source configuration info) as files and Visual Basic programs (plain text).

To minimize the risks mentioned above, Generic consumers should encrypt sensitive OLE DB connection information using the crypto API (DP, data protection API).

Host File Transfer Object Security

The Microsoft Host File Transfer ActiveX control provides the ability to transfer files between a local computer and an MVS, OS/390, AS/400, or AS/36 host system. Host Integration Server 2009 provides this service through a single ActiveX control that depends on other core Host Integration Server DLLs.

This section discusses security features and issues that you should be aware of before you use with the Host File Transfer object in your programs.

Threats and mitigations for the Host File Transfer object

Programmers who use these features should be aware of the following security practices and issues.

Validate input parameters for the Host File Transfer control

You should validate all input parameters before passing them on to the Host File Transfer control.

You should verify all values received from end users before passing values (such as filenames) to the ActiveX control.

The SAM and VSAM data sets, as well as PDS/PDSE members, must be referenced in the host column description (HCD) file the same way as they are referenced in the command text of the OLE DB command object, using the following command text syntax:

```
EXEC OPEN FileName
```

where FileName represents one of the following host file naming conventions:

- Host file type File naming convention
- VSAM Data Sets:

  ```
  DATASETNAME.FILENAME
  ```

- Partitioned Data Sets:

  ```
  DATASETNAME.FILENAME(MEMBER)
  ```

- OS/400 Files:

  ```
  LIBRARY/FILE
  ```

- OS/400 Files:

  ```
  LIBRARY/FILENAME
  ```

- OS/400 File Members:

  ```
  LIBRARY/FILE(MEMBER)
  ```

- OS/400 File Members:

  ```
  LIBRARY.FILENAME(MEMBER)
  ```

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as

follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

Please note that you must utilize the full path to the mainframe data set. In the example below, there are two path elements and one name element to describe the target data set:

```
XXXXX.XXX.XXX
```

Whenever you allocate a data set, it is given a unique name composed of one or more segments. Each segment of a data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully qualified data set name.

```
WNW999.DEMO.KSDS.TITLES
```

The high-level qualifier is WNW999. The low-level qualifier is TITLES. Each segment can be from 1-8 characters in length (first character must be alphabetic; remainder can be alphanumeric or hyphens). The data set name must be no more than 44 characters in length and contain no more than 22 segments.

Store the HCD files for the Host File Transfer control in a secure location

File Transfer reads host column description (HCD) files at run time as a means to support data conversion from host data types to OLE DB data types. You should store HCD files in a secure location that only the application can access at run time. This ensures that a malicious user may not modify the file to submit embedded commands.

Network Integration Programmer's Guide

This section describes how to create applications in a Systems Network Architecture (SNA) environment.

For API references and other technical information about network integration, see the Network Integration Programmer's Reference section of the SDK.

For sample code that illustrates network integration, see the Network Integration Samples section of the SDK.

For additional information about network integration, see the Network Integration User's Guide section of the Operations guide.

APPC Programmer's Guide

This section of the Host Integration Server 2009 Developer's Guide provides information about using the Advanced Program-to-Program Communications (APPC) in a distributed processing environment.

For API references and other technical information about APPC, see APPC Programmer's Reference.

For sample code using APPC, see APPC Samples.

This section contains:

- About the APPC Guide
- Introduction to APPC
- About Transaction Programs
- Windows CSV Overview
- Support for APPC Automatic Logon

APPC Guide

This section provides information required to develop C-language applications that use Advanced Program-to-Program Communications (APPC) to exchange data in a Systems Network Architecture (SNA) environment.

This section is intended for the developer writing applications that use Common Programming Interface for Communications (CPI-C) to exchange data. It provides conceptual information and detailed reference information.

To use this section effectively, you should be familiar with:

- Microsoft Host Integration Server 2009
- Microsoft Windows Server 2003 or Windows 2000
- SNA concepts

This section contains:

Operating Systems Support for APPC Development

Microsoft Host Integration Server 2009 supports the development of Advanced Program-to-Program Communications (APPC) applications for Microsoft Windows Server 2003 and Microsoft Windows 2000.

Finding Further Information about APPC

This section does not describe the products, architectures, or standards developed by other companies or organizations.

For more information about SNA and about 3270 information display systems, see the following manuals:

- *IBM 3270 Information Display System: 3274 Control Unit Description and Programmers Guide*
- *IBM 3270 Information Display System: Color and Programmed Symbols*

- *IBM SNA: Technical Overview*
- *IBM SNA: ACF/VTAM Programming for LU Type 6.2*

Introduction to APPC

This section introduces the fundamental concepts of Advanced Program-to-Program Communications (APPC) in a distributed processing environment. These concepts include the following:

- APPC verbs
- Microsoft® Windows® APPC extensions
- Using APPC verbs in C programs
- Operating system considerations

Detailed descriptions of APPC verbs are provided in:

- APPC Management Verbs
- APPC TP Verbs
- APPC Conversation Verbs

APPC is an application programming interface (API) that enables peer-to-peer communications in a Systems Network Architecture (SNA) environment. Through APPC, programs distributed across a network can work together, communicating with each other and exchanging data, to accomplish a single processing task such as querying a remote database, copying a remote file, or sending and receiving electronic mail.

This section contains:

- APPC Verb Overview
- APPC Verb Summary
- Windows APPC Overview
- Using APPC Verbs in C Programs
- Windows Server 2003, Windows XP, and Windows 2000 Considerations

APPC Verb Overview

APPC verbs fall into three categories: management, transaction program (TP), and conversation.

Management Verbs

Management verbs provide management functions. They are:

ACTIVATE_SESSION

CNOS

DEACTIVATE_SESSION

DISPLAY

TP Verbs

TP verbs start and end TPs, and get and set TP properties. They are:

GET_TP_PROPERTIES

SET_TP_PROPERTIES

TP_ENDED

TP_STARTED

Conversation Verbs

Conversation verbs enable TPs to allocate and deallocate conversations, send and receive data, and change conversation states. The conversation verbs are listed in the following table.

Conversation verbs fall into two groups: mapped conversation verbs and basic conversation verbs. The mapped conversation is intended for programs that use the conversation directly. The basic conversation is intended for more complex programs that provide services to other users. In typical situations, end-user TPs use mapped conversations and service TPs use basic conversations.

Mapped conversation verbs can only be issued by a TP in mapped conversations, while basic conversation verbs are reserved for basic conversations. There is one exception to this rule: ALLOCATE can be used to start either a basic or a mapped conversation.

Mapped conversation verbs	**Basic conversation verbs**
MC_ALLOCATE	ALLOCATE
MC_CONFIRM	CONFIRM
MC_CONFIRMED	CONFIRMED
MC_DEALLOCATE	DEALLOCATE
MC_FLUSH	FLUSH
MC_GET_ATTRIBUTES	GET_ATTRIBUTES
GET_LU_STATUS	GET_LU_STATUS
GET_STATE	GET_STATE
GET_TYPE	GET_TYPE
MC_POST_ON_RECEIPT	POST_ON_RECEIPT

MC_PREPARE_TO_RECEIVE	PREPARE_TO_RECEIVE
RECEIVE_ALLOCATE	RECEIVE_ALLOCATE
MC_RECEIVE_AND_POST	RECEIVE_AND_POST
MC_RECEIVE_AND_WAIT	RECEIVE_AND_WAIT
MC_RECEIVE_IMMEDIATE	RECEIVE_IMMEDIATE
MC_RECEIVE_LOG_DATA	RECEIVE_LOG_DATA
MC_REQUEST_TO_SEND	REQUEST_TO_SEND
MC_SEND_CONVERSATION	SEND_CONVERSATION
MC_SEND_DATA	SEND_DATA
MC_SEND_ERROR	SEND_ERROR
MC_TEST_RTS	TEST_RTS

Mapped and basic verbs have the same functions in their respective types of conversation. For example, **MC_CONFIRM** performs the same function in a mapped conversation that **CONFIRM** performs in a basic conversation.

APPC Verb Summary

This section briefly describes each APPC verb, grouped by function.

Verbs for Starting Conversations
ALLOCATEor MC_ALLOCATE

Issued by the local transaction program (TP). This verb allocates a session between the local logical unit (LU) and a partner LU, and establishes a conversation between the local TP and the partner TP.

ALLOCATE can establish either a basic or a mapped conversation. **MC_ALLOCATE** can start only a mapped conversation. After the conversation is allocated, APPC uses this verb to return a conversation identifier (**conv_id**).

RECEIVE_ALLOCATE

Issued by the partner TP. This verb confirms that the partner TP is ready to begin a conversation with the local TP that issued **ALLOCATE** or **MC_ALLOCATE**. Upon successful execution, this verb returns a TP identifier (**tp_id**) for the partner TP and the **conv_id**.

TP_STARTED

Issued by the local TP. This verb notifies APPC that the local TP is starting. Upon successful execution, this verb returns a **tp_id** for the local TP.

Verbs for Sending Data
CONFIRMor MC_CONFIRM

Sends the contents of the local LU's send buffer and a confirmation request to the partner TP.

FLUSHor MC_FLUSH

Flushes the local LU's send buffer, sending the contents of the buffer to the partner LU and TP. If the send buffer is empty, no action takes place.

PREPARE_TO_RECEIVEor MC_PREPARE_TO_RECEIVE

Changes the state of the conversation from SEND to RECEIVE. Before changing the conversation state, this verb performs the equivalent of **FLUSH**, **MC_FLUSH**, **CONFIRM**, or **MC_CONFIRM**. After this verb has successfully executed, the local TP can receive data.

REQUEST_TO_SENDor MC_REQUEST_TO_SEND

Informs the partner TP that the local TP wants to send data. The local TP must wait until the partner TP issues **PREPARE_TO_RECEIVE**, **MC_PREPARE_TO_RECEIVE**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT**, and the conversation state changes to RECEIVE for the partner TP, before the local TP begins sending data.

SEND_DATAor MC_SEND_DATA

Puts data in the local LU's send buffer for transmission to the partner TP.

The data collected in the local LU's send buffer is transmitted to the partner LU and partner TP when one of the following occurs:

- The send buffer fills up.
- The local TP issues **FLUSH**, **MC_FLUSH**, **CONFIRM**, **MC_CONFIRM**, **DEALLOCATE**, **MC_DEALLOCATE**, or another verb that flushes the local LU's send buffer.

Verbs for Receiving Data
POST_ON_RECEIPTor MC_POST_ON_RECEIPT

Issuing this verb allows the application to register to receive a notification when data or status arrives at the local LU without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state.

When the TP issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied, the Win32® event specified as a parameter is signaled and the verb completes. Then the TP looks at the return code in the verb control block to determine whether or not any data or status notification has arrived at the local LU and issues a

RECEIVE_IMMEDIATE or **RECEIVE_AND_WAIT** verb to actually receive the data or status notification.

RECEIVE_AND_POSTor MC_RECEIVE_AND_POST

Issuing this verb while the conversation is in RECEIVE state changes the conversation state to PENDING_POST and causes the local TP to receive data asynchronously. This allows the local TP to proceed with processing while data is still arriving at the local LU.

Issuing this verb while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to PENDING_POST. The local TP then begins to receive data asynchronously.

RECEIVE_AND_WAITor MC_RECEIVE_AND_WAIT

Issuing this verb while the conversation is in RECEIVE state causes the local TP to receive any data that is currently available from the partner TP. If no data is available, the local TP waits for data to arrive.

Issuing this verb while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to RECEIVE. The local TP then begins to receive data.

RECEIVE_IMMEDIATEor MC_RECEIVE_IMMEDIATE

Receives any data that is currently available from the partner TP. If no data is available, the local TP does not wait.

TEST_RTSor MC_TEST_RTS

Determines whether a **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND** or notification has been received.

Verbs for Confirming Data or Reporting Errors
CONFIRMEDor MC_CONFIRMED

Replies to a confirmation request from the partner TP. It informs the partner TP that the local TP has received and processed the data without error.

RECEIVE_LOG_DATAor MC_RECEIVE_LOG_DATA

Issuing this verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another buffer (that is, until the TP issues another **RECEIVE_LOG_DATA** or **MC_RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all).

SEND_CONVERSATIONor MC_SEND_CONVERSATION

Issued by the invoking TP, this verb allocates a session between the local LU and partner LU, sends data on the session, and then deallocates the session.

SEND_ERRORor MC_SEND_ERROR

Notifies the partner TP that the local TP has encountered an application-level error.

Verbs for Getting and Setting Information
GET_ATTRIBUTESor MC_GET_ATTRIBUTES

Used by a TP to get the attributes of the conversation.

GET_LU_STATUS

Used to report the status of a particular remote LU.

GET_STATE

Used by a TP to interrogate the state of a particular conversation.

GET_TP_PROPERTIES

Returns attributes of the TP and the current transaction.

GET_TYPE

Used by a TP to determine the conversation type (basic or mapped) of a particular conversation. With this information, the TP can decide whether to issue basic or mapped conversation verbs.

SET_TP_PROPERTIES

Used to set the attributes of the TP and the current transaction.

Verbs that Provide Management Functions

ACTIVATE_SESSION

Activates a session between the local LU and a specified partner LU, using a specified mode.

CNOS(Change Number of Sessions)

Establishes APPC LU 6.2 session limits.

DEACTIVATE_SESSION

Deactivates a particular session, or all sessions on a particular mode.

DISPLAY

Returns configuration information and current operating values for the SNA node.

Verbs for Ending Conversations

DEALLOCATEor MC_DEALLOCATE

Deallocates a conversation between two TPs. Before deallocating the conversation, this verb performs the equivalent of **FLUSH**, **MC_FLUSH**, **CONFIRM**, or **MC_CONFIRM**.

TP_ENDED

Issued by both the local and partner TPs. It notifies APPC that the TP is ending. Issuing this verb also terminates any active conversations.

Windows APPC Overview

The information provided in this guide is source code and executable code compatible with the following implementations of APPC:

- APPC applications based on Host Integration Server 2009 residing on the server or on a client. These applications run on Microsoft Windows Server, Windows XP, and Windows 2000.

Programs written to use this implementation of APPC can exchange data with programs written to use other implementations of APPC that adhere to the SNA LU 6.2 architecture.

The use of the Windows APPC interface on Windows Server 2003 and Windows 2000 causes additional threads to be created within the calling process. These other threads perform interprocess communication with the Host Integration Server 2009 or SNA service over the LAN interface that the client is configured to use (TCP/IP, IPX/SPX, or named pipes, for example).

If an application using Windows APPC is running on Windows Server 2003 and Windows 2000, stopping the SNABASE service causes the application to be unloaded from memory.

In This Section

Windows APPC Asynchronous Support

APPC Verbs and Windows Extensions

Windows APPC Asynchronous Support

A program that issues a call and does not regain control until the call completes cannot perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients. Asynchronous call completion returns the initial call immediately so the application can continue with other processes.

Host Integration Server 2009 uses the **RegisterWindowsMessage** function for asynchronous support for APPC applications. With "WinAsyncAPPC" as the input string, an application passes a window handle by which it can be notified of verb completion. The application then issues the verb. When the verb completes, a message is posted to the window handle that was passed, notifying the application that the verb is complete.

With the exception of asynchronous RECEIVE_AND_WAIT, MC_RECEIVE_AND_WAIT, RECEIVE_AND_POST, and MC_RECEIVE_AND_POST, which can issue certain other verbs while pending, a conversation can have only one incomplete operation at any time.

APPC Verbs and Windows Extensions

This topic describes the APPC verbs and Windows extensions that are supported by Host Integration Server 2009:

APPC Verbs

The following APPC verb descriptions contain important features and should be read before using this version of Windows APPC.

ALLOCATEor **MC_ALLOCATE**

Issued by the invoking transaction program (TP), this verb allocates a session between the local logical unit (LU) and partner LU and (in conjunction with **RECEIVE_ALLOCATE**) establishes a conversation between the invoking TP and the invokable TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

For a user or group using TPs, 5250 emulators, or APPC applications, you can assign default local and remote LUs. In this case, the field for LU alias is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information about using default LUs, see the **Network Integration**section of the Microsoft Host Integration Server Help.

RECEIVE_ALLOCATE

Issued by the invokable TP to confirm that it is ready to begin a conversation with the invoking TP that issued **ALLOCATE** or **MC_ALLOCATE**. This must be the first APPC verb issued by the invokable TP. The initial state is RESET. If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RECEIVE.

RECEIVE_AND_POSTor **MC_RECEIVE_AND_POST**

Receives application data and status information asynchronously. This enables the local TP to proceed with processing while data is still arriving at the local LU. RECEIVE_AND_POST and MC_RECEIVE_AND_POST are only supported by the Windows 2000 operating system.

While an asynchronous RECEIVE_AND_POST or MC_RECEIVE_AND_POST is outstanding, the following verbs can be issued:

REQUEST_TO_SEND or MC_REQUEST_TO_SEND

GET_TYPE

GET_ATTRIBUTES or MC_GET_ATTRIBUTES

TEST_RTS or MC_TEST_RTS

DEALLOCATE

SEND_ERROR or MC_SEND_ERROR

TP_ENDED

RECEIVE_AND_WAITor **MC_RECEIVE_AND_WAIT**

Receives any data that is currently available from the partner TP. If no data is currently available, the local TP waits for data to arrive.

RECEIVE_AND_WAIT and MC_RECEIVE_AND_WAIT have been altered to act like RECEIVE_AND_POST and MC_RECEIVE_AND_POST. While an asynchronous RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT is outstanding, the following verbs can be issued:

REQUEST_TO_SEND or MC_REQUEST_TO_SEND

GET_TYPE

GET_ATTRIBUTES or MC_GET_ATTRIBUTES

TEST_RTS or MC_TEST_RTS

DEALLOCATE

SEND_ERROR or MC_SEND_ERROR

TP_ENDED

TP_STARTED

Issued by the invoking TP, this verb notifies APPC that the TP is starting. For a user or group using TPs, 5250 emulators, or APPC applications, you can assign default local and remote APPC LUs. These default LUs are accessed when the user or group member starts an APPC program (a TP, 5250 emulator, or APPC application) and the program does not specify LU aliases. For more information about using default LUs, see **Network Integration Help**.

Limits

Host Integration Server 2009 permits one outstanding Windows APPC asynchronous call per connection and one blocking verb per thread. For example:

```
void ProcessVerbCompletion (WPARAM wParam, LPARAM lParam)
{
    int i;
    for (i = 0; i < nPendingVerbs; i++)
        if (pPendingVerbs[i].hAsync == wParam)
            ProcessVCB( (LPVCB) lParam);
}    . . .
LRESULT CALLBACK SampleWndProc ( ... )
{
    if (msg == uAsyncAPPC) {
        ProcessVerbCompletion(wParam; lParam);
    }
        else switch (msg) {
        case WM_USER:
            if (hAsync = WinAsyncAPPC(hwnd, &vcb))
               pPendingVerbs [nPendingVerbs++].hAsync = hAsync;
            break;
    }
}
WinMain ( ... )
{
    if ( ( WinAPPCStartup ( ...) = = FALSE ) {
    return FALSE ;
    }
    uAsyncAPPC = RegisterWindowsMessage ("WinAsyncAPPC") ;
    while (GetMessage ( ...)  )  {
    ...
    WinAPPCCleanup ( ... )
}
```

Note

The exceptions to the rule of one outstanding asynchronous call are **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, and **MC_RECEIVE_AND_WAIT**. While these verbs are outstanding, certain other verbs can also be called.

Using APPC Verbs in C Programs

This implementation of APPC is available for programs written in Microsoft® C version 5.1 or later. A C program calls APPC through the external function **APPC**. For compatibility with previous versions of Microsoft C, the external function **APPC_C** is also supported.

Note
Compilers other than the Microsoft C compiler can also be used to build applications using this implementation of APPC.

This section contains:

- Verb Control Block
- APPC Definition
- Issuing an APPC Verb

Verb Control Block

The only parameter passed to the **APPC** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that:

- Identify the APPC verb to be executed.
- Supply information to be used by the verb.
- Contain information returned by the verb when execution is complete.

Each APPC verb has its own VCB structure, which is declared in the WINAPPC.H header file. For compatibility with earlier versions, the APPC_C.H header file is also supported.

The WINAPPC.H file is supplied as part of the Host Integration Server 2009 Software Development Kit (SDK).

APPC Definition

The prototype definitions of the **APPC** function are as follows:

Syntax

```
void WINAPI APPC(long);
HANDLE WINAPI WinAsyncAPPC (hWnd, LPAPPC);
```

Remarks

The verb control block (VCB) address parameter, a 32-bit pointer, is declared as a long integer and thus requires casting from a pointer to a long integer.

Issuing an APPC Verb

The following procedure is required to issue a blocking APPC verb. In the sample code, the verb issued is **MC_SEND_DATA**.

To issue a blocking APPC verb

1. Create a structure variable from the verb control block (VCB) structure that applies to the APPC verb to be issued.

```
#include <winappc.h>
    .
    .
struct mc_send_data  mcsend;
The VCB structures are declared in WINAPPC.H; one of these structures is:
mc_send_data
```

2. Clear (set to zero) the variables within the VCB structure.

```
memset( mcsend, '\0', sizeof( mcsend ) );
```

3. Assign values to the VCB variables that supply information to APPC.

```
mcsend.opcode = AP_M_SEND_DATA;
mcsend.opext = AP_MAPPED_CONVERSATION;
memcpy( mcsend.tp_id, tp_id, sizeof( tp_id ) );
mcsend.conv_id = conv_id;
mcsend.dlen = datalen;
mcsend.dptr = sharebufptr;
```

   The values AP_MAPPED_CONVERSATION and AP_M_SEND_DATA are symbolic constants representing integers. These constants are defined in WINAPPC.H.

4. Invoke the **APPC** function. The only parameter is a pointer to the address of the structure containing the VCB for the desired verb.

```
APPC ( ( long ) (void FAR * ) &mcsend );
```

   Use WinAsyncAPPC if you are running the application under Windows version 3.*x*.

   To call **WinAsyncAPPC**:

```
HANDLE WINAPI WinAsyncAPPC (hWnd, 1pVCB)
```

   When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncAPPC" as the input string.

5. Use the variables that were returned by APPC.

```
if( mcsend.primary_rc != AP_OK )
/* Do error routine */
    .
    .
    .
```

Windows Server 2003, Windows XP, and Windows 2000 Considerations

This topic summarizes information about developing transaction programs (TPs) using APPC on the following operating systems:

- Microsoft Windows Server 2003
- Microsoft Windows XP Professional
- Microsoft Windows 2000

Byte ordering

The values of constants defined in WINAPPC.H and WINCSV.H are dependent on the byte ordering of the hardware used. Macros are used to set the constants to the correct value.

By default, Intel little-endian byte ordering is used, with the low byte of a 16-bit value followed by the high byte. However, when defining inline macros, the NON_INTEL_BYTE_ORDER macro used in WINAPPC.H and WINCSV.H will not reverse (flip) the byte order for constants. Non-constant input parameters in verb control blocks (VCBs) (such as lengths, pointers, and so on) are always in the native format.

For example, the primary return code of AP_PARAMETER_CHECK is defined to have a value of 0x0001. Depending on the environment (byte ordering), the constant AP_PARAMETER_CHECK may or may not be 0x0001. Some formats define the value as it appears in memory; others define it as a 2-byte variable. Because you cannot assume that the application always uses provided constants rather than hardwired values, you can define a macro to swap the bytes. The following is an example of using the macro:

```
/* when NON_INTEL_BYTE_ORDER is specified, the APPC_FLIPI macro defined in WINAPPC.H macr
o becomes */
#define APPC_FLIPI(x)    (x)

/* otherwise this macro flips bytes by defining */
#define APPC_FLIPI(X) APPC_MAKUS(APPC_HI_UC(X),APPC_LO_UC(X))

/* the AP_PARAMETER_CHECK macro is now defined using the APPC_FLIPI macro */
#define AP_PARAMETER_CHECK APPC_FLIPI (0X0001)      /* X '0001' */
```

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the VCB. This event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

Library names

In order to support the coexistence of Win16 and Win32 API libraries on the same computer, the Win32 DLL names have been changed.

Old DLL names	New DLL names
WINAPPC.DLL	WAPPC32.DLL
WINCSV.DLL	WINCSV32.DLL

The new DLL names should be used for Win32-based applications that are intended to run only on Host Integration Server 2009.

Limits

For Windows Server 2003 and Windows 2000, the number of simultaneous common service verbs (CSVs) allowed per process is 64. Only one of these verbs per thread can be synchronous (blocking).

Using APPC, the maximum number of simultaneous conversations per process is 15,000. Each process supports up to 15,000 simultaneous TPs.

Multiple threads

A TP can have multiple threads that issue verbs. Windows APPC makes provisions for multithreaded Windows-based processes. A process contains one or more threads of execution. All references to threads refer to actual threads in the multithreaded Windows Server 2003 and Windows 2000 environments.

With the exception of RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT, only one conversation verb can be outstanding at a time on any conversation; however, other verbs can be issued for other conversations. This guideline also applies to TP verbs and TPs. Although multiple TP verbs can be issued, only one TP verb can be outstanding at a time on a TP. This applies to both multithreaded applications and single-threaded applications that use asynchronous calls.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or DWORD (4-byte) boundaries, whichever is smaller. As a result, DWORDs are aligned on DWORD boundaries, WORDs are aligned on WORD boundaries, and BYTEs are aligned on BYTE boundaries. This means, for example, that there is a 2-byte gap between the primary and secondary return codes. Therefore, the elements in a VCB should only be accessed using the structures provided.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers. For compatibility with the supplied logical unit application (LUA) libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Registering and deregistering applications

All Windows APPC applications must call WinAPPCStartup at the beginning of the session to register the application and WinAPPCCleanup at the end of the session to deregister the application.

All Windows CSV applications must call the Windows SNA extension WinCSVStartup at the beginning of the session to register the application and WinCSVCleanup to deregister the application when the session is finished.

Run-time linking

For a TP to be dynamically linked to APPC at run time, the TP must issue the following calls:

- **LoadLibrary** to load the dynamic-link libraries WINAPPC.DLL or WAPPC32.DLL.
- **GetProcAddress** to specify APPC on all the desired entry points to the DLL such as **APPC**, **WinAsyncAPPC**, **WinAPPCStartup**, and **WinAPPCCleanup**.

For a TP to be dynamically linked to CSV at run time, the TP must issue the following calls:

- **LoadLibrary** to load WINCSV.DLL or WINCSV32.DLL, the dynamic-link libraries for Windows CSV.
- **GetProcAddress** to specify CSV on all the desired entry points to the DLL such as **ACSSVC**, **WinAsyncCSV**, **WinCSVStartup**, and **WinCSVCleanup**.

The TP must issue the **FreeLibrary** call when the APPC or CSV library is no longer required.

Yielding to other components

Because the Windows Server 2003 and Windows 2000 environments are multithreaded, there is no need to yield to other components.

Transaction Programs Overview

A processing task accomplished by programs using Advanced Program-to-Program Communications (APPC) is called a transaction. Consequently, programs that use APPC are called transaction programs (TP)s. These programs communicate as peers, on an equal (rather than hierarchical) basis. The TPs use APPC verbs to exchange status information and application data. Each TP uses APPC verbs to supply parameters to APPC, which performs the desired function and returns parameters to the TP.

TPs distributed across a local or wide area network perform distributed transaction processing.

This section describes how to write TPs and how to configure the systems on which TPs run. The topics in this section cover the following general areas:

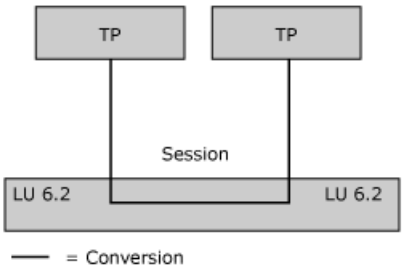
- Understanding fundamental concepts related to TPs
- Designing and coding TPs
- Configuring registry and environment variables for invokable TPs
- Configuring Host Integration Server 2009 to work with your TPs
- Sync Point Level 2 support

This section contains:

Communication between TPs

Various hardware and software elements in the SNA environment are required for two transaction programs (TPs) to communicate with each other. The following figure shows several fundamental elements.

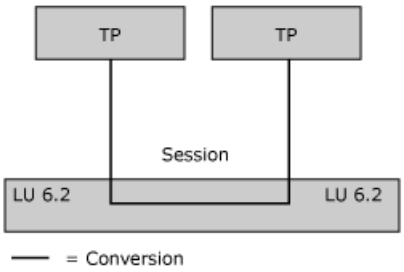
Fundamental communications elements between type 6.2 logical units



Each TP is associated with a logical unit (LU) of type 6.2. The LU allows the TP to access the network. Several TPs can be associated with the same LU.

A partner TP can invoke another TP, which, in turn, invokes another TP, and so on. In the following figure, TP A invokes TP B and TP B invokes TP C.

TP A invoking TP B and TP B invoking TP C.



This section contains:

- Fundamental Terms for TPs and LUs
- Sample TPs Illustrating Fundamental Concepts
- Configuring and Controlling TPs
- Creating TPs and Their Supporting Configuration

Fundamental Terms for TPs and LUs

The following terms describe some fundamental characteristics of transaction programs (TPs) communicating through logical units (LUs):

asynchronous verb
An APPC verb for which the initial function call returns immediately, so that the normal operation of the program is not blocked while processing of the verb completes. For more information, see Receiving Data Asynchronously.

basic conversation
A type of conversation more complex than a mapped conversation and generally used by service TPs (SNA-based programs that provide services to other programs). For more information, see Basic and Mapped Conversations Compared.

conversation
The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously, as shown with TP B in Communication between TPs.

invokable TP
A TP that can be invoked by another TP. Invokable TPs are usually server-type applications; that is, they work in the same general way that an application such as CICS works. Parameters for an invokable TP are configured through registry or environment variables.

There are several types of invokable TPs:

operator-started invokable TP

A TP that is started manually in preparation for being invoked.

autostarted invokable TP

A TP that is automatically started by APPC when invoked.

queued TP

A TP that, when invoked multiple times, loads once and then queues up subsequent requests to be dealt with one at a time. All operator-started TPs and some autostarted TPs are queued.

nonqueued TP

A TP loaded multiple times, once for every time it is invoked. Some autostarted TPs are nonqueued but no operator-started TPs are nonqueued.

For more information, see Invokable TPs.

invoking TP
A TP that can invoke (that is, initiate a conversation with) other TPs. Invoking TPs are usually client-type applications; that is, they work in the same general way that an emulator works. For more information, see Invoking TPs.

local LUand **local TP**
An LU and TP working together, when viewed as the "home base" for a particular conversation. From this viewpoint, some other LU and TP are seen as the "partner" or "remote" LU and TP.

LU alias
The string that identifies an LU to a TP. The alias can be up to eight characters long.

LU-LU session
The communication between two LUs over a specific connection for a specific amount of time. An LU-LU session is needed for two TPs to interact. One session can be used serially by many pairs of TPs.

An LU 6.2 can have multiple sessions (two or more concurrent sessions with different partner LUs) and parallel sessions (two or more concurrent sessions with the same partner LU).

LUs as well as LU-LU pairs and modes are configured using the SNA Manager on Host Integration Server.

mapped conversation
A type of conversation simpler than a basic conversation and generally used by application TPs (programs that accomplish

tasks for end users). The characters **MC_** at the beginning of a verb stand for mapped conversation. For more information, see Basic and Mapped Conversations Compared.

partner LUand **partner TP**, or **remote LU**and **remote TP**
An LU and TP working together, when viewed as being at the far end of a particular conversation.

synchronous verb
An APPC verb that blocks further program operations until the processing of the verb is complete.

Sample TPs Illustrating Fundamental Concepts

A set of sample transaction programs (TPs) is provided on the Host Integration Server CD-ROM in the \SDK\SAMPLES directory. Included with the sample code in the \SDK\SAMPLES\SNA\TPSETUP directory on the Host Integration Server CD-ROM is TPSETUP, a program that simplifies the setting of registry or environment variables needed by autostarted invokable TPs. Without an interface like that provided by TPSETUP, configuring such variables can be complicated and error-prone. Therefore, it is recommended that you use code like TPSETUP in installation programs for autostarted invokable TPs.

The source code for TPSETUP (INSTALL.C) can be compiled to work in the Microsoft Windows Server™ 2003 and Windows® 2000 environment.

For information about TPSETUP and about the sample TPs, see APPC Samples.

Configuring and Controlling TPs

The following table shows how the characteristics of the transaction programs (TPs) and selection of the logical units (LUs) for a conversation are controlled.

Characteristic	How controlled
Type of verb: synchronous or asynchronous	Written into the code. Synchronous verbs use blocking calls; asynchronous verbs avoid blocking calls. See Receiving Data Asynchronously and WinAsyncAPPC.
Type of conversation: basic or mapped	Written into the code. The **MC_** prefix is used on verbs in mapped conversations and omitted on verbs in basic conversations. For two TPs to communicate successfully, both must use the same type of conversation, basic or mapped. See Basic and Mapped Conversations Compared.
Type of TP: invoking or invokable	Written into the code. Invoking TPs start with TP_STARTED, which identifies the invoking TP, and ALLOCATE or MC_ALLOCATE, which identifies the requested invokable TP. Invokable TPs start with RECEIVE_ALLOCATE, which identifies the invokable TP. See Invoking TPs and Invokable TPs.
The local LU alias to be used by an invoking TP	Three options: • Written into the code in TP_STARTED. • Configured (in Host Integration Server Manager as the default local APPC LU for the user who starts the invoking TP. • Configured as a member of the default outgoing local APPC LU pool using the SNA Manager on Host Integration Server 2009. See Configuring Invoking TPs on Host Integration Server.
The invokable TP requested by an invoking TP	Written into the ALLOCATE or MC_ALLOCATE request in the invoking TP.
The LU alias to be used by an invokable TP	Two options: • Written into the invoking TP (not the invokable TP), in ALLOCATE or MC_ALLOCATE. • Configured as the default remote APPC LU for the user who starts the invoking TP. See Configuring Invoking TPs on Host Integration Server and Matching Invoking and Invokable TPs.
Type of autostarted invokable TP: queued or nonqueued	Configured with registry or environment variables. See Configuring Invokable TPs.
Local LU and remote LU aliases	Configured using SNA Manager on Host Integration Server 2009.
The pairing of local and remote LUs, and the mode used for each LU-LU pair	Configured using SNA Manager on Host Integration Server 2009.

Creating TPs and Their Supporting Configuration

The following procedure describes how to create transaction programs (TPs) and set up a supporting configuration.

To create TPs and set up a supporting configuration

1. Write, compile, and link each TP.
2. Place each TP on an appropriate computer.

   For TPs that you start many times or that are started by a user, arrange for the TP to be started easily. That is, for graphical interfaces, create a program icon for starting the TP; for non-graphical interfaces, make sure the TP is in the path.
3. On one or more servers running Host Integration Server, configure logical units (LUs), modes, and LU-LU pairs for use by the TPs.

   For information about how to set up LU-LU pairs to support TPs, see Using Invoking and Invokable TPs.
4. Set any registry or environment variables needed for the invokable TP.

   For autostarted invokable TPs, it is recommended that you use the sample TP configuration program, TPSETUP, for this step. When you write an installation program for autostarted invokable TPs, it is recommended that you include code similar to TPSETUP.

   For information about registry or environment variables, see Configuring Invokable TPs. For information about TPSETUP, see APPC Samples.
5. If the invokable TP is operator-started, start it, or arrange for it to be started when the computer is restarted and then restart the computer.

   If the invokable TP is autostarted, Host Integration Server 2009 will start it when needed.
6. Start the invoking TP.

Designing and Coding TPs

The following topics provide background information about designing and coding transaction programs (TPs).

This section contains:

- Conversation States
- Confirmation Processing
- Receiving Data Asynchronously
- Conversation Security
- Basic and Mapped Conversations Compared
- Using Invoking and Invokable TPs

Conversation States

The state of the conversation (as viewed by a particular TP) governs which APPC verbs the TP can issue at a particular time. For example, a TP cannot issue MC_SEND_DATA if the conversation is not in SEND state for that TP.

The state of a conversation depends on the TP from which it is viewed. A local TP can view a conversation as being in SEND state while the partner TP views the conversation as being in RECEIVE state. A particular TP can be in several conversations, each of which is in a different state.

The possible conversation states are summarized here.

CONFIRM
The TP has received a request for confirmation of receipt of data; it must respond positively or send error information to the partner TP.

CONFIRM_DEALLOCATE
The TP has received a request for confirmation; it must respond positively or send error information. If the TP responds positively, the conversation is automatically deallocated.

CONFIRM_SEND
The TP has received a request for confirmation; it must respond positively or send error information. After responding, the TP can begin to send data.

PENDING_POST
The TP is receiving data asynchronously. The TP can perform other processing not related to this conversation.

RECEIVE
The TP can receive application data and status information from the partner TP. When the conversation is in RECEIVE state, the TP can also send error information and request permission to send data.

RESET
The conversation has not started or has been terminated.

SEND
The TP can send data to the partner TP and request confirmation. When the conversation is in SEND state, the TP can also begin to receive data, which changes the state to RECEIVE.

SEND_PENDING
The TP issued a receive verb and the **what_rcvd** parameter returned by that verb indicated both data received and a status indication of SEND. This only affects the use of the **err_dir** parameter for SEND_ERROR and MC_SEND_ERROR. Otherwise, the state is the same as the SEND state.

This section contains:

State Checks

A state check occurs when a TP issues an APPC verb and the conversation is not in the appropriate state. For example, a state check occurs if a TP issues MC_SEND_DATA while the conversation is in RECEIVE state. When a state check occurs, APPC does not execute the verb; it returns state check information through primary and secondary return codes.

Changing Conversation States

A change in the conversation state can result from:

- A verb issued by the local TP.
- A verb issued by the partner TP.
- An error condition.

The following example shows how APPC verbs can change the state of the conversation from SEND to RECEIVE and from RECEIVE to SEND.

Note
Any TP can send or receive data, regardless of whether it is the invoking TP (the TP that started the conversation) or the invokable TP (the TP that responded to a request to start a conversation).

This example shows how APPC verbs can change the conversation state. In this table, each conversation state appears in bold and precedes the APPC verbs that are used while in that state.

Issued by the invoking TP	**Issued by the invokable TP**
TP_STARTED	
Conversation state: RESET	
MC_ALLOCATE	
(synclevel=AP_CONFIRM_SYNC_LEVL)	
Conversation state: SEND	
MC_SEND_DATA	
MC_PREPARE_TO_RECEIVE	
(ptr_type=AP_SYNC_LEVEL)	
	Conversation state: RESET
	RECEIVE_ALLOCATE
	Conversation state: RECEIVE
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)

	MC_CONFIRMED
Conversation state: RESET	**Conversation state: RESET**
TP_ENDED	TP_ENDED

Initial States

Before the conversation is allocated, the state is RESET for both TPs.

In the example, after the conversation is allocated, the initial state is SEND for the invoking TP and RECEIVE for the invokable TP.

Changing to RECEIVE State

MC_PREPARE_TO_RECEIVE allows a TP to change the conversation from SEND to RECEIVE state. This verb:

- Flushes the local LU's send buffer.
- Sends the AP_CONFIRM_SEND indicator to the partner TP through the **what_rcvd** parameter of a receive verb. This indicator tells the partner TP that an MC_CONFIRMED response is expected before the partner TP can begin to send data.

Confirmation processing is performed when the following conditions are true:

- The **ptr_type** parameter is set to AP_SYNC_LEVEL.
- The synchronization level of the conversation is set to AP_CONFIRM_SYNC_LEVEL.

For more information about confirmation processing, see Confirmation Processing.

Note
Issuing MC_RECEIVE_AND_WAIT while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to RECEIVE. Changing the conversation state in this manner does not support confirmation processing.

Changing to SEND State

MC_REQUEST_TO_SEND informs the partner TP (for which the conversation is in SEND state) that the local TP (for which the conversation is in RECEIVE state) wants to send data. This request is communicated to the partner TP through the **rts_rcvd**

parameter of MC_CONFIRM. (The **rts_rcvd** parameter is also returned to MC_SEND_DATA and other verbs.)

When the partner TP issues MC_PREPARE_TO_RECEIVE, the conversation state changes to RECEIVE for the partner TP, making it possible for the local TP to send data.

Note
Issuing MC_REQUEST_TO_SEND does not change the state of the conversation. Upon receiving a request to send, the partner TP is not required to change the conversation state; it can ignore the request.

Confirmation Processing

The sequence of events for confirmation processing is as follows:

1. Establish the synchronization level.
2. Send a confirmation request.
3. Receive data and confirmation request.
4. Respond to the confirmation request.
5. Deallocate the conversation.

Using confirmation processing, a TP sends a confirmation request with the data; the partner TP confirms receipt of the data or indicates that an error occurred. Each time the two TPs exchange a confirmation request and response, they are synchronized.

Note
Although the example in this section does not show this, any TP can send or receive data, regardless of whether the TP is the invoking TP or the invokable TP.

The following example illustrates confirmation processing.

Issued by the invoking TP	**Issued by the invokable TP**
TP_STARTED	
MC_ALLOCATE	
(synclevel=AP_CONFIRM_SYNC_LEVEL)	
MC_SEND_DATA	
(type=AP_SEND_DATA_CONFIRM)	
	RECEIVE_ALLOCATE
	MC_RECEIVE_AND_WAIT
MC_SEND_DATA	
(type=AP_SEND_DATA_DEALLOC_SYNC_LEVEL)	
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_YES)
	(what_rcvd= AP_DATA_COMPLETE_CONFIRM_ DEALLOCATE)
	MC_CONFIRMED

TP_ENDED	TP_ENDED

Establishing the Synchronization Level

The **synclevel** parameter of MC_ALLOCATE determines the synchronization level of the conversation. There are three possible synchronization levels:

- AP_NONE, under which confirmation processing does not occur.
- AP_CONFIRM_SYNC_LEVEL, under which the TPs can request confirmation of receipt of data and respond to requests for confirmation of data.
- AP_SYNCPT, under which the TPs operate under Sync Point Level 2 support for confirmation of receipt of data.

Sending a Confirmation Request

MC_SEND_DATA with type AP_SEND_DATA_CONFIRM has two effects:

- It flushes the local LU's send buffer and sends any data contained in the buffer to the partner TP.
- It sends a confirmation request that the partner TP receives through the **what_rcvd** parameter of a receive verb.

After issuing **MC_SEND_DATA**, the local TP waits for confirmation from the partner TP.

Receiving Data and Confirmation Request

The **what_rcvd** parameter of MC_RECEIVE_AND_WAIT indicates:

- Status of the data received: complete or incomplete.
- Future processing expected of the local TP.

In the example, **what_rcvd** is AP_DATA_COMPLETE_CONFIRM, indicating that the status is complete and a confirmation is requested.

Responding to a Confirmation Request

The partner TP issues MC_CONFIRMED to confirm receipt of data. This frees the local TP to resume processing.

Deallocating the Conversation

MC_SEND_DATA sends a confirmation request with the data when all of the following conditions are true:

- The conversation's synchronization level (established by the **synclevel** parameter of MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL.
- The type parameter of **MC_SEND_DATA** is set to AP_SEND_DATA_DEALLOC_SYNC_LEVEL.
- The **what_rcvd** parameter of the final MC_RECEIVE_AND_WAIT is AP_DATA_COMPLETE_CONFIRM_DEALLOCATE, indicating that a confirmation of receipt of data is required before APPC will deallocate the conversation. The local TP waits for this confirmation until the partner TP issues MC_CONFIRMED.

Receiving Data Asynchronously

When using Windows 2000, a TP can receive data asynchronously, without regard to other events occurring within the TP. The following table shows the methods by which a TP can receive data asynchronously. The table also indicates how asynchronous methods can be applied to actions other than receiving data.

Operating system	Method
Windows 2000	**Through a Windows message:** Issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** with **WinAsyncAPPC**; the application is notified of completion through a **PostMessage** to the defined window handle. This method is not restricted to **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT**, but can be applied to any APPC verb.
Windows 2000	**Through a Win32® event:** Issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** with **WinAsyncAPPCEx**; the application is notified of completion through a Win32 event. This method is not restricted to **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT**, but can be applied to any APPC verb.
Windows 2000	With **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST:** Issue the **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** verb.

The following list gives details about these methods of receiving data asynchronously. For complete information, see the verb descriptions.

RECEIVE_AND_WAITor MC_RECEIVE_AND_WAITwith WinAsyncAPPC
This method enables an application to issue a verb and be notified through a **PostMessage** when the action is complete. To retrieve the message number that will be posted to the window, call **RegisterWindowMessage** with "WinAsyncAPPC" as the input string. Then issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** using the **WinAsyncAPPC** entry point.

RECEIVE_AND_WAITor **MC_RECEIVE_AND_WAIT**with WinAsyncAPPCEx
This method enables an application to be notified through a Win32 event. This is particularly useful when writing applications that need to service multiple conversations simultaneously. The event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

RECEIVE_AND_POSTor MC_RECEIVE_AND_POST
When using **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** with Windows 2000, the application is notified through a Win32 event. The event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

While receiving data asynchronously, the TP performs tasks not related to this conversation; the TP cannot issue most APPC verbs until notification is received. For information about the verbs that can be issued, see the descriptions of WinAsyncAPPC or WinAsyncAPPCEx.

After a verb has completed asynchronously, check the primary_rc to find out whether the data was received without error.

Note

If the initial call to issue the verb returns successfully, the application is guaranteed to be notified (by the applicable method) when the verb completes, regardless of whether the verb is ultimately successful.

Conversation Security

You can use conversation security to require that the invoking TP provide a user identifier and password before APPC will allocate a conversation with the invokable TP. If security is activated, the invoking TP must supply a combination of the user identifier and password as parameters of ALLOCATE or MC_ALLOCATE. Conversation security is activated and configured through registry or environment variables on the computer where the invokable TP is located.

With communication involving more than two TPs, the verification of a user identifier and password can be passed from one TP to another. Suppose that TP A invokes TP B, which requires security information, and TP B in turn invokes TP C, which also requires security information. Through **ALLOCATE** or **MC_ALLOCATE**, TP B can inform TP C that conversation security has already been verified.

For information about the registry or environment variables affecting conversation security, see Configuring Invokable TPs.

Basic and Mapped Conversations Compared

The following table offers some guidelines for choosing between basic and mapped conversations for your TPs. For definitions of basic and mapped conversations, see Fundamental Terms for TPs and LUs.

Characteristic	Basic conversations	Mapped conversations
Common use	Generally used for service TPs.	Generally used for application TPs.
Partnering	Must be used to communicate with an existing TP that uses basic verbs.	Must be used to communicate with an existing TP that uses mapped verbs.
Sending and receiving method	Before a TP can begin a send operation, it must convert data records into logical records. The TP does this by adding a 2-byte prefix that indicates the length of the record. A TP can send several logical records at one time. When a partner TP receives logical records, it must reconstruct them into usable data records. For more information, see Logical Records Used in Basic Conversations.	A TP sends data one record at a time. Neither the sending TP nor the receiving TP needs to convert data records between different forms.
Abnormal termination	In the DEALLOCATE verb, a TP can indicate whether an error or ABEND (abnormal program termination) was caused by a TP or by a program using the TP.	A TP can indicate an error or ABEND, but cannot tell whether a problem was caused by a TP or by a program using a TP.
	A TP can indicate whether an ABEND was caused by a timeout or by a critical error.	A TP cannot indicate the cause of an ABEND.
Error logging	For an error or ABEND, a TP can send an error message, in the form of a general data stream (GDS) error log variable, to the local log and to the partner LU.	For an error or ABEND, a TP cannot send an error message to the local log or to the partner LU.

This section contains:

- Logical Records Used in Basic Conversations
- An Example of a Mapped Conversation

Logical Records Used in Basic Conversations

Logical records are sent and received in basic conversations only.

A TP can send or receive multiple logical records with a single SEND_DATA or receive verb. The receive verbs are RECEIVE_AND_POST (Windows 2000), RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT. A TP can also send or receive a logical record in successive portions: beginning, middle, and end.

A logical record is made up of:

- A 2-byte record-length (LL) field.
- A data field that can range in length from 0 bytes through 32765 bytes.

The LL field contains a hexadecimal value that is the length of the data field plus two bytes (for the LL field). For example, if a record contains 228 bytes of application data, the logical record length is 230. The LL field is 0x00E6, the hexadecimal equivalent of 230. If the length of the data field is 0, the value contained in the LL field is 0x0002.

Logical records are sent from or received in a data buffer established by the TP. In the data buffer, the LL field must not be in Intel byte-swapped format. For example, a length of 230 must be 0x00E6, not 0xE600.

The LL field cannot be 0x0000 or 0x0001, which allow less than the two bytes required for the LL field itself. The LL field also cannot be greater than or equal to 0x8000, which is equivalent to decimal 32768 and therefore allows for a data field greater than 32765 or an LL field greater than 2.

Setting the most significant bit of the LL field to 1 indicates that the information contained in the current logical record is continued in the next logical record.

An Example of a Mapped Conversation

For background information about mapped conversations, see Basic and Mapped Conversations Compared.

The following example of a mapped conversation shows the APPC verbs used to start a conversation, exchange data, and end the conversation. APPC verb parameters are in parentheses.

Issued by the invoking TP	Issued by the invokable TP
TP_STARTED	
MC_ALLOCATE	
MC_SEND_DATA	
MC_DEALLOCATE	
TP_ENDED	RECEIVE_ALLOCATE
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_NO)
	(what_rcvd=AP_DATA_COMPLETE)
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_DEALLOC_NORM)
	TP_ENDED

The following paragraphs describe the verbs that are used in a mapped conversation.

Verbs for Starting a Mapped Conversation

To start a mapped conversation, the invoking TP issues the following verbs:

- TP_STARTED, which notifies APPC that the local TP is beginning a conversation.
- MC_ALLOCATE, which requests that APPC establish a conversation between the local TP and the partner TP.

The invokable TP issues RECEIVE_ALLOCATE, which informs APPC that it is ready to begin a conversation with the invoking TP.

Verbs for Sending Data in a Mapped Conversation

MC_SEND_DATA puts one data record (a record containing application data to be transmitted) in the send buffer of the local LU. Data transmission to the partner TP does not happen until one of the following events occurs:

- The send buffer fills up.
- The sending TP issues a verb that forces APPC to flush the buffer and send data to the partner TP.

In the preceding example, the send buffer contains both the data record and the MC_ALLOCATE request (which precedes the data record). Therefore, in the example, MC_DEALLOCATE flushes the buffer, sending the **MC_ALLOCATE** request and data record to the partner TP. Other verbs that flush the buffer are MC_CONFIRM and MC_FLUSH.

Verbs for Receiving Data in a Mapped Conversation

The MC_RECEIVE_AND_WAIT verb allows a TP to receive a data record or status information. If no data is currently available, the TP waits for data to arrive. For Windows 2000 systems, issue **MC_RECEIVE_AND_WAIT** in conjunction with WinAsyncAPPC rather than the blocking version of this call.

In the example, the receiving TP issues **MC_RECEIVE_AND_WAIT** twice. The first time, it issues the verb to receive data. When it finishes receiving the complete data record (**what_rcvd** is AP_DATA_COMPLETE), it issues **MC_RECEIVE_AND_WAIT** again to receive a return code. The return code AP_DEALLOC_NORMAL indicates that the conversation has been deallocated.

Note
MC_RECEIVE_IMMEDIATE performs the same function as **MC_RECEIVE_AND_WAIT**, except that it does not wait if data is no t currently available from the partner TP. Instead, it returns a no-data-available response to the calling TP.

Verbs for Ending a Mapped Conversation

To end a mapped conversation, one of the TPs issues MC_DEALLOCATE, which causes APPC to deallocate the conversation between the two TPs.

After the conversation has been deallocated, both TPs issue TP_ENDED.

Note
A TP can participate in multiple conversations simultaneously. In this case, the TP issues **TP_ENDED** after all conversations h ave been deallocated.

Using Invoking and Invokable TPs

There are two kinds of TPs: TPs that can invoke (that is, initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

The topics in this section describe the following:

- How invoking TPs request invokable TPs.
- How invokable TPs identify themselves to Host Integration Server in preparation for being invoked.
- How an invokable TP is matched to an invoking TP's request.

For information about how to configure LUs to support TPs, see Configuring TPs on Host Integration Server and Host Integration Server 2009 Help.

InThis Section

Invoking TPs

An invoking TP can be located on any system on the SNA network. An invoking TP identifies itself by issuing TP_STARTED, which specifies the name of the invoking TP and can specify the LU alias that the TP uses. If the LU alias is not specified in **TP_STARTED**, Host Integration Server must be configured to supply it through one of two types of default local LU; otherwise, **TP_STARTED** will fail. For more information, see Configuring Invoking TPs on Host Integration Server.

Next, the invoking TP initiates the invoking process by issuing ALLOCATE or MC_ALLOCATE, in which it specifies the name of the invokable TP, and can also specify the partner LU alias (the LU alias to be used by the invokable TP). If the partner LU is not specified in **ALLOCATE** or **MC_ALLOCATE**, Host Integration Server 2009 must be configured to supply one through the default remote APPC LU assigned to the user who started the invoking TP; otherwise, **ALLOCATE** or **MC_ALLOCATE** will fail. For more information, see Configuring Invoking TPs on Host Integration Server.

After a TP successfully issues an **ALLOCATE** or **MC_ALLOCATE** verb, an allocation request flows. For more information about what happens after an invoking TP requests an invokable TP, see Matching Invoking and Invokable TPs.

Invoking TPs and Contention

The following information applies only to cases where LUs are communicating in complex ways (such as chains of LUs) over multiple sessions. In such cases, two LUs may attempt to allocate a conversation on the same session at the same time. If this happens, one LU must win (the contention winner) and one must lose (the contention loser). The contention-winner LU and the contention-loser LU are determined for each session when the session is established. During that particular session, the contention-loser LU must receive permission from the contention-winner LU before allocating a conversation. In contrast, the contention-winner LU on that session allocates a conversation as needed.

Note that when two LUs are communicating over multiple sessions, one LU can be the contention winner for some of the sessions, and the other LU the contention winner for others.

An invoking TP will operate most efficiently if the number of concurrent **ALLOCATE** or **MC_ALLOCATE** requests that the TP issues is matched by the number of sessions on which the local LU is the contention winner. The choice of contention winner is controlled through the modes configured at the two ends of the communication. The mode is configured using SNA Manager on Host Integration Server 2009. A mode must be configured to work with the mode on the remote system for communication to begin between two LUs. For more information about modes, see Microsoft Host Integration Server Help.

Invokable TPs

An invokable TP is a TP that can be invoked by another TP. Invokable TPs are written or configured through registry or environment variables to supply their names to Host Integration Server 2009 as a notification that they are available for incoming requests. Invokable TPs can be run on any Host Integration Server client or server running Windows 2000.

There are two types of invokable TPs:

Operator-started invokable TPs

An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies Host Integration Server of its availability by issuing a RECEIVE_ALLOCATE verb. The **RECEIVE_ALLOCATE** causes the name of the invokable TP, along with the alias of an associated LU if one has been configured through a registry or environment variable, to be communicated to all the servers running Host Integration Server in the SNA domain.

Autostarted invokable TPs

An autostarted invokable TP can be started by Host Integration Server when needed. The TP must be registered through registry entries or environment variables on its local system, so that it can be identified to the SnaBase component of the Host Integration Server client software. The registered information defines the TP as autostarted and must specify the TP name. The registered information can also specify the local LU alias that the invokable TP will use.

The recommended method for setting registry or environment variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP, or similar code written into your own installation program. For more information about registry or environment variables for invokable TPs, see Configuring Invokable TPs. For information about TPSETUP, see APPC Samples.

If no local LU alias is registered with autostarted TPs, the resulting Host Integration Server configuration can be more flexible in responding to invoking requests. For more information about such flexible configurations, see TP Name Not Unique; Local LU Alias Unspecified.

After an autostarted invokable TP is started by Host Integration Server, the TP issues RECEIVE_ALLOCATE just as an operator-started TP does. **RECEIVE_ALLOCATE** must provide the TP name that was registered for the TP.

Autostarted TPs must be configured through registry or environment variables to be either queued or nonqueued. All operator-started TPs act as queued TPs.

Queued TPs

If an autostarted TP is configured as queued, or if the TP is operator-started, incoming allocation requests are queued and then sent only when the invokable TP issues **RECEIVE_ALLOCATE**. For autostarted invokable TPs, if a copy of the TP is not yet running, one is started when an incoming allocation request specifies that TP.

Note
For Windows 2000, only one copy of a service can be running at any given time; this means that all autostarted TPs that run as services under Windows 2000 must be queued. To write an autostarted TP so it will run under Windows 2000 as a service and also run in a nonqueued way, write a multithreaded program with a **RECEIVE_ALLOCATE** always outstanding.

Nonqueued TPs

If an autostarted TP is configured as nonqueued, a new copy will be started every time an ALLOCATE or MC_ALLOCATE is received for the TP. Nonqueued TPs should process the conversation they have been allocated and then exit, since they will not receive any additional **ALLOCATE** or **MC_ALLOCATE** requests.

Subcategories for Invokable TPs

The following figure shows subcategories for invokable TPs.

Queued or nonqueued	Application or service	Starting method
Queued	Running as an application or a service	Autostarted or operator-started
Nonqueued	Running as an application	Autostarted

The concept of a TP "running as a service" or "running as an application" is distinct from a service TP or an application TP. Service TP and application TP are SNA terms that describe how a TP is used: either as a supportive service program for other APPC programs, or directly by a user, as an application. For detailed information about services and applications on Windows, see the Microsoft Developer Network (MSDN®) Platform Software Development Kit.

To write an autostarted TP so it will run under Windows as a service and also run in a nonqueued way, write a multithreaded program with a RECEIVE_ALLOCATE always outstanding. See Invokable TPs.

Matching Invoking and Invokable TPs

Each computer running Host Integration Server 2009 maintains a list of available invokable TP names and any LU aliases to be associated with the TP names. This information is obtained as follows:

- For autostarted invokable TPs, registry or environment variables identify a TP name containing a maximum of eight characters, and can specify an associated LU. This information is sent from the client to the server that sponsors the client. A client learns about the domain through a sponsor connection to a server; clients must establish the sponsor connection before proceeding with any other tasks.

- For operator-started invokable TPs, a TP name (with a maximum of 64 characters) is specified with the RECEIVE_ALLOCATE verb. The TP name is truncated to eight characters and sent from the client to the server that sponsors the client, along with the alias of an associated LU if one has been configured through a registry or environment variable.

Note
If you want a TP name to be unique, it is recommended that you limit the name to eight characters or fewer, or make the name unique within the first eight characters. This is because the preliminary routing of allocation requests is carried out using the first eight characters. Although further matching is later carried out between the full TP names specified in ALLOCATE or MC_ALLOCATE and **RECEIVE_ALLOCATE**, it is inefficient to allow the preliminary routing to succeed when in some cases the later matching will fail.

The next step in the matching of invoking and invokable TPs is that the invoking TP issues the **ALLOCATE** or **MC_ALLOCATE** verb. After an invoking TP in a Host Integration Server domain successfully issues this verb, an allocation request flows to the partner LU specified in the **ALLOCATE** or **MC_ALLOCATE** verb, stating the name of the invokable TP that has been requested.

When an allocation request arrives, Host Integration Server compares the requested invokable TP name and LU alias to the list of available invokable TPs (which can include associated LU aliases). The comparison can be modified by registry variables, but by default is carried out as follows:

- Although the TP name requested in the **ALLOCATE** or **MC_ALLOCATE** verb can be as long as 64 characters, any name received through a registry or environment variable is limited to eight characters or less. Therefore, only the first eight characters of TP names are used in comparisons.

- The comparison is carried out first on both the TP name and the LU alias. An invokable TP for which there is a match on both TP name and LU alias will be chosen ahead of a TP for which no LU alias has been configured through a registry or environment variable. A TP for which no LU alias has been configured can be matched with any request that specifies that TP name, since there cannot be a mismatch based on LU alias.

- The comparison of requested and available TP names is carried out in a specific order:

    1. Host Integration Server first checks for operator-started invokable TPs on the local system (the local computer running Host Integration Server 2009).

    2. If no match is found, Host Integration Server checks for autostarted invokable TPs on the local system (the local computer running Host Integration Server 2009).

    3. If no match is found, Host Integration Server checks for operator-started invokable TPs on other Host Integration Server 2009 clients or servers.

    4. If no match is found, Host Integration Server checks for autostarted invokable TPs on other Host Integration Server clients or servers.

This comparison can be modified somewhat by registry entries for the SnaServer service. The entries are called **DloadMatchTPOnly** and **DloadMatchLocalFirst**, and are described in the *Microsoft Host Integration Server Reference online*

book.

If a match is found, Host Integration Server signals the system containing the requested TP to connect to that server running Host Integration Server 2009. If no match is found, Host Integration Server rejects the incoming request.

For suggestions about specific ways to handle TP names and LU aliases, see Arranging TPs Within an SNA Network.

Note

Because of the way APPC works, an allocation request will not flow until local data buffers are full, or a confirm or flush verb i s issued. This can mean that the allocation request does not flow until some time after the ALLOCATE or MC_ALLOCATE verb is issued. Therefore, any allocation failure caused by the rejection of the allocation request at the partner LU will be observed as the failure of a later verb with one of the allocation failure return codes.

Configuring Invokable TPs

The following topics discuss how to configure invokable transaction programs (TPs) for Microsoft Host Integration Server 2009 clients.

This section contains:

- Clients Running Windows

Clients Running Windows

On clients running Microsoft® Windows® 2000, Windows XP, and Windows Server 2003, invokable TPs are configured through the Windows registry.

Note
The recommended method for setting registry variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile INSTALL.C, the source code for TPSETUP, for the Windows environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see APPC Samples.

It is recommended that autostarted invokable TPs be written as Windows services. Be sure to include code like that in TPSETUP in the program that installs your TPs. Among other things, TPSETUP shows how to use the **CreateService** function when installing a TP. For important information about how services work under Windows, see the Microsoft Developer Network (MSDN®) Platform Software Development Kit.

The following table lists the registry entries used for the types of invokable TPs that can be run on Windows clients:

Type of TP	Location in registry	Possible registry entries
Autostarted invokable TP running as a service	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services *TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— **Linkage OtherDependencies:**REG_MULTI_SZ:SnaBase **Parameters SNAServiceType:**REG_DWORD:0x5**LocalLU:**REG_SZ:*LUalias***Parameters:**REG_SZ:*ParameterList***Timeout:**REG_DWORD:*number***ConversationSecurity:**REG_SZ:{ YES | NO }**AlreadyVerified:**REG_SZ:{ YES | NO }2***Username1:***REG_SZ:*Password12* ...***UsernameX:***REG_SZ:*PasswordX*2

Note
Before an autostarted TP can be started as an application on a Windows client, the TPSTART program must be started. For more information, see APPC Samples.

Note
AlreadyVerified and **Username/Password** entries are used only if **ConversationSecurity** is set to YES.

This section contains:

- Registry Entries for Clients Running Windows 2000
- Example of Windows 2000 Registry Entries for an Invokable TP

Registry Entries for Clients Running Windows 2000

The following list gives details about registry entries for clients running Windows 2000. For each TP type, the applicable variables and their locations are shown in Clients Running Windows.

Registry Entries for TPName on Clients Running Windows 2000
TPName:REG_MULTI_SZ

The name of the transaction program (TP) that is executed. A TP name is up to 64 ASCII characters in length and cannot contain spaces or nulls.

SNA service TPs are a special set of TPs defined by the SNA protocols. Each service TP is a specially-defined function with a special name. An SNA service TP name is represented by up to four EBCDIC bytes; the first byte is a hexadecimal number in the range 0x00 to 0x3F, and the remaining bytes are EBCDIC characters. The first byte defines the function class of the TP. Therefore, to convert a service TP name to an ASCII TP name form, convert the first byte as shown in the following table, and convert the EBCDIC values to ASCII letter equivalents.

First byte of TP name (hexadecimal number)	ASCII character equivalent for WIN.INI
0x07	DDM
0x20	DIA
0x21	SNAD
0x24	FS
0x30	PO
All others	UN

For example, an EBCDIC service TP name of 0x21 0xD7 0xD7 is equivalent to a TP name of SNADPP (0x21 converts to SNAD and each 0xD7 converts to P).

Registry Entries for the TPName Subtree on Clients Running Windows 2000
OtherDependencies:REG_MULTI_SZ:SnaBase

For a TP running as a service, ensures that the SnaBase service will be started before the TP is started. This entry belongs under the **Linkage** subkey.

SNAServiceType:REG_DWORD:{ 0x5 | 0x6 | 0x1A }

Indicates the type of TP. Use a value of 0x5 for an autostarted queued TP, 0x6for an autostarted nonqueued TP, and 0x1A for an operator-started TP.

Note that the value for an autostarted TP running as a service must be 0x5, because these TPs are always queued, as described in Invokable TPs.

PathName:REG_SZ **:***path*

For an autostarted TP running as an application, specifies the path and file name of the TP. The data type of REG_EXPAND_SZ means that the path can contain an expandable data string; for example, %SystemRoot% represents the directory containing the Windows 2000 system files. Note that for a TP running as a service, an equivalent entry is inserted by the **CreateService** call; no additional path entry is needed.

LocalLU:REG_SZ: *LUalias*

Specifies the alias of the local LU to be used when this TP is started on this computer.

Parameters:REG_SZ: *ParameterList*

Lists parameters to be used by the TP. Separate parameters with spaces.

Timeout:REG_DWORD: *number*

Specifies the time, in milliseconds, that a RECEIVE_ALLOCATE will wait before timing out. Specify *number* in decimal; the

registry editor converts this to hexadecimal before displaying it. The default is infinity (no limit).

ConversationSecurity:REG_SZ:{ YES | NO }

Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified:REG_SZ:{ YES | NO }

Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO. The default value is NO.

For a diagram of three TPs in a conversation, where the third TP can be invoked with a password that is already verified by the second TP, see Communication between TPs. The following table shows the requirements for using password verification in a chain of TPs.

First TP (invoking TP)	Second TP (invokable TP that confirms password and then invokes another TP)	Third and subsequent TPs (invokable TPs that invoke other TPs)
Does not need registry or environment variables.	**ConversationSecurity** setting must be YES.	**ConversationSecurity** setting must be YES.
Does not need registry or environment variables.	**AlreadyVerified** setting can be YES or NO.	**AlreadyVerified** setting must be YES.
ALLOCATE or MC_ALLOCATE in this TP has a **security** parameter of AP_PGM; as a result, the TP passes along the **user_id** and **pwd** values supplied in **ALLOCATE** or **MC_ALLOCATE**.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, after confirming the user identifier and password, the TP passes along the user identifier and an already-verified flag.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, the TP passes along the user identifier as received, along with the already-verified flag.

If you set **AlreadyVerified** to NO, this TP cannot join in a chain of conversations where password verification is already done. The exception to this is when **ConversationSecurity** is set to NO, in which case the TP could be the final TP in such a chain, since it performs no checking.

If you are configuring a TP that sometimes needs to confirm a password and sometimes accepts an already-verified flag, set **AlreadyVerified** to YES and configure the *UsernameX* variable appropriately. In this case, whenever the TP is invoked without the already-verified flag set, **AlreadyVerified** is ignored; verification is attempted with the user identifier and password configured for the TP.

If you want to have a chain of conversations where the user identifier and password are reverified at every step, carry out the following. For all the TPs, set **ConversationSecurity** to YES, and in each **ALLOCATE** or **MC_ALLOCATE** issued, set the security parameter to AP_PGM and the **pwd** and **user_id** parameters to valid combinations.

If you set **AlreadyVerified** to YES, make sure that **ConversationSecurity** is also set to YES.

Username1:REG_SZ:Password1 ...**UsernameX:**REG_SZ:PasswordX

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can each be as many as 10 characters. Both parameters are case-sensitive.

This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the **AlreadyVerified** entry.

Example of Windows 2000 Registry Entries for an Invokable TP

For an autostarted invokable TP called **BounceTP** and running as a service, the following registry entries might be added to a Windows 2000-based client. The entries would be added to **HKEY_LOCAL_MACHINE\ SYSTEM\ CurrentControlSet\ Services\ SnaBase**, under the subkeys shown in bold type.

Note

In the following list, the parameters listed directly under the **BounceTP** key (such as **DisplayName** and **ErrorControl**) are service parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code; they should not be set manually. For more information about TPSETUP, see APPC Samples.

Configuring TPs on Host Integration Server

The following topics describe how configuration of invoking and invokable transaction programs (TPs) works on Host Integration Server 2009.

This section contains:

- Configuring Invoking TPs on Host Integration Server
- Configuring Invokable TPs on Host Integration Server

Configuring Invoking TPs on Host Integration Server

For a server running Host Integration Server 2009 to support the beginning of the invoking process (that is, to accept the TP_STARTED and ALLOCATE or MC_ALLOCATE verbs issued by an invoking TP), the following parameters must be configured correctly:

- If the invoking TP specifies in **TP_STARTED** the LU alias that it uses, that LU alias must match a local APPC LU alias on the supporting server running Host Integration Server 2009. If the invoking TP leaves the LU alias blank in **TP_STARTED**, one of two methods for designating a default LU must be carried out on the supporting server running Host Integration Server 2009:

    - Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which **TP_STARTED** is issued).

    - Designate one or more LUs as members of the default outgoing local APPC LU pool. The Host Integration Server first attempts to determine the default local APPC LU of the user who started the TP, and then attempts to assign an available LU from the default outgoing local APPC LU pool; if these attempts fail, the Host Integration Server rejects the request.

- In most situations, the supporting Host Integration Server must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, the server running Host Integration Server 2009 contains two local LUs paired together (for invoking and invokable TPs that are in the same domain); in this situation, a connection to a host or peer is not necessary.

- If the invoking TP specifies in ALLOCATE or MC_ALLOCATE the partner LU alias, that LU alias must match an LU alias that is paired with the local LU alias specified in TP_STARTED. If the partner LU alias is left unspecified in **ALLOCATE** or **MC_ALLOCATE**, a default remote APPC LU must be assigned to the user who started the invoking TP. The default remote APPC LU is configuring using SNA Manager on Host Integration Server 2009. If the default remote APPC LU is used, it must be paired with the local LU that will be used. Otherwise, **ALLOCATE** or **MC_ALLOCATE** fails.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured as described in Configuring Invokable TPs on Host Integration Server.

Configuring Invokable TPs on Host Integration Server

For a computer running Host Integration Server 2009 to receive allocation requests from an invoking TP on another system and route those requests to an invokable TP, certain parameters must be configured correctly:

- The Host Integration Server must have a connection to the system from which the invoking TP's request is sent.

- The Host Integration Server must have a remote LU capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly.

  When configured explicitly, there is an explicit match between a remote LU alias on the Host Integration Server and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an implicit incoming remote LU (with its implicit incoming mode) is used. This means that several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the Host Integration Server receiving the request. Second, the local LU on the Host Integration Server 2009 server must have an implicit incoming remote LU assigned to it. The properties of the implicit incoming remote LU will be used for that LU-LU session. For more details about how an implicit incoming remote LU works, see Microsoft Host Integration Server 2009 Help.

- Appropriate local LUs must be defined in the Host Integration Server configuration. For descriptions of several ways to set up these local LUs, see Arranging TPs Within an SNA Network.

Arranging TPs Within an SNA Network

If your installation of Microsoft® Host Integration Server contains multiple systems (multiple clients and/or multiple computers running Host Integration Server), you can place a given invokable transaction program (TP) on more than one system. When an invoking request is received in such an installation, there can be a choice of systems on which to run the invokable TP.

You can maintain specific control over this choice or you can allow Host Integration Server to make the choice randomly to distribute the load. To do this, follow the instructions in TP Name Not Unique; Local LU Alias Unspecified.

You can maintain specific control over the choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique LU alias. With this arrangement, the information provided by the invoking TP (in the **ALLOCATE** or **MC_ALLOCATE** verb) specifies the system on which the invokable TP should run.

You can allow Host Integration Server to make the system choice randomly by setting the **DloadMatchLocalFirst** registry entry to NO and using invokable TPs that leave the local logical unit (LU) alias unspecified. Then, when an incoming request is received, it is routed randomly, rather than preferentially to the local Host Integration Server; in addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. Host Integration Server starts one instance of the requested TP, choosing randomly among the available systems.

This section contains:

- TP Name Unique for Each TP
- TP Name Not Unique; Local LU Alias Unique
- TP Name Not Unique; Local LU Alias Unspecified

TP Name Unique for Each TP

One way to specify the intended system where the invokable TP will run is to use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the intended invokable TP (and system) simply by naming the TP. This makes it unnecessary for an invokable TP to specify any LU alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unique

Another way to specify the intended system where the invokable TP will run is to give the same name to multiple invokable TPs, but associate each TP with a unique local LU alias. To do this, configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable TP runs, use the same name for multiple invokable TPs and do not specify an LU alias in the registry or environment variables for the TPs. In this situation, there are no associated LU aliases in the list of available invokable TP names on a Host Integration Server. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

In this situation, if you set the **DloadMatchLocalFirst** registry entry to NO, Host Integration Server randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems and provides hot backup (the ability to take systems online and offline without disrupting service).

Troubleshooting for Invokable TPs

If there are difficulties with starting an invokable TP, there may be a mismatch between the information for the invokable TP, the invoking TP, and/or LUs in the Host Integration Server 2009 configuration. That is, there may be a mismatch between the parameters for RECEIVE_ALLOCATE, TP_STARTED, ALLOCATE, or MC_ALLOCATE and/or LU aliases specified in server configuration. LU aliases are configured using SNA Manager on Host Integration Server 2009.

Simplifying APPC Configuration

There are several features in Host Integration Server 2009 that can simplify configuration for APPC:

- The implicit incoming remote LU and the implicit incoming mode, which allow Host Integration Server to accept requests that arrive by unrecognized remote LUs and modes.
- The default local APPC LU and the default remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.
- The default outgoing local APPC LU pool, which allows LUs to be allocated dynamically to any invoking TP that does not specify a local LU.
- Automatic partnering, which automatically creates LU-LU pairs and assigns modes to the pairs.

Sync Point Level 2 Support in Host Integration Server

The following topics describe additions to Host Integration Server 2009 that enable Sync Point Level 2 support to the LU 6.2 protocol stack.

This section assumes familiarity with the existing Host Integration Server APPC basic and mapped conversation interfaces. It does not attempt to explain the SNA formats and protocols for implementing Sync Point protocols, which are described in *SNA LU6.2 Reference: Peer Protocols* published by IBM (Document SC31-6808-1).

This section contains:

Sync Point Functional Overview

The Sync Point support additions to Host Integration Server allow vendors to provide Sync Point services over LU 6.2 conversations provided by the LU 6.2 protocol stack in Host Integration Server. These additions do not implement the architected Sync Point components and TPs necessary for a complete Sync Point implementation. In particular, the following Sync Point components are not implemented, and must be provided by the vendor.

- Sync Point Services (SPS)
- Conversation-Protected Resource Manager (C-PRM)
- Resynchronization TP

These vendor-supplied components and applications are expected to implement the **SYNCPT** and **BACKOUT** verbs used for Sync Point services. The **SYNCPT** verb is used to synchronize transactions. The **BACKOUT** verb is used to back out of a transaction.

SPS, C-PRM, and the Resynchronization TP are specific components of the SNA Sync Point architecture described in *SNA LU6.2 Reference: Peer Protocols* published by IBM.

Host Integration Server has been modified to add the features necessary to support these components, namely:

- Additions to the existing APPC API to support implementation of Sync Point verbs.
- Accounting support for Sync Point protocols.
- Modifications to invokable transaction program (TP) initiation.

Changes to the APPC basic and mapped conversation APPC APIs are made so as to ensure backward compatibility with existing APPC applications that adhere strictly to the API.

Note
Applications must zero all reserved verb control block (VCB) members before issuing an APPC verb. If this is not done, the application may inadvertently invoke one of the new APPC features.

Sync Point Support Architecture

The Sync Point support provided by Host Integration Server 2009 assumes a particular implementation architecture by the vendor, as follows:

- The vendor provides a communication interface to its own clients requiring Sync Point Services (SPS).
- The vendor API maps its communication and Sync Point requests to the Host Integration Server APPC API.
- The vendor provides a single Microsoft Windows 2000 process, the Transaction Monitor, that is responsible for:
    - Issuing all APPC verbs.
    - Implementing the architected Resynchronization TP.
    - Implementing the architected Conversation-Protected Resource Manager (C-PRM) component of the logical unit (LU).
    - Implementing the architected SPS component of the LU.

  The Transaction Monitor must reside on the same computer as the Host Integration Server containing the LUs for which it is providing Sync Point services. Both incoming and outgoing Sync Point conversations for this Transaction Monitor will be routed through this Host Integration Server 2009 server only.

Detailed descriptions of the three architected Sync Point components can be found in *SNA LU6.2 Reference: Peer Protocols* published by IBM.

Sync Point Session Support

This section discusses support for Sync Point session activation and deactivation in Host Integration Server 2009.

In This Section

Sync Point Session Activation

If Host Integration Server 2009 is to support Sync Point conversations, this must be specified at session activation time. The configuration of Host Integration Server is modified to allow the system administrator to specify which (if any) local LUs will be used for Sync Point conversations.

The **Local LU Configuration** property page in Host Integration Server contains a new check box. When checked, it indicates that the local LU can participate in Sync Point sessions. Host Integration Server uses this option to determine the parameters it sends on BIND requests and responses.

When Host Integration Server initiates an LU 6.2 session on an LU designated as supporting Sync Point, it sets the synchronization level on BIND requests to indicate that the session can support Sync Point and Backout. If the partner LU also supports Sync Point and Backout, the session is available for conversations requiring Sync Point support. If the partner LU does not support Sync Point, the session will not be used for Sync Point conversations.

Similarly, if the local LU is configured for Sync Point and the partner LU's BIND request indicates that it supports Sync Point, Host Integration Server sends BIND responses specifying that Sync Point is supported. In this case, the session can be used for Sync Point conversations.

Sync Point Session Deactivation

A Sync Point implementation needs to determine whether it has lost connectivity to a partner when establishing Sync Point conversations so that it can know whether or not to resynchronize. To obtain this information, Host Integration Server provides a new APPC verb, GET_LU_STATUS that reports the status of a particular remote LU. The information returned by this verb is as follows:

- Current number of active LU 6.2 sessions between the remote LU and the TP's local LU.
- Whether or not the number of active sessions dropped to zero at any time since this verb was last issued for the remote LU.

Note that the zero sessions indicator is reset to AP_NO each time the verb is issued by any process. It is therefore imperative that only one process issues this verb; otherwise information may be lost.

Starting Local Sync Point TPs

Local TPs are created by issuing the TP_STARTED verb to Host Integration Server. The **TP_STARTED** verb has been modified by adding the new verb control block (VCB) member **syncpoint_rqd** to allow a TP to specify that it requires Sync Point services.

By setting **syncpoint_rqd** to AP_YES, a TP indicates that it requires Sync Point services from Host Integration Server. A value of AP_NO (the default) indicates that Sync Point services are not required.

Since this member cannot be incorporated within the existing **TP_STARTED** VCB, the TP must use a larger VCB structure. To indicate that the VCB is longer than usual, the **opext** member of the VCB must be combined using OR with the value AP_EXTD_VCB before calling APPC.

Conversations started by TPs requiring Sync Point support will be routed only by the Host Integration Server software running on the same computer. They will not be routed to other LAN-attached servers.

Sync Point Conversation Activation

This section discusses support for Sync Point conversation activation in Host Integration Server.

This section contains:

- Locally Initiated Conversations
- Remotely Initiated Conversations
- Already Verified Support
- Presentation Header Support in Data Transfers
- User Control Data
- Implied Forget

Locally Initiated Conversations

Conversations are initiated locally by issuing an ALLOCATE or MC_ALLOCATE verb. The **ALLOCATE** and **MC_ALLOCATE** verbs are modified to support additional parameters required by Sync Point support. The supplied **synclevel** parameter of the **ALLOCATE** and **MC_ALLOCATE** verbs can take on a value of AP_SYNCPT, which specifies that the conversation requested is a Sync Point conversation.

Remotely Initiated Conversations

Applications that want to receive remotely initiated conversations (incoming Attaches) issue a RECEIVE_ALLOCATE verb. To accommodate Sync Point support, the **RECEIVE_ALLOCATE** verb is modified in a number of ways as follows:

- The returned **sync_level** parameter of the **RECEIVE_ALLOCATE** verb can take on a value of AP_SYNCPT, specifying that the conversation is a Sync Point conversation. The value of the **sync_level** parameter can also be determined by issuing a GET_ATTRIBUTES verb on the new conversation.

- Support is added for the receipt of program initiation parameters (PIP) data by a new parameter to the **RECEIVE_ALLOCATE** verb:

  The **pip_incoming** parameter is set by the application to indicate whether it is willing to accept incoming PIP data, and is returned by Host Integration Server to indicate whether PIP data is available to be received. If the application does not want to receive PIP data, this member should be set to AP_NO, the default, before issuing the **RECEIVE_ALLOCATE** verb. If it is willing to accept PIP data, this member should be set to AP_YES. On completion of the **RECEIVE_ALLOCATE** verb, this member will be set to AP_YES if PIP data is available to be received by the application and to AP_NO otherwise.

- If PIP data is available, the application can receive it by issuing one of the verbs for receiving data on completion of the RECEIVE_ALLOCATE verb. For basic conversations, these receive verbs include RECEIVE_AND_POST, RECEIVE_AND_WAIT, and RECEIVE_IMMEDIATE. On basic conversations the PIP data will be returned inclusive of the general data stream (GDS) header for PIP data (GDS identifier 0x12F5). For mapped conversations, these receive verbs include MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE. On mapped conversations, Host Integration Server 2009 removes the 4-byte GDS header, and returns the PIP data only.

- For basic conversations, if the application issues a SEND_ERROR, DEALLOCATE, or TP_ENDED verb before the PIP data is received, the PIP data will be discarded. For mapped conversations, if the application issues an MC_SEND_ERROR, MC_DEALLOCATE, or **TP_ENDED** verb before the PIP data is received, the PIP data will be discarded.

- If PIP data is received for a TP that cannot or does not want to receive it, the conversation is rejected with a primary return code of AP_ALLOCATION_ERROR, and a secondary return code of AP_PIP_NOT_ALLOWED.

Already Verified Support

In an implementation where a Host Integration Server application acts as a gateway between an SNA network and a non-SNA network, it is possible that non-Host Integration Server clients of the gateway may require Sync Point Level 2 conversation security. Since the originating client will have validated the relevant user identifier and password, the gateway application should specify conversation security of AP_SAME when starting a conversation on behalf of the client. In this case, however, Host Integration Server assumes that the user identifier to be used has previously been received on an Attach targeted at the TP. In the case of a non-Host Integration Server client this is not the case.

To allow such a gateway to support Sync Point Level 2 conversation security, Host Integration Server provides a new verb, SET_TP_PROPERTIES, which allows the gateway application to set the user identifier for the TP before allocating a conversation with security of AP_SAME. This verb will normally be issued once, immediately after TP_STARTED, to set the user identifier for all the TP's conversations.

Presentation Header Support in Data Transfers

For basic conversations, Sync Point commands are sent by means of presentation headers (PS) across LU 6.2 conversations using the SEND_DATA or MC_SEND_DATA verb. All presentation headers contain length fields that specify a length of 1, which is usually illegal. To support Sync Point conversations, the following modifications are made to the Host Integration Server presentation services component:

- On basic conversations with a **synclevel** of AP_SYNCPT, data transferred specifying a general data stream (GDS) variable length of 1 will not be rejected. If the **synclevel** is not AP_SYNCPT, they will be rejected as before.

- On mapped conversations, PS headers will not be wrapped as mapped conversation application data logical records (with GDS identifier 0x12FF) when they are sent, or have the GDS header stripped off when they are received.

- On mapped conversations, it is the responsibility of the application to provide the complete PS header including the length field. Similarly, the length field will be included in PS header data returned by receive verbs.

To achieve the latter the MC_SEND_DATA verb and the receive verbs (MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE) require modifications as follows:

- A new parameter, **data_type**, is added to the **MC_SEND_DATA** verb. When this is set to AP_APPLICATION (the default, 0x00), the data is sent as application data (GDS identifier 0x12FF) as usual. When it is set to AP_PS_HEADER, the data is sent as described above.

- The following two new values are added for the **what_rcvd** member of the receive verbs to specify that the received data is a PS header:

  AP_PS_HEADER_COMPLETE

  AP_PS_HEADER_INCOMPLETE

- If an application issues a receive verb with **rtn_status** set to AP_YES, Host Integration Server will return status in combination with AP_PS_HEADER_COMPLETE, with the exception of AP_DEALLOCATE_NORMAL and AP_CONFIRM_DEALLOCATE. This is to prevent the conversation being prematurely disconnected from the LU 6.2 session when a COMMIT PS header arrives with the end of conversation indication.

It is the responsibility of the vendor-supplied Sync Point support component to convert these PS headers into the appropriate Sync Point return codes (for example, TAKE_SYNCPT).

User Control Data

For mapped conversations, the MC_SEND_DATA verb and the receive verbs (MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE) are modified to allow applications to send and receive data in user control data general data stream (GDS) variables instead of the regular application data GDS variables. The **MC_SEND_DATA** verb is modified as follows:

- A new parameter, **data_type**, is added. When **data_type** is set to AP_USER_CONTROL_DATA, the data is sent as user control data (GDS identifier 0x12F2). When it is set to AP_APPLICATION (the default), the data is sent as application data (GDS identifier 0x12FF). Note that the APPC library automatically creates the GDS header on behalf of the application for both AP_APPLICATION and AP_USER_CONTROL_DATA data records.

- The mapped conversation receive verbs are modified to allow applications to receive user control data by adding two new values for the **what_rcvd** parameter, as follows:

  AP_USER_CONTROL_DATA_COMPLETE

  AP_USER_CONTROL_DATA_INCOMPLETE

Implied Forget

LU 6.2 Sync Point sessions can use an optimization of the architected message flows known as implied forget. When the protocol specifies that a FORGET presentation header (PS) is required, the next data flow on the session implies that a FORGET has been received, even though it has not. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However it is possible that the last message that flows is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. To provide the TP with this notification, the DEALLOCATE and MC_DEALLOCATE verbs are modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a data link control (DLC) outage.

The callback procedure can take any name because the address of the procedure is passed into the APPC DLL.

Note that the **DEALLOCATE** and **MC_DEALLOCATE** verbs will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

The DEALLOCATE and MC_DEALLOCATE verbs are modified as follows to support implied forget:

- A new member, **callback**, is added to allow the TP to specify the address of the function to call on the next data flow on the session being used by the conversation being deallocated. If this member is NULL, no notification will be provided. A vendor would normally supply this callback function.
- The **DEALLOCATE** and **MC_DEALLOCATE** verbs also contain a correlator member which is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

Host Integration Server allows TPs to deallocate conversations immediately after sending data by specifying the **type** member in the SEND_DATAand MC_SEND_DATAverbs as AP_SEND_DATA_DEALLOC_FLUSH, AP_SEND_DATA_DEALLOC_SYNC_LEVEL, AP_SEND_DATA_DEALLOC_ABEND, and AP_SEND_DATA_DEALLOC_CONFIRM. However, the **SEND_DATA** and **MC_SEND_DATA** verbs do not contain the implied forget callback function. TPs wishing to receive implied forget notification must issue a DEALLOCATE or MC_DEALLOCATE verb explicitly.

Sync Point Level 2 Confirm Support

The current APPC implementation in Host Integration Server supports conversations with **synclevel** of AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT. The DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs specify a **type** member indicating the synchronization level required. This parameter is interpreted as follows:

Allocated synclevel	Type specified	Action performed
AP_NONE	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_NONE	AP_SYNCLEVEL	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_SYNCPT	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_SYNCPT or AP_CONFIRM_SYNC_LEVEL	AP_CONFIRM_TYPE	Action of CONFIRM or MC_CONFIRM verb before deallocation or change of direction.
AP_SYNCPT	AP_SYNCLEVEL	It is assumed that a Sync Point implementation built using the APPC API in Host Integration Server implements the defer states appropriately. See the note below.

Note

With an allocated **synclevel** of AP_SYNCPT and a specified **type** of AP_SYNCLEVEL, it is assumed that a vendor-supplied Sync Point component implements the defer states appropriately. A vendor-supplied Sync Point system must:

- Intercept DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs on Sync Point Level 2 conversations when type AP_SYNCLEVEL is specified for **synclevel**.
- Maintain the defer state until one of the verbs valid in that state completes.
- On completion of the verb, issue the original **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, or **MC_PREPARE_TO_RECEIVE** verb to Host Integration Server 2009.

Host Integration Server does not implement the defer states directly. In particular, when a **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, or **MC_PREPARE_TO_RECEIVE** verb is received with a **type** specified as AP_SYNCLEVEL on a Sync Point conversation, this is treated as if the conversation has a **synclevel** of AP_NONE.

So that Sync Point Level 2 conversations can use confirm type synchronization, the **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, and **MC_PREPARE_TO_RECEIVE** verbs are modified to support a type member of AP_CONFIRM_TYPE.

The DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs specify a type member indicating the synchronization level required. This parameter is interpreted as follows:

Allocated synclevel	Type specified	Action performed
AP_NONE	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_NONE	AP_SYNCLEVEL	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_CONFIRM_SYNC_LEVEL	AP_FLUSH	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_CONFIRM_SYNC_LEVEL	AP_SYNCLEVEL	Action of CONFIRM or MC_CONFIRM verb before deallocation or change of direction.

Sync Point Backout Support

This section describes back out support for Sync Point conversations.

This section contains:

Additional Sync Point Return Codes

When a remote transaction program (TP) issues a **BACKOUT** verb, the back out is reported to the local TP as a new primary return code value, AP_BACKED_OUT, on the next (current) verb issued. The local TP is provided access to the sense code information contained in the Backout FMH-7 by setting the **secondary_rc** field as follows:

- AP_BO_NO_RESYNC for sense code 0x08240000
- AP_BO_RESYNC for sense code 0x08240001

This new return code will only be supplied on conversations with **synclevel** AP_SYNCPT, and therefore will not be presented to existing applications.

The verbs on which this new return code can be returned are:

CONFIRM

MC_CONFIRM

MC_PREPARE_TO_RECEIVE

MC_RECEIVE_AND_POST

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_SEND_DATA

MC_SEND_ERROR

PREPARE_TO_RECEIVE

RECEIVE_AND_POST

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

SEND_DATA

SEND_ERROR

Sending Backout on Sync Point Conversations

To send a Backout, an FMH-7 containing a sense code of 0x08240000 or 0x08240001 is sent on the session. This is done using the SEND_ERROR or MC_SEND_ERROR verb. To enable Host Integration Server 2009 to send the appropriate sense data, the **SEND_ERROR** and **MC_SEND_ERROR** verbs are modified as follows:

- A new field, **err_type**, is added to allow the TP to specify the type of error. The default is AP_PROG (0x00), which means existing TPs will continue to work unmodified.

- The **err_type** field in both verbs can take one of two new values, specifying the sense codes to be generated by Host Integration Server 2009:

  AP_BACKOUT_NO_RESYNC for sense code 0x08240000

  AP_BACKOUT_RESYNC for sense code 0x08240001

LUWID, Conversation Correlators, and Session Identifiers

The logical unit-of-work identifier (LUWID), conversation correlators, and session identifiers are important for all Sync Point operations and accounting purposes. The following sections describe how Host Integration Server provides access to these components and, where appropriate, facilities to modify this information.

This section contains:

Generating and Setting LUWIDs

The unit-of-work identifier (LUWID) is used to identify conversations that are part of a single Sync Point transaction. All conversations with the same LUWID are committed (or backed out) at the same time.

Host Integration Server assigns two LUWIDs to a transaction program when the TP is started. For locally started TPs, this is when the TP_STARTED verb is issued. The first LUWID is the TP's protected LUWID. It is used by Host Integration Server 2009 as the LUWID for all **synclevel** AP_SYNCPT conversations allocated by the TP. When the TP issues an ALLOCATE or MC_ALLOCATE verb with a **synclevel** of AP_SYNCPT, Host Integration Server generates an Attach containing the TP's current protected LUWID.

The second LUWID is the TP's unprotected LUWID. It is used on all conversations allocated by the TP with a **synclevel** other than AP_SYNCPT.

For remotely initiated TPs, the incoming Attach may contain an LUWID for the TPit is mandatory if the conversation has a **synclevel** of AP_SYNCPT. For Sync Point conversations, Host Integration Server saves the LUWID as the TP's protected LUWID and generates a new unprotected LUWID for it. For conversations with a **synclevel** other than Sync Point (AP_SYNCPT), Host Integration Server saves the LUWID as the TP's unprotected LUWID and generates a new protected LUWID.

Host Integration Server generates LUWIDs by concatenating the following:

- The fully qualified name of the local LU, preceded by a single byte indicating its length (exclusive of the length byte).
- A 6-byte LUW instance number, generated from the current date and time (modified to ensure uniqueness if necessary).
- A 2-byte LUW sequence number, initialized to 1.

If the fully qualified LU name component of the LUWID is not 17 bytes long, Host Integration Server does not add any padding between it and the LUW instance number. The application can determine the length of the LUWID, and the offsets within it of the LUW instance number and LUW sequence number, by examining the first byte of the LUWID, which indicates the length of the fully qualified LU name.

When Host Integration Server generates both a protected and an unprotected LUWID for a TP, the unprotected LUWID is created by incrementing the protected LUWID's instance number.

The protected LUWID needs to be changed by a TP for one of four reasons:

- When a transaction is backed out or committed, the LUWID sequence number must be incremented.
- If the transaction tree is split, a new LUWID must be generated for the TP.
- If the application uses multiple logical TPs to implement a transaction, each TP must have the same LUWID (different from that assigned by Host Integration Server).
- If the application is acting as a gateway from a non-SNA environment and LUWIDs are received by a means other than an Attach.

To allow a TP to set or generate new LUWIDs, a new verb, SET_TP_PROPERTIES, is provided by the APPC API. This verb allows the TP to either set its LUWIDs to an existing value, by providing the LUWIDs, or generate new ones and use them from then on. When a new LUWID is generated by Host Integration Server, it is guaranteed to be unique.

Note that it is the responsibility of the application (the Sync Point system component) to transmit the new LUWID PS header to the partner Sync Point system when the protected LUWID is changed. Similarly, when a new LUWID PS header is received, the application must inform the LU by issuing **SET_TP_PROPERTIES**.

Extracting LUWIDs

Both LUWIDs for a particular TP can be determined by issuing the GET_TP_PROPERTIES verb. The **GET_TP_PROPERTIES** verb returns the TP's unprotected LUWID in the **luw_id** field.

If the TP needs to access the protected LUWID, it must combine the **opext** member of the verb control block (VCB) with the value AP_EXTD_VCB using OR before issuing the verb. The protected LUWID will then be returned in the **prot_luw_id** field. If the **opext** field does not contain the AP_EXTD_VCB bit, the verb control block is presumed to end immediately before the **prot_luw_id** field.

The LUWID for a particular conversation can be determined by issuing a GET_ATTRIBUTES or MC_GET_ATTRIBUTES verb on the conversation. These verbs are modified as follows:

- A new field, **luw_id**, is added in which the LUWID is returned. The LUWID returned is the protected one if the conversation was allocated with **synclevel** field of the ALLOCATE or MC_ALLOCATE verb set to Sync Point (AP_SYNCPT); otherwise it is the unprotected one.

- Since the **luw_id** field cannot be incorporated within the existing verb control blocks, the TP must use a larger VCB structure. To indicate that the VCB is longer than usual, the **opext** field of the VCB must be combined with the value AP_EXTD_VCB using OR before calling APPC.

- The **sync_level** field of the **GET_ATTRIBUTES** or **MC_GET_ATTRIBUTES** verb can take an additional value, AP_SYNCPT, when the conversation was allocated with the **synclevel** field of the **ALLOCATE** or **MC_ALLOCATE** verb of Sync Point (AP_SYNCPT).

Session Identifiers

Host Integration Server maintains a unique identification for every LU 6.2 session it has with a remote LU. This 8-byte identifier is generated by Host Integration Server every time it starts a new session (or is received by Host Integration Server when a session is initiated remotely). The Sync Point resynchronization protocols require knowledge of the session identifier.

To provide this, the MC_GET_ATTRIBUTES and the GET_ATTRIBUTES verbs have been modified to return the session identifier of the session over which a particular conversation is allocated. The **MC_GET_ATTRIBUTES** and **GET_ATTRIBUTES** verbs can be used to retrieve this **sess_id** field of the VCB if the **opext** field of the VCB is combined with the value AP_EXTD_VCB using OR before calling APPC.

Configuration Changes for Sync Point Support

A new check box is added to the Local LU Configuration dialog box. When selected, this indicates that the local LU is able to participate in **synclevel** Sync Point sessions. Host Integration Server uses this option to determine the **synclevel** BIND parameters it sends on BIND requests and responses.

This field is added to the Host Integration Server configuration file in a field that is no longer used by Host Integration Server. Existing configurations from earlier versions of Host Integration Server will therefore continue to work unmodified.

Accepting Incoming Attaches

The Sync Point support in Host Integration Server is intended for use only by gateway applications that implement the architected SNA Sync Point components, including Conversation-Protected Resource Manager (C-PRM). In a Sync Point implementation, it is necessary for C-PRM to be aware of all protected conversations, both locally initiated and remotely initiated. This can be achieved in Host Integration Server by C-PRM intercepting the conversation allocation and deallocation verbs and issuing them on behalf of the transaction program (TP). Note that since Host Integration Server does not allow TP or conversation identifiers to be shared across processes, this also means that the process containing C-PRM must also intercept all APPC verbs issued by the client TPs.

For locally initiated TPs, this is straightforward. However for incoming Attaches, the situation is made more complex by the requirement that the RECEIVE_ALLOCATE verb specify the name of the TP to be matched with the Attach.

In some implementations, this will not be an issue, as the gateway will be aware of the names of all the transactions passing through it. To support this situation, the **RECEIVE_ALLOCATE** verb has been enhanced as described in the following topic to permit the gateway to indicate that it can accept Sync Point conversations.

In other implementations, the gateway does not know the names of the transactions passing through it. This is particularly so when the gateway is providing a conversion between SNA and another communications protocol. In this case, Host Integration Server allows the gateway process to register itself as a Sync Point Attach Service, indicating that it is willing to accept incoming Attaches for any Sync Point conversation. In this case, the gateway must be implemented as a Sync Point Attach Manager.

This section contains:

- Sync Point Knows Transaction Names
- Sync Point Attach Manager
- Rejecting Remotely Initiated Conversations

Sync Point Knows Transaction Names

A Sync Point implementation that knows the names of all the transactions that can be supported (for example, through configuration of the gateway) may accept incoming Sync Point conversations by issuing a RECEIVE_ALLOCATE verb specifying the name of the transaction and indicating that it is willing to accept Sync Point conversations.

The **RECEIVE_ALLOCATE** verb was modified to allow a TP to specify that it can accept Sync Point conversations by adding a new **syncpoint_rqd** field to the VCB. When this field is set to AP_YES it indicates that the transaction program can accept Sync Point conversations from Host Integration Server. When this field is set to AP_NO (the default), it indicates that Sync Point conversations are not supported.

Sync Point Attach Manager

Instead of issuing separate RECEIVE_ALLOCATE verbs for each possible transaction name, a Sync Point implementation may instead register as the Sync Point Attach Manager for Host Integration Server 2009. It does so by issuing a **RECEIVE_ALLOCATE** verb specifying a TP name consisting of all 0x00s.

When a Sync Point Attach Manager is registered, the following changes are effected in server's incoming Attach support on Host Integration Server:

- When an Attach message arrives for any TP name on a conversation with the **syncpoint_rqd** field of the VCB set to AP_YES, Host Integration Server matches it with the application that issued the special **RECEIVE_ALLOCATE** verb registering itself as the Sync Point Attach Manager.

- Any Attach message arriving for the Resynchronization TP (0x06F2) will automatically be routed to the Sync Point Attach Manager.

- If no **RECEIVE_ALLOCATE** has been issued for the Sync Point Attach Manager, or for the specific TP name, Host Integration Server will queue the Attach for a configured period of time. If no **RECEIVE_ALLOCATE** is issued in that time, the Attach will be rejected with a return code of TP_NOT_AVAILABLE_RETRY.

- If a **RECEIVE_ALLOCATE** is matched with the Attach message, the verb is returned to the TP with the **tp_name** field of the VCB set to the TP name contained in the Attach message.

Applications using this feature must adhere to two restrictions:

- All verbs issued on conversations started in this manner must be issued by the same process, as Host Integration Server cannot pass **tp_id**s between processes.

- Only a single process may register as the Sync Point Attach Manager on any server running Host Integration Server. If a second process attempts to register, its **RECEIVE_ALLOCATE** verb will return immediately with the primary return code set to AP_SYNCPOINT_MANAGER_ACTIVE.

Sync Point Attach Manager applications must reside on a Host Integration Server 2009 server. They may not be distributed across Host Integration Server clients. This restriction is imposed to ensure that only a single instance of Sync Point Services (SPS) and Conversation-Protected Resource Manager (C-PRM) exists for each LU on the Host Integration Server (which might not be the case if Sync Point Attach Managers were visible from multiple servers in the Host Integration Server domain).

The structure of the RECEIVE_ALLOCATE verb control block does not require modification to support this function.

Rejecting Remotely Initiated Conversations

In an environment where a Sync Point Attach Manager is receiving all Attach messages as described above, it may be necessary for it to reject an Attach for a particular TP name, either because the TP name is not valid or because there is another problem with the received Attach message. To enable the application to generate the correct return code at the initiating TP, the DEALLOCATE and MC_DEALLOCATEverbs are enhanced with new **deallocate_type** field values in the VCB that allow the application to specify the return code to be sent to the initiating TP. The new values for **deallocate_type** are:

AP_TP_NOT_AVAIL_RETRY

AP_TP_NOT_AVAIL_NO_RETRY

AP_TPN_NOT_RECOGNIZED

AP_PIP_DATA_NOT_ALLOWED

AP_PIP_DATA_INCORRECT

Sync Point Examples

This section contains example verb sequences for implementing the architected Sync Point verbs using the Sync Point facilities provided by Host Integration Server.

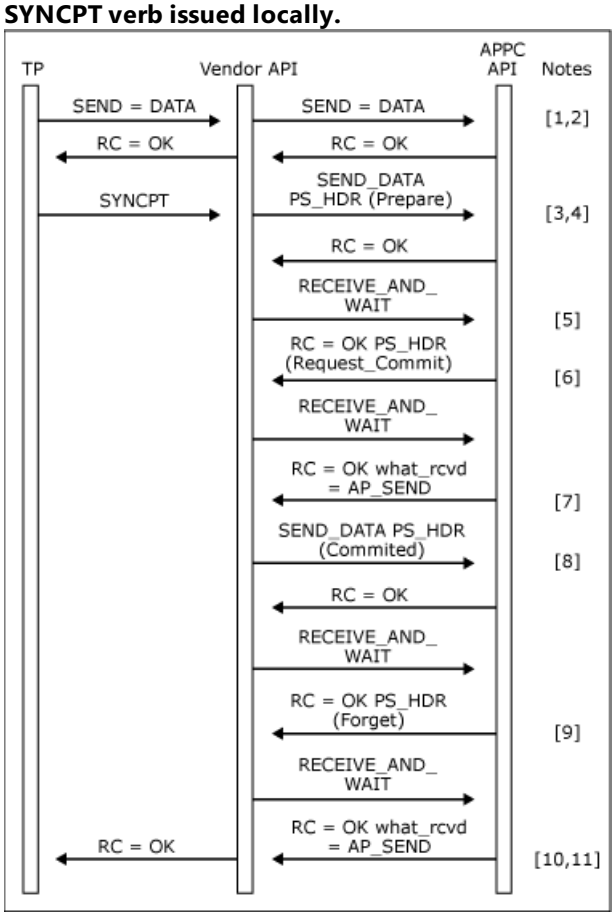
In the following figures, TP is the transaction program that requires Sync Point services. Vendor API is the vendor-supplied APPC API. This component provides the SPS and C-PRM components and a mapping between the vendor's APPC syntax and that of Host Integration Server. APPC API is the Host Integration Server APPC basic and mapped conversation interface.

This section contains:

SYNCPT Verb Issued Locally

This section provides an example verb sequence with a verb issued locally.

SYNCPT verb issued locally.



1. The transaction program issues a SEND_DATA or MC_SEND_DATAverb depending on whether a basic or mapped conversation is being used.

2. The **SEND_DATA** or **MC_SEND_DATA** VCB is passed transparently through the vendor API to Host Integration Server 2009. When the verb completes, the return code from Host Integration Server is returned to the transaction program.

3. The transaction program issues a **SYNCPT** verb to the vendor API.

4. The vendor API creates a PREPARE PS header and transmits it by issuing a **SEND_DATA** or **MC_SEND_DATA** verb. For a mapped conversation, the data_type field of the **MC_SEND_DATA** VCB must be set to AP_PS_HEADER.

5. On completion of the **SEND_DATA** or **MC_SEND_DATA** verb, the vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb.

6. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB with a value of AP_PS_HEADER. The data buffer is filled with the received REQUEST_COMMIT PS header.

7. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued to get send direction. Note that the vendor API can combine these two verbs into a single request by setting the **rtn_status** field of the VCB to AP_YES in order to receive status with data on the first RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT.

8. A COMMITTED PS header is then transmitted using a SEND_DATA or MC_SEND_DATA verb.

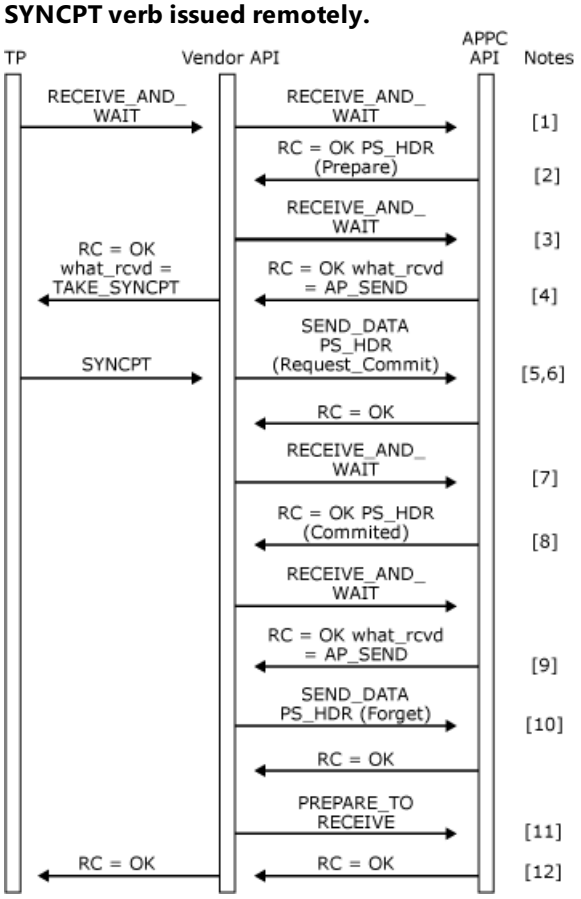
9. The Vendor API issues a **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb to receive the FORGET PS header from the remote TP.

10. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued with the **what_rcvd** field of the VCB set to AP_SEND to get send direction (again the **rtn_status RECEIVE_AND_WAIT** field of the VCB can be set to AP_YES to combine these two verbs).

11. When send indication is received, the vendor API returns the **SYNCPT** verb to the local transaction program with an OK return code.

SYNCPT Verb Issued Remotely

SYNCPT verb issued remotely.



1. The local TP issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAITverb (depending on whether a basic or mapped conversation is being used) to receive data from the remote transaction program. The vendor API passes the verb transparently to Host Integration Server.

2. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with **what_rcvd** = AP_PS_HEADER. The data buffer contains a PREPARE PS header.

3. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued by the vendor API to receive the send indication from the remote TP.

4. The vendor API returns the transaction program's **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb with the **what_rcvd** field of the VCB set to TAKE_SYNCPT.

5. The transaction program issues a **SYNCPT** verb.

6. The vendor API generates a REQUEST_COMMIT PS header and transmits it using a SEND_DATA or MC_SEND_DATA verb. If the conversation is mapped, the **MC_SEND_DATA** verb is issued with the **data_type** field of the VCB set to AP_PS_HEADER.

7. The vendor API then issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb to give the remote TP direction to send.

8. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB set to AP_PS_HEADER. The data buffer contains a COMMITTED PS header.

9. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued to get permission to send.

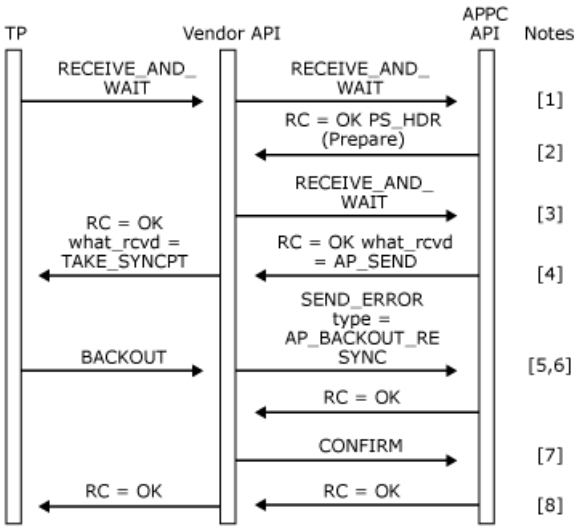
10. A FORGET PS header is prepared and sent to the remote transaction program.

11. The FORGET is flushed and direction given to the remote transaction program by issuing a PREPARE_TO_RECEIVE or MC_PREPARE_TO_RECEIVE with the **ptr_type** field of the VCB set to AP_FLUSH.

12. When the **PREPARE_TO_RECEIVE** or **MC_PREPARE_TO_RECEIVE** verb completes, the vendor API returns the **SYNCPT** verb to the local transaction program.

BACKOUT Verb Issued Locally

BACKOUT verb issued locally.



1. The local transaction program issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb (depending on whether a basic or mapped conversation is being used) to receive data from the remote transaction program. The vendor API passes the verb transparently to Host Integration Server.

2. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB set to AP_PS_HEADER. The data buffer contains a PREPARE PS header.

3. Another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb is issued by the vendor API to receive the send indication from the remote TP.

4. The vendor API returns the transaction program's **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb with the **what_rcvd** field of the VCB set to **TAKE_SYNCPT**.

5. The transaction program issues a **BACKOUT** verb to back out the transaction.

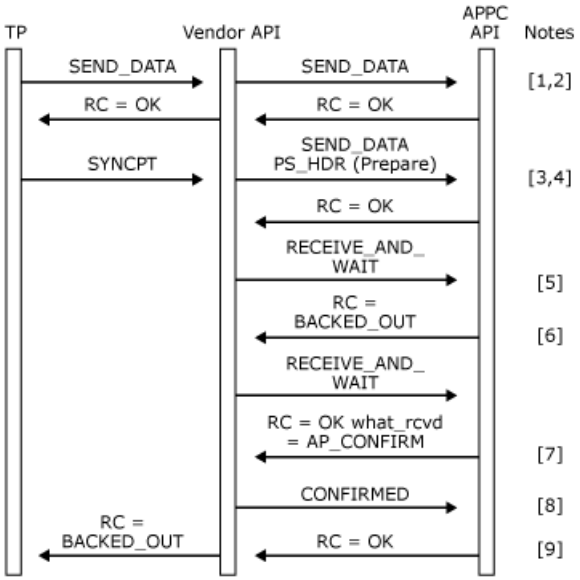
6. The vendor API generates a SEND_ERROR or MC_SEND_ERROR verb of type BACKOUT_RESYNC to send the Backout sense code 0x08240001.

7. The vendor API then issues a CONFIRM or MC_CONFIRM verb to flush the **SEND_ERROR** or **MC_SEND_ERROR** verb and request a response from the remote transaction program.

8. The CONFIRM or MC_CONFIRM verb completes when the remote transaction program issues a CONFIRMED or MC_CONFIRMED verb. The vendor API then returns the **BACKOUT** verb to the local transaction program.

BACKOUT Verb Issued Remotely

BACKOUT verb issued remotely.



1. The transaction program issues a SEND_DATA or MC_SEND_DATAverb depending on whether a basic or mapped conversation is being used.

2. The **SEND_DATA** or **MC_SEND_DATA** VCB is passed transparently through the vendor API to Host Integration Server. When the verb completes the return code from Host Integration Server is returned to the transaction program.

3. The transaction program issues a **SYNCPT** verb to the vendor API.

4. The vendor API creates a PREPARE PS header and transmits it by issuing a **SEND_DATA** or **MC_SEND_DATA** verb. For a mapped conversation, the data_type field of the **MC_SEND_DATA** VCB must be set to AP_PS_HEADER.

5. On completion of the **SEND_DATA** or **MC_SEND_DATA** verb, the vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb.

6. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb returns with a return code of AP_BACKED_OUT, indicating that the remote transaction program issued a **BACKOUT** verb.

7. The vendor API issues another **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb to receive the Confirm indication.

8. When the verb completes with the **what_rcvd** field of the VCB set to AP_CONFIRM, the vendor API issues a CONFIRMED or MC_CONFIRMED verb to acknowledge the **BACKOUT** verb.

9. The **SYNCPT** verb is returned to the transaction program with a BACKED_OUT return code when the **CONFIRMED** or **MC_CONFIRMED** verb completes.

Windows CSV Overview

Common service verbs (CSVs) are a set of programming functions provided by Host Integration Server 2009. The CSVs provide convert, log, trace, and transfer services to applications.

The CSVs and information presented in this section represent an evolving CSV API that is composed of IBM Extended Services for OS/2 and a set of Microsoft Windows extensions that allow for registering and deregistering the application, and that provide an asynchronous entry point for TRANSFER_MS_DATA.

This section describes the verbs available to you and explains how to use them with your applications. A detailed description of each verb is provided in the reference portion of the SDK.

The CSVs are as follows:

CONVERT

Converts a character string from ASCII to EBCDIC or from EBCDIC to ASCII.

COPY_TRACE_TO_FILE

Concatenates the contents of the individual application programming interface (API)/link service trace files to form a single trace file.

DEFINE_TRACE

Enables or disables tracing for specific APIs.

GET_CP_CONVERT_TABLE

Creates and returns a 256-byte conversion table to translate character strings from a source code page to a target code page.

LOG_MESSAGE

For OS/2 only, takes a message from a message file, adds specified data to it, and records the message in the error log file. This verb optionally displays the message on the user's screen.

TRANSFER_MS_DATA

Builds a Systems Network Architecture (SNA) request unit (RU) containing Network Management Vector Transport (NMVT) data. The verb can send the NMVT data to NetView for centralized problem diagnosis and resolution. The data is optionally logged in the event log for Windows 2000.

Host Integration Server Asynchronous Support

Asynchronous call completion returns the initial call immediately so the application can continue with other processes. An application that issues a call and does not regain control until the operation completes is not able to perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients.

Through **RegisterWindowsMessage** with "WinAsyncCSV" as the string, you pass a window handle by which you will be notified of call completion. You then make your call and when it completes, a message is posted to the window handle that you passed, notifying you that the call is complete.

Before Using Windows CSV

The following Microsoft® Windows® extensions are of particular importance and should be reviewed before using Windows CSV:

WinAsyncCSV

Provides an asynchronous entry point for TRANSFER_MS_DATA only. If used for any other verb, the behavior will be synchronous. Use this extension instead of the blocking version of the verb if you run your application under Microsoft® Windows® version 3.*x*.

When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncCSV" as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call. The *lParam* argument contains the original verb control block (VCB) pointer and can be dereferenced to determine the final return code.

If the function returns successfully, a "WinAsyncCSV" message is posted to the application when the operation completes or the conversation is canceled.

WinCSVCleanup

Terminates and deregisters an application from a Windows CSV implementation.

Important
An application must call this function to deregister itself from the Windows CSV implementation.

WinCSVStartup

Allows an application to specify the version of Windows CSV required and to retrieve details of the specific CSV implementation.

Important
An application must call this function to register itself with a Windows CSV implementation before issuing any further Win dows CSV calls.

Creating Specific NetView User Alerts

You can create NetView user alerts for users to send. Users identify the alerts by number; each number corresponds to a specific collection of information or requests that the user wants to send via NetView to a host operator.

Microsoft® Host Integration Server leaves blank fields for the user alert information in the structure that is returned from the sepdcrec function. To create specific user alerts, create appropriate data structures and call the TRANSFER_MS_DATA verb to send the user alert to NetView.

Using CSVs in C Programs

CSVs are available to C applications through the external function **WINCSV**.

Sample Programs

A collection of sample programs is delivered with the Microsoft® Host Integration Server Software Development Kit (SDK) in the \SDK\SAMPLES directory on the Host Integration Server CD. For more information, see APPC Samples.

CSV Verb Control Block

The only parameter passed to the **WINCSV** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that identify the verb to be executed, supply information to be used by the verb, and contain information returned by the verb when execution is complete. Each verb has its own VCB structure, which is declared in the file WINCSV.H.

Bit Ordering

Bit 0 refers to the high-order bit in a byte or word. To set bit 0 on in a byte, use the bitwise **OR** operation (=) with a value of 128.

WINCSV Definition

The prototype definition of the **WINCSV** function is as follows:

```
extern void WINAPI WINCSV (LPCSV);
```

The verb control block (VCB) address parameter, a 32-bit pointer, is declared as a long integer and requires casting from a pointer to a long integer.

WINCSV.H File

Use the **#include** command to include the WINCSV.H file in any application that issues CSVs.

The WINCSV.H file, which is included with the Microsoft® Host Integration Server Software Development Kit (SDK), contains:

- The CSV function prototype.
- The structure declarations for the CSV verb control blocks (VCBs).
- The **#define** statements that substitute meaningful symbolic constants for hexadecimal values supplied to and returned by CSVs.

If a **#define** statement pertains to a hexadecimal value that is longer than one byte, a comment shows how the hexadecimal value is stored in memory.

When setting or testing CSV parameters, use the symbolic constants defined by the WINCSV.H file. When examining trace files or the contents of memory, use the hexadecimal values.

Issuing a CSV

The procedure for issuing a CSV is shown in the following sample code that uses CONVERT.

To issue a CSV

1. Create a structure variable from the verb control block (VCB) structure that applies to the verb to be issued.

```
#include <wincsv.h>
    .
    .
struct convert  conv_block;
```

   The VCB structures are declared in the WINCSV.H file; one of these structures is named **CONVERT**.

2. Clear (set to zero) the variables within the structure.

```
memset( conv_block, '\0', sizeof( conv_block ) );
```

   This procedure is not required. However, it helps in debugging and reading the contents of memory. It also eliminates the possibility that future versions of a verb are sensitive to fields that are ignored in the current version.

3. Assign values to the required VCB variables.

```
conv_block.opcode = SV_CONVERT;
conv_block.direction = SV_ASCII_TO_EBCDIC;
conv_block.char_set = SV_AE;
conv_block.len = sizeof(tpstart_name);
conv_block.source = (LPBYTE) tpstart_name;
conv_block.target = (LPBYTE) tpstart.tp_name;
```

   The values SV_CONVERT, SV_ASCII_TO_EBCDIC, and SV_AE are symbolic constants representing integers. These constants are defined in the WINCSV.H file.

   The character array TPSTART_NAME contains an ASCII string to be converted to EBCDIC and placed in the character array TPSTART.TP_NAME.

4. Invoke the verb. The only parameter is a pointer to the address of the structure containing the VCB for the verb.

```
ACSSVC((LONG) &conv_block);
```

   You can also use the following statement:

```
ACSSVC_C((LONG) &conv_block);
```

5. Use the values returned by the verb.

```
if( conv_block.primary_rc == SV_OK ) {
/* other statements */
    .
    .
    .
```

Support for APPC Automatic Logon

This section describes the support for automatic logon for Advanced Program-to-Program Communications (APPC) applications available in Host Integration Server 2009. This feature requires specific configuration by the network administrator.

The APPC application must be invoked on the local area network (LAN) side from a client of Host Integration Server. The client must be logged on to a Microsoft Windows Server 2003, Microsoft Windows XP, or Windows 2000 domain.

The client application is coded to use "program" level security, with a special hard-coded APPC user name (MS$SAME) and password (MS$SAME). When this session allocation flows from client to Host Integration Server, the server looks up the host account and password corresponding to the Windows 2000 account under which the client is logged on, and substitutes the host account information into the APPC attach message it sends to the host.

To use this feature for an APPC application, the **user_id** and **pwd** fields in the ALLOCATE or MC_ALLOCATE verbs must be hard-coded to use the string mentioned above, and **security** must be set to AP_PGM.

CPI-C Programmer's Guide

This section of the Host Integration Server 2009 Developer's Guide provides information about developing applications with the Common Programming Interface for Communications (CPI-C).

For API references and other technical information for CPI-C, see the CPI-C Programmer's Reference section of the SDK.

For sample code using CPI-C, see CPI-C Samples section of the SDK.

In This Section

Introduction to CPI-C

Common Programming Interface for Communications (CPI-C) is an application programming interface (API) that enables peer-to-peer communications among programs in a Systems Network Architecture (SNA) environment.

Through CPI-C, programs distributed across a network can work together, communicating with each other and exchanging data, to accomplish a single processing task such as querying a remote database, copying a remote file, or sending and receiving electronic mail.

The CPI-C calls and information presented in this section represent an evolving Microsoft® Windows® CPI-C that is composed of CPI-C version 1.2 and a set of Windows extensions that enable multiple applications and asynchronous call completion.

CPI-C version 1.0 was first introduced to provide a means by which two applications could speak and listen to each other; in other words, have a conversation. A conversation is the logical connection between two programs that enables the programs to communicate with each other. Programs using CPI-C converse with each other by making program calls. These calls are used to establish the full characteristics of the conversation, to exchange data, and to control the information flow between the two programs.

CPI-C version 1.1 includes four new areas of function:

- Support for resource recovery (not supported in Windows CPI-C).
- Automatic parameter conversion.
- Support for communicating with non-CPI-C programs.
- Local and remote transparency.

Built upon CPI-C version 1.1, X/Open CPI-C provided the following:

- Support for nonblocking calls.
- The ability to accept multiple conversations.
- Support for data conversion (beyond parameters).
- Support for security parameters.

CPI-C version 1.2 consolidated CPI-C version 1.1 and X/Open CPI-C and provided all the functions described previously. Windows CPI-C adds to this functionality by providing a set of extensions for asynchronous communication in addition to supporting most features in CPI-C version 1.2 with the exception of the following features:

- Full duplex operation.
- Nonblocking call behavior (as defined in the CPI-C 1.2 specification).
- Some data conversion functions.

For a complete list of unsupported functions, see CPI-C Functions Not Supported.

The use of the Windows CPI-C interface on Microsoft® Windows Server™ 2003 and Windows 2000 causes additional threads to be created within the calling process. These other threads perform interprocess communication with the SNA service over the local area network (LAN) interface that the client is configured to use (TCP/IP, IPX/SPX, or named pipes, for example).

Stopping the SNABASE service causes the application to be unloaded from memory.

Windows CPI-C Asynchronous Support

A program that issues a call and does not regain control until the call completes cannot perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients. Asynchronous call completion returns the initial call immediately, so the application can continue with other processes.

Windows Common Programming Interface for Communications (CPI-C) support is related to asynchronous communications and includes the following calls and extensions:

Set_Processing_Mode

Specify_Windows_Handle

Wait_For_Conversation

WinCPICExtractEvent

WinCPICIsBlocking

WinCPICSetBlockingHook

WinCPICSetEvent

WinCPICUnhookBlockingHook

Two methods under Microsoft Windows Server 2003 and Windows 2000 are available for asynchronous verb completion:

- Message posting using window handles.
- Waiting for Win32 events.

The traditional method uses messages posted to a window handle to notify an application of verb completion. This method was used in earlier versions of the product to support Windows 3.*x*.

Asynchronous support using message posting is appended to the Set_Processing_Mode call and enables an application to be notified of call completion on a window handle. Calling **RegisterWindowsMessage** with "WinAsyncCPIC" as the string, an application passes a window handle by which the application is notified of call completion. The application then makes the CPI-C call, and when it completes a message is posted to the window handle that was passed, notifying the application that the call is complete.

With the exception of an asynchronous Receive call that can issue certain other calls while pending, a conversation can have only one incomplete operation at any time. For more information about using an asynchronous **Receive** call, see Using Asynchronous Call Completion. In the case of an incomplete operation, the program can issue Wait_For_Conversation to test for its completion or Cancel_Conversation to end the conversation and the incomplete operation.

A second method using Win32 events for notification is supported in Host Integration Server 2009.

If an event has been registered with the conversation using **WinCPICSetEvent**, an application can call the Win32 **WaitForSingleObject** or **WaitForMultipleObjects** function to wait to be notified of the completion of the verb.

The only Windows extension functions required for Windows CPI-C are for initialization (WinCPICStartup) and termination (WinCPICCleanup) purposes. Depending on your application, other Windows extensions for handling asynchronous verb completion can be useful, but they are not required. For an example of how to use Windows CPI-C asynchronous calls and Windows extensions, see Using Asynchronous Call Completion. For a complete description of all Windows CPI-C calls and extensions, see CPI-C Calls and Extensions for the Windows Environment.

Before Using Windows CPI-C

The following Common Programming Interface for Communications (CPI-C) calls and Windows extensions are of particular importance. You should review them before using Host Integration Server 2009.

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonym. For example, **Set_Processing_Mode** is the pseudonym for a call. The actual function name is **cmspm**.

Set_Processing_Mode(**cmspm**)

Specifies for the conversation whether subsequent calls are returned when the operation they request is complete (blocking) or immediately after the operation is initiated (nonblocking). A program is notified of the completion of nonblocking calls when it issues **Wait_For_Conversation** or through a Windows message sent to a WndProc identified by *hwndNotify* in **Specify_Windows_Handle**. When the processing mode is set for a conversation, it applies to all subsequent calls on the conversation until the mode is set again.

Specify_Windows_Handle(**xchwnd**)

Sets the window handle to which a message is sent on completion of an operation in nonblocking mode.

Wait_For_Conversation(**cmwait**)

Waits for the completion of an operation that was initiated when theprocessing mode conversation characteristic was set to CM_NON_BLOCKING and CM_OPERATION_INCOMPLETE was returned in the *return_code* parameter. Use **Wait_For_Conversation** when running a background thread or a single-threaded application for Microsoft Windows Server 2003 or Windows 2000. This most likely occurs when porting code from older versions of Host Integration Server and SNA Server.

Important
An application can set the processing mode by calling **Set_Processing_Mode**. If the window handle is set to NULL, or this call is never issued, the application must call **Wait_For_Conversation** to be notified when the outstanding operation completes.

When an asynchronous operation is complete, the applications window *hwndNotify* receives the message returned by **RegisterWindowMessage** with "WinAsyncCPIC" as the input string. The *wParam* value contains the conversation return code from the operation that is completing. Its values depend on which operation was originally issued. The *lParam* argument contains the CM_PTR to the conversation identifier specified in the original function call.

WinCPICCleanup

Terminates and unregisters an application from a Windows CPI-C implementation.

Important
This function must be called by an application when finished to unregister the application from the Windows CPI-C implementation.

WinCPICExtractEvent

Provides a method for an application to determine the event handle being used for a CPI-C conversation.

WinCPICIsBlocking

Determines if a task is executing while waiting for a previous blocking call to finish. This was used when Windows version 3.*x* went into a **PeekMessageLoop** while allowing Windows to continue. Although a call issued on a blocking function appears to an application as though it blocks, the Windows CPI-C dynamic-link library (DLL) has to relinquish the processor to allow other applications to run. This means that it is possible for the application that issued the blocking call to be re-entered, depending on the messages it receives. In this instance, **WinCPICIsBlocking** can be used to determine whether the application task currently has been re-entered while waiting for an outstanding blocking call to finish.

This extension is intended to provide help to an application written to use the CM_BLOCKING characteristic of the Windows **Specify_Processing_Mode** function. **WinCPICIsBlocking** serves the same purpose as **InSendMessage** in the Windows

API.

Older applications that were originally targeted at Windows version 3.*x* and that support multiple conversations must specify CM_NONBLOCKING in **Specify_Processing_Mode** so they can support multiple outstanding operations simultaneously. Applications are still limited to one outstanding operation per conversation in all environments.

Note
Windows CPI-C prohibits more than one outstanding blocking call per thread.

WinCPICSetBlockingHook

Allows a Windows CPI-C implementation to block CPI-C function calls by means of a new function. Blocking calls apply only if you do not use asynchronous calls. If a function needs to block, the blocking call is called repeatedly until the original request completes. This allows Windows to continue to run while the original application waits for the call to return. Note that while inside the blocking call, the application can be re-entered. **WinCPICSetBlockingHook** was used by Windows version 3.*x* applications that went into a **PeekMessageLoop** to make blocking calls without blocking the rest of the system.

Note
By default, Windows Server2003 and Windows2000 do not go into a **PeekMessageLoop**. Rather, they block an event waiting for the call to complete. The only time you need to use **WinCPICSetBlockingHook** for Windows Server 2003 or Windows 2000 is when a single-threaded application for Windows Server 2003 or Windows 2000 shares common source code. In this case, you must explicitly make this call. Contrast this call with **WinCPICIsBlocking** and **WinCPICUnhookBlockingHook**.

WinCPICSetEvent

Associates a Win32 event handle with a verb completion.

WinCPICStartup

Allows an application to specify the version of Windows CPI-C required and to retrieve details of the specific CPI-C implementation.

Important
An application must call this function to register itself with a Windows CPI-C implementation before issuing any further Windows CPI-C calls.

WinCPICUnhookBlockingHook

Removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism.

Using Asynchronous Call Completion

With one exception, Microsoft® Host Integration Server permits one outstanding Windows® SNA asynchronous call per connection and one blocking verb per thread. The exception to this is that when issuing an asynchronous Receive call, the following calls can be issued while the **Receive** is outstanding:

- Cancel_Conversation
- Deallocate
- Request_To_Send
- Send_Error
- Test_Request_To_Send_Received

This enables an application, in particular a 5250 emulator, to use an asynchronous **Receive** to receive data. Use of this feature is strongly recommended.

The following example illustrates how to use asynchronous call completion with Host Integration Server:

```
void ProcessVerbCompletion (WPARAM wParam LPARAM lParam)
{
    for ( i = 0; i<nPendingVerbs; i++ )
        if (memcmp  (pPending [i].ConvID, (Conversation_ID) lParam)== 0)
            ProcessCommand  (wParam, lParam);
}

LRESULT CALLBACK SampleWndProc  ( . . .)
{
    if (msg = = uAsyncCPIC ) {
        ProcessVerbCompletion (wParam, lParam);
    }
    else switch  (msg)  {
       case WM_USER:
        Initialize_Conversation (lpConvId, "GORDM", &lError  );
        if  (lError  ! = CM_OK )   {
            ErrorDisplay ( ) ;
            break ;
        }
        Set_Processing_Mode (lpConvId, CM_NON_BLOCKING, &lError  ) ;
        if  ( lError ! = CM_OK )  {
            ErrorDisplay ( ) ;
            break ;
        }
        Allocate  (lpConvId,  &lError )  ;
        switch  (lError )  {
        case CM_OK:
            break ;
        case CM_OPERATION_INCOMPLETE:
            memcopy (pPending [nPending ++].ConvId, lpConvId, sizeof (C) ;
            break ;
        default:
            ErrorDisplay ( ) ;
        }
        break ;
}
WinMain  ( . . . )
{
    if  ( ( WinCPICStartup  ( . . . )  =  =  FALSE  )   {
        return FALSE;
    }
    uAsyncCPIC = RegisterWindowMessage  ("WinAsyncCPIC"");
```

```
    Specify_Windows_Handle  (hwndSample) ;
    while  (GetMessage  ( . . . )   )   {
    . . . . .
    }
    WinCPICCleanup  ( . . . )
}
```

For more information about CPI-C calls and Windows extensions, see CPI-C Calls and Extensions for the Windows Environment. For additional information about using CPI-C, see the *IBM Systems Application Architecture Common Programming Interface Communications Reference*, part number SC26-4399-04.

Initial Conversation Characteristics

Common Programming Interface for Communications (CPI-C) maintains a set of internal values called characteristics for each conversation. Some characteristics affect the overall operation of the conversation, such as the conversation type. Others affect the behavior of specific calls, such as the receive type.

Many of these characteristics are initially derived from the side information table (see Side Information for CPI-C Programs) in memory. Initialize_Conversation specifies the symbolic destination name (*sym_dest_name*) associated with the wanted side information table entry.

The following table lists the initial values of the conversation characteristics and tells which call can change a given value.

Characteristic	**Initial value set by Initialize_Conversation**	**Initial value set by Accept_Conversation**	**Can be changed by**
Conversation state	CM_INITIALIZE_STATE	CM_RECEIVE_STATE	Depends on call
Conversation type	CM_MAPPED_ CONVERSATION	The value specified by the invoking program.	Set_Conversation_Type
Deallocate type	CM_DEALLOCATE_ SYNC_LEVEL	CM_DEALLOCATE_ SYNC_LEVEL	Set_Deallocate_Type
Error direction	CM_RECEIVE_ERROR	CM_RECEIVE_ ERROR	Set_Error_Direction
Fill	CM_FILL_LL	CM_FILL_LL	Set_Fill
Log data	Null	Null	Set_Log_Data
Log data length	0	0	Set_Log_Data
Mode name	The mode name contained in the side information. If no *sym_dest_name* is specified, this is a null string.	The mode name for the session on which the conversation startup request arrived.	Set_Mode_Name
Mode name length	Length of mode name. If no *sym_dest_name* is specified, this is zero.	Length of mode name.	Set_Mode_Name
Partner LU name	The partner logical unit (LU) name contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	The partner LU name for the session on which the conversation startup request arrived.	Set_Partner_LU_Name
Partner LU name length	Length of partner LU name. If no *sym_dest_name* is specified, this is 1.	Length of partner LU name.	Set_Partner_LU_Name
Partner program name	The program name contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	Not applicable.	Set_TP_Name
Partner program name length	Length of partner program name. If no *sym_dest_name* is specified, this is 1.	Not applicable.	Set_TP_Name
Password	The password contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	The value specified by the invoking program.	Set_Conversation_Security_Password
Password length	Length of password. If no *sym_dest_name* is specified, this is 1.	Length of password.	Set_Conversation_Security_Password

Prepare-to-receive type	CM_PREP_TO_ RECEIVE_SYNC_ LEVEL	CM_PREP_TO_ RECEIVE_SYNC_ LEVEL	Set_Prepare_To_Receive_Type
Receive type	CM_RECEIVE_AND_ WAIT	CM_RECEIVE_AND_ WAIT	Set_Receive_Type
Return control	CM_WHEN_SESSION_ ALLOCATED	Not applicable.	Set_Return_Control
Security type	The security type contained in the side information.	The value specified by the invoking program.	Set_Conversation_Security_Type
Send type	CM_BUFFER_DATA	CM_BUFFER_DATA	Set_Send_Type
Synchronization level	CM_NONE	The value specified by the invoking program.	Set_Sync_Level
User identifier	The user identifier contained in the side information. If no *sym_dest_name* is specified, this is a single blank.	The value specified by the invoking program.	Set_Conversation_Security_User_ID
User identifier length	Length of user identifier. If no *sym_dest_name* is specified, this is 1.	Length of user identifier.	Set_Conversation_Security_User_ID

Side Information for CPI-C Programs

The information required for two Common Programming Interface for Communications (CPI-C) programs to communicate is stored as a table, called the side information table, in memory. The table is derived from the symbolic destination name (configured in Host Integration Server) and from the Set_CPIC_Side_Information, Extract_CPIC_Side_Information, and Delete_CPIC_Side_Information calls.

The side information is maintained by the system administrator.

If you are developing commercial programs or programs that will be installed on multiple computers within your organization, it is recommended that you include logic that enables a user or system administrator to specify configuration information for each copy of the program.

Each side information entry contains the following fields:

Symbolic destination name
This is the *sym_dest_name* parameter specified by Initialize_Conversation. It is the identifier for the side information entry. The name can be up to eight ASCII characters. See Set_CPIC_Side_Information for the allowed characters.

Partner LU name
This is the name by which the partner logical unit (LU) is known to the local program. It can be an alias of up to eight ASCII characters or a fully qualified network name of up to 17 characters. For the allowed characters, see Set_Partner_LU_Name.

Partner program type and name
These fields indicate whether the partner program is an application transaction program (TP) or an SNA service TP, and provide the partner program name. An application TP name can contain up to 64 ASCII characters. A service TP name can contain up to four characters. For the allowed characters, see Set_TP_Name.

Mode name
This name represents a set of characteristics to be used in an LU-to-LU session. The mode name can contain up to eight ASCII characters. For the allowed characters, see Set_Mode_Name.

Conversation security type
This field indicates whether security will be used and if so, what type.

You can use conversation security to require that the invoking program provides a user identifier and password before CPI-C allocates a conversation with the invoked program.

For an invoked program that in turn invokes another program, the security type can inform the second invoked program that security has already been verified.

For further information about conversation security, see Set_Conversation_Security_Type.

Security user identifier and password
If you intend to use conversation security, a valid combination of user identifier and password is required to access the invoked program. The user identifier and password can be up to 10 ASCII characters. For information about allowed characters, see Set_Conversation_Security_User_ID and Set_Conversation_Security_Password.

Configuration for CPI-C Programs

In addition to maintaining the side information (specified by *sym_dest_name*), the system administrator must define the following entities during configuration:

- Modes
- Local logical units (LUs)
- Partner LUs
- Invokable programs
- User identifiers and passwords

Note
For a user or group using transaction programs (TPs), 5250 emulators, or Advanced Program-to-Program Communications (APPC) applications, you can assign a default local APPC LU and a default remote APPC LU. These default LUs are accessed wh en the user or group member starts an APPC program (TP, 5250 emulator, or APPC application) and the program does not s pecify LU aliases by leaving the field NULL or filling with blanks.

CPI-C Considerations on Windows Server 2003, Windows XP, and Windows 2000

This topic summarizes information you should keep in mind when you develop programs based on Microsoft® Windows Server™ 2003, Windows® XP, and Windows 2000.

Asynchronous completion notification using message posting

When an asynchronous operation is complete, the applications window *hwndNotify* receives the message returned by **RegisterWindowMessage** with "WinAsyncCPIC" as the input string. The *wParam* value contains the *conversation_return_code* from the operation that is completing. Its values depend on which operation was originally issued. The *lParam* argument contains the CM_PTR to the *conversation_ID* specified in the original function call.

Asynchronous completion notification using Win32® events

When a verb is issued on a nonblocking conversation, it returns CM_OPERATION_INCOMPLETE if it is going to complete asynchronously. If an event has been registered with the conversation, the application can call **WaitForSingleObject** or **WaitForMultipleObjects** to be notified of the completion of the verb. WinCPICExtractEvent allows a Common Programming Interface for Communications (CPI-C) applicationto determine this event handle. After the verb has completed, the application must call Wait_For_Conversationto determine the return code for the asynchronous verb. The Cancel_Conversationfunction can be called to cancel an operation and the conversation itself.

It is the responsibility of the application to reset the event, as it is with other APIs.

If no event has been registered, the asynchronous verb completes as it does at present, which is by posting a message to the window that the application has registered with the CPI-C library.

Byte ordering

By default, Intel-byte ordering is used. For inline environments, defining NON_INTEL_BYTE_ORDER does all the required flipping for constants. Nonconstant input parameters in verb control blocks (VCBs)—for example, lengths and pointers—are always in the native format.

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the VCB. This event must be in the nonsignaled state when passed to CPI-C, and the handle must have EVENT_MODIFY_STATE access to the event.

Library name

The Win32® DLL name is WINCPIC32.DLL.

Multiple threads

A transaction program (TP) can have multiple threads that issue verbs. Windows CPI-C makes provisions for multithreaded Windows-based processes. A process contains one or more threads of execution. All references to threads refer to actual threads in a multithreaded Windows environment.

Packing

For performance reasons, the VCBs are not packed. As a result, DWORDs are on DWORD boundaries, WORDs on WORDs, and BYTEs on BYTEs. VCBs should be accessed using the structures provided.

Run-time linking

For a TP to be dynamically linked to CPI-C at run time, the TP must issue:

- **LoadLibrary** to dynamically load WINCPIC.DLL or WINCPIC32.DLL, the libraries for WINCPIC.
- **GetProcAddress** to specify WINCPIC as the desired entry point to the dynamic-link library (DLL).
- **FreeLibrary** when the CPI-C library is no longer required.

Simultaneous conversations

A program can simultaneously participate in as many as 64 conversations per process.

Terminating applications

In Microsoft® Windows Server™ 2003 and Windows® 2000, CPI-C cannot tell when an application terminates. Therefore, if an application must close (for example, it receives a WM_CLOSE message as a result of an ALT+F4 from a user), the application should call WinCPICCleanup.

Yielding to other components

When processing CPI-C and Common Service Verbs (CSV), it may be necessary for the library code to yield to enable another component, such as the SnaBase, to receive messages and pass them to the application. This can be accomplished by using the Windows extensions WinCPICSetBlockingHook and WinCPICUnhookBlockingHook.

WinCPICSetBlockingHook enables a Windows CPI-C implementation to block CPI-C function calls by means of a new function. To call **WinCPICSetBlockingHook**:

```
FARPROC WINAPI WinCPICSetBlockingHook (FARPROC lpBlockFunc)
```

WinCPICUnhookBlockingHook removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism. To call **WinCPICUnhookBlockingHook**:

```
BOOL WINAPI WinCPICUnhookBlockingHook (void)
```

Operating Systems Support for CPI-C Development

Host Integration Server 2009 supports the development of CPI-C applications for Microsoft Windows Server 2003, Windows XP and Windows 2000. Support for CPI-C applications is provided only for the Win32 system.

The previous Microsoft SNA Server products also supported the development of CPI-C applications for Microsoft Windows NT, Windows 98, Windows 95, Windows 3.*x*, and OS/2. Most CPI-C applications developed for Windows 3.*x* and OS/2 with SNA Server can be used with Host Integration Server.

Finding Further Information about CPI-C

For information about SNA architecture, refer to your system network documentation.

CPI-C Call Summary

This section briefly describes each Common Programming Interface for Communications (CPI-C) call. The features provided by a CPI-C call can be broader than this section indicates. The calls are grouped in categories according to the function they perform. There are calls that start and stop a conversation, send and receive data, get information, and get side information.

This section contains:

Starting a Conversation

The calls in this category are used to start a conversation between two programs.

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Accept_Conversation(**cmaccp**)
Issued by the invoked program to accept the incoming conversation and set certain conversation characteristics. Upon successful execution of this call, Common Programming Interface for Communications (CPI-C) generates a conversation identifier.

Allocate(**cmallc**)
Issued by the invoking program to allocate a conversation with the partner program, using the current conversation characteristics. CPI-C can also start a session between the local logical unit (LU) and partner LU if one does not already exist. The type of conversation allocated depends on the conversation type characteristic—mapped or basic.

Initialize_Conversation(**cminit**)
Issued by the invoking program to obtain a conversation identifier and to set the initial values for the conversation's characteristics. The initial values are derived from side information associated with the symbolic destination name or are CPI-C defaults.

After issuing **Initialize_Conversation**, the invoking program can issue any of the following **Set_** calls to change the initial conversation characteristics. These calls cannot be issued after **Allocate** has been issued.

Call	**Sets**
Set_Conversation_Security_Password (**cmscsp**)	Security password
Set_Conversation_Security_Type(**cmscst**)	Conversation security type
Set_Conversation_Security_User_ID (**cmscsu**)	Security user identifier
Set_Conversation_Type (**cmsct**)	Conversation type
Set_Mode_Name (**cmsmn**)	Mode name
Set_Partner_LU_Name (**cmspln**)	Partner LU name
Set_Return_Control (**cmsrc**)	Return control
Set_Sync_Level (**cmssl**)	Synchronization level
Set_TP_Name (**cmstpn**)	Program name

Sending Data

The following calls are used to send data to the partner program:

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Confirm(**cmcfm**)
Sends the contents of the local logical unit's (LU) send buffer and a confirmation request to the partner program and waits for confirmation.

Flush(**cmflus**)
Sends the contents of the local LU's send buffer to the partner LU (and partner program). If the send buffer is empty, no action takes place.

Prepare_To_Receive(**cmptr**)
Changes the state of the conversation for the local program from SEND to RECEIVE, making it possible for the local program to begin receiving data. Before changing the conversation state, this call performs the equivalent of the **Flush** or **Confirm** call.

Request_To_Send(**cmrts**)
Notifies the partner program that the local program wants to send data. The partner program may or may not act on this request.

Send_Data(**cmsend**)
Puts data in the local LU's send buffer for transmission to the partner program. The data collected in the local LU's send buffer is transmitted to the partner LU (and partner program) when one of the following occurs:

- The send buffer fills up.
- The local program issues a **Flush**, **Confirm**, or Deallocate call or other call that flushes the LU's send buffer. (Some send types, set by **Set_Send_Type**, include flush functionality.)

Set_Prepare_To_Receive_Type(**cmsptr**)
Sets the conversation's prepare-to-receive type, which specifies whether subsequent **Prepare_To_Receive** calls will include **Flush** or **Confirm** functionality. The prepare-to-receive type affects all subsequent **Prepare_To_Receive** calls. It can be changed by reissuing **Set_Prepare_To_Receive_Type**.

Set_Send_Type(**cmsst**)
Sets the conversation's send type. The send type specifies how data will be sent by **Send_Data**. The send type can specify that only data be sent or that, in addition to sending data, Common Programming Interface for Communications (CPI-C) executes the equivalent of **Flush**, **Confirm**, **Prepare_To_Receive**, or Deallocate. The send type value affects all subsequent **Send_Data** calls. It can be changed by reissuing **Set_Send_Type**.

Receiving Data

The following calls or extensions enable a program to receive data from its partner program:

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Receive(**cmrcv**)
Issuing this call while the conversation is in RECEIVE state causes the local program to receive any data that is currently available from the partner program. If no data is available and the receive type is set to CM_RECEIVE _AND_WAIT, the local program waits for data to arrive. If the receive type is set to CM_RECEIVE_IMMEDIATE, the program does not wait.

Issuing this call while the conversation is in SEND or SEND_PENDING state is allowed only if the receive type is set to CM_RECEIVE_AND_WAIT. This flushes the logical unit's (LU) send buffer and changes the conversation state to RECEIVE. The local program then begins to receive data.

Set_Fill(**cmsf**)
Used in a basic conversation, this call sets the conversation's fill type, which specifies whether programs will receive data in the form of logical records or as a specified length of data. This call has an effect only in basic conversations. The fill value affects all subsequent **Receive** calls. It can be changed by reissuing **Set_Fill**.

Set_Processing_Mode(**cmspm**)
Specifies for the conversation whether subsequent calls will be returned when the operation they have requested is complete (blocking) or immediately after the operation is initiated (non-blocking). A program is notified of the completion of non-blocking calls when it issues Wait_For_Conversation or through a Microsoft® Windows® message sent to a WndProc identified by the *hwndNotify* parameter in **Specify_Windows_Handle**.

Set_Receive_Type(**cmsrt**)
Sets the conversation's receive type, which specifies whether a program issuing a **Receive** call will wait for data to arrive if data is not available. The receive type value affects all subsequent **Receive** calls. It can be changed by reissuing **Set_Receive_Type**.

Specify_Windows_Handle(**xchwnd**)
Sets the window handle to which a message is sent on completion of an operation in non-blocking mode. An application can set the processing mode by calling **Set_Processing_Mode**. If the window handle is set to NULL or this call is never issued, then the application must call **Wait_For_Conversation** to be notified when the outstanding operation completes.

WinCPICSetBlockingHook
Allows a Windows Common Programming Interface for Communications (CPI-C) implementation to block CPI-C function calls by means of a new function. This call had to be explicitly issued for Windows version 3.*x* applications to make blocking calls without blocking the rest of the system. Under Windows 2000 and later, this is not necessary.

A Windows CPI-C implementation has a default mechanism by which blocking CPI-C functions are implemented. This function enables the application to execute its own function at blocking time in place of the default function.

Confirming Receipt of Data and Reporting Errors

The following calls confirm receipt of data or report an error:

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Confirmed(**cmcfmd**)
Replies to a confirmation request from the partner program. It informs the partner program that the local program has not detected an error in the received data. Because the program issuing the confirmation request waits for a confirmation, **Confirmed** synchronizes the processing of the two programs.

Send_Error(**cmserr**)
Notifies the partner program that the local program has encountered an application-level error. The local program can use **Send_Error** to inform the partner program of an error encountered in received data, to reject a confirmation request, or to truncate an incomplete logical record it is sending.

Set_Error_Direction(**cmsed**)
Specifies whether a program detected an error while receiving data or while preparing to send data. Error direction is relevant only when a program issues **Send_Error** in SEND_PENDING state—immediately after issuing Receive and receiving data as well as a *status_received* value of CM_SEND_RECEIVED.

Set_Log_Data(**cmsld**)
Used in a basic conversation, this call specifies a log message (log data) and its length to be sent to the partner logical unit (LU). This call has an effect only in basic conversations. If present, log data is sent when **Send_Error** is issued or when the conversation is abnormally deallocated. After the log data is sent, Common Programming Interface for Communications (CPI-C) resets the log data to NULL and the log data length to zero.

Getting Information

The following calls retrieve information about the characteristics of a specified conversation:

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Extract_Conversation_Security_Type(**xcecst**)
Retrieves security type.

Extract_Conversation_Security_User_ID(**cmecsu**)
Retrieves security user identifier.

Extract_Conversation_State(**cmecs**)
Retrieves conversation state.

Extract_Conversation_Type(**cmect**)
Retrieves conversation type.

Extract_Mode_Name(**cmemn**)
Retrieves mode name.

Extract_Partner_LU_Name(**cmepln**)
Retrieves partner LU name.

Extract_Sync_Level(**cmesl**)
Retrieves synchronization level.

Test_Request_To_Send_Received(**cmtrts**)
Determines whether a request-to-send notification has been received from the partner program.

Ending a Conversation

The following calls end a conversation:

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Deallocate(**cmdeal**)
Deallocates a conversation between two programs. Before deallocating the conversation, this call performs the equivalent of the Flush or Confirm call, depending on the current conversation synchronization level and deallocate type.

Set_Deallocate_Type(**cmsdt**)
Specifies how the conversation is to be deallocated. The deallocation instructions specified by this call take effect when **Deallocate** is issued or when the send type is set to CM_SEND_AND_DEALLOCATE and Send_Data is issued.

Administering Side Information

The following calls let CPI-C applications add, replace, retrieve, or delete side information entries from memory:

Note
The names of the calls are pseudonyms. The actual C function names appear in parentheses after the pseudonyms. For example, **Accept_Conversation** is the pseudonym for a call. The actual function name is **cmaccp**.

Delete_CPIC_Side_Information **(xcmdsi)**
Deletes side information entry.

Extract_CPIC_Side_Information **(xcmesi)**
Retrieves side information.

Set_CPIC_Side_Information **(xcmssi)**
Adds or replaces side information entry.

Side Information for CPI-C Programs

Writing CPI-C Applications

A processing task accomplished by programs using Common Programming Interface for Communications (CPI-C) is called a transaction. Consequently, programs that use CPI-C are called transaction programs (TPs). These programs communicate as peers, on an equal (rather than hierarchical) basis. The TPs use CPI-C calls to exchange status information and application data. Each TP uses CPI-C calls to supply parameters to CPI-C, which performs the preferred function and returns parameters to the TP.

TPs distributed across a local or wide area network perform distributed transaction processing.

This section describes how to write transaction programs using CPI-C and how to configure the systems on which TPs run. The topics in this section cover the following general areas:

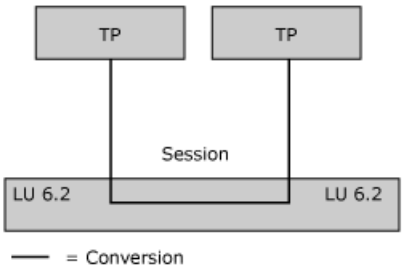
- Understanding fundamental concepts related to TPs.
- Designing and coding TPs.
- Configuring registry and environment variables for invokable TPs.
- Configuring Microsoft® Host Integration Server to work with your TPs.

This section contains:

Communication Between TPs

Various hardware and software elements in the SNA environment are required for two transaction programs (TPs) to communicate with each other. The following figure illustrates several fundamental elements.

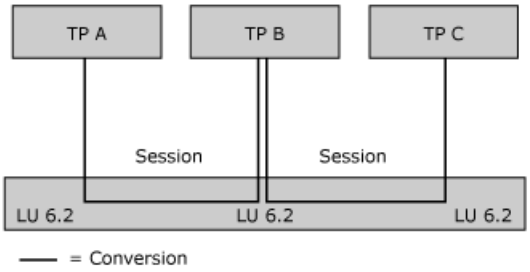
Fundamental hardware and software elements in the SNA environment



Each TP is associated with a logical unit (LU) of type 6.2. The LU enables the TP to access the network. Note that several TPs can be associated with the same LU.

A partner TP can invoke another TP, which, in turn, invokes another TP, and so on. In the following figure, TP A invokes TP B, and TP B invokes TP C.

Partner TP's invoking other partners



This section contains:

- Fundamental Terms for TPs and LUs
- Sample TPs Illustrating Fundamental Concepts
- Configuring and Controlling TPs
- Creating TPs and Their Supporting Configuration

Fundamental Terms for TPs and LUs

The following terms describe some fundamental characteristics of transaction programs (TPs) communicating through logical units (LUs):

basic conversation

A type of conversation more complex than a mapped conversation and generally used by service TPs (SNA-based programs that provide services to other programs). For a basic conversation, use Set_Conversation_Type and specify CM_BASIC_CONVERSATION for the *conversation_type*. For more information, see Basic and Mapped Conversations Compared.

conversation

The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously, as shown with TP B in Communication Between TPs.

invokable TP

A TP that can be invoked by another TP. Invokable TPs are usually server-type applications. That is, they work in the same general way that an IBM CICS application works. Parameters for an invokable TP are configured through registry or environment variables.

There are several types of invokable TPs:

operator-started invokable TP

A TP that is started manually in preparation for being invoked.

autostarted invokable TP

A TP that is automatically started by Common Programming Interface for Communications (CPI-C) when invoked.

queued TP

A TP that, when invoked multiple times, loads once, and then queues up subsequent requests to be dealt with one at a time. All operator-started TPs and some autostarted TPs are queued.

nonqueued TP

A TP loaded multiple times, once for every time it is invoked. Some autostarted TPs are nonqueued but no operator-started TPs are nonqueued.

For more information, see Invokable TPs.

invoking TP

A TP that can invoke (that is, initiate a conversation with) other TPs. Invoking TPs are usually client-type applications. That is, they work in the same general way that an emulator works. For more information see Invoking TPs.

local LU and local TP

An LU and TP working together, when viewed as the home base for a particular conversation. From this viewpoint, some other LU and TP are seen as the partner or remote LU and TP.

LU alias

The string that identifies an LU to a TP. The alias can be up to eight characters long.

LU-LU session

The communication between two LUs over a specific connection for a specific amount of time. An LU-LU session is needed for two TPs to interact. One session can be used serially by many pairs of TPs.

An LU 6.2 can have multiple sessions (two or more concurrent sessions with different partner LUs) and parallel sessions (two or more concurrent sessions with the same partner LU).

LUs are configured through SNA Manager on Host Integration Server 2009. This administration tool is also used to configure LU-LU pairs and modes. The LU and mode configurations control how many sessions a particular LU-LU pair supports.

mapped conversation

A type of conversation simpler than a basic conversation and generally used by application TPs (programs that accomplish tasks for end users). The default for conversation type is mapped. The conversation type can be changed with the Set_Conversation_Type call. For more information, see Basic and Mapped Conversations Compared.

partner LU and partner TP, or remote LU and remote TP

An LU and TP working together, when viewed as being at the far end of a particular conversation.

Sample TPs Illustrating Fundamental Concepts

A set of sample transaction programs (TPs) is provided on the Host Integration Server 2009 CD in the \SDK\Samples\SNA subdirectory. Included with the sample code is TPSETUP, a program that simplifies the setting of registry or environment variables needed by autostarted invokable TPs. Without an interface like that provided by TPSETUP, configuring such variables can be complicated and error-prone. Therefore, it is recommended that you use code like TPSETUP in installation programs for autostarted invokable TPs.

For information about TPSETUP and about the sample TPs, see CPI-C Samples.

Configuring and Controlling TPs

The following table shows how the characteristics of the transaction programs (TPs) and selection of the logical units (LUs) for a conversation are controlled.

Characteristic	How controlled
Type of conversation: basic or mapped.	Written into the code. For two TPs to communicate successfully, both must use the same type of conversation, basic or mapped. The default for conversation type is mapped. The type can be changed with the Set_Conversation_Type call. For more information, see Basic and Mapped Conversations Compared.
Type of TP: invoking or invokable.	Written into the code. Invoking TPs start with Initialize_Conversation and Allocate. Invokable TPs start with Accept_Conversation. For more information, see Invoking TPs and Invokable TPs.
The local LU alias to be used by an invoking TP.	Three options: • Configured with a registry or environment variable. • Configured (using SNA Manager) as the default local APPC LU for the user who starts the invoking TP. • Configured (using SNA Manager) as a member of the default outgoing local APPC LU pool. For more information, see Invoking TPs and SNA Service Configuration.
The symbolic destination name used by an invoking TP.	Written into the code, in Initialize_Conversation.
The invokable (partner) TP requested by an invoking TP.	Specified within the symbolic destination name, which can be configured using SNA Manager.
The LU alias to be used by an invokable TP (the partner LU alias from the point of view of the invoking TP).	Specified within the symbolic destination name, which can be configured through SNA Management using SNA Manager. For more information, see Invoking TPs and SNA Service Configuration and Matching Invoking and Invokable TPs.
Type of autostarted invokable TP: queued or nonqueued.	Configured with registry or environment variables. For more information, see Configuring Invokable TPs.
Local LU and remote LU aliases.	Configured using SNA Manager.
The pairing of local and remote LUs, and the mode used for each LU-LU pair.	Configured using SNA Manager.

Creating TPs and Their Supporting Configuration

The following procedure describes how to create transaction programs (TPs) and set up a supporting configuration.

To create TPs and set up a supporting configuration

1. Write, compile, and link each TP.
2. Place each TP on an appropriate computer.

   For TPs that you start many times or that are started by a user, arrange for the TP to be started easily. That is, for graphical interfaces, create a program icon for starting the TP and for non-graphical interfaces, make sure the TP is in the path.
3. On one or more computers running Host Integration Server, configure logical units (LUs), modes, LU-LU pairs, and a symbolic destination name for use by the TPs.

   For information about how to set up LU-LU pairs to support TPs, see Using Invoking and Invokable TPs.

   For information about symbolic destination names and side information, see Side Information for CPI-C Programs.
4. Set any registry or environment variables needed for the invoking and invokable TPs.

   For autostarted invokable TPs, it is recommended that you use the sample TP configuration program, TPSETUP, for this step. When you write an installation program for autostarted invokable TPs, it is recommended that you include code similar to TPSETUP.

   For information about registry or environment variables, see Configuring Invokable TPs and Invoking TPs. For information about TPSETUP, see CPI-C Samples.
5. If the invokable TP is operator-started, start it, or arrange for it to be started when the computer is restarted, and then restart the computer.

   If the invokable TP is autostarted, Host Integration Server will start it when needed.
6. Start the invoking TP.

Designing and Coding TPs

The following topics provide background information about designing and coding transaction programs (TPs).

This section contains:

CPI-C Calls in C Programs

This implementation of Common Programming Interface for Communications (CPI-C) is available to programs written in Microsoft® C version 6 or later.

The WINCPIC.H header file defines the prototypes for each CPI-C function. Other definitions include:

- Types specifically defined for use by CPI-C parameters.
- The structure of the side information entries.
- Symbolic names defined for integer parameters.

To use CPI-C calls, the C program must include WINCPIC.H and declare the variables to be used in passing parameters on CPI-C calls.

Note that you must define WIN32® before including WINCPIC.H

For example:

```
#define WIN32
#include <wincpic.h>
```

Note also that previous operating systems such as Microsoft® Windows® 98, Windows 95 and OS/2 are no longer supported.

In the case of strings, the program must also determine the preferred string length.

CPI-C and LU 6.2

Common Programming Interface for Communications (CPI-C) applications can communicate with non-CPI-C LU 6.2 applications, such as Advanced Program-to-Program Communications (APPC).

CPI-C supports all functions of logical unit (LU) 6.2 except for the following:

- Sync Point/back out processing
- PIP data
- LOCKS=LONG
- MAP_NAME
- FMH_DATA

Conversation States

The state of the conversation (as viewed by a particular transaction program (TP)) governs which Common Programming Interface for Communications (CPI-C) calls can be made by the TP at a particular time. For example, a TP cannot issue Send_Data if the conversation is not in SEND or SEND_PENDING state for that TP.

The state of a conversation depends on the TP from which it is viewed. A local TP can view a conversation as being in SEND state while the partner TP views the conversation as being in RECEIVE state. A particular TP can be in several conversations, each of which is in a different state.

The possible conversation states are summarized in this topic.

CONFIRM
The TP has received a request for confirmation of receipt of data. It must respond positively or send error information to the partner TP.

CONFIRM_DEALLOCATE
The TP has received a request for confirmation and must respond positively or send error information. If the TP responds positively, the conversation is automatically deallocated.

CONFIRM_SEND
The TP has received a request for confirmation. It must respond positively or send error information. After responding, the TP can begin to send data.

INITIALIZE
The conversation has been initialized successfully.

RECEIVE
The TP can receive application data and status information from the partner TP. When the conversation is in RECEIVE state, the TP can also send error information and request permission to send data.

RESET
The conversation has not started or has been terminated.

SEND
The TP can send data to the partner TP and request confirmation. When the conversation is in SEND state, the TP can also begin to receive data, which can cause the state to change to RECEIVE.

SEND_PENDING
The TP issued a Receive call and received data as well as a send indicator (*status_received* = CM_SEND_RECEIVED), indicating that the TP can begin to send data. This state differs from the SEND state, which occurs when the TP receives data on one **Receive** call and the send indicator on a subsequent **Receive** call.

This section contains:

- State Checks
- Changing Conversation States

State Checks

A state check occurs when a transaction program (TP) issues a Common Programming Interface for Communications (CPI-C) call and the conversation is not in the appropriate state. For example, a state check occurs if a TP issues Send_Data while the conversation is in RECEIVE state. When a state check occurs, CPI-C does not execute the call. It returns state check information through the *return_code* parameter.

Changing Conversation States

A change in the conversation state can result from:

- A call made by the local transaction program (TP).
- A call made by the partner TP.
- An error condition.

The following example shows how Common Programming Interface for Communications (CPI-C) calls can change the state of the conversation from SEND to RECEIVE and from RECEIVE to SEND.

Note
Any TP can send or receive data, regardless of whether it is the invoking TP (the TP that started the conversation) or the invokable TP (the TP that responded to a request to start a conversation).

This example shows how CPI-C calls can change the conversation state. In this table, each conversation state appears in bold and precedes the CPI-C calls that are used while in that state.

Issued by the invoking TP	**Issued by the invokable TP**
Conversation state: RESET	
Initialize_Conversation	
Conversation state: INITIALIZE	
Set_Sync_Level	
(sync_level=CM_CONFIRM)	
Allocate	
Conversation state: SEND	
Send_Data	
Prepare_to_Receive	**Conversation state: RESET**
	Accept_Conversation
	Conversation state: RECEIVE
	(status_received= CM_CONFIRM_SEND_RECEIVED)
	Conversation state: CONFIRM_SEND
	Confirm
	Conversation state: SEND
(return_code=CM_OK)	Send_Data

Conversation state: RECEIVE	Confirm
(status_received= CM_CONFIRM_RECEIVED)	
Conversation state: CONFIRM	
Request_To_Send	
Confirmed	
Conversation state: RECEIVE	(return_code=CM_OK)
	(request_to_send_received= CM_REQ_TO_SEND_RECEIVED)
	Prepare_To_Receive
Receive	
(status_received= CM_CONFIRM_SEND_RECEIVED)	
Conversation state: CONFIRM_SEND	
Confirmed	
Conversation state: SEND	(return_code=CM_OK)
	Conversation state: RECEIVE
Send_Data	
Deallocate	
	Receive
	(status_received= CM_CONFIRM_DEALLOC_RECEIVED)
	Conversation state: CONFIRM_DEALLOCATE
	Confirmed
(return_code=CM_OK)	**Conversation state: RESET**
Conversation state: RESET	

Initial States

Before the conversation is allocated, the state is RESET for both TPs.

In the example, after the conversation is allocated, the initial state is SEND for the invoking TP and RECEIVE for the invokable TP.

Changing to RECEIVE State

The Prepare_To_Receive call allows a TP to change the conversation from SEND to RECEIVE state. This call:

- Flushes the local LU's send buffer.

- Sends a CM_CONFIRM_SEND indicator to the partner TP through the *status_received* parameter of a Receive call, because the synchronization level is set to CM_CONFIRM. This indicator tells the partner TP that a Confirmed response is expected before the partner TP can begin to send data.

Changing to SEND State

The Request_To_Send call informs the partner TP (for which the conversation is in SEND state) that the local TP (for which the conversation is in RECEIVE state) wants to send data. This request is communicated to the partner TP through the *request_to_send_received* parameter of the Confirm call. (The *request_to_send_received* parameter is also returned to Send_Data and other calls.)

When the partner TP issues the Prepare_To_Receive call, the conversation state changes to RECEIVE for the partner TP, making it possible for the local TP to send data.

Important
Issuing Request_To_Send does not change the state of the conversation. Upon receiving a request to send, the partner TP is not required to change the conversation state. It can ignore the request.

Confirmation Processing

The sequence of events for confirmation processing is as follows:

1. Establish the synchronization level.
2. Send a confirmation request.
3. Receive data and confirmation request.
4. Respond to the confirmation request.
5. Deallocate the conversation.

Using confirmation processing, a transaction program (TP) sends a confirmation request with the data. The partner TP confirms receipt of the data or indicates that an error occurred. Each time the two TPs exchange a confirmation request and response, they are synchronized.

Note
Although the example in this section does not show this, any TP can send or receive data, regardless of whether the TP is the invoking TP or the invokable TP.

The following table illustrates the steps involved in confirmation processing.

Step	**Issued by the invoking TP**	**Issued by the invokable TP**
1	Initialize_Conversation	
2	Set_Sync_Level (*sync_level*=CM_CONFIRM)	
3	Allocate	
4	Send_Data	
5	Confirm	
6		Accept_Conversation
7		Receive (data_received= CM_COMPLETE_DATA_RECEIVED) (status_received= CM_CONFIRM_RECEIVED)
8		Confirmed
9	(*return_code*=CM_OK)	
10	Send_Data	
11	Deallocate	

12		Receive
13		(status_received= CM_CONFIRM_DEALLOC_RECEIVED)
14		Confirmed
15	(return_code=CM_OK)	

Establishing the Synchronization Level

The Set_Sync_Level call lets you override the default synchronization level of the conversation. The synchronization level is one of the conversation's characteristics. There are two possible synchronization levels:

- CM_CONFIRM, under which the TPs can request confirmation of receipt of data and respond to such requests.
- CM_NONE, the default, under which confirmation processing does not occur.

The Initialize_Conversation call sets the default characteristics of a conversation. There are several calls that begin with **Set**_. These calls let you override the default conversation characteristics.

Sending a Confirmation Request

Issuing the Confirm call has two effects:

- It flushes the local LU's send buffer and sends any data contained in the buffer to the partner TP.
- It sends a confirmation request that the partner TP receives through the *status_received* parameter of a Receive call.

After issuing **Confirm**, the local TP waits for confirmation from the partner TP.

Receiving a Confirmation Request

The *status_received* parameter of the Receive call indicates any future action required by the local TP.

In the example, the first Receive has a *status_received* of CM_CONFIRM_RECEIVED, indicating that a confirmation is required before the partner TP can continue.

Responding to a Confirmation Request

The partner TP issues the Confirmed call to confirm receipt of data. This frees the local TP to resume processing.

Deallocating the Conversation

Because the synchronization level of the conversation is set to CM_CONFIRM, Deallocate sends a confirmation request with the data flushed from the buffer.

For the second Receive call, *status_received* is CM_CONFIRM_DEALLOC_RECEIVED, indicating that the partner TP requires a confirmation, generated by the Confirmed call, before the conversation can be deallocated.

Conversation Security

You can use conversation security to require that the invoking transaction program (TP) provides a user identifier and password before Common Programming Interface for Communications (CPI-C) allocates a conversation with the invokable TP.

For the invoking TP, conversation security is activated and configured (with user identifier and password) through the symbolic destination name in SNA Manager or by the following calls, which override the symbolic destination name:

- Set_Conversation_Security_Type
- Set_Conversation_Security_User_ID
- Set_Conversation_Security_Password

For the invokable TP, conversation security is activated and configured through registry or environment variables on the computer where the invokable TP is located.

With communication involving more than two TPs, the verification of a user identifier and password can be passed from one TP to another. Suppose that TP A invokes TP B, which requires security information, and TP B in turn invokes TP C, which also requires security information. TP B can inform TP C that conversation security has already been verified.

For information about the registry or environment variables affecting conversation security, see Configuring Invokable TPs. For information about symbolic destination names and side information, see Side Information for CPI-C Programs.

Basic and Mapped Conversations Compared

The following table offers some guidelines for choosing between basic and mapped conversations for your transaction programs (TPs). The default for conversation type is mapped. To change to a basic conversation, use Set_Conversation_Type, and specify CM_BASIC_CONVERSATION for the *conversation_type*. For definitions of basic and mapped conversations, see Fundamental Terms for TPs and LUs.

Characteristic	**Basic conversations**	**Mapped conversations**
Common use	Generally used for service TPs.	Generally used for application TPs.
Partnering	Must be used to communicate with an existing TP that uses basic verbs.	Must be used to communicate with an existing TP that uses mapped verbs.
Sending and receiving method	Before a TP can begin a send operation, it must convert data records into logical records. The TP does this by adding a 2-byte prefix that indicates the length of the record. A TP can send several logical records at one time. When a partner TP receives logical records, it must reconstruct them into usable data records. For more information, see Logical Records Used in Basic Conversations.	A TP sends data one record at a time. Neither the sending TP nor the receiving TP needs to convert data records between different forms.
Abnormal termination	In theDeallocate call, a TP can indicate whether an error or ABEND (abnormal program termination) was caused by a TP or by a program using the TP.	A TP can indicate an error or ABEND, but cannot tell whether a problem was caused by a TP or by a program using a TP.
ABEND	A TP can indicate whether an ABEND was caused by a time-out or by a critical error.	A TP cannot indicate the cause of an ABEND.
Error logging	For an error or ABEND, a TP can send an error message, in the form of a general data stream (GDS) error log variable, to the local log and to the partner logical unit (LU).	For an error or ABEND, a TP cannot send an error message to the local log or to the partner LU.

This section contains:

- Logical Records Used in Basic Conversations
- An Example of a Mapped Conversation

Logical Records Used in Basic Conversations

Logical records are sent and received in basic conversations only.

A transaction program (TP) can send or receive multiple logical records with a single Send_Data or Receive call. A TP can also send or receive a logical record in successive portions: beginning, middle, and end.

A logical record is made up of:

- A 2-byte record-length (LL) field.
- A data field that can range in length from 0 bytes through 32765 bytes.

The LL field contains a hexadecimal value that is the length of the data field plus two bytes (for the LL field). For example, if a record contains 228 bytes of application data, the logical record length is 230. The LL field is 0x00E6, the hexadecimal equivalent of 230. If the length of the data field is 0, the value contained in the LL field is 0x0002.

Logical records are sent from or received in a data buffer established by the TP. In the data buffer, the LL field must not be in Intel byte-swapped format. For example, a length of 230 must be 0x00E6, not 0xE600.

The LL field cannot be 0x0000 or 0x0001, which allow less than the two bytes required for the LL field itself. The LL field also cannot be greater than or equal to 0x8000, which is equivalent to decimal 32768 and therefore allows for a data field greater than 32765 or an LL field greater than 2.

Setting the most significant bit of the LL field to 1 indicates that the information contained in the current logical record is continued in the next logical record.

An Example of a Mapped Conversation

The following example of a mapped conversation shows the Common Programming Interface for Communications (CPI-C) calls used to start a conversation, exchange data, and end the conversation. Call parameters are in parentheses.

Issued by the invoking TP	**Issued by the invokable TP**
Initialize_Conversation	
Allocate	
Send_Data	
Deallocate	Accept_Conversation
	Receive
	(data_received=
	CM_COMPLETE_DATA_RECEIVED)
	(*return_code*=
	CM_DEALLOCATED_NORMAL)

The following paragraphs describe the calls that are used in a mapped conversation.

Calls for Starting a Mapped Conversation

To start a conversation, the invoking transaction program (TP) issues the following calls:

- Initialize_Conversation, which requests CPI-C to set the values defining the characteristics of the conversation. The **Initialize_Conversation** call specifies a symbolic destination name that is associated with an entry in a side information table in memory. The side information specifies partner TP, partner LU, mode, security, and so on.

- Allocate, which requests that CPI-C establish a conversation between the invoking TP and the invokable TP.

The invokable TP issues the Accept_Conversation call, which informs CPI-C that it is ready to begin a conversation with the invoking TP.

Calls for Sending Data in a Mapped Conversation

The Send_Data call puts one data record (a record containing application data to be transmitted) in the send buffer of the local logical unit (LU). Data transmission to the partner TP does not happen until one of the following events occurs:

- The send buffer fills up.

- The sending TP makes a call that forces CPI-C to flush the buffer and send data to the partner TP.

In addition to the data record, the send buffer also contains the allocation request (which precedes the data record).

In the preceding example, Deallocate flushes the send buffer, sending the allocation request and data to the partner TP. Other calls that flush the buffer are Confirm and Flush.

Calls for Receiving Data in a Mapped Conversation

The **Receive** call receives the data record and status information from the partner TP. If no data or status information is currently available, the local TP, by default, waits for data to arrive.

The *data_received* parameter of Receive tells the program whether it received data and if so, whether or not the data is

complete.

Calls for Ending a Mapped Conversation

To end a conversation, one of the TPs issues Deallocate, which causes CPI-C to deallocate the conversation between the two TPs.

Using Invoking and Invokable TPs

There are two kinds of transaction programs (TPs): TPs that can invoke (that is, initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

The following topics describe how:

- Invoking TPs request invokable TPs.
- Invokable TPs identify themselves to the SNA service in preparation for being invoked.
- An invokable TP is matched to an invoking TP's request.

For information about how to configure logical units (LUs) to support TPs, see Configuring Host Integration Server to Support TPs.

This section contains:

Invoking TPs

An invoking transaction program (TP) can be located on any system on the SNA network. An invoking TP identifies itself by issuing Initialize_Conversation, which specifies the name of the invoking TP and the symbolic destination name to be used. A local logical unit (LU) alias can be specified for the invoking TP by using a registry or environment variable, as shown in the following table.

Operating system on computer that contains invoking TP	**Location and name of variable**
Windows 2000, Windows XP and Windows server 2003	Location in Windows 2000 registry: HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters Client <*exename*>:REG_SZ:*localLUalias* Any *exename* registry entries under the Client key represent the file names of Win32 executable files (without the file extension) for any invoking TPs. A REG_SZ value associated with each *exename* registry entry specifies the local LU alias for the invoking TP. For example, the APING.EXE Common Programming Interface for Communications (CPI-C) sample included with the Microsoft® Host Integration Server software development kit (SDK) would have the following registry entry: HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters Client APING:REG_SZ:*localLUalias*

The registry parameter for the local LU alias takes greatest precedence when associating a local LU to an invoking CPI-C application. If a registry value is not configured, two other methods are used to associate a local LU to the CPI-C application.

A local APPC LU can be associated with the user context under which the CPI-C application is running A local APPC LU can be configured by checking the **member of default local APPC LU pool** check box. Of the two possible options, a local LU associated with user context has the higher precedence.

If the local LU alias is not specified in a registry or environment variable, SNA service must be configured to supply it through one of these two types of default local LUs. Otherwise, Initialize_Conversation will fail. For more information, see Invoking TPs and SNA Service Configuration.

Next, the symbolic destination name specified in Initialize_Conversation provides the name of the invokable (or partner) TP and the partner LU alias (the LU alias to be used by the invokable TP). With this information available, the invoking TP can issue the Allocate call.

After a TP successfully issues an Allocate call, an allocation request flows. For more information about what happens after an invoking TP requests an invokable TP, see Matching Invoking and Invokable TPs.

Invoking TPs and Contention

The following information applies only to cases where logical units (LUs) are communicating in complex ways (such as chains of LUs) over multiple sessions. In such cases, two LUs may attempt to allocate a conversation on the same session at the same time. If this happens, one LU must win (the contention winner) and one must lose (the contention loser). The contention-winner LU and the contention-loser LU are determined for each session when the session is established. During that particular session, the contention-loser LU must receive permission from the contention-winner LU before allocating a conversation. In contrast, the contention-winner LU on that session allocates a conversation as needed.

Note that when two LUs are communicating over multiple sessions, one LU can be the contention winner for some of the sessions, and the other LU the contention winner for others.

An invoking transaction program (TP) operates most efficiently if the number of concurrent Allocate requests that the TP issues is matched by the number of sessions on which the local LU is the contention winner. The choice of contention winner is controlled through the modes configured at the two ends of the communication. A mode must be configured to work with the mode on the remote system for communication to begin between two LUs.

Invokable TPs

An invokable transaction program (TP) is a TP that can be invoked by another TP. Invokable TPs are written or configured through registry or environment variables to supply their names to the SNA service as a notification that they are available for incoming requests. An SNA service invokable TP can be run on any computer running Host Integration Server or client.

There are two types of invokable TPs:

Operator-started invokable TPs

An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies the SNA service of its availability by issuing an Accept_Conversation call. The **Accept_Conversation** call causes the name of the invokable TP to be communicated to all the SNA services in the domain, along with the alias of an associated LU if one has been configured through a registry or environment variable.

Autostarted invokable TPs

An autostarted invokable TP can be started by the SNA service when needed. The TP must be registered through registry entries or environment variables on its local system, so that it can be identified to the SnaBase component of the SNA service. The registered information defines the TP as autostarted and must specify the TP name. The registered information can also specify the local LU alias that the invokable TP will use.

The recommended method for setting registry or environment variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP, or similar code written into your own installation program. For more information about registry or environment variables for invokable TPs, see Configuring Invokable TPs. For information about TPSETUP, see CPI-C Samples.

If no local LU alias is registered with autostarted TPs, the resulting SNA service configuration can be more flexible in responding to invoking requests. For more information about such flexible configurations, see TP Name Not Unique; Local LU Alias Unspecified.

After an autostarted invokable TP is started by SNA service, the TP issues Accept_Conversation just as an operator-started TP does. Accept_Conversation must provide the TP name that was registered for the TP.

Autostarted TPs must be configured through registry or environment variables to be either queued or nonqueued. All operator-started TPs act as queued TPs.

Queued TPs

If an autostarted TP is configured as queued, or if the TP is operator-started, incoming allocation requests are queued, and then sent only when the invokable TP issues **Accept_Conversation**. For autostarted invokable TPs, if a copy of the TP is not yet running, one is started when an incoming allocation request specifies that TP.

Note
For the Microsoft® Windows Server™2003 and Windows2000 system, only one copy of a service can be running at any gi ven time. This means that all autostarted TPs that run as services under Windows Server2003 and Windows2000 must be queued. To write an autostarted TP so it runs under Windows Server2003 and Windows2000 as a service and also runs in a nonqueued way, write a multithreaded program with an **Accept_Conversation** always outstanding.

Nonqueued TPs

If an autostarted TP is configured as nonqueued, a new copy will be started every time an Allocate is received for the TP. Nonqueued TPs should process the conversation they have been allocated, and then exit, because they will not receive any additional **Allocate** requests.

Subcategories for Invokable TPs

The following table shows subcategories for invokable transaction programs (TPs).

Queued or nonqueued	Application or service	Starting method
Queued	Running as an application or a service	Autostarted or operator-started
Nonqueued	Running as an application	Autostarted

The concept of a TP running as a service or running as an application is distinct from a service TP or an application TP. Service TP and application TP are SNA terms that describe how a TP is used: either as a supportive service program for other Common Programming Interface for Communications (CPI-C) programs, or directly by a user, as an application. For detailed information about services in Windows Server 2003 and Windows 2000, see the documentation for Windows Server 2003 and Windows 2000.

To write an autostarted TP so it runs under Windows Server 2003 and Windows 2000 as a service and also runs in a nonqueued way, write a multithreaded program with an Accept_Conversation always outstanding. For more information, see Invokable TPs.

To run an autostarted TP as an application under Windows Server 2003 and Windows 2000, make sure the TPSTART program is always started before the TP. For more information, see CPI-C Samples.

Matching Invoking and Invokable TPs

Each SNA service maintains a list of available invokable transaction program (TP) names and any logical unit (LU) aliases to be associated with the TP names. This information is obtained as follows:

- For autostarted invokable TPs, registry or environment variables identify a TP name containing a maximum of eight characters, and can specify an associated LU. This information is sent from the client to the server that sponsors the client. A client learns about the domain through a sponsor connection to a server. Clients must establish the sponsor connection before proceeding with any other tasks.

- For operator-started invokable TPs, a TP name (with a maximum of 64 characters) is specified in Specify_Local_TP_Name. The TP name is truncated to eight characters and sent from the client to the server that sponsors the client, along with the alias of an associated LU if one has been configured through a registry or environment variable.

Note
If you want a TP name to be unique, it is recommended that you limit the name to eight characters or fewer, or make th e name unique within the first eight characters. This is because the preliminary routing of allocation requests is carried out using the first eight characters. Although further matching is later carried out between the full TP names, it is ineffic ient to allow the preliminary routing to succeed when in some cases the later matching will fail.

The next step in the matching of invoking and invokable TPs is the creation of a side information table from the parameters in the symbolic destination name. Then the invoking TP issues the Allocate call and an allocation request flows to the partner LU specified in the side information table, stating the name of the invokable TP that has been requested (also listed in the side information table).

When an allocation request arrives, the SNA service compares the requested invokable TP name and LU alias to the list of available invokable TPs (which can include associated LU aliases). The comparison can be modified by registry variables, but by default is carried out as follows:

- Although the TP name requested in the symbolic destination name can be as long as 64 characters, any name received through a registry or environment variable is limited to eight characters or less. Therefore, only the first eight characters of TP names are used in comparisons.

- The comparison is carried out first on both the TP name and the LU alias. An invokable TP for which there is a match on both TP name and LU alias will be chosen ahead of a TP for which no LU alias has been configured through a registry or environment variable. A TP for which no LU alias has been configured can be matched with any request that specifies that TP name, because there cannot be a mismatch based on LU alias.

- The comparison of requested and available TP names is carried out in a specific order:

    1. The SNA service first checks for operator-started invokable TPs on the local system (the local Host Integration Server).

    2. If no match is found, the SNA service checks for autostarted invokable TPs on the local system (the local Host Integration Server).

    3. If no match is found, the SNA service checks for operator-started invokable TPs on other computers running Host Integration Server or clients.

    4. If no match is found, the SNA service checks for autostarted invokable TPs on other computers running Host Integration Server or clients.

This comparison can be modified somewhat by registry entries for the SnaServr service. The entries are called **DloadMatchTPOnly** and **DloadMatchLocalFirst**.

If a match is found, the SNA service signals the system containing the requested TP to connect to that SNA service. If no match is found, the SNA service rejects the incoming request.

For suggestions about specific ways to handle TP names and LU aliases, see Arranging TPs Within an SNA Network.

Note

Because of the way Common Programming Interface for Communications (CPI-C) works, an allocation request does not flow until local data buffers are full, or a Confirm or Flush call is made. This may mean that the allocation request does not flow until some time after the Allocate call is made. Therefore, any allocation failure caused by the rejection of the allocation request at the partner LU will be observed as the failure of a later call with one of the allocation failure return codes.

Configuring Invokable TPs

The following topics tell how to configure invokable transaction programs (TPs) for the various Microsoft® SNA service client types.

This section contains:

- Clients Running Windows XP or Windows 2000

Clients Running Windows XP or Windows 2000

On clients running Microsoft® Windows® XP or Windows 2000, invokable transaction programs (TPs) are configured through the Windows XP or Windows 2000 registry.

Note
With WindowsXP and Windows2000, the recommended method for setting registry variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile INSTALL.C, the source code for TPSETUP, for the Windows XP and Windows2000 environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see CPI-C Samples.

For clients running Windows XP or Windows 2000, it is recommended that autostarted invokable TPs be written as Windows XP or Windows 2000 services. Be sure to include code like that in TPSETUP in the program that installs your TPs. Among other things, TPSETUP shows how to use the **CreateService** function when installing a TP. For important information about how services work under Windows 2000, see the documentation for Windows 2000.

The following table lists the registry entries used for the types of invokable TPs that can be run on Windows XP or Windows 2000 clients.

Type of TP	**Location in registry**	**Possible registry entries**
Autostarted invokable TP running as a service on Windows XP or Windows 2000 client.	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services *TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— Linkage OtherDependencies:REG_MULTI_SZ:SnaBase Parameters SNAServiceType:REG_DWORD:0x5 LocalLU:REG_SZ:*LUalias* Parameters:REG_SZ:*ParameterList* Timeout:REG_DWORD:*number* AcceptNames:REG_SZ:*TPNameList* ConversationSecurity:REG_SZ:{ YES | NO } AlreadyVerified:REG_SZ:{ YES | NO }*Username1*:REG_SZ:*Password1* ...*UsernameX*:REG_SZ:*PasswordX* For more information, see the notes following this table.
Autostarted invokable TP running as an application on a Windows XP or Windows 2000 client. For more information, see the notes following this table.	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters TPs *TPName*** Parameters	**SNAServiceType:**REG_DWORD:{ 0x5 | 0x6 }**PathName:**REG_EXPAND_SZ:*path***LocalLU:**REG_SZ:*LUalias***Parameters:**REG_SZ:*ParameterList***TimeOut:**REG_DWORD:*number***AcceptNames:**REG_SZ:*TPNameList***ConversationSecurity:**REG_SZ:{ YES | NO }**AlreadyVerified:**REG_SZ:{ YES | NO }***Username1*:**REG_SZ:*Password1* ...***UsernameX*:**REG_SZ:*PasswordX* For more information, see the notes following this table.
Operator-started invokable TP running as a service on a Windows XP or Windows 2000 client.	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services *TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— Linkage OtherDependencies:REG_MULTI_SZ:SnaBase Parameters SNAServiceType:REG_DWORD:0x1A LocalLU:REG_SZ:*LUalias* Timeout:REG_DWORD:*number* ConversationSecurity:REG_SZ:{ YES | NO } AlreadyVerified:REG_SZ:{ YES | NO }*Username1*:REG_SZ:*Password1* ...*UsernameX*:REG_SZ:*PasswordX* For more information, see the note following this table.

Operator-started invokable TP running as an application on a Windows XP or Windows 2000 client.	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters TPs *TPName*** Parameters	**SNAServiceType:**REG_DWORD:0x1A**LocalLU:**REG_SZ:*LUalias***TimeOut:**REG_DWORD:*number***ConversationSecurity:**REG_SZ:{ YES | NO }**AlreadyVerified:**REG_SZ:{ YES | NO }***Username1*:**REG_SZ:*Password1* ...***UsernameX*:**REG_SZ:*PasswordX* For more information, see the note following this table.

Note

Before an autostarted TP can be started as an application on a Windows 2000 or later client, the TPSTART program must be started. For more information, see CPI-C Samples.

Note

AlreadyVerified and Username/Password entries are used only if ConversationSecurity is set to YES.

This section contains:

- Registry Entries for Clients Running Windows XP or Windows 2000
- Example of Registry Entries for Windows XP or Windows 2000

Registry Entries for Clients Running Windows XP or Windows 2000

The following list gives details about registry entries for clients running Windows XP or Windows 2000. For each transaction program (TP) type, the applicable variables and their locations are shown in Clients Running Windows XP or Windows 2000.

OtherDependencies:REG_MULTI_SZ:SnaBase
For a TP running as a service, ensures that the SnaBase service is started before the TP is started. This entry belongs under the **Linkage** subkey.

SNAServiceType:REG_DWORD:{ 0x5 | 0x6 | 0x1A }
Indicates the type of TP. Use a value of 0x5 for an autostarted queued TP, 0x6 for an autostarted nonqueued TP, and 0x1A for an operator-started TP.

Note that the value for an autostarted TP running as a service must be 0x5, because these TPs are always queued, as described in Invokable TPs.

PathName:REG_EXPAND_SZ: *path*
For an autostarted TP running as an application, specifies the path and file name of the TP. The data type of REG_EXPAND_SZ means that the path can contain an expandable data string For example, %SystemRoot% represents the directory containing the Windows 2000 system files. Note that for a TP running as a service, an equivalent entry is inserted by the **CreateService** call. No additional path entry is needed.

LocalLU:REG_SZ: *LUalias*
Specifies the alias of the local LU to be used when this TP is started on this computer.

Parameters:REG_SZ: *ParameterList*
Lists parameters to be used by the TP. Separate parameters with spaces.

Timeout:REG_DWORD: *number*
Specifies the time, in milliseconds, that an Accept_Conversation will wait before timing out. Specify *number* in decimal. The registry editor converts this to hexadecimal before displaying it. The default is infinity (no limit).

AcceptNames:REG_SZ: *TPNameList*
With Windows 2000, used for autostarted TPs only. Lists additional names under which the invokable TP can be invoked. Separate TP names with spaces. The default is none. If an invokable TP does not issue a Specify_Local_TP_Name for each name configured under AcceptNames in the registry, that TP will fail.

ConversationSecurity:REG_SZ:{ YES | NO }
Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified:REG_SZ:{ YES | NO }
Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO.

For a diagram of three TPs in a conversation, where the third TP can be invoked with a password that is already verified by the second TP, see Communication Between TPs. The following table shows the requirements for using password verification in a chain of TPs.

First TP (an invoking TP)	Second TP (invokable TP that confirms password, and then invokes another TP)	Third and subsequent TPs (invokable TPs that invoke other TPs)
Does not need registry or environment variables.	**ConversationSecurity** setting must be YES.	**ConversationSecurity** setting must be YES.
Does not need registry or environment variables.	**AlreadyVerified** setting can be YES or NO.	**AlreadyVerified** setting must be YES.

Symbolic destination name or **Set_Conversation_ Security_Type** in this TP specifies PROGRAM for the security type. As a result, the TP passes along the user identifier and password supplied in the symbolic destination name (or through calls (1)).	Symbolic destination name or **Set_Conversation_ Security_Type** in this TP specifies SAME for the security type. As a result, after confirming the user identifier and password, the TP passes along the user identifier and an already-verified flag.	Symbolic destination name or **Set_Conversation_ Security_Type** in this TP specifies SAME for the security type. As a result, the TP passes along the user identifier as received, along with the already-verified flag.

Note

Set_Conversation_Security_User_ID or **Set_Conversation_Security_Password** overwrites the user identifier and password specified in the symbolic destination name.

Note

If you set **AlreadyVerified** to NO, this TP cannot join in a chain of conversations where password verification is already done. (The exception to this is when **ConversationSecurity** is set to NO, in which case the TP could be the final TP in such a chain, because it performs no checking.)

Note

If you are configuring a TP that sometimes needs to confirm a password and sometimes accepts an already-verified flag, set AlreadyVerified to YES and configure the *UsernameX* variable appropriately. In this case, whenever the TP is invoked without the already-verified flag set, AlreadyVerified is ignored. Verification is attempted with the user identifier and password configured for the TP.

Note

The default for AlreadyVerified is NO. If you set AlreadyVerified to YES, make sure that ConversationSecurity is also set to YES.

Username1 :REG_SZ: *Password1*... ***UsernameX***:REG_SZ: *PasswordX*

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can each be as many as 10 characters. Both parameters are case-sensitive.

This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the AlreadyVerified entry.

Example of Registry Entries for Windows XP or Windows 2000

For an autostarted invokable transaction program (TP) called **BounceTP** and running as a service, the following registry entries might be added to a client running Windows XP or Windows 2000. The entries would be added to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services**, under the subkeys shown in bold type.

Note

In the following list, the parameters listed directly under the **BounceTP** key (such as **DisplayName** and **ErrorControl**) are service parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code. They should not be set manually. For more information about TPSETUP, see CPI-C Samples.

BounceTP
DisplayName:REG_SZ:BounceTP**ErrorControl:**REG_DWORD:0x1**ImagePath:**REG_EXPAND_SZ:c:\sna\system\bouncetp.exe**ObjectName:**REG_SZ:LocalSystem**Start:**REG_DWORD:0x3**Type:**REG_DWORD:0

Configuring Host Integration Server to Support TPs

The following topics describe how the Host Integration Server 2009 configuration works with invoking and invokable transaction programs (TPs.)

In This Section

Invoking TPs and SNA Service Configuration

For an SNA service to support the beginning of the invoking process, the following parameters must be configured correctly:

- If the invoking transaction program (TP) specifies the logical unit (LU) alias that it uses (in a registry or environment variable), that LU alias must match a local Advanced Program-to-Program Communications (APPC) LU alias on the supporting SNA service. If the invoking TP does not specify a local LU alias, one of two methods for designating a default LU must be carried out on the supporting SNA service:

    - Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which Initialize_Conversation is issued).

      —or—

    - Designate one or more LUs as members of the default outgoing local APPC LU pool. Host Integration Server or SNA service first attempts to determine the default local APPC LU of the user who started the TP, then attempts to assign an available LU from the default outgoing local APPC LU pool. If these attempts fail, SNA service rejects the request.

- In most situations, the supporting SNA service must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, the SNA service contains two local LUs paired together (for invoking and invokable TPs that are in the same domain). In this situation, a connection to a host or peer is not necessary.

- The partner LU alias specified in the symbolic destination name must match an LU alias that is paired with the local LU alias used by the invoking TP.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured as described in Invokable TPs and the SNA Service Configuration.

Invokable TPs and the SNA Service Configuration

For an SNA service to receive allocation requests from an invoking transaction program (TP) on another system and route those requests to an invokable TP, certain parameters must be configured correctly:

- The SNA service must have a connection to the system from which the invoking TP's request is sent.

- The SNA service must have a remote logical unit (LU) capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly.

  When configured explicitly, there is an explicit match between a remote LU alias on the SNA service and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an implicit incoming remote LU (with its implicit incoming mode) is used. This means that several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the SNA service receiving the request. Second, the local LU on the server must have an implicit incoming remote LU assigned to it. The properties of the implicit incoming remote LU will be used for that LU-LU session.

- Appropriate local LUs must be defined in the SNA service configuration. For descriptions of several ways to set up these local LUs, see Arranging TPs Within an SNA Network.

Arranging TPs Within an SNA Network

If your Host Integration Server installation contains multiple systems (clients or SNA services), you can place a given invokable transaction program (TP) on more than one system. When an invoking request is received in such an installation, there can be a choice of systems on which to run the invokable TP. You can maintain specific control over this choice. Alternatively, by following the instructions in TP Name Not Unique; Local LU Alias Unspecified, you can enable SNA service to make the choice randomly to distribute the load.

You can maintain specific control over this choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique logical unit (LU) alias. With this arrangement, the information provided by the invoking TP (in the symbolic destination name) specifies the system on which the invokable TP should run.

You can allow the SNA service to make the system choice randomly by setting the **DloadMatchLocalFirst** registry entry to NO and using invokable TPs that leave the local LU alias unspecified. Then, when an incoming request is received, it is routed randomly, rather than preferentially to the local server. In addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. SNA service starts one instance of the requested TP, choosing randomly among the available systems.

The following topics describe some of the possible arrangements that can be made for running TPs.

This section contains:

- TP Name Unique for Each TP
- TP Name Not Unique; Local LU Alias Unique
- TP Name Not Unique; Local LU Alias Unspecified

TP Name Unique for Each TP

One way to specify the intended system where the invokable transaction program (TP) will run is to use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the intended invokable TP (and system) simply by naming the TP. This makes it unnecessary for an invokable TP to specify any logical unit (LU) alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unique

Another way to specify the intended system where the invokable transaction program (TP) will run is to give the same name to multiple invokable TPs, but associate each TP with a unique local logical unit (LU) alias. To do this, configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable transaction program (TP) runs, use the same name for multiple invokable TPs and do not specify a logical unit (LU) alias in the registry or environment variables for the TPs. In this situation, there are no associated LU aliases in the list of available invokable TP names on a computer running Host Integration Server. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

In this situation, if you set the **DloadMatchLocalFirst** registry entry to NO, the SNA service randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems and provides hot backup (the ability to take systems online and offline without disrupting service).

Troubleshooting for Invokable TPs

If there are difficulties with starting an invokable transaction program (TP), there may be a mismatch between the information for the invokable TP, the invoking TP, or logical units (LUs) in the SNA service configuration. That is, there may be a mismatch between the symbolic destination parameters, the registry or environment variables, or LU aliases specified in SNA Manager. For details about how to specify LU aliases in SNA Manager, see Invoking TPs and SNA Service Configuration.

Simplifying CPI-C Configuration

There are several features in Host Integration Server 2009 that can simplify configuration for Common Programming Interface for Communications (CPI-C):

- The implicit, incoming remote logical unit (LU) and the implicit, incoming mode which allow SNA service to accept requests that arrive by unrecognized remote LUs and modes.

- The default local Advanced Program-to-Program Communications (APPC) LU and the default remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.

- The default outgoing local APPC LU pool, which enables LUs to be allocated dynamically to any invoking TP that does not specify a local LU.

- Automatic partnering, which automatically creates LU-LU pairs and assigns modes to the pairs.

Support for CPI-C Automatic Logon

This section describes the support for automatic logon for Common Programming Interface for Communications (CPI-C) applications that is available in Host Integration Server 2009. This feature requires specific configuration by the network administrator. The CPI-C application must be invoked on the local area network (LAN) side from a client of Host Integration Server. The client must be logged into a Microsoft Windows domain, and the client application must be running on Windows Server 2003, Windows XP, or Windows 2000.).

To use this feature, the CPI-C client application is coded to use program level security, with a special hard-coded user name of MS$SAME and password of MS$SAME. When this session allocation flows from client to SNA services, Host Integration Server looks up the host account and password corresponding to the Windows 2000 account under which the client is logged on, and substitutes the host account information into the APPC attach message it sends to the host.

Use the following function calls to use CPI-C:

- Call the Set_Conversation_Security_Type function with the *conversation_security_type* parameter set to CM_SECURITY_PROGRAM.

- Call the Set_Conversation_Security_User_ID function with the *security_user_ID* parameter set to the MS$SAME string and the *security_user_ID_length* parameter set to 7.

- Call the Set_Conversation_Security_Password function with the *security_password* parameter set to the MS$SAME string and the *security_password_length* parameter set to 7.

LUA Programmer's Guide

This section of the Host Integration Server 2009 Developer's Guide provides the programmatic techniques and procedures for creating applications with the logical unit application (LUA) programming interface.

For API references and other technical information about LUA, see LUA Programmer's Reference.

For sample code using LUA, see LUA Samples.

This section contains:

- LUA Guide
- LUA Concepts
- Writing LUA Applications
- Support for LUA Single Sign-On

LUA Guide

This section provides information required to develop C-language applications that use the conventional logical unit application (LUA) programming interface to exchange data in a Systems Network Architecture (SNA) environment.

This implementation of LUA is compatible with the Request Unit Interface (RUI) and the Session Level Interface (SLI) of earlier versions of the LUA for the Microsoft Windows NT and Microsoft Windows 95 operating systems, the Windows graphical environment, and the IBM Extended Services for OS/2 version 1.0.

This section provides conceptual information and detailed reference information.

To use this section effectively, you should be familiar with:

- Microsoft Host Integration Server 2009
- Microsoft Windows Server™ 2003 and Windows 2000 Server
- SNA concepts
- General concepts for the communications software you have installed. (Refer to your product documentation for information.)
- Microsoft Visual C++ version 6.0 or later

In This Section

Operating Systems Support for LUA Development

This section contains information relating to Microsoft Windows Server 2003 and Windows 2000 Server.

Host Integration Server 2009 supports the development of logical unit application (LUA) applications for Windows Server 2003 and Windows 2000 Server. Support for LUA applications is provided only for the Win32 system.

Finding Further Information about LUA

This section does not provide a detailed explanation of products, architectures, or standards other than those directly pertaining to the Microsoft® Windows® logical unit application (LUA) programming interface. For information about specific operating environments, refer to your system documentation. For information about SNA, refer to your system network documentation.

The following topics provide additional information about Microsoft Host Integration Server application programming interfaces (APIs) based on SNA architecture:

- About the APPC Guide
- APPC Programmer's Guide
- CPI-C Programmer's Guide

For more information about SNA and about 3270 information display systems, see the following manuals:

- *IBM 3270 Information Display System: 3274 Control Unit Description and Programmers Guide*
- *IBM 3270 Information Display System: Color and Programmed Symbols*
- *IBM 3270 Information Display System: 3274 Control Unit Display Station: Operators Guide*
- *IBM Systems Network Architecture: Technical Overview*
- *IBM Systems Network Architecture: Concepts and Products*
- *IBM Advanced Communications Function Products Installation Guide*
- *IBM Installation and Resource Definition*
- *IBM 9370 LAN Token Ring Support*
- *IBM SNA Format and Protocol Reference Manual: Architectural Logic*

For background information about logical unit (LU) 6.2, Advanced Program-to-Program Communications (APPC), and/or the Common Programming Interface for Communications (CPI-C), see the following manuals:

- *IBM SNA: ACF/VTAM Programming for LU Type 6.2*

LUA Concepts

The conventional logical unit application (LUA) programming interface is an application programming interface (API) that enables you to write LUA applications to communicate with host applications.

The interface is provided at the request/response unit and session levels, enabling programmable control over the Systems Network Architecture (SNA) messages sent between your communications software and the host. It can be used to communicate with any of the logical unit types 0, 1, 2, or 3 at the host. The application must send the appropriate SNA messages as required by the host.

For example, you can use LUA to write a 3270 emulation program that communicates with a host 3270 application.

This section contains:

- Windows LUA Overview
- LUs and Sessions
- Configuring for LUA
- LUA Verb Summary
- A Sample LUA Communication Sequence

Windows LUA Overview

To provide one common application programming interface (API) to port applications from various operating environments to Microsoft® Windows Server™ 2003 or Windows® 2000 Server, a Windows Systems Network Architecture (SNA) standard was created. As a direct result of this work, Windows logical unit application (LUA) was developed. The LUA verbs, routines, and information presented in this guide represent an evolving Windows LUA that is based on IBM Extended Services for OS/2 version 1.0 and includes a set of Windows extensions.

The use of the Windows LUA interface on Windows Server 2003 or Windows 2000 causes additional threads to be created within the calling process. These other threads perform interprocess communication with the SNA service over the LAN interface that the client is configured to use (for example, TCP/IP, IPX/SPX, or named pipes).

If an application using Windows LUA is running on Windows Server 2003 or Windows 2000, stopping the SNABASE service causes the application to be unloaded from memory.

This section contains:

Windows LUA Asynchronous Support

Asynchronous verb completion returns immediately from issuing an initial verb (before results have been received) so the application can continue with other processes. A program that issues a verb and does not regain control until the operation completes cannot perform any other operations. This synchronous type of operation, called blocking, is not suited to a server application designed to handle multiple requests from many clients.

By design, logical unit application (LUA) is asynchronous and uses semaphores for notification messages. Semaphores work well for Windows Server 2003 or Windows 2000. Windows LUA provides the following functions for issuing the Request Unit Interface (RUI) and Session Level Interface (SLI) verbs:

- RUI
- SLI
- WinRUI
- WinSLI

WinRUI and **WinSLI** provide asynchronous message notification for all Windows-based RUI and SLI verbs, while **RUI** and **SLI** provide support for event notification. Windows version 3.*x* applications use **WinRUI** and **WinSLI** for asynchronous message notification.

Asynchronous support allows you to be notified of verb completion based on a window handle. You can register a window handle using the RegisterWindowsMessage function with "WinRUI" or "WinSLI" as the string. You then issue a verb using the WinRUI or WINSLI function and passing a window handle. When the LUA verb conversation completes, a message is posted to the window handle that you passed, notifying you that the verb is complete.

The only other Windows extension functions required for Windows LUA are for initialization (WinRUIStartup or WinSLIStartup) and termination (WinRUICleanup or WinSLICleanup) purposes. Depending on your application, other Windows extensions may be useful, but they are not required. A complete description of all Windows LUA verbs, routines, and extensions is provided in LUA RUI Verbs, LUA SLI Verbs, and LUA Extensions for the Windows Environment.

Before Using Windows LUA

The following Windows extensions are of particular importance and should be reviewed before using the logical unit application (LUA) application programming interface (API) and this version of Host Integration Server 2009:

- RUI

  Provides event notification for all Request Unit Interface (RUI) verbs. The application must provide a handle to an event in the **lua_post_handle** member of the verb control block (VCB). The event must be in the not-signaled state. When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

- SLI

  Provides event notification for all Session Level Interface (SLI) verbs. The application must provide a handle to an event in the **lua_post_handle** member of the VCB. The event must be in the not-signaled state. When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

- WinRUI

  Provides asynchronous notification for all Windows-based RUI verbs. When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinRUI" as the input string. The *lParam* argument of the message contains the address of the VCB being posted as complete. The *wParam* argument of the message is undefined.

  An application must call WinRUIStartup for initialization before calling WinRUI.

- WinRUICleanup

  An application must call this function when finished using RUI verbs to deregister itself from the Windows LUA implementation. This function terminates and deregisters an application from a Windows LUA implementation.

- WinRUIStartup

  An application must call this function to register itself with a Windows LUA implementation before issuing any further Windows LUA calls using RUI verbs. This function allows an application to specify the version of Windows LUA required and to retrieve details of the specific LUA implementation.

- WinSLI

  Provides asynchronous notification for all Windows-based SLI verbs. When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinSLI" as the input string. The *lParam* argument of the message contains the address of the VCB being posted as complete. The *wParam* argument of the message is undefined.

  An application must call WinSLIStartup for initialization before calling WinSLI.

- WinSLICleanup

  An application must call this function when finished using SLI verbs to deregister itself from the Windows LUA implementation. This function terminates and deregisters an application from a Windows LUA implementation.

- WinSLIStartup

  An application must call this function to register itself with a Windows LUA implementation before issuing any further Windows LUA calls using SLI verbs. This function allows an application to specify the version of Windows LUA required

and to retrieve details of the specific LUA implementation.

Using LUA and Asynchronous Verb Completion

Host Integration Server permits one outstanding Windows SNA asynchronous call per connection and one blocking verb per thread. When the asynchronous verb completes, logical unit application (LUA) does the following for a Windows Server 2003 or Windows 2000 system.

Two types of notification are possible:

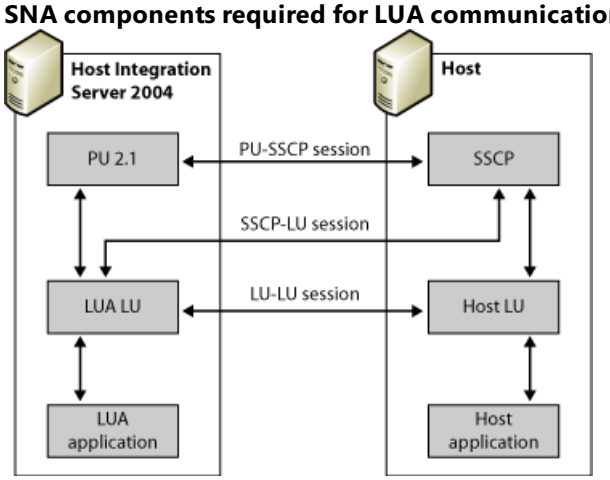
- The preferred type is the event method, in which the LUA application issues **WaitForSingleObject/WaitForMultipleObject**.

- The application can also post the"WinRUI"/"WinSLI" notification message to the window handle of the **WinRUI/WinSLI** message.

LUs and Sessions

The following figure shows the SNA components required for logical unit application (LUA) communications.

SNA components required for LUA communications



An LUA application uses a local LU, which uses Host Integration Server 2009 to communicate with the host system. There are three progressive sessions when Host Integration Server connects to the host node:

- The PU-SSCP session, between the Host Integration Server physical unit (PU) and the host's system services control point (SSCP). This is used mainly for diagnostic information. LUA communications require only the capabilities of PU 2.0. Host Integration Server provides these capabilities, plus the additional capabilities included in PU 2.1.
- The SSCP-LU session, between the LUA LU at the computer and the SSCP. This is used for controlling the LU.
- The LU-LU session, between the LUA LU at the computer and the host LU. This is used for data transfer between the computer and the host application.

LUA allows applications to send and receive data on the SSCP-LU session and on the LU-LU session. An LUA application can send data on this session using the common service verb TRANSFER_MS_DATA. LUA does not provide access to the PU-SSCP session.

The SSCP and LU sessions each provide two priorities of messages, normal and expedited. Expedited messages take precedence over other messages waiting to be transmitted on the same session. There are four different flows on which a message can be sent or received:

- SSCP session (expedited flow)
- LU session (expedited flow)
- SSCP session (normal flow)
- LU session (normal flow)

The LU session normal flow carries most of the data. The other flows are used only for control purposes.

Note
The implementation of LUA in Host Integration Server 2009 does not allow applications to send data on the SSCP expedited flow and does not return data to an application on this flow.

Configuring for LUA

The Host Integration Server 2009 configuration file, which is set up and maintained by the system administrator, contains information that is required for logical unit application (LUA) applications to communicate. An LUA LU is configured by the link service to use a connection to the host, and is given an LU number that matches that of an LU on the host.

The configuration can include LUA LU pools. A pool is a group of LUs with similar characteristics, and it enables an application to use any free LU from the pool. This feature can be used to allocate LUs on a first-come, first-served basis when there are more applications than LUs available, or to provide a choice of LUs on different connections.

The following communications components are configured for use with an LUA application.

Component	**Description**
Link service	A link service for communicating with the host. This component is normally configured by the Setup program during Host Integration Server 2009 installation.
Connection	A connection to the host that uses the link service.
Local node	A local node that owns the connection. This component is configured automatically.
LUA LU	An LUA LU on the local node, configured to use the connection, with an LU number that matches an LU on the host.
LUA LU pool (optional)	If necessary, you can configure more than one LUA LU for the application, and group the LUs into a pool. This means that an application can specify the pool rather than a specific LU when issuing the RUI_INIT verb to start a session. Host Integration Server 2009 uses this name in one of the following ways: • If the name supplied is the name of an LU that is not in a pool, a session is assigned using that LU if it is available (that is, if it is not already in use by an LUA application). • If the name supplied is the name of an LU pool, or the name of any LU within the pool, a session is assigned using the first available LU in the pool (if one is available). Note that this may not be the LU whose name was specified by the RUI_INIT verb.

LUA Verb Summary

Logical unit application (LUA) application programs can establish and use SNA sessions with either the Request Unit Interface (RUI) application programming interface (API) or the Session Level Interface (SLI) API. If an LUA application establishes an SNA session using **RUI_INIT**, it cannot issue any SLI verbs for that session. Likewise, if an LUA application establishes an SNA session using **SLI_OPEN**, it cannot issue any RUI verbs for that session.

Following is a brief summary of each LUA verb or user-supplied routine. Each verb supplies parameters to LUA, which performs the desired function and returns parameters to the application:

RUI_BID
: Allows the application to determine when information from the host is available to be read.

RUI_INIT
: Sets up the SSCP-LU session for an LUA application.

RUI_PURGE
: Cancels an outstanding **RUI_READ**.

RUI_READ
: Receives data or status information sent from the host to the LUA application's LU, on either the SSCP session or the LU session.

RUI_TERM
: Ends the SSCP session for an LUA application. It also terminates the LU session if it is active.

RUI_WRITE
: Sends data to the host on either the SSCP session or the LU session.

SLI_BID
: Notifies the SLI application that a message is waiting to be read using **SLI_RECEIVE**. It also provides the current status of the session to the LUA application.

SLI_BIND_ROUTINE
: An optional, user-supplied exit routine that notifies the LUA application that a BIND request has come from the host. It allows the routine to examine the request and formulate a response.

SLI_CLOSE
: Ends a session opened with **SLI_OPEN**.

SLI_OPEN
: Transfers control of the specified LU to the LUA application. It establishes a session between the SSCP and the specified LU, as well as an LU-LU session.

SLI_PURGE
: Cancels **SLI_RECEIVE** verbs issued with a wait condition.

SLI_RECEIVE
: Receives responses, SNA commands, and data into the buffer of an LUA application. It also provides the current status of the session to the LUA application.

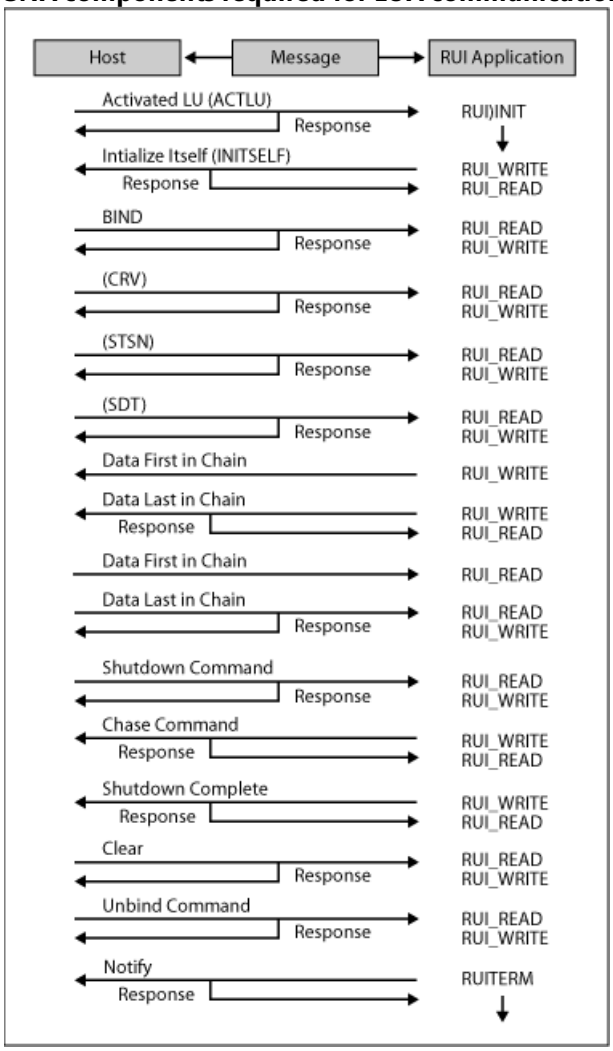
SLI_SEND
: Sends responses, SNA commands, and data from an LUA application to a host LU.

SLI_STSN_ROUTINE
: An optional, user-supplied exit routine that notifies the LUA application that a set and test sequence number (STSN) command has come from the host. It allows the routine to examine the request and formulate a response.

A Sample LUA Communication Sequence

This section illustrates how Request Unit Interface (RUI) and Session Level Interface (SLI) verbs are used for a logical unit application (LUA) communication sequence. The two figures illustrate the LUA verbs used to start a session, to exchange data, and to end the session, as well as the SNA messages sent and received. The arrows indicate the direction in which SNA messages flow.

Communication Sequence Using RUI Verbs
SNA components required for LUA communications



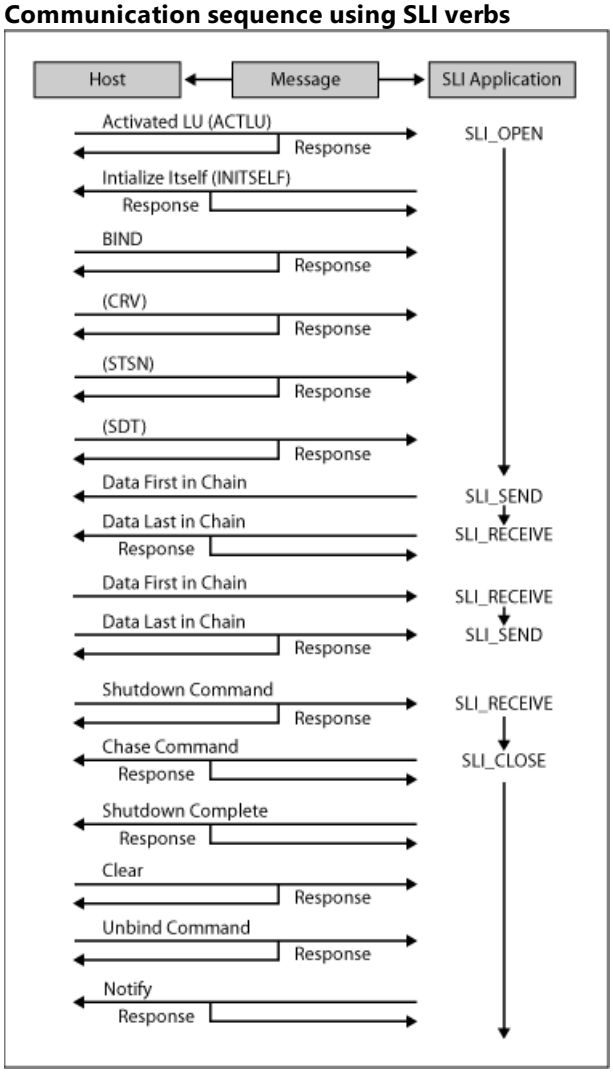
In this example, the application performs the following tasks:

- Issues an RUI_INIT verb to establish the system services control point (SSCP) session. (**RUI_INIT** does not complete until the LUA application has received an ACTLU message from the host and sent a positive response. However, these messages are handled by Host Integration Server 2009 and are not exposed to the LUA application.)
- Sends an INITSELF message to the SSCP to request a BIND and reads the response.
- Reads a BIND message from the host and writes the response. This establishes the LU session.
- Reads an SDT message from the host, which indicates that initialization is complete and data transfer can begin.
- Sends a chain of data consisting of three request/response units (RUs) and reads the response. The last RU indicates that a definite response is required.
- Reads a chain of data consisting of three RUs and writes the response.
- Reads an UNBIND message from the host and writes the response. This terminates the LU session.

- Issues RUI_TERM to terminate the SSCP session. (Host Integration Server sends a NOTIFY message to the host and waits for a positive response. However, these messages are handled by Host Integration Server and are not exposed to the LUA application.)

Communication Sequence Using SLI Verbs

Communication sequence using SLI verbs



In the example shown here, the application performs the following tasks:

- Issues an SLI_OPEN verb to establish the SSCP session.
- Sends an INITSELF message to the SSCP to request a BIND and reads the response.
- Reads a BIND message from the host and writes the response. This establishes the LU session.
- Reads an SDT message from the host, which indicates that initialization is complete and data transfer can begin.

> **Note**
> INITSELF, BIND, and SDT messages are handled by Host Integration Server if the application is using SLI. The **SLI_OPEN** does not return until Host Integration Server has sent an SDT and response.

- Issues SLI_SEND and SLI_RECEIVE to transfer data, SNA commands, or SNA responses between the host and the application.
- Issues SLI_CLOSE to terminate the SSCP session. (Host Integration Server sends a NOTIFY message to the host and waits for a positive response. However, these messages are handled by Host Integration Server and are not exposed to the LUA application.)

Writing LUA Applications

The information contained in this section will help you write logical unit application (LUA) application programs for use with Microsoft® Host Integration Server.

This section contains:

- Using LUA Verbs
- LUA VCB Format
- LUA Synchronous and Asynchronous Verb Completion
- Compiling and Linking an LUA Application
- Resetting LUA LUs
- Multiple Processes and Multiple Sessions Using LUA
- Programming Techniques for LUA Pools
- Writing Portable LUA Applications
- LUA System Considerations on Microsoft Windows Server 2003 or Windows 2000
- SNA Considerations Using LUA

Using LUA Verbs

This implementation of logical unit application (LUA) is available to applications written in Microsoft® C++® version 6.0 or later. Applications access all LUA functions on Microsoft Windows™ Server 2003 or Windows® 2000 Server by issuing verbs using the external C functions RUI,SLI,WinRUI, and WinSLI.

Symbolic constants are defined in the WINLUA.H header file for many parameter values. Refer to the WINLUA.H file (contained in the Microsoft Host Integration Server SDK) for a list of LUA constants.

You should use the symbolic constant and not the hexadecimal value when setting values for supplied parameters, or when testing values of returned parameters.

Parameters marked as reserved should always be set to zero.

This section contains:

- RUI and SLI Definitions
- Using an LUA Verb

RUI and SLI Definitions

The definitions of the RUI and SLI functions are as follows:

```
void WINAPI RUI(struct LUA_VERB_RECORD FAR * verb);
void WINAPI SLI(struct LUA_VERB_RECORD FAR * verb);
int WINAPI WinRUI(HWND handle, struct LUA_VERB_RECORD FAR * verb);
int WINAPI WinSLI(HWND handle, struct LUA_VERB_RECORD FAR * verb);
```

The WINLUA.H header file supplied with your Host Integration Server SDK includes prototypes of these functions.

The only parameter passed to the **RUI** or **SLI** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that:

- Identify the logical unit application (LUA) verb to be executed.
- Supply information used by the verb.
- Contain information returned by the verb when execution is complete.

The parameters passed to the WinRUIor WinSLI function are a window handle and the address of a VCB. The window handle is used for message notification when the issued verb has completed.

The VCB structure is declared in the WINLUA.H header file. For general VCB information, see LUA VCB Format. For verb-specific VCB information, see the reference documentation for each verb.

Issuing an LUA Verb

The following procedure is required to issue a logical unit application (LUA) verb. In this example, the verb issued is RUI_INIT.

To issue an LUA verb

1. Create a variable for the verb control block (VCB) structure. For example:

```
#include <winlua.h>
        .
        .
struct LUA_VERB_RECORD rui_init;
```

2. The LUA_VERB_RECORD structure is declared in the WINLUA.H header file.

3. Clear (set to zero) the variables within the VCB:

```
memset( &rui_init, 0, sizeof( rui_init) );
```

   LUA requires that all reserved parameters, and all parameters not required by the verb being issued, must be set to zero. The simplest way to do this is to set the entire VCB to zeros before setting the parameters required for this particular verb.

4. Assign values to the VCB parameters that supply information to LUA:

```
rui_init.common.lua_verb = LUA_VERB_RUI;
rui_init.common.lua_verb_length = sizeof(struct LUA_COMMON);
rui_init.common.lua_opcode = LUA_OPCODE_RUI_INIT;
memcpy (rui_init.common.lua_luname, "THISLU  ", 8);
```

   The values LUA_VERB_RUI and LUA_OPCODE_RUI_INIT are symbolic constants. These constants are defined in the WINLUA.H header file in the Host Integration Server SDK. To ensure portability between different systems, use symbolic constants and not integer values.

5. Invoke LUA. The only parameter is a pointer to the address of the structure containing the VCB for the desired verb.

```
RUI( &rui_init );
```

6. Check the asynchronous flag (**rui_init.common.lua_flag2.async**) to determine whether the verb completed asynchronously. If events are being used and the verb did complete asynchronously, wait for the event to complete.

```
if (rui_init.common.lua_flag2.async)
{
/* verb will complete asynchronously so continue
with other processing */
/* then wait */
WaitForSingleObject (...)
}
```

   Do not check the return code. It may have changed from LUA_IN_PROGRESS to LUA_OK by the time you check it.

7. Check the variables returned by LUA.

```
if( rui_init.common.lua_prim_rc == LUA_OK )
{
/* Init OK */
```

```
        .
        .
}
else
{
/* Do error routine */
        .
        .
}
```

LUA VCB Format

The logical unit application (LUA) verb control block (VCB) is called LUA_VERB_RECORD. It is a structure with two parts:

- A structure, LUA_COMMON, which is used for all the LUA verbs.
- A union, LUA_SPECIFIC, which is used only by RUI_BID,SLI_BID,SLI_OPEN, and SLI_SEND.

This section contains:

- LUA_VERB_RECORD
- LUA_COMMON
- LUA_SPECIFIC

LUA_VERB_RECORD

The logical unit application (LUA) verb control block (VCB) structure is as follows:

```
typedef struct LUA_VERB_RECORD {
    struct LUA_COMMON common;
    union LUA_SPECIFIC specific;
} LUA_VERB_RECORD;
```

Remarks

To access parameters in the common part of the VCB, you need to include the structure member name **common**. For example, when using a verb record structure named **Lua_Verb**, you access its **lua_prim_rc** member as **Lua_Verb.common.lua_prim_rc**.

To access parameters in the specific part of the VCB, you need to include the union member name **specific.** For example, when issuing RUI_BID using a verb record structure named **Lua_Verb**, you access its **lua_peek_data** member as **Lua_Verb.specific.lua_peek_data**.

For a complete listing of the structures and related values in the LUA VCB, see LUA Verb Control Blocks.

LUA_COMMON

The following structure lists the common data structure parameters used by all the logical unit application (LUA) verbs.

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
} LUA_COMMON;
```

Remarks

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs or LUA_VERB_SLI for Session Level Interface (SLI) verbs. For both of these macros the value is 0x5200.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, for example, LUA_OPCODE_RUI_BID for the RUI_BID verb.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_OPEN and RUI_INIT require this parameter. Other Windows LUA verbs only require this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Specifies the offset from the start of the VCB to the extension list of user-supplied dynamic-link libraries (DLLs). Not used by RUI in Host Integration Server and should be set to zero.

lua_cobol_offset

Offset of the COBOL extension. Not used by LUA in Host Integration Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Specifies the length of received buffer for RUI_READand SLI_RECEIVE. For other RUI and SLI verbs, it is not used and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of data returned in **lua_peek_data** for the RUI_BID verb.

lua_data_ptr

Pointer to the application-supplied buffer that contains the data to be sent for SLI_SEND and RUI_WRITE or that will receive data for **SLI_RECEIVE** and **RUI_READ**. For other RUI and SLI verbs, this parameter is not used and should be set to zero.

lua_post_handle

Supplied parameter. Used under Windows Server 2003 or Windows 2000 if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message sent or received. Various sub parameters are set for write functions and returned for read and bid functions.

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits.

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for the write function and returned by the read and bid functions.

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits.

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. This parameter is used by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, SLI_RECEIVE, and SLI_SEND. For other LUA verbs, this parameter is not used and should be set to zero.

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

SSCP expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. This is a returned parameter for RUI_INIT and SLI_OPEN and a supplied parameter for SLI_SEND. For other LUA verbs, this variable is not used and should be set to zero.

Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_CLEAR

LUA_MESSAGE_TYPE_CRV

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SHUTD

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_SDT

LUA_MESSAGE_TYPE_STSN

LUA_MESSAGE_TYPE_UNBIND

The SLI receives and responds to the BIND, CRV, and STSN requests through the LUA interface extension routines.

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. This parameter is returned by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, SLI_RECEIVE, and SLI_SEND. For other LUA verbs this parameter is not used and should be set to zero.

lua_flag2.bid_enable

Indicates that **RUI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Supplied parameter. Reserved field used by SLI_OPEN and RUI_INIT. For all other LUA verbs, this parameter is reserved and should be set to zero.

lua_encr_decr_option

Field for cryptography options. On **RUI_INIT**, only the following are supported:

- **lua_encr_decr_option** = 0
- **lua_encr_decr_option** = 128

For all other LUA verbs, this parameter is reserved and should be set to zero.

LUA_SPECIFIC

The following union shows the specific data structure that is included for functions that use the **LUA_SPECIFIC** part of a verb control block. The only logical unit application (LUA) verbs that use this union are RUI_BID,SLI_BID,SLI_OPEN, and SLI_SEND.

```
union LUA_SPECIFIC {
    struct SLI_OPEN open;
    unsigned char lua_sequence_number[2];
    unsigned char lua_peek_data[12];
} LUA_SPECIFIC;
```

Remarks

Members

open

The union member of **LUA_SPECIFIC** used by the **SLI_OPEN** verb.

lua_sequence_number

The union member of **LUA_SPECIFIC** used by the **SLI_SEND** verb. Returned parameter. Sequence number of the RU to the host.

lua_peek_data

The union member of **LUA_SPECIFIC** used by the **RUI_BID** and **SLI_BID** verbs. Returned parameter. Contains up to 12 bytes of the data waiting to be read.

LUA_SPECIFIC.SLI_OPEN

The following structure shows the **SLI_OPEN** fields of the **LUA SPECIFIC** union member for the SLI_OPEN verb.

```
struct SLI_OPEN {
    unsigned char lua_init_type;
    unsigned char lua_resv65;
    unsigned short lua_wait;
    struct LUA_EXT_ENTRY lua_open_extension[3];
    unsigned char lua_ending_delim;
} SLI_OPEN;
```

Remarks

Members

lua_init_type

Type of session initiation.

lua_resv65

Reserved field.

lua_wait

Secondary retry wait time.

lua_open_extension

Supplied parameter. Specifies any user-supplied dynamic-link libraries (DLLs) used to process specific LUA messages.

lua_ending_delim

Extension list delimiter.

LUA_EXT_ENTRY

The following structure shows the **LUA_EXT_ENTRY** fields of the LUA SPECIFIC.SLI_OPEN union member for the SLI_OPEN verb.

```
struct LUA_EXT_ENTRY {
     unsigned char lua_routine_type;
     unsigned char lua_module_name[9];
     unsigned char lua_procedure_name[33];
};
```

Remarks

Members

lua_routine_type

Extension routine type.

lua_module_name

Extension DLL module name.

lua_procedure_name

Procedure name to call in the extension DLL module.

LUA Synchronous and Asynchronous Verb Completion

Logical unit application (LUA) verbs can complete execution either synchronously or asynchronously.

Synchronous Verb Completion

When LUA is able to complete all the processing for a verb as soon as it is issued, the verb has completed synchronously. When this happens, the primary return code is set to a value other than LUA_IN_PROGRESS, and the **lua_flag2.async** bit is set to zero.

The value of the **lua_flag2.async** bit should be tested, not the primary return code being not equal to LUA_IN_PROGRESS. (For information about these returned parameters, see individual verb descriptions.)

Asynchronous Verb Completion

Some LUA verbs (for example, RUI_PURGE) complete quickly after local processing. However, most verbs take some time to complete because they require messages to be sent to and received from the local node or the host application.

When LUA must wait for information from the remote LU or from the local node before it can complete a verb, the verb completes asynchronously.

When this happens, the **lua_flag2.async** bit is set to 1. The primary return code is also normally set to LUA_IN_PROGRESS, but this value cannot be relied on. The value of the **lua_flag2.async** bit should be tested. The application can now perform other processing, or wait for notification from LUA that the verb has completed. LUA issues this notification by setting the primary return code to its final value and leaving **lua_flag2.async** set to 1.

When the verb completes, LUA does the following depending on your environment:

- For Windows Server 2003 or Windows 2000, two types of notification are possible. The LUA application either:

  Issues **WaitForSingleObject** or **WaitForMultipleObject**.

  —or—

  Posts the "WinRUI/WinSLI" notification message to the window handle of the **WinRUI**/**WinSLI** message.

  The event method using **WaitForSingleObject** or **WaitForMultipleObject** is the preferred way to receive asynchronous notification on Windows Server 2003 or Windows 2000.

- In the Windows environment, it notifies the completion of an asynchronous request by posting the "WinRUI/WinSLI" notification message to the window handle of the **WinRUI**/**WinSLI** message. A window handle has been added as the first parameter passed to the WinRUI and WinSLI entry points.

Compiling and Linking an LUA Application

Use the following procedure to compile and link a logical unit application (LUA) application.

To compile and link an LUA application for use with Host Integration Server

1. Update the path statement to include the directory containing the LUA application.
2. Set any required environmental variables.
3. Compile the application, including the WINLUA.H header file provided in the Host Integration Server SDK, to produce the .obj files.
4. Link the application with the WINLUA.LIB library to produce an .exe file.

Resetting LUA LUs

Microsoft® Host Integration Server provides a facility for resetting logical unit application (LUA) LUs or forcing off LUA applications, which is useful if an application has become deadlocked or is looping.

The NetView command **deactivate-oldlu** can also be used to reset an LUA LU. These facilities interact with the LUA application as described in the following paragraphs.

When an LUA LU is reset through Host Integration Server or by using the **deactivate-oldlu** command, Host Integration Server sends an UNBIND message to the application (as though the host had issued it).

The UNBIND message sent to the application is 0x32 0x0E, indicating a recoverable LU failure, and is returned to the application on a subsequent RUI_READ. The LU session is terminated, but the system services control point (SSCP) session remains active. (The LU is returned to the same state as if RUI_INIT has just completed.)

Multiple Processes and Multiple Sessions Using LUA

Two processes cannot use the same logical unit application (LUA) session. Only the process that issues RUI_INIT can use the session that is started by the verb. Before another process can use LUA, it must issue **RUI_INIT** to obtain a new session. However, different threads of the same process can issue verbs for the same LUA session.

A single process can simultaneously use more than one LUA session by issuing multiple **RUI_INIT** verbs. Win32® processes support for up to 15,000 sessions for applications based on the Microsoft® Windows Server™ 2003 or Windows® 2000 Server. Each session must use a different LU. Two or more sessions can use the same pool, but the **lua_luname** member (which is either the name of the pool or the name of an LU within the pool) must be different for each **RUI_INIT**.

Two or more instances of the same LUA application can run as different processes, but they must use different LUs. This can be done by using LU pools. The two processes can specify the same pool, but are allocated different LUs from that pool.

Programming Techniques for LUA Pools

When working with a logical unit application (LUA) LU pool, specify the pool name at the beginning of the conversation and then use the **lua_sid** member (not the pool name) with subsequent calls. This is necessary because the **lua_sid** member is a unique identifier, but the pool name is not, because a pool is designed to supply LUs for multiple conversations.

When using RUI_INIT or SLI_OPEN with an LUA pool, specify the pool name with the **lua_luname** member. For subsequent calls in the same conversation, use the **lua_sid** member returned from **RUI_INIT** or **SLI_OPEN** to specify the conversation.

Note
On completion of RUI_INIT or SLI_OPEN, the lua_luname member contains the actual name of the LU used. This allows you t o create code for a display for the user, showing the actual LU name used in a particular conversation.

Writing Portable LUA Applications

Use the following guidelines for writing logical unit application (LUA) applications that are portable to other environments:

- Use the symbolic constant names for parameter values and return codes, and not the numeric values shown in the WINLUA.H file. (For more information, see the WINLUA.H file in the Microsoft® Host Integration Server SDK.)

- When accessing SNAsense codes in a data buffer, use the symbolic constants rather than the numeric values. This ensures that the byte storage order is correct for your particular system. You should use **memcpy** to set the values, and **memcmp** to test them. For example:

```
memcpy (this_verb.common.lua_data_ptr, LUA_INCORRECT_REQ_CODE, 4);
if (memcmp (this_verb.common.lua_data_ptr,
LUA_INCORRECT_REQ_CODE, 4) == 0)
{
.....
}
```

- Ensure that any parameters shown as reserved are set to zero.

- Set the **lua_verb_length** parameter as described in the verb description.

LUA System Considerations on Microsoft Windows Server 2003 or Windows 2000

This section provides specific information about developing logical unit application (LUA) applications for the following operating systems.

This section contains:

- LUA Considerations on Microsoft Windows Server 2003 or Windows 2000

LUA Considerations on Windows Server 2003 or Windows 2000

This topic summarizes information for developing Win32 logical unit application (LUA) applications for Microsoft Windows Server 2003 or Windows 2000 Server.

Byte ordering

The values of constants defined in the WINLUA.H file are dependent on the byte ordering of the hardware used. Macros are used to set the constants to the correct value.

Currently, the include files in Windows Server 2003 or Windows 2000 to indicate the hardware. These same macros are used by Host Integration Server 2009, along with the Win32 macro, to indicate the byte ordering needs. The macros must be defined in the application or on the command line when building the application.

For example, the primary return code of LUA_PARAMETER_CHECK is defined to have a value of 0x0001. Depending on the environment, the constant LUA_PARAMETER_CHECK may or may not be 0x0001. Some formats define the value as it appears in memory. Others define it as a 2-byte variable. Because it cannot be assumed that an application will always use provided constants rather than hardwired values, a macro can be defined to swap the bytes. The following example shows how the macro can be used:

```
#define LUA_PARAMETER_CHECK LUA_FLIPI (0X0001)
```

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the verb control block (VCB). This event must be in the non-signaled state when passed to LUA, and the handle must have EVENT_MODIFY_STATE access to the event.

Library names

To support the coexistence of Win16 and Win32 API libraries on the same computer, the Win32 dynamic-link library (DLL) names were changed from the names used by Win16 API libraries. Win32 stub DLL libraries using the old names are supplied with Host Integration Server 2009 so that older applications will still run, although these platforms are no longer supported.

Old DLL names	New DLL names
WINRUI.DLL	WINRUI32.DLL
WINSLI.DLL	WINSLI32.DLL

The new DLL names should be used for all new applications intended to run on Host Integration Server.

Load-time linking

To be dynamically linked to LUA at load time, you must do one of the following at link time:

- Insert the following **IMPORTS** statements in the definition (.def) file used to link the application:

  (For RUI)

  ```
  IMPORTS WINRUI.RUI
  IMPORTS WINRUI WinRUI
  IMPORTS WINRUI.WinRUIStartup
  IMPORTS WINRUI.WinRUICleanup
  ```

  (For SLI)

  ```
  IMPORTS WINSLI.SLI
  IMPORTS WINSLI.WinSLI
  IMPORTS WINSLI.WinSLIStartup
  IMPORTS WINSLI.WinSLICleanup
  ```

- Link the application to WINRUI.LIB (for RUI) or WINSLI.LIB (for SLI), which contain the entry-point linkage information.

Multiple threads

An LUA application can have multiple threads that issue verbs. LUA for the Win32 system makes provisions for multithreading processes on Windows Server 2003 or Windows 2000. A process contains one or more threads of execution. All references to threads refer to actual threads in a multithreaded Windows Server 2003 or Windows 2000.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or DWORD boundaries, whichever is smaller. As a result, DWORDs are aligned on DWORD boundaries, WORDs are aligned on WORD boundaries, and BYTEs are aligned on BYTE boundaries. This means, for example, that there is a 2-byte gap between the primary and secondary return codes. Therefore, the elements in a VCB should only be accessed using the structures provided.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers. For compatibility with the supplied LUA libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Registering and deregistering applications

All LUA applications for the Windows Server 2003 or Windows 2000 system must call the Windows SNA extension WinRUIStartup or WinSLIStartup at the beginning of the session to register the application and WinRUICleanup or WinSLICleanup at the end of the session to deregister the application.

Restrictions on 3270-style LUs

A Windows Server 2003 or Windows 2000 process cannot access 3270-style LUs from both the function management interface (FMI) and LUA APIs at the same time. However, the process can use the LUA APIs to access LUA LUs while using FMI APIs to access 3270-style LUs.

Run-time linking

For an application to be dynamically linked to LUA at run time, it must issue the following calls:

- **LoadLibrary** to load the specified library module for Windows LUA. That is, WINRUI32.DLL (for RUI), and WINSLI32.DLL (for SLI).

- **GetProcAddress** to retrieve the address of the LUA function entry points exported by the DLL. For RUI, the function entry points are RUI, WinRUI, WinRUIStartup, and WinRUICleanup. For SLI, the function entry points are SLI, WinSLI, WinSLIStartup, and WinSLICleanup.

SNA Considerations Using LUA

This section explains SNA information you need to consider when writing logical unit application (LUA) applications.

BIND checking

During initialization of the LU session, the host sends to the LUA application a BIND message that contains information such as request/response unit (RU) sizes for use by the LU session. Microsoft® Host Integration Server returns this message to the LUA application on RUI_READ. The LUA application must verify that the parameters specified on the BIND are suitable. The application has the following options:

- It can accept the BIND as it is, by issuing RUI_WRITE containing an OK response to the BIND. No additional BIND data can be sent on the response.
- It can try to negotiate one or more BIND parameters. (This is only permitted if the BIND is negotiable.) To do this, the application issues **RUI_WRITE** containing an OK response, but including the modified BIND as data.
- It can reject the BIND by issuing **RUI_WRITE** containing a negative response, using an appropriate SNA sense code as data.

  Validating the BIND parameters and ensuring that all messages sent are consistent with them is the responsibility of the LUA application. However, the following two restrictions apply:

- Host Integration Server rejects any **RUI_WRITE** that specifies an RU length greater than the size specified on the BIND.
- Host Integration Server requires the BIND to specify that the secondary LU is the contention winner and that error recovery is the responsibility of the contention loser.

Note
For SLI, an application must specify that it will use SLI_BIND_ROUTINE on the SLI_OPEN if it will do any BIND checking.

Courtesy acknowledgments

Host Integration Server keeps a record of requests received from the host to correlate any response sent by the application with the appropriate request. When the application sends a response, Host Integration Server correlates the response with the data from the original request, and can then free the storage associated with it.

If the host specifies exception response only (a negative response can be sent but a positive response should not be sent), Host Integration Server must still keep a record of the request in case the application subsequently sends a negative response. If the application does not send a response, the storage associated with this request cannot be freed.

Because of this, Host Integration Server enables the LUA application to issue a positive response to an exception-response-only request from the host. (This is known as a courtesy acknowledgment.) The response is not sent to the host, but is used by LUA to clear the storage associated with the request.

Note
The application does not need to send a courtesy acknowledgment for each exception-response-only request. For efficiency, t he application can respond less frequently. The node treats a courtesy acknowledgment as an implicit acknowledgment for al l prior pending requests.

Distinguishing SNA sense codes from other secondary return codes

A secondary return code that is not a sense code always contains a value of zero in its first two bytes.

An SNA sense code always contains a nonzero value in its first two bytes. The first byte gives the sense code category and the second identifies a particular sense code within that category. (The third and fourth bytes can contain additional information or can be zero.)

Information on SNA sense codes

If you need information about a returned sense code, see

- Status-Error Message
- Error and Sense Codes

Negative responses and SNA sense codes

SNA sense codes can be returned to an LUA application in the following cases:

- When the host sends a negative response to a request from the LUA application, it includes an SNA sense code indicating the reason for the negative response. This is reported to the application on a subsequent RUI_READ or SLI_RECEIVE with the following information.

Sense code	Description
Primary return code	LUA_OK.
Request/response indicator, response type indicator, and sense data included indicator	All set to 1, indicating a negative response that includes sense data.
Data returned	The SNA sense code.

- When Host Integration Server receives invalid data from the host, it generally sends a negative response to the host and does not pass the invalid data to the LUA application. This is reported to the application on a subsequent RUI_READ,SLI_RECEIVE, RUI_BID,orSLI_BID with the following information:

Sense code	Description
Primary return code	LUA_NEGATIVE_RESPONSE.
Secondary return code	The SNA sense code sent to the host.

- In some cases, Host Integration Server detects that data supplied by the host is invalid, but cannot determine the correct sense code to send. In this case, it passes the invalid data in an exception request (EXR) to the LUA application on RUI_READ or SLI_RECEIVE with the following information.

Sense code	Description
Request/response indicator	Set to 0, indicating a request.
Sense data included indicator	Set to 1, indicating that sense data is included. (This indicator is normally used only for a response.)
Message data	A suggested SNA sense code.

The application must then send a negative response to the message. It can use the sense code suggested by Host Integration Server, or it can alter the sense code.

- Host Integration Server can send a sense code to the application to indicate that data supplied by the application was invalid. This is reported to the application on RUI_WRITE or SLI_SEND with the following information.

Sense code	Description
Primary return code	LUA_UNSUCCESSFUL.
Secondary return code	SNA sense code.

The sense codes that can be returned as secondary return codes on LUA verbs are listed in the WINLUA.H header file. For this file, see the Host Integration Server or SNA SDK.

Pacing

Pacing is handled by the LUA interface. An LUA application does not need to control pacing and should never set the pacing indicator flag.

If pacing is being used on data sent from the LUA application to the host (determined by the BIND), RUI_WRITE or SLI_SEND may take some time to complete. This is because LUA has to wait for a pacing response from the host before it can send more data.

If an LUA application transfers large quantities of data in one direction, either to the host or from the host (for example, a file transfer application), the host configuration should specify that pacing is used in that direction. This ensures that the node receiving the data is not flooded with data and does not run out of data storage.

Purging data to end of chain

When the host sends a chain of request units to an LUA application, the application can wait until the last RU in the chain is received before sending a response, or it can send a negative response to an RU that is not the last in the chain. If a negative response is sent mid-chain, LUA purges all subsequent RUs from this chain and does not send them to the application.

When LUA receives the last RU in the chain, it indicates this to the application by setting the primary return code of RUI_READ or RUI_BID to LUA_NEGATIVE_RESPONSE with a zero secondary return code.

The host can terminate the chain by sending a message such as CANCEL while in mid-chain. In this case, the CANCEL message is returned to the application on RUI_READ. The LUA_NEGATIVE_RESPONSE return code is not used.

Segmentation

Segmentation of RUs is handled by the LUA interface. LUA always passes complete RUs to the application, and the application should pass complete RUs to LUA.

Support for LUA Single Sign-On

This section describes the logical unit application (LUA) support for Single Sign-On using 3270 display sessions that is available in Host Integration Server 2009.

Over 3270 LUs, a Single Sign-On feature for LUA applications is supported to automate the overall logon process. When configured for this feature, Host Integration Server 2009 automatically replaces special keywords in the data stream with the actual host user name and password at appropriate points in the session.

Note
Single Sign-On is not supported over LUA logical units (LUs).

To open 3270 LUs from an LUA application using Request Unit Interface (RUI), the **lua_resv56[1]** field must be set to a nonzero value when this verb control block (VCB) is passed to RUI_INIT. To open 3270 LUs from an LUA application using a Session Level Interface (SLI), the **lua_resv56[2]** field must be set to a nonzero value when this VCB is passed to SLI_OPEN. For details, see the reference sections in RUI_INIT and SLI_OPEN.

This section contains:

- Prerequisites for LUA Single Sign-On
- Registry Settings Used for LUA Single Sign-On
- LUA User Name and Password Replacement

Prerequisites for LUA Single Sign-On

In preparation for using Single Sign-On over 3270 logical units (LUs), the system administrator must define a host security domain containing host connections. This host security domain must be initially created or modified to enable the Single Sign-On feature. The system administrator must enable a users Microsoft® Windows Server™ 2003 or Windows® 2000 Server account in the host security domain and either the administrator or the user must establish a mapped host account for the Windows Server 2003 or Windows 2000 domain user name.

The user must be logged on to a Windows Server 2003 or Windows 2000 domain with a user name and password. Note that this Single Sign-On feature is only supported over 3270 LUs.

Registry Settings Used for LUA Single Sign-On

The logical unit application (LUA) Single Sign-On feature depends on Host Integration Server 2009 scanning 3270 logical units (LUs) used in the logon process for special keywords that are defined in the registry on the computer running Host Integration Server 2009. The values for these special keywords can be defined by the system administrator on the computer running Host Integration Server 2009.

The registry settings used by the LUA Single Sign-On process are located under the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services** registry node. Installed under the **SNASERVR\PARAMETERS** subkey are the following entries:

3270SSOPadByte

This entry should be set to an ASCIIZ string to use as the character for padding replacement text in the user name or password if these strings are shorter than the length of the special tag strings. The default value for this pad character is the ASCII space character.

3270SSOPostReplaceCount

This entry should be set to a DWORD that represents the number of message chains of request/response units (RUs) to scan after replacement of text for user name or password. The default value for this number is 10.

3270SSOPrefix

This entry should be set to an ASCIIZ string to use as the special prefix tag string in combination with the user name and password tags. The default value of this string is MS$.

3270SSOPwdTag

This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special host password string that will be replaced. The default value of this string is SAMEP, so the default host password string that is scanned for and replaced is MS$SAMEP. Note that length of the password string that is scanned for (MS$SAMEP, for example) determines the maximum length of the password string that can sent to the host using Single Sign-On. This limit occurs because the password substitution cannot change the length of the data message. Note that the value of this string must be different from the value of the **3270SSOUserTag** entry for Single Sign-On to function properly.

3270SSOReplaceCount

A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can be reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceCount** registry entry is defined and the **3270SSOReplaceTimer** registry entry is not defined, the node counts this number of RUs (on PLU-SLU session only) before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined, and the node defaults to a time-out of 30 seconds.

3270SSOReplaceTimer

A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can be reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceTimer** registry entry is defined and **3270SSOReplaceCount** is not defined, the node uses this value in seconds before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined and the node defaults to a time-out of 30 seconds.

3270SSOUserTag

This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special user name string that will be replaced. The default value of this string is SAMEU, so the default user name string that is scanned for and replaced is MS$SAMEU. Note that length of the user name string that is scanned for (MS$SAMEU, for example) determines the maximum length of the user name string that can sent to the host using Single Sign-On. This limit occurs because the user name substitution cannot change the length of the data message. Note that the value of this string must be different from the value of the **3270SSOPwdTag** entry for Single Sign-On to function properly.

LUA User Name and Password Replacement

The SNA node on the host monitors the inbound session for a replacement sequence consisting of the **3270SSOPrefix** string immediately followed by one of the strings **3270SSOUserTag** or **3270SSOPwdTag**. Thus, the default user name string that would be scanned for and replaced is MS$SAMEU. When this string is found in the inbound session data, the node looks up the corresponding information (host user name in the current host security domain) and overwrites MS$SAMEU with this information. The same process occurs for the password string that would be scanned for and replaced, which defaults to MS$SAMEP.

Note that this operation cannot change the length of the data message. If the actual user name or password that is retrieved from the current host security domain is shorter than the replacement sequence, it is padded out with the first character of the **3270SSOPadByte** string used as a padding character. If the actual host user name or password string is longer than the string that is scanned for, these strings are truncated to the length of the scanned string so that the data message length is not affected.

Note that because the user name and password can be sent in any order, the registry string values for the **3270SSOUserTag** and **3270SSOPwdTag** entries must be different for Single Sign-On to function properly.

The SNA node monitors the SSCP-LU session for these special tag strings at all times and replaces all occurrences of these strings with corresponding looked-up data. On the LU-LU session, the node starts monitoring at start of session (BIND). The node stops monitoring when it has received **3270SSOPostReplaceCount** chains of request/response units (RUs) without seeing a substitution tag. The node will not restart monitoring until it receives an UNBIND–BIND sequence for that session.

Note that the node considers the sequence:

```
BIND, data, UNBIND(BIND FORTHCOMING), BIND
```

as a continuation of the same LU-LU session and does not restart monitoring on receipt of the second BIND. This sequence is often used by host session managers handing off a session to an application system, and is considered a single terminal session.

User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the node has received **3270SSOPostReplaceCount** chains of RUs without seeing a substitution tag or a timer expires. By default the timer is set to 30 seconds, but this behavior can be reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node. After the timer expires, the node will stop scanning messages for the 3270 replacements strings for the user ID and password. If the replacement strings arrive after the timer expires, the replacement strings will be sent to the host unmodified causing the sign-on to fail. The application will not receive any notification that the timer has expired. The only indication of a problem will likely be that the sign-on to the host session has failed.

Note

All strings are specified in the registry in ASCII, but the node translates them to EBCDIC through AE character mapping before scanning for a match.

3270 Emulation Programmer's Guide

This section provides information for independent software vendors who are developing their own 3270 Emulator client software to work with Microsoft Host Integration Server 2009 or Microsoft SNA Server.

To use this section of the guide effectively, you should be familiar with:

- Host Integration Server 2009
- Microsoft Windows Server™ 2003 or Windows® 2000
- System Network Architecture (SNA) concepts

Operating systems support for 3270 development

Host Integration Server 2009 supports the development of 3270 client applications for Windows Server 2003, Windows XP, and Windows 2000.

Network operating systems support for 3270 development

Host Integration Server 2009 supports the following network operating systems:

- Native TCP/IP
- Novell NetWare

For API references and other technical information about the 3270 Emulator, see the3270 Emulator Programmer's Reference section of the SDK.

In This Section

- Host Integration Server Concepts for 3270 Client Access
- DL-BASE/DMOD Interface
- Function Management Interface
- FMI Status, Error, and Sense Codes
- Configuration Information
- Compiling and Linking 3270 Client Applications
- Support for 3270 Single Sign-On

Host Integration Server Concepts for 3270 Client Access

This section describes some key concepts used in Host Integration Server 2009 when providing 3270 client access. The purpose of this section is to provide information that enables independent software vendors to integrate their 3270 emulators with Host Integration Server. Only the relevant parts of the Host Integration Server architecture are described.

In This Section

Structure of 3270 Client Access Components

The components of Host Integration Server 2009 that apply to 3270 client access are:

- Local nodes
- Link services
- 3270 emulation program

This section introduces the structure of these components and explains specialized terms.

In This Section

Role of the Base

The Base is a part of each Host Integration Server gateway component, such as the local 2.1 node or a link service that provides the operating environment for the core functions of that component. It passes messages between components and provides functions common to all components, such as diagnostic tracing.

The Base type used with Host Integration Server 3270 emulation programs is DL-BASE. The Host Integration Server DL-BASE supports a single Host Integration Server component or a single user application, and has entry points for initialization, sending messages, receiving messages, and termination.

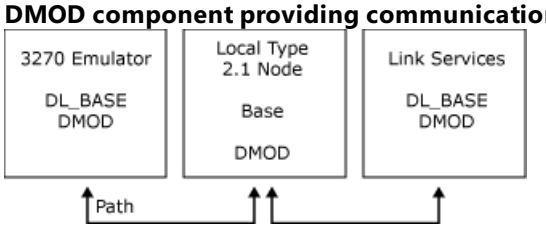
Localities and DMODs

A Base and the components within it are called a locality. The Host Integration Server system consists of one or more communicating localities, all running Host Integration Server executable programs within the local area network (LAN) Manager domain. For each Host Integration Server system, there is a single configuration file.

In a system such as Host Integration Server 2009, where the number of localities and their types are not configured in advance, the relationships between the localities are set up dynamically. Localities that can enter and leave a system in this way are called dynamic localities. Dynamic localities can enter or leave the system at any time.

Dynamic localities communicate using the Dynamic Access Module (DMOD) component, which provides the communications facilities needed to pass messages between the Bases. The following figure shows a system consisting of three dynamic localities.

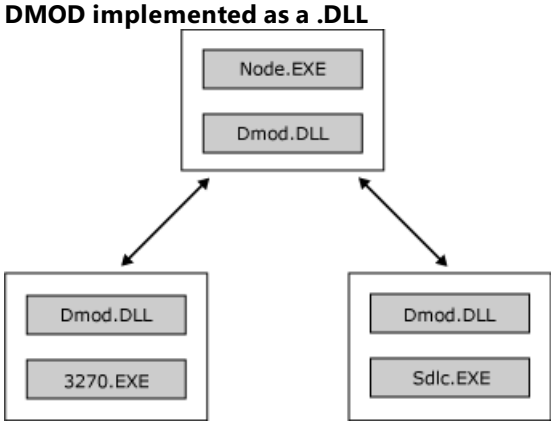
DMOD component providing communications



This figure shows a system consisting of three dynamic localities. Dynamic localities can enter or leave this system at any time.

The DMOD is implemented as a dynamic-link library (DLL). The preceding figure can therefore be represented as follows.

DMOD implemented as a .DLL



Application Localities

Applications such as 3270 emulators can enter dynamically into an SNA server system. The application, in conjunction with the Base, acts as a whole locality and communicates with the other localities in the system using a Dynamic Access Module (DMOD).

The topic DL-BASE/DMOD Interface describes the interface to the Base and the DMOD that enables an application to participate in an SNA server system.

Partners

For Host Integration Server components and applications to communicate with each other, it must be possible to identify a partner within a locality. A partner is an addressable component of a locality; that is, code to which messages can be sent. In a Host Integration Server system, there is generally only one partner within a locality (such as a link service or the 3270 emulation program). However, separate functions within the local 2.1 node (such as the 3270 and APPC functions) can be considered to be separate partners.

Messages

Messages are used to pass data between partners in Microsoft Host Integration Server 2009. This section provides information about message formats.

This section contains:

- Overview of Message Formats
- Buffer Header Format
- Buffer Element Format

Overview of Message Formats

A message always contains fixed-format header information such as a message type and addressing information. It can also contain other header information specific to a particular message type (such as the message subtype) and an indefinite amount of extra data.

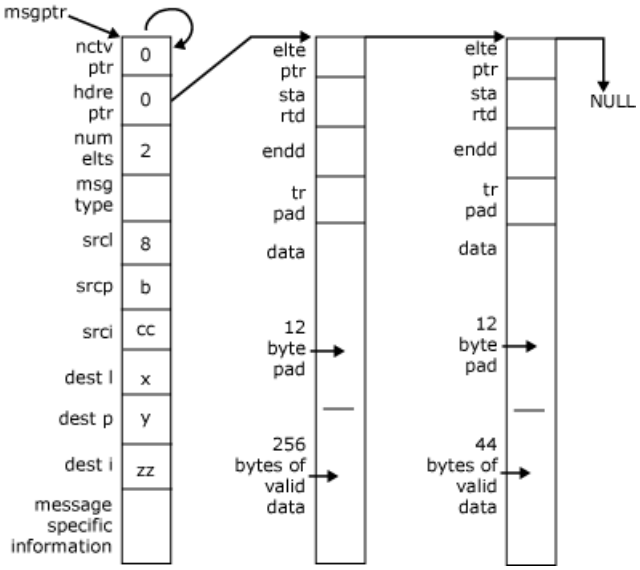
Messages are saved in buffers that consist of one header and zero or more elements:

- The header contains the fixed-format information and a pointer to an element. (This pointer is NULL if there are no elements associated with the message.)
- An element contains any extra data for a message and a pointer to another element if the data continues into another element.

Buffer headers and elements are regarded as contiguous (8-bit) byte sequences. Messages of any length can be built by chaining sufficient elements to a header.

The following figure shows a typical message with two elements.

Typical message with two elements



Buffer Header Format

The following table lists the common fields that always occur at the start of a buffer header. These are followed by further fields specific to the particular message. For details about individual message formats, see FMI Message Formats.

Field	Type	Description
nxtqptr	PTRBFHDR	When the buffer is in a queue, this field points to the header of the next buffer in the queue (NULL if it is the last buffer in the queue). When the buffer is not in a queue, this field points to itself. The SNA server buffer management routines use this field to check for buffer corruption.
hdreptr	PTRBFELT	Pointer to the first buffer element in the associated chain of buffer elements. NULL if the message consists only of a buffer header.
numelts	CHAR	Number of buffer elements chained from the header. Zero if the message consists only of a buffer header.
msgtype	CHAR	Message type. For details, see individual message descriptions in FMI Message Formats.
srcl	CHAR	Source locality. For details, see LPI Addresses.
srcp	CHAR	Source partner. For details, see LPI Addresses.
srci	INTEGER	Source index. For details, see LPI Addresses.
destl	CHAR	Destination locality. For details, see LPI Addresses.
destp	CHAR	Destination partner. For details, see LPI Addresses.
desti	INTEGER	Destination index. For details, see LPI Addresses.

Note

Fields that occupy two bytes, such as **opresid** in Open(PLU) Request are normally represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. However, the following fields are exceptions:

- The **srci** and **desti** fields in buffer headers are stored in the local format of the application that assigns them (only the assigning application needs to interpret these values).
- The **startd** and **endd** fields in elements are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).

Buffer Element Format

The following table lists the common fields that always occur at the start of a buffer element. The **dataru** field contains information specific to the particular message. For details about individual message formats, see FMI Message Formats.

Field	Type	Description
hdreptr->elteptr	PTRBFELT	Pointer to next buffer element in the chain. NULL if this element is the last or only element in the chain.
hdreptr->startd	INTEGER	Start of valid data in this element. The index into **dataru** of the first byte of valid data.
hdreptr->endd	INTEGER	End of valid data in this element. The index into **dataru** of the last byte of valid data.
hdreptr->trpad	CHAR	Pad byte (reserved).
hdreptr->dataru	CHAR[268]	An array of characters that contains the data for this element. Note that the valid data might not occupy the whole of the element. The **startd** and **endd** fields give the indexes into this array of the start and end of the valid data.

Use the following information to help you interpret the message formats:

- Certain messages are shown as having two elements in the message formats. For example, the Open(PLU) Request has the **CICB** field in the first element and the **BIND RU** in the second element. This indicates that the message consists of two distinct linked element chains. The **elteptr** field in the first element points to the second element.

- Fields that occupy two bytes are represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. The exceptions to this are the **startd** and **endd** fields in elements, which are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).

- The offsets indicated by the **startd** and **endd** fields are expressed in terms of the first byte of **dataru** being offset 1. The first byte of valid data is at **dataru[startd–1]**. For example, if **startd** is 11 and **endd** is 18, **dataru** begins with 10 bytes that are not valid data, followed by 8 bytes of valid data.

- It is possible for an element to arrive with **startd** greater than **endd**. This indicates there is no valid data in **dataru**.

In the sample message format shown in Overview of Message Formats, each element has a **startd** of 13, indicating 12 bytes of padding before the start of the valid data. This leaves room for 256 bytes of data, and so the element data (300 bytes long in this example) requires two elements.

LPI Connections

Partners communicate by passing messages to each other. If two partners want to communicate with each other, a locality partner index (LPI) connection is set up between the two partners. Messages then flow between the partners over this connection. The term LPI connection is explained in LPI Addresses. Note that this is not related to the Microsoft® Host Integration Server concept of a connection between the local node and a remote system.

This section contains:

- Paths and DMODs
- LPI Addresses
- Making Connections

Paths and DMODs

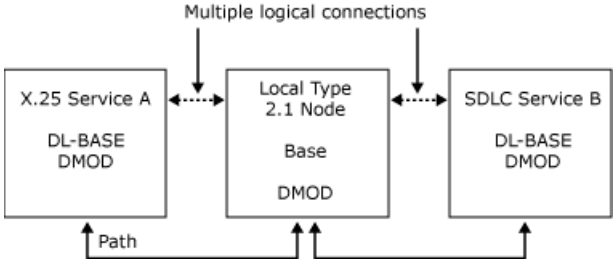
Dynamic Access Modules (DMODs) are responsible for the communication between localities. When the DMODs in two localities can successfully pass messages between them, a path exists between the two localities. A path must exist between two localities before a connection can exist between partners in those localities.

Host Integration Server establishes a path using an appropriate method for the network operating system in use. For example, with Microsoft LAN Manager, a named pipe is used. With NetWare, an SPX connection is used. When the two localities are on the same computer, a local pipe is used. This is implemented using shared buffers to increase performance, but is used by the application in exactly the same way as communication with a remote locality.

The DMOD provides communication between dynamic localities and provides guaranteed in-order delivery of messages flowing over paths between localities. If the DMOD loses its path to another locality, it informs the Base.

The following figure illustrates the paths and connections between an SNA services local node and two 3270 emulation programs. Program A has two connections to the local node (one for each of two sessions). Program B has one connection to the local node.

Paths and connections between an SNA server local node and two 3270 emulation programs



LPI Addresses

An LPI address is used to identify each end of a connection. It has three components: locality (L), partner (P), and index (I), as described in the following list:

- **Locality** is a 1-byte identifier that uniquely identifies a locality within a system. This locality corresponds to an SNA services component (local node, link service, 3270 emulator, and so on).

- **Partner** is a 1-byte identifier that uniquely identifies a partner within the locality. This is not always used, but can be used to distinguish between parts of a component (for example, the 3270 functions in the local node rather than the Advanced Program-to-Program Communications (APPC) functions).

- **Index** is a 2-byte identifier that uniquely identifies a logical entity within the partner. The meaning and use of this field is defined by the communicating partners. It is used to distinguish multiple connections between the same partners (for example, to identify one of many 3270 sessions between the local node and a particular 3270 emulator). The value of zero should not be used as an index value. Applications must assign unique index values for every active LPI connection with the node.

A message flowing over a connection carries a pair of LPIs that identify the source and destination of the message. These are the source LPI and destination LPI of the message. Together they identify the connection on which the message is flowing.

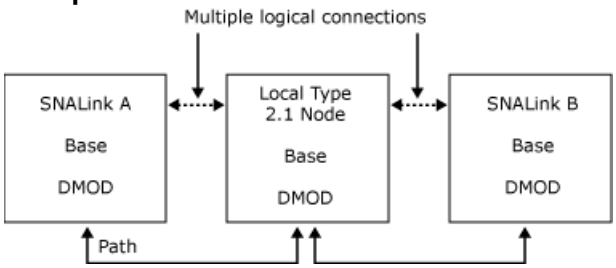
More than one connection can exist between any pair of partners. The I values are then used to distinguish the connections. For example, in communications between the local node and a 3270 emulator, the L and P values identify the message as being 3270 data for that local node, and the I value indicates which session the data is intended for.

The LPIs are assigned by a combination of the partners and the DMODs when the connection is opened, as described in Making Connections.

Because they are assigned dynamically for each component, the L values are not the same across an entire system. For example, a local 2.1 node locality could be known as locality 4 to one 3270 locality, and locality 6 to a second 3270 locality. However, from the viewpoint of any locality, there exists a unique L value for each remote locality within which a path exists. This L value is used as an index into an internal table that identifies the path to that locality.

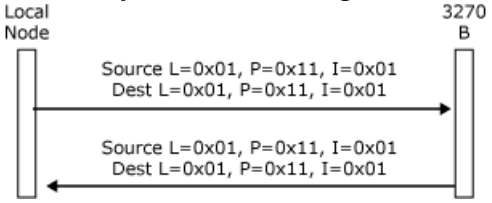
The following figures show an example of the L values that could be used between the components shown in Paths and DMODs, and examples of the LPI values that would be used by the local node on messages flowing between the components. (For more information about how the LPI values are assigned and used, see Opening the PLU Connection.)

Example L values



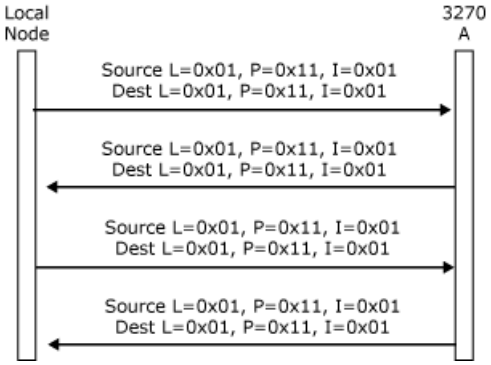
Example L values

L values specified on messages between the local node and 3270 B



L values specified on messages between the local node and 3270 B

LPI values specified on messages flowing on two different connections between the local node and 3270 A



LPI values specified on messages flowing on two different connections between the local node and 3270 A

The Base is called by any piece of code that wants to send a message. It uses the destination L value on the message to determine where to send it. When the message reaches the remote locality, the Base in that locality routes it to the appropriate partner if the locality contains more than one partner.

Making Connections

Before messages can flow across a connection, the connection must be established or opened. This is necessary because a partner (P1) does not initially know the locality partner index (LPI) address of the partner with which it wants to communicate. There may not even be a suitable partner with which to communicate.

A component of the Base, known as the Resource Locator, and a message with a type of Open, known as an Open message, are used to establish a connection between partners.

The following procedure outlines how a connection is established. More specific information is available in Function Management Interface.

To establish a connection between partners

1. The Open message has two forms: an Open request and an Open response. The Open request contains information on the type of partner P1 is looking for.

   P1 fills in an Open request and calls the Base with it. Because it does not know the LPI address of its partner, it sets the destination LPI values to zero.

2. The Base cannot forward the Open to a particular partner, because it has no destination LPI address. Therefore it passes the Open to the Resource Locator, which attempts to find a locality that will accept the Open. The Dynamic Access Module (DMOD) has a record of all the localities that could accept this type of Open. The Resource Locator tries each of these localities until the Open is accepted. If no locality is found, the Resource Locator returns a negative response to the Open to inform the sender that no partner could be found.

3. When a remote locality receives an Open, the Base passes the Open to the partner (P2). If P2 can accept the Open, it responds by sending a positive Open response message to P1.

4. The Open response message returned to P1 contains both the source and destination LPI values for the particular connection. At the end of this exchange, both P1 and P2 know each other's addresses and can communicate over the connection.

The terms source and destination in the context of LPIs refer to the source and destination of the particular message. When the 3270 emulator builds a message to send to the local 2.1 node, it needs to swap the source and destination LPIs received on the Open response from the local 2.1 node.

For a detailed example of how LPI addresses are assigned during initialization of the system services control point (SSCP) and primary logical unit (PLU) sessions, see Opening the PLU Connection.

DL-BASE/DMOD Interface

This section describes the interface to the Host Integration Server 2009 DL-BASE. It includes a listing of the entry points that an application such as a 3270 emulator can call. These entry points allow messages to be sent to and received from services such as the local 2.1 node.

In This Section

DL-BASE/DMOD

The following topics describe an example in which a 3270 emulator is to be adapted to use Host Integration Server 2009. The emulator must communicate with the local 2.1 node.

In This Section

Initialization

The 3270 emulator should initialize the DL-BASE and then call the Dynamic Access Module (DMOD) to obtain the necessary configuration information. This also registers the user name with the DMOD. It can then obtain further system information such as the Host Integration Server version number, if required.

The following table lists the functions involved with this process.

Function	Description
sbpuinit	Initializes the DL-BASE.
sepdcrec	Gets configuration information.
sepdgetinfo	Gets system information.

The **sbpuinit** entry point should always be called before any other DL-BASE/DMOD entry points except SNAGetVersion. For new emulators, **sepdcrec** should be called after **sbpuinit**. (Because of the order of calls used in older emulators, a call to **sepdcrec** before **sbpuinit** is still supported, but this order is not recommended.)

Sending Messages

The 3270 emulator inserts a message in a buffer and then calls the DL-BASE to send it. The message contains source and destination locality partner indexes (LPIs), which are set up when the connection is opened. For more information, see LPI Connections.

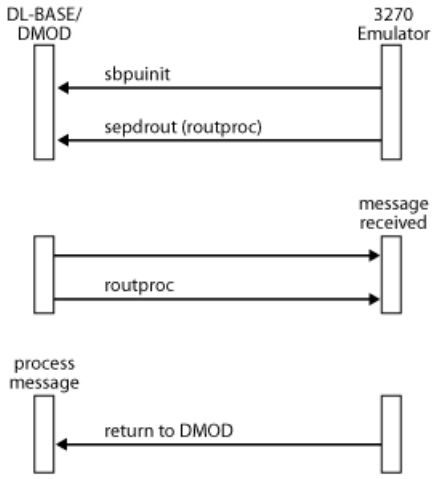
The application can either obtain a new buffer to contain the message to be sent (using sepdbubl), or reuse a buffer in which it previously received a message. The application is responsible for any buffer it has obtained or in which it has received a message. The application must either use (or reuse) the buffer to send a message or release it (using sepdburl). If the buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using sbpibegt) or release existing ones (using sbpiberl). In this case, it must also ensure that the **numelts** field in the buffer header indicates the correct number of elements.

The function used to send the message is sbpusend.

Receiving Messages

The following figure shows the method for receiving messages from the Dynamic Access Module (DMOD).

Receiving messages using a routing procedure



After DMOD initialization, the 3270 emulator registers the routing procedure by calling sepdrout. When the DMOD receives a message, it calls the 3270 emulator routing procedure, which can then process the message.

With this approach, there is no context switch between the DMOD thread and the 3270 emulator thread. However, the routing procedure must return control to the DMOD quickly. For instance, it cannot suspend waiting for a keyboard input.

The application must determine whether the received message is for this application or for another application. If the message is not for this application, the routing procedure must return, indicating that the message was not processed. If the application processes the message, it is responsible for freeing the buffer when the processing is finished.

In some cases, the routing procedure can process the message to completion. An alternative is for the routing procedure to put the message on an application queue and then clear an application semaphore. The application can then subsequently process the message.

Performance can be improved further by sending a Status-Resource message (to return credit to the local node, enabling it to send further data) from the routing procedure when a message is received, rather than waiting until the message is processed to completion. This usage is illustrated in Sample Code: Initialization and Routing Procedure. For more information about credit and flow control, see Pacing and Chunking.

After the application has received a message, the application is responsible for the buffer in which the message was received. The application must either reuse the buffer to send a message (using sbpusend) or release it (using sepdburl). If the buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using sbpibegt) or release existing ones (using sbpiberl). In this case, the application must also ensure that the **numelts** field in the buffer header indicates the correct number of elements.

Opening a Connection

Before a locality partner index (LPI) connection can be used to transfer data, it needs to be opened. This is performed by sending Open messages, starting with an Open request. The format of an Open message is defined by the interface being used. For example, the 3270 emulator uses the function management interface (FMI) to communicate with the local 2.1 node.

The interface also defines the initiator of the Open request. In this case, the 3270 emulator sends the Open(SSCP) Request, and the local 2.1 node sends the Open(PLU) Request.

On the **Open(SSCP) Request**, the 3270 emulator sets all the source and destination LPIs to zero, except for the source index, which can be used by the 3270 emulator for internal routing (for example, to distinguish between two sessions).

The DL-BASE and Dynamic Access Module (DMOD) ensure that Open messages are routed to a suitable destination. If a routing procedure is used, it should always first call sbpurcvx to process Open responses. When **sbpurcvx** indicates that it has not processed a received message, and the received message is an Open OK response, the application is informed that the connection was established successfully.

Termination

The 3270 emulator must call sbputerm to free DL-BASE/Dynamic Access Module (DMOD) resources before it terminates.

DL-BASE/DMOD Entry Point Summary

The following table shows entry points divided into the categories DL-BASE, Dynamic Access Module (DMOD), and buffer management, and listed in alphabetical order within each category.

DL-BASE entry points

DL-BASE entry points	Description
sbpuinit	Initializes the DL-BASE.
sbpurcvx	Processes Open from routing procedure.
sbpusend	Sends message.
sbputerm	Terminates.

DMOD entry points

DMOD entry points	Description
routproc	Sample routing procedure.
sepdchnk	Gets the function management interface (FMI) chunk size.
sepdcrec	Gets user and diagnostics records from configuration file.
sepdgetinfo	Gets SNA server system information.
sepdrout	Sets up the routing procedure (Microsoft® Windows Server™ 2003 and Windows® 2000 Server only).

Buffer management entry points

Buffer management entry points	Description
sbpibegt	Gets the buffer element.
sbpiberl	Releases the buffer element.
sepdbubl	Gets the buffer.
sepdburl	Releases the buffer.

Note

The standard-call convention (CDECL) is used on Windows Server2003 and Windows2000.

Note

The format of buffer headers and elements is described in Messages. The formats of individual messages contained in buffer s are defined in FMI Message Formats.

Sample Code: Initialization and Routing Procedure

This topic contains an outline of source code for receiving messages from the Dynamic Access Module (DMOD).

Note

TRACE*n*() is a macro used to specify data to be traced. This data can include variable parameters. The value **n** identifies the severity level of the trace. The unmatched parentheses are deliberate. They are resolved by the expansion of the macro.

Function Management Interface

The function management interface (FMI) provides applications with direct access to SNA data flows and information about SNA control flows by means of status messages. This section provides information about the SNA sessions and connections over which FMI messages can flow, and summarizes the messages. The FMI is particularly suited to the requirements of 3270 emulation applications.

In This Section

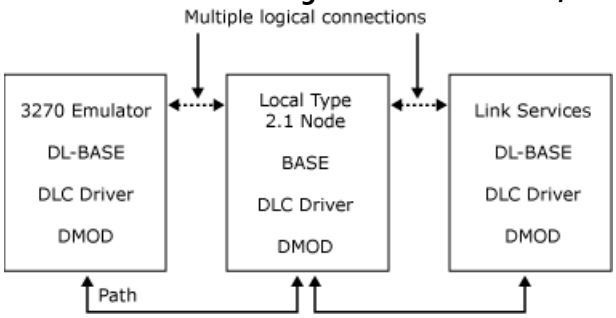
FMI Concepts

The local node provides the SNA layers of path control, transmission control, and data flow control (DFC), as well as logical unit (LU) services as shown in the following figure. In terms of the SNA layers, the function management interface (FMI) is between presentation services and DFC. This means that most of the SNA protocol handling is performed by the local node. In particular, the DFC layer of the local node is responsible for the state changes associated with chaining, bracket, and quiesce protocols.

The FMI is defined in terms of the messages that are sent across the interface. Note that this is logically distinct from the definition of the DL-BASE/Dynamic Access Module (DMOD) interface, which defines the mechanism for sending messages between two components in Microsoft® Host Integration Server (for example, between the local node and the 3270 emulator).

The FMI is used by LU types 0, 1, 2, and 3, but not by LU type 6.2. It provides access to the system services control point (SSCP)-LU session as well as the main primary logical unit (PLU)-SLU session. (For more information about these sessions, see Sessions and Connections.) An application can use the FMI to access multiple sessions and hence multiple LUs, simultaneously.

Emulator communicating with the local node, which communicates with the link service



In this example, the 3270 emulator on the client communicates over the local area network (LAN) with the local node on the server by exchanging messages. The content and format of the messages are defined by the FMI. The DMOD is used to transport the messages, but does not interpret them. The local node provides the SNA service for formatting the message. The link service and the data link control (DLC) driver are responsible for transferring data between the local node and the DLC adapter.

- Sessions and Connections
- Application Flags

Sessions and Connections

An application using the function management interface (FMI) can communicate with the host on two SNA sessions as described in the following list:

- The system services control point (SSCP) session, between an SNA server logical unit (LU) and the host SSCP, provides information about the activation of the LU and supports communication with the SSCP for commands such as character-coded and field-formatted logon and logoff commands. There is one SSCP session for each SNA server LU.

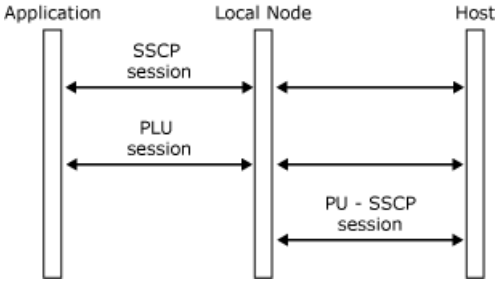
- The primary logical unit (PLU) session, between an SNA server LU and the host PLU, is the main session for data transfer between the local application and the host application. There is one PLU session for each SNA server LU.

The local node communicates directly with the host on the physical unit (PU)-SSCP session:

- The PU-SSCP session, between the PU (local node) and the host SSCP, supports the reporting of alert information and link statistics to the host SSCP.

The following figure shows the three sessions.

Three sessions



The application can communicate with the local node by means of two locality, partner, index (LPI) sessions. Rather than specifying the session on which a message is to flow, the application sends the message to the local node on one of these connections. The local node then routes it to the appropriate SNA session.

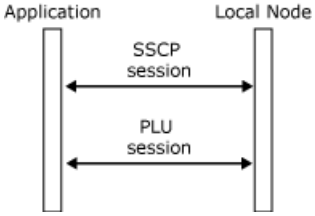
The connections are used as follows:

- The SSCP session is used for the initial startup and logon information for a 3270 session. The Host Integration Server 3270 emulation programs also send network management information, such as user alerts and Response Time Monitor (RTM) statistics, to the local node on this session. For more information about this connection, see SSCP Connection.

- The PLU session is used for the transfer of application data, and for status and flow control messages between the application and the local node. For more information about this connection, see PLU Connection.

The following figure shows these sessions.

Connections between an Application and a local node



These sessions are specific to the local node and the application. Data and status messages passed across a connection result in SNA data and SNA control requests being sent on the appropriate SNA session. Similarly, SNA data and SNA control responses received on an SNA session result in data and control messages being passed to the application on the appropriate connection.

The relationship between the three SNA sessions and the two connections is as follows:

- SNA messages on the SSCP session from the host to the local node result in messages from the local node to the application on the SSCP connection. Messages from the application to the local node on the SSCP connection normally

result in SNA messages on the SSCP session from the local node to the host (with the exception of network management information, which results in messages on the PU-SSCP session).

- SNA messages on the PLU session from the host to the local node result in messages from the local node to the application on the PLU connection. Messages from the application to the local node on the PLU connection result in SNA messages on the PLU session from the local node to the host.

- SNA messages on the PU-SSCP session from the local node to the host are generated by messages from the application to the local node on the SSCP connection. When the application sends network management information such as 3270 user alerts on the SSCP connection, the local node distinguishes it from other data on this connection (which normally corresponds to the SSCP session) and sends the appropriate information about the PU-SSCP session to the host. For more information, see 3270 User Alerts.

Note the distinction between these SNA sessions and 3270 emulation sessions. A 3270 emulator can have more than one 3270 emulation session. For each emulation session, there are separate SSCP and PLU sessions.

Each connection between the application and the local node is opened, managed, and closed separately. This means that an application must maintain a separate internal control block containing the LPI pair, message keys, and state of the connection for each of the SNA sessions associated with each 3270 emulation session. For example, an application using three 3270 emulation sessions, each with an SSCP session and a PLU session, will require six control blocks.

An application identifies the connection (and hence the session) to which a particular message belongs using the LPI pair present in the message. On a received message, the destination index (I) value contains the application's identifier for the connection, and the source I value contains the local node's identifier for the connection. These are reversed for messages sent by the application.

The application selects the LU within the local node that it can use for communications by the relationship in the configuration table between the LU record and APPL record. (For more information, see Opening the SSCP Connection.) The application may be unaware of which LU it accesses if the LUs are arranged within LU groups.

Application Flags

Application Flags

Application flags are included on the following messages:

- All Data messages (both inbound and outbound)
- Status-Acknowledge(Ack) (outbound only)
- Status-Acknowledge(Nack-1) (outbound only)
- All Status-Control messages (both inbound and outbound)

These flags represent key indicators of the state of the session to which the message relates and are closely related (but not always equivalent) to the request header or response header (RH) indicators in the SNA request or response. Note that for inbound messages, applications need to set the flags on **Data** messages and **Status-Control** messages only.

For outbound messages, the local node sets the application flags to reflect the contents of the RH in the corresponding SNA message. The local node performs checks on the SNA message before sending it to the application. Therefore, the application can assume that the RH indicators follow the SNA protocols and need not perform its own checks. The application's task in interpreting the application flags is much simpler than if the local node presented the message with the uninterpreted RH. For example:

- If the application specified the segment delivery option when the primary logical unit (PLU) connection was opened, the end chain indicator (ECI) on an SNA request will occur on the first segment of the last request/response unit (RU) in a chain, but the chain is not complete until the last segment of that RU is received. In this case, the local node manipulates the application flags so that the ECI flag is set in the last segment rather than the first. (For more information, see Opening the PLU Connection.)
- Applications using Transmission Service profile 4 (TS profile 4) on the PLU session can receive the definite response 2 (DR2) RH indicator in combination with definite response 1 (DR1) or exception response (ER) to give RQD2, RQD3, RQE2, and RQE3 requests. The local node interprets the RH indicators and sets the **COMMIT** application flag accordingly.

For inbound Data and Status-Control messages, you should set the application flags to control session characteristics such as chaining, direction control, and brackets. For **Status-Acknowledge** messages, the local node generates an SNA response and sets the RH indicators using information saved from the corresponding request. The application does not need to set the flags on this message.

For information about application flag usage when you are using function management interface (FMI) chunking, see Chunking.

In most cases, the application does not need to use the application flags on Status-Acknowledge(Ack) messages, which derive from the response header indicators on the corresponding response. However, certain applications do require access to the response header flags on responses. For example, transaction-processing applications using TS profile 4 can receive the DR2 flag on responses, which appear as the **COMMIT** flag in the application flags.

Application flag usage on Status-Control (SC) messages is derived from the response header indicators in the corresponding data flow control or session control request unit. Applications may need to be aware of the response header flags for Status-Control messages. For example, LUSTAT request type 6 is a no-op used solely to enable response header flags to be sent when no other request is allowed. The local node delivers the request to the application as a Status-Control(LUSTAT) Request with the relevant application flags set. For summaries of valid request header usage for data flow control request units and of valid response header indicators for SC requests, see *SNA Format and Protocol Reference Manual: Architectural Logic* (IBM publication SC30-3112).

In the summary of the application flags in the table that follows, bits are numbered with bit 0 as the most significant bit in a byte and bit 7 as the least significant. An application flag is set if the relevant bit for the flag is 1 and not set if the bit is 0.

Flag 1 occurs in all messages.

The following table lists the meanings of the individual bits.

Bits in flag 1	Meaning
FMHI [bit 0, flag 1] Value: AF_FMH (0x80)	Function management header indicator. Set if a function management header is present in the message, or if the message is a function management data network services (FMD NS) request. Only valid on Data messages. This flag is always set for 3270 user alerts, which are sent on the system services control point (SSCP) connection. For more information, see 3270 User Alerts.
BCI [bit 1, flag 1] Value: AF_BC (0x40)	Begin chain indicator. Set if this message starts a chain. For more information, see Outbound Chaining and Inbound Chaining.
ECI [bit 2, flag 1] Value: AF_EC (0x20)	End chain indicator. Set if this message ends a chain. For more information, see Outbound Chaining and Inbound Chaining.
COMMIT [bit 3, flag 1] Value: AF_COMM (0x10)	Commit indicator. Set if chain carries DR2.
BBI [bit 4, flag 1] Value: AF_BB (0x08)	Begin bracket indicator. Set if chain carries begin bracket (BB). Note that this does not necessarily indicate that the bracket has been initiated. For more information, see Brackets.
EBI [bit 5, flag 1] Value: AF_EB (0x04)	End bracket indicator—set if chain carries end bracket (EB). Note that this does not indicate that the bracket has terminated. For more information, see Brackets .
CDI [bit 6, flag 1] Value: AF_CD (0x02)	Change direction indicator. Set if chain carries change direction (CD). For more information, see Direction.
SDI [bit 7, flag 1] Value: AF_SD (0x01)	System detected error indicator. Set if the local node detects an error in outbound data. For more information, see Outbound Data.

Flag 2 occurs in all messages except **Status-Control(STSN)**, where the indicators included in this byte are not applicable.

The meanings of the individual bits are listed in the following table.

Bits in flag 2	Meaning
CODE [bit 0, flag 2] Value: AF_CODE (0x80)	Alternate code indicator. Set if the alternate code set (usually ASCII) is used for this Data message. Note that function management headers are unaffected by the code selection indicator.
ENCRYP [bit 1, flag 2] Value: AF_ENCR (0x40)	Enciphered data indicator. Set to indicate that the information in the **Data** message is enciphered under session level cryptography protocols. You must provide the necessary support for data encryption. The Host Integration Server local node does not support cryptography.
ENPAD [bit 2, flag 2] Value: AF_ENPD (0x20)	Padded data indicator. Set in conjunction with the **ENCRYP** flag to indicate that the data was padded at the end to the next integral multiple of eight bytes before enciphering.
QRI [bit 3, flag 2] Value: AF_QRI (0x10)	Queued response indicator. Set if the response to this request is to be queued in the transmission control and data flow control layers. This flag is only significant for inbound messages.
CEI [bit 4, flag 2] Value: AF_CEI (0x08)	Chain ending indicator. Set on a message corresponding to an outbound SNA request with EC and begin basic information unit (BBIU). This flag is provided solely for the use of SNA server components. Your application should not attempt to use it.

BBIUI [bit 5, flag 2] Value: AF_BBIU (0x04)	Begin basic information unit indicator. Set on a message corresponding to an outbound SNA request with BBIU. This flag is provided for the use of SNA server components and for applications using segment delivery and outbound pacing together. Your application should not attempt to use it. (For more information, see Pacing and Chunking.)
EBIUI [bit 6, flag 2] Value: AF_EBIU (0x02)	End basic information unit indicator. Set on a message corresponding to an outbound SNA request with end basic information unit (EBIU). This flag is provided solely for the use of SNA server components. Your application should not attempt to use it.
RBI [bit 7, flag 2] Value: AF_RBI (0x01)	Real BID indicator. Set on **Status-Control(BID) Request** messages from the local node only. 0x01 indicates that the message is due to an SNA BID RU. 0x00 indicates that the message is due to an outbound function management data (FMD) RU with BB set.

Concepts

Sessions and Connections

SSCP Connection

The system services control point (SSCP) connection of the application to the local node provides access to the SSCP session between the Microsoft® Host Integration Server secondary logical unit (LU) and the host SSCP.

For simplicity, this section describes the SSCP connection as if an application only uses a single SNA server LU (and therefore a single SSCP connection). In practice, applications can use multiple LUs.

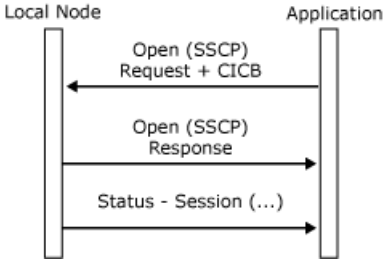
In This Section

Opening the SSCP Connection

An application gains access to the system services control point (SSCP) session by opening an SSCP connection to the local node. To do this, an application sends an Open(SSCP) Request message to the local node, which responds with an Open(SSCP) Response. The local node follows a positive **Open(SSCP) Response** with a Status-Session message reporting the current state of the SSCP session. (For more information, see Using the SSCP Session.)

The following figure shows the message flow. For a figure showing a more detailed message flow, including locality, partner, index (LPI) values used during initialization of both the SSCP and primary logical unit (PLU) sessions, see Opening the PLU Connection.

Message flow between a local node and an application



In This Section

- LU Groups
- Resource Location for Open SSCP

LU Groups

Note that Host Integration Server supports logical unit (LU) groups. An LU group consists of a number of LUs of the same type, such as 3270 display LUs or logical unit application (LUA) LUs. Any of the LUs in the group can be used for the same task.

If an application sends an Open(SSCP) Request specifying the name of a 3270 display LU group, the local node can select any LU within the group to be used by the application. LUA LU groups are used in the same way, except that the application can specify either the name of the group or the name of any LU within the group to access the group.

Concepts

Resource Location for Open SSCP

Resource Location for Open SSCP

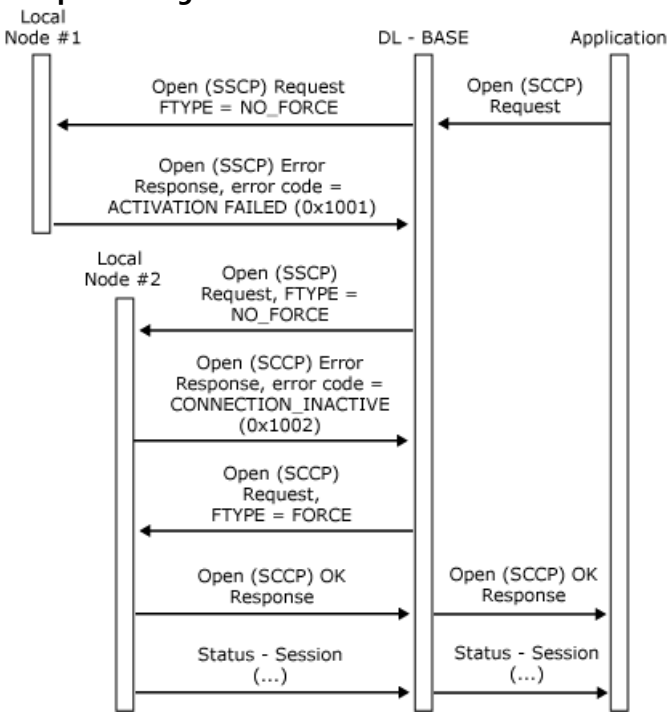
When attempting to find a free logical unit (LU) across more than one local node, the application does not need to know which local node owns the LU. The DL-BASE is responsible for finding a suitable local node, using the mechanism described. The description is intended to assist in interpreting traces of the message flows involved, and is not needed to write an application

The open force type field in the Open(SSCP) Request specifies either a forced or nonforced Open. If the LU for which the Open is intended does not have an active system services control point (SSCP) session because its link is inactive, a forced Open instructs the local node to attempt to activate the link and the SSCP session. A nonforced Open succeeds only if the SSCP session is already active, and otherwise returns with an error code indicating the state of the LU's connection.

When the application issues the **Open(SSCP) Request**, it does not set the open force type field. The DL-BASE issues a nonforced Open to each node in turn until it finds an LU that already has an active SSCP session. If none of these Opens succeeds, the DL-BASE issues a forced Open to the node that returned the best error code—that is, the one most likely to be able to activate the session.

The sample message flows in the following figure show this process for two local nodes. The DL-BASE tries each in turn, using nonforced Opens. The error code from node #2 indicates that it is more likely to be able to activate the SSCP session than node #1, so the DL-BASE sends a forced Open to node #2. The application is aware only of the first request and its response.

Sample message flow for two local nodes



To enable applications to restart after a disastrous failure (such as terminating the 3270 emulation program), the local node also accepts an Open(SSCP) Request from an application that has failed and has been restarted, providing the same source locality, partner, index (LPI) fields are used. In this case, a **TERM-SELF** message is sent to the host if the LU is bound.

The SNA server LU through which the application communicates is selected by the relationship between the APPL record and the LU or LU group record in the configuration file. The application specifies its name using the source name field on the **Open(SSCP) Request**. The local node fills in the LU or LU group number, selects an unused LU within the LU group (if the association is to an LU group), and informs the application of this LU number on the Open(SSCP) Response.

The **Open(SSCP) Request** specifies the following:

- The source application name.
- A resource identifier that can be used by the application to correlate the Open(PLU) Request that is sent to the application. (For more information, see Opening the PLU Connection.)
- A connection information control block, which specifies the response header usage, checks that the local node should perform for the LU. If the field for a code is set to 0x01, that receive check will be carried out by the data flow control layer of the local node on data arriving from the host. The corresponding send checks are unaffected and are always performed. The connection information control block is provided because these receive checks are optional in SNA.

However, it is anticipated that most applications will require all these checks to be performed (all values set to 0x01).

- An indicator that specifies whether the application is to be treated as high or low priority. All SNA server 3270 LUs are marked as high priority (printers do not send significant data inbound). The effect of high priority is to enable data to be progressed faster to the host when the link is busy.

- An indicator that specifies whether the application is an LUA. This determines whether the local node and the application will communicate using the LUA variant of the function management interface (FMI). (For more information, see FMI Concepts.)

- An indicator that specifies a nonforced or forced Open. This determines whether the local node will attempt to activate the SSCP session if it is not currently active.

The Open(SSCP) Request can fail for one of several reasons, which can be determined from the error codes on the Open(SSCP) Response sent to the application, as detailed in the following list:

- The local node may still be initializing (retrieving information from the configuration file). In this case, the application can retry immediately.

- The configuration file may not have an entry for the application, or the application record in the configuration file may not point to an LU or LU group record.

- For a nonforced Open, the SSCP session may be inactive.

Resource Location for Open SSCP

Closing the SSCP Connection

To close the system services control point (SSCP) connection, an application sends a Close(SSCP) Request to the local node, which responds with a Close(SSCP) Response. The **Close(SSCP) Request** is unconditional. The **Close(SSCP) Response** always reports that the connection was successfully closed. The **Close(SSCP) Response** is provided so that applications can determine when outstanding data and status messages on the session have been delivered.

If the logical unit (LU) is bound, the local node sends a **TERM-SELF** message to the SSCP on behalf of the application to elicit an **UNBIND**. An application that needs to be unbound can issue **Close(PLU)**. (For more information, see Closing the PLU Connection.) Normally, the SSCP connection can be maintained while the application task is active, even if it is idle.

Closing the connection invalidates the locality, partner, index (LPI) pair for the connection, but does not alter the state of the SSCP session. The following figure shows the message flow.

Message flow for closing a connection

Opening the SSCP Connection

Using the SSCP Session

Using the SSCP Session

When the application has opened a system services control point (SSCP) connection, it has access to the SSCP session and can send data to the host SSCP.

In This Section

- SSCP Session Characteristics
- SSCP Session Status

SSCP Session Characteristics

For SNA type 2.1 nodes, the system services control point (SSCP) session uses function management (FM) profile 0 and Transmission Service profile (TS profile) 1. This combination of profiles provides the following session characteristics:

- The primary and secondary half-sessions both use immediate request mode.
- The primary and secondary half-sessions both use immediate response mode.
- Only definite-response single request unit chains are allowed.
- The maximum request unit size is limited to 256 bytes.
- Data flow control request units are not supported.
- Pacing is not supported.
- Identifiers are used (rather than sequence numbers) on the normal flows.

This implies that the SSCP connection has the following characteristics:

- All Data messages have the acknowledgment required (ACKRQD) field set.
- All Data messages have the begin chain indicator (BCI) and end chain indicator (ECI) application flags set.
- Status-Control messages do not flow on the connection.
- Status-Session messages from the local node to the application only report changes in the activation state of the session.
- The chaining, bracket, confirmation, and recovery protocols (described in PLU Connection) do not apply.

Using the SSCP connection, the application can send and receive **Data** messages corresponding to function management data network services (FMD NS) (session services) requests and FMD data requests. Examples of FMD NS (session services) requests are:

- **INIT-SELF.** Requests from the secondary to the host SSCP requesting that the SSCP assist in the initiation of a session to the host PLU, effectively requesting a **BIND**. (For more information, see Opening the PLU Connection.)
- **TERM-SELF.** Requests from the secondary to the host SSCP requesting that the PLU-SLU session be terminated with an **UNBIND**. (For more information, see Closing the PLU Connection.)
- **Character-coded requests.** Requests such as logon, logoff, or test commands from the secondary display, or a logon prompt from the host application.
- **NOTIFY.** Requests used by the secondary to notify the host SSCP that a device is available after a **BIND** was rejected with sense code 0x0845, for example, where a device emulator supports logical power-off.

The local node sends a **NOTIFY** request to the SSCP on behalf of the LU whenever the application's SSCP connection state changes while the LU is active. A **NOTIFY** (vector key 0x0C with byte 5 set to 0x03), which can act as secondary LU, is sent in the following cases:

- When an Open(SSCP) Request is received when the LU is already active.
- When an ACTLU request is accepted when the SSCP connection is already opened.

A **NOTIFY** (vector key 0x0C with byte 5 set to 0x01), which cannot currently act as secondary LU, is sent in the following cases:

- When an ACTLU is received when the SSCP connection is not open.
- When a Close(SSCP) Request is received when the PLU session is not bound.
- When an **UNBIND** request is received when the SSCP connection is not open.
- When the long response including the **NOTIFY** vector is used for ACTLU requests.

These **NOTIFY** messages can be used by the host in conjunction with the negative response 0x0845 that the local node gives to a **BIND** received when the SSCP connection is not open. (For more information, see Opening the PLU Connection.)

SSCP Session Status

While the system services control point (SSCP) connection is open, the local node reports the initial state and any subsequent changes of state of the SSCP session to the application using Status-Session messages. There are four distinct **Status-Session** status codes that can occur for the SSCP connection:

- **No-Session.** The SSCP session between the SNA server logical unit (LU) and the host SSCP is not active because the SNA server physical unit (PU) or LU is not activated. The **Status-Session** carries a qualifying status code to indicate why the SSCP session is inactive. The application cannot use the SSCP connection to send data to the host SSCP. The qualifiers are:

    - **PU-INACTIVE.** Activate PU (ACTPU) has not been received or Deactivate PU (DACTPU) has been received.

    - **PU-ACTIVE.** ACTPU(COLD) has been received from the SSCP.

    - **PU-REACTIVATED.** ACTPU(COLD) has been received while the PU was active. (The application is not informed if ACTPU(ERP) is received while the PU is active.)

    - **LU-INACTIVE.** ACTLU has not been received, or DACTLU has been received.

- **Link-Error.** The SSCP session between the SNA server LU and the host SSCP is not active, due to a data link control (DLC) error. The **Status-Session** carries a qualifying status code that gives the error code reported by the DLC. The application cannot use the SSCP connection to send data to the host SSCP.

  Note that this session state is reported when the local node is informed that the locality containing the Host Integration Server Synchronous Data Link Control (SDLC) link service has been lost due to a path failure. The qualifier 0x0D is used. The link service will close the link when it is informed of the path error so the application can treat this as an outage.

- **LU-Active.** The SSCP session is active due to the receipt of ACTLU. The application can use the SSCP connection to send data to the host SSCP.

- **LU-Reactivated.** The SSCP session has been reactivated due to the receipt of an ACTLU from the host SSCP. The SSCP connection is still active, but data may have been lost.

For more information, see Status-Session Codes.

RTM Parameters

The Status-RTM message is sent to the application by the local node to indicate the Response Time Monitor (RTM) parameters being used by the host. The host can specify the following parameters:

- Whether RTM measurement is active or inactive.
- Whether local display of RTM data by the application is permitted.
- The definition by which response times are to be measured:
    - Until the first character of a response is written to the screen.
    - Until the keyboard is unlocked.
    - Until the application is allowed to send data. Change direction (CD) or end bracket (EB) is received.
- The boundaries by which response times are to be classified into time bands.
- The initial values of the counters, which indicate how many responses have been received in each time band (as defined by the boundaries).

The local node is responsible for interpreting the response times reported to it by the application, and for sending RTM statistics to the host when required. The application is responsible for measuring the response times and reporting them to the local node. (The application reports response times to the local node using the Status-Acknowledge message. For more information about measuring and reporting response times, see Response Time Monitor Data.)

If the application does not need to provide a local display of RTM data, it only needs to determine whether RTM measurement is active. If active, it needs to determine the definition by which response times are measured. It can ignore the other parameters. If RTM measurement is not active, the application need not measure and report response times.

If the application needs to provide a local display of RTM data, it should use the information from the Status-RTM message to ensure that the local interpretation of response times matches the interpretation used by the host. In particular, it should not display RTM data at all if the **Status-RTM** message indicates that local display is not permitted (or if the **permission to view RTM data** field in the 3270 user configuration record indicates that it is not permitted). The application is responsible for maintaining its own RTM statistics for local display, that is, for classifying the response times according to the boundaries specified by the host and maintaining counts of responses in each category. Although the local node maintains these statistics for sending to the host when required, it does not report them to the application.

Note
RTM statistics are maintained for a specific logical unit (LU), not for a specific application's use of that LU. This means that wh en the **Status-RTM** message is received at start of day, the counters can be nonzero to include a previous use of the LU. The counters are only reset when the host requests the local node to reset them or when the local node sends unsolicited RTM da ta to the host.

Opening the SSCP Connection
Using the SSCP Session

3270 User Alerts

The Host Integration Server 3270 emulation program can send 3270 user alerts to the local node on the system services control point (SSCP) connection. This enables the local node to route each alert to the appropriate host for the 3270 session on which it was sent.

To send a 3270 user alert, the application should send it as a Data message on the SSCP connection. The local node will recognize it as a 3270 user alert if both of the following are true:

- The function management header indicator (FMHI) bit in the application flag is set.
- The first three bytes of the data are 0x41038D, indicating a Network Management Vector Transport (NMVT).

The local node sends the alert to the appropriate host for the 3270 session on which it was received. If a relative time subvector is present (0x42) with increment type 0xEF (sequence), the local node sets the sequence number in each message (starting at one from power-up and incrementing by one for each message sent). Host Integration Server 2009 allows sequence number values up to 2^16. Apart from this, the local node does not alter the contents of the alert.

Note
There can be some delay before the application receives a response to the alert. The response is sent on the SSCP connection in the same way as other data on this connection. The application must not send further data on the SSCP connection (including further alerts) until it has received a response to this alert.

PLU Connection

The primary logical unit (PLU) connection of the application to the local node provides access to the PLU session between the Microsoft® Host Integration Server's logical unit (LU) and a PLU in the host.

This section describes how an application opens and closes its PLU connection, and the use of the PLU connection.

For simplicity, this section describes the PLU connection as if an application uses only a single SNA server LU (and therefore a single PLU connection). In practice, applications can use multiple LUs.

In This Section

Opening the PLU Connection

The opening of the primary logical unit (PLU) connection is closely associated with the establishment of the PLU session. The local node opens the PLU connection when it receives a **BIND** command from the host for a logical unit (LU) for which an application has previously opened a system services control point (SSCP) connection. Possible sequences are:

- An application opens its SSCP connection and sends a character-coded logon request or **INIT-SELF** request to the host SSCP. A host PLU subsequently sends a **BIND** request to the SNA server LU, and the local node opens the PLU connection.

- A host PLU sends an unsolicited **BIND** command to the SNA server LU. If the SSCP connection for the LU is open, the local node opens the PLU connection. If the local node is supporting **NOTIFY**, the host can be configured to send a **BIND** when it receives the **NOTIFY** message sent by the local node when the application opens its SSCP connection. (For more information, see SSCP Connection.)

- A host PLU sends a **BIND** command to the SNA server LU. If the SSCP connection for the LU is not open, the local node returns a negative response to the **BIND** request. The sense code used is 0x0845 (**NOTIFY** will be sent). The local node does not open the PLU connection. In this case, the local node sends **NOTIFY** when the SSCP connection is opened. (For more information, see SSCP Connection.)

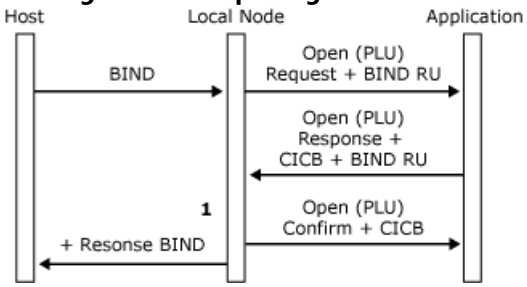
To successfully open the PLU connection, the local node sends an Open(PLU) Request to the application. The application responds with an Open(PLU) OK Response. Finally the local node sends an Open(PLU) OK Confirm to the application. This exchange of messages opens the PLU connection and establishes the PLU session. It should be noted that a successful PLU opening sequence is a three-way handshake, in comparison to the opening of the SSCP connection, which is a two-way handshake.

The **Open(PLU) Request** is delivered to the application using the SSCP connection for the LU. The **Open(PLU) Request** contains the application name and open resource identifier to allow applications to correlate the PLU and SSCP connections.

The **Open(PLU) Request** indicates the logical unit that the **BIND** request was directed to, references the resource identifier supplied in the Open(SSCP) Request for that LU, and carries the actual **BIND** request/response unit (RU) received from the host. (For more information, see Open(PLU).) It also carries the maximum RU sizes, chunk sizes (if appropriate), and pacing windows for the PLU session, to enable the application to determine the initial credit if it needs to be involved in outbound pacing. (For more information, see Pacing and Chunking.)

The message flow for a successful opening of the PLU connection (on receipt of a nonnegotiable **BIND**) is shown in the following figure. Note that the **BIND** parameters are verified (at [1]) only when the application has supplied the **BIND** check table index as part of the connection information control block (CICB).

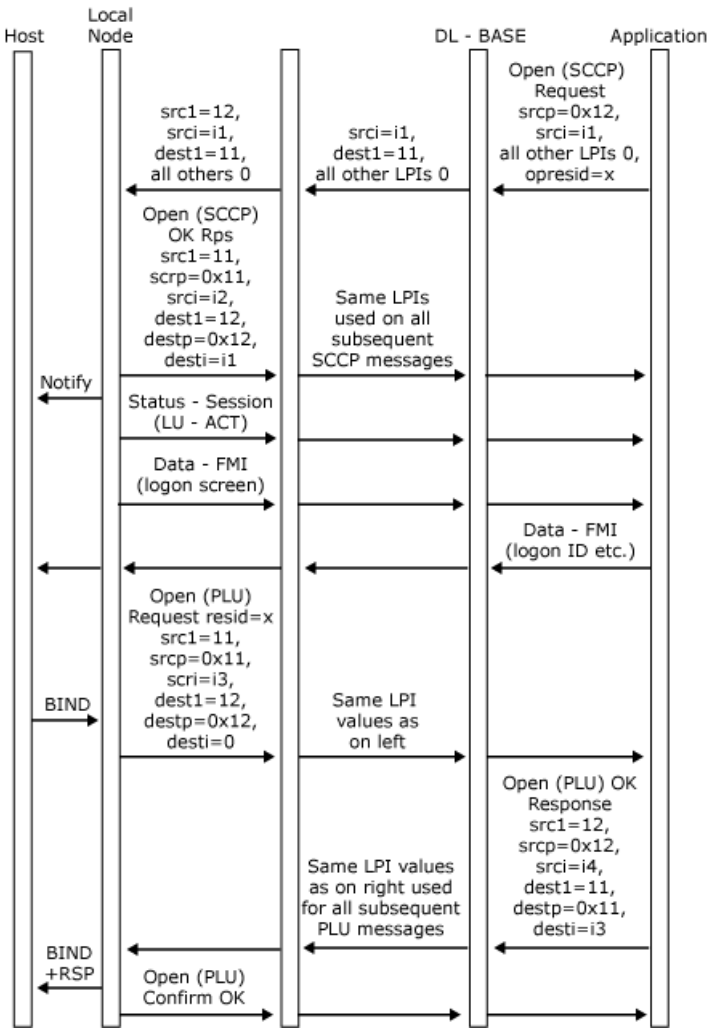
Message flow for opening a PLU connection



The following figure shows the message sequence for the initiation of both the SSCP and PLU sessions, including details of where the Locality Partner Index (LPI) values are assigned. (The application's source P value of 0x12 indicates that it is a 3270 emulator. For more information about how the source LPI values are set, see Open(SSCP) Request.) The message flow shown assumes that the connection to the host is already established and that both the configuration and the **BIND** are valid.

After this message sequence, there are two valid sets of LPI values, one for the SSCP session and one for the PLU session. The application can access either session at any time until **UNBIND** and can use the LPI values to distinguish between received data on the two sessions.

Message sequence for the initiation of both the SSCP and PLU sessions



In This Section

- BIND Checking

BIND Checking

The Open(PLU) OK Response contains the connection information control block (CICB), which enables the application to customize certain characteristics of the connection and contains information used in **BIND** verification. Note that the local node verifies the **BIND** parameters carried on the **Open(PLU) OK Response**. It does not maintain a copy of the original **BIND** request/response unit (RU) from the host. If the **BIND** is negotiable, the application is permitted to modify the parameters in the **BIND** RU, but if it is nonnegotiable the application should return the **BIND** RU unmodified. A negotiable **BIND** flag is provided in the Open(PLU) Request.

Although many characteristics of the PLU session are determined by the **BIND** parameters, the application can select certain characteristics by specifying fields in the CICB. For more information, see the following table. More detailed information about CICB usage and the effect on the PLU session of selecting various CICB options is given in context in the topics of this section that deal with PLU session characteristics such as chaining and pacing.

The **BIND** is verified using a **BIND** check table entry (whose index is specified in the CICB). The entries in this correspond to the various fields in the **BIND**. The **BIND** check table entries are stored in the configuration file. For example, the **BIND** check table entry can specify that the **BIND** be accepted if the secondary chain response protocol is either "definite response" or "definite or exception response" (byte 5 bits 2 and 3 = B10 or B11). This would be appropriate if the application did not want to send Request Exception (RQE) chains.

Connection information control block usage is shown in the following table.

Field	Explanation
Segment delivery option	A value of 0x00 indicates that the local node should perform outbound segment assembly and only deliver complete RUs. A value of 0x01 indicates that the application wants the local node to deliver RU segments. For more information, see Segment Delivery.
Application pacing option	A value of 0x00 indicates that the application requires the local node to handle pacing. A value of 0x01 indicates that the application needs to be involved with outbound pacing through Status-Resource messages. For more information, see Pacing and Chunking.
Application cancel option	A value of 0x00 indicates that the local node should automatically generate CANCEL. A value of 0x01 indicates that the application will generate CANCEL. For more information, see Inbound Chaining.
Application transaction numbers option	A value of 0x00 indicates that the application does not support transaction numbers. A value of 0x01 indicates that the application does support transaction numbers. For more information, see Recovery.
BIND check index	Gives the index of the **BIND** check table entry against which the BIND parameters should be verified. One of the following values should be used: • 0x01 —3270 printer session • 0x02 —3270 display session • 0x10 —LUA (LU type 0) application

The **Open(PLU) Confirm** from the local node to the application indicates whether the **BIND** verification was successful, and if so, supplies the bind information control block (BICB). The BICB summarizes the session **BIND** parameters in a format suitable for high-level languages and effectively defines the characteristics of the PLU session. The application not negotiating the **BIND** should usually not require to examine the **BIND** on the Open(PLU) Request and should use the BICB on the Open(PLU) OK Confirm.

The following table summarizes the fields in the BICB and their correspondence to the parameters in the **BIND** RU. For more detailed information, see the IBM manual *Systems Network Architecture: Formats,* (GA27-3136).

Position on Open(PLU) OK Confirm	Position in Bind RU [byte,bit]	Description

Note

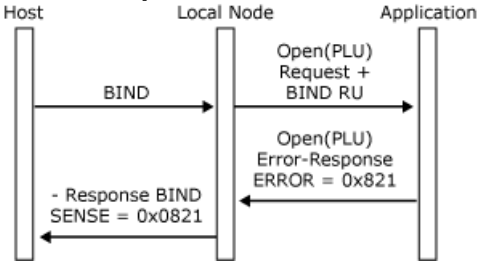
20x01 = Bracket reset state is BETB (between-brackets). 0x02 = Bracket reset state is INB (in-bracket).

Note

These values are of type INTEGER (all others are of type CHAR).

The opening PLU sequence can fail if the application rejects the Open(PLU) Request (for example, if the **BIND** parameters are unacceptable on a nonnegotiable **BIND**) by sending Open(PLU) Error Response and appropriate sense codes. The local node sends to the host a negative response to the **BIND** request containing the supplied sense codes. The PLU connection is considered to be closed after an **Open(PLU) Error Response**, and the local node does not generate an **Open(PLU) Confirm**. The following figure shows a failure to open the PLU connection (for a nonnegotiable **BIND**), due to the application rejecting the **Open(PLU) Request**.

Failure to open the PLU connection



- The opening PLU sequence can also fail if the **BIND** verification against the **BIND** check table entry specified by the application fails. In this case, the local node does the following: Sends to the host a negative response to the **BIND** request with appropriate sense codes.

- Sends to the application an Open(PLU) Error Confirm with the first word of the sense codes as the first error code and the index of the **BIND** parameter in error as the second error code.

The PLU connection is considered to be closed after the **Open(PLU) Error Confirm**. The following figure shows failure to open the PLU connection due to **BIND** verification failure. Note that error code 2 gives the index in the RU of the **BIND** parameter in error.

Closing the PLU Connection

Either the application or the local node can terminate the primary logical unit (PLU) connection. The criteria for closing are:

- The local node closes the PLU connection if it receives an **UNBIND** request from the host PLU, which terminates the PLU session. If the **UNBIND** type is **BIND forthcoming** (0x02), the local node sets the **BIND**-forthcoming indicator in the Close(PLU) Request, so that the application can reserve any necessary resources.
- The local node closes the PLU connection if it receives a Deactivate Logical Unit (DACTLU) or Deactivate Physical Unit (DACTPU) request from the system services control point (SSCP).
- The local node closes the PLU connection if it receives an outage notification from data link control.
- The local node closes the PLU connection if it detects a critical error in a message from the application, putting the application in a critically failed state. In this case, the local node sends a **TERM-SELF** request to the host to elicit an **UNBIND**.
- The application should close the PLU connection for logical power-off conditions. For example, if its resources are temporarily unavailable, or when the user finishes using the session.

When the local node issues a Close(PLU) Request, the application can determine the reason from the **Close** control field. There may be an associated status message on either the PLU connection (a Status-Acknowledge(Nack-2)) or the SSCP connection (a Status-Session message if the LU has been deactivated).

Whether the local node or the application closes the connection, the message is the same. The initiator of the **Close** sequence sends a **Close(PLU) Request** to its partner, which responds with a **Close(PLU) Response**. The **Close(PLU) Request** is unconditional. The **Close(PLU) Response** always reports that the connection was successfully closed.

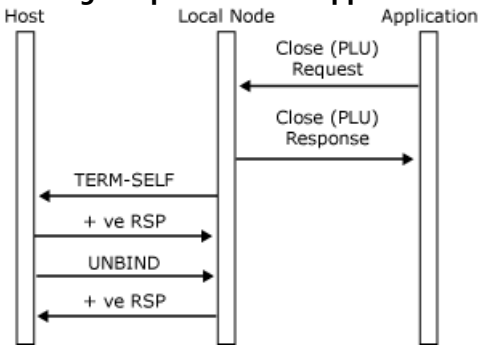
The **Close(PLU) Response** is provided so that the initiator of the **Close** sequence can determine when outstanding data and status messages have been delivered. To avoid possible race conditions, the application should discard all messages it receives on the PLU connection after issuing a **Close(PLU) Request**, including any **Close(PLU) Request** messages from the local node, until it receives the **Close(PLU) Response**.

Note that, if the application sends a Close(SSCP) Request while the PLU session is active, the local node will close the PLU connection (as if **Close(PLU) Request** had been sent) as well as the SSCP connection.

The message sequence for an application-initiated **Close** is shown in the following figure. The local node sends a **TERM-SELF** request to the host to elicit an **UNBIND**.

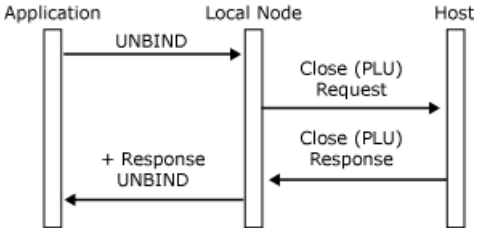
If the host generates an **UNBIND** automatically on receipt of a **TERM-SELF**, the application can view **Close(PLU)** as equivalent to the termination of the PLU-SLU session.

Message sequence for an application-initiated Close



The message flow for a local node-initiated **Close** after receiving an **UNBIND** request from the host is shown in the following figure.

Message flow for a local node-initiated Close after receiving an UNBIND request



When an application is using the logical unit application (LUA) variant of the FMI, issuing a Close(PLU) Request causes the node to immediately unbind the PLU session by sending an **UNBIND** request to the PLU. The **Close(PLU) Response** is returned to the application on receipt of the **UNBIND** response, as shown in the following figure.

Message flow for the Close(PLU) Response

Using the PLU Session

When the primary logical unit (PLU) connection is open, the application has access to the PLU session and can communicate with the host PLU.

In This Section

- PLU Session Characteristics
- PLU Session Status

PLU Session Characteristics

The local node provides support on the primary logical unit (PLU) session for function management (FM) profiles 2, 3, 4, and 7 and Transmission Service profiles (TS profiles) 2, 3, 4, and 7. Support of these profiles means that the local node supports LU-LU session types 0, 1, 2, and 3. Using the PLU connection, the application can send and receive any FM data that is valid for these LU-LU types.

The protocols appropriate to a particular session are determined by the parameters in the **BIND** request that establishes the session. The **BIND** parameters are reported to the application in the bind information control block (BICB) on the Open(PLU) OK Confirm message. It is the application's responsibility to conform to the session protocols reported in the BICB.

Due to the wide range of **BIND** parameters allowable on a session and the options available to an application in the CICB on the Open(PLU) OK Response, this section does not attempt a complete description of the protocols for a particular session. The remaining topics in this section describe the general protocol characteristics of the PLU session, such as chaining, brackets, and so on.

Most of the protocol descriptions in the remainder of this section are accompanied by figures to illustrate the important features. The figures show:

- The relevant response header flags in SNA requests/responses.
- The sequence number of SNA requests/responses.
- Any sense data (shown as "SENSE=...") on SNA responses or **Data** messages.
- The acknowledgment required (ACKRQD) field in Data and Status-Control messages.
- The relevant application flags in **Data** and **Status-Control** messages. (For more information, see Application Flags.)
- The message key field in **Data** messages.
- Any error codes (shown as "ERROR=...") in Status-Acknowledge or **Status-Control** messages.

For simplicity, it is assumed that all messages are function management data flowing on the same PLU session that:

- Uses half-duplex flip-flop protocols.
- Uses brackets, with reset state of between-bracket.
- Does not use the PLU CICB segment delivery option. (For more information, see Segment Delivery).

PLU Session Status

While the primary logical unit (PLU) connection is open, the local node reports any changes of state to the application through Status-Session messages. There is only one **Status-Session** status code that can occur on the PLU connection, which is listed in the following table.

Status code	Description
BETB	The PLU session has made the transition from the in-bracket state to the between-bracket state. (For more information, see Brackets.)

Status-Session Codes describes the **Status-Session** status codes.

Outbound Chaining

The local node checks that outbound chains of requests conform to the correct SNA usage, to the chaining usage for the session, and to the current state of the session. The local node will accept valid outbound chains of data from the host if one of the following is true:

- Data traffic is active on a full-duplex session.
- The session is in a state where it can receive data.
- The session is between brackets with neither half-session currently sending, or the session is in contention for a half-duplex contention session. (For more information, see Brackets.)
- The session is waiting for the host to initiate a recovery procedure. For example, the local node has sent a negative response to an outbound chain. (For more information, see Recovery.)

The local node sends a Data message to the application for each outbound request, but note the effects of the application specifying the segment delivery option in the connection information control block. (For more information, see Segment Delivery.) If the application does not specify segment delivery, the begin chain indicator (BCI) and end chain indicator (ECI) application flags in the message header reflect the chaining indicators in the request header of the request.

An outbound chain can terminate in several ways:

- The chain is received complete and without error. All the requests in the chain have been passed to the application as **Data** messages and have been acknowledged where applicable.
- The application detects an error in a Data message while receiving the chain. The application should send a Status-Acknowledge(Nack-1) with associated sense data to the local node, which sends a negative response plus the sense data to the host for the request corresponding to the **Data** message in error. The local node will not purge the remainder of the chain, so the application will see End Chain (EC). Alternatively, the host can terminate the chain with a CANCEL, which is delivered to the application as a **Status-Control(CANCEL)** with ACKRQD set.
- The local node detects an error in a request and presents the application with a system detected error **Data** message to report the premature termination of the chain. This message carries the system detected error indicator (SDI) and ECI application flags, the sense codes for the error, and the ACKRQD indicator. It does not carry user data. When the application responds with Status-Acknowledge(Ack), the local node generates a negative response to the chain using the appropriate sense code. The application can use the reported sense codes to generate diagnostic information for the user. (For example, a 3270 emulator would generate **PROG** check codes.) The local node will purge the remainder of the chain, so the application may not see EC. Alternatively, the host can terminate the chain with a **CANCEL**, which is delivered to the application as a **Status-Control(CANCEL)** with ACKRQD set.
- The host can cancel the chain while sending, by sending the **CANCEL** request. The local node sends a **Status-Control(CANCEL)** message to the application, which the application must acknowledge.

If an error occurs while receiving a chain, and the session uses half-duplex flip-flop protocols, the application must assume an error-recovery-pending state. (For more information, see Recovery.)

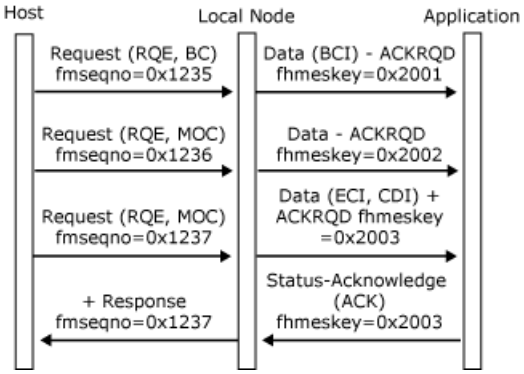
For a session using half-duplex flip-flop protocols, if the application flags in the last Data message of the chain have the CDI (change direction) flag set:

- If the chain was received without error, the application has direction.
- If the application rejected any message in the chain, the host retains direction.

The following four figures illustrate outbound chaining protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

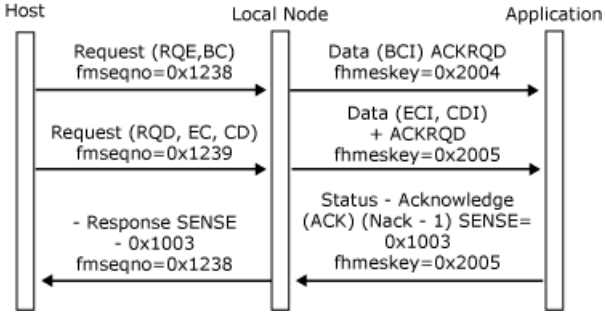
In the first figure, a complete outbound chain is received without error and accepted by the application. Note that after sending **Status-Acknowledge(Ack)**, the application has direction.

Outbound chain received without error and accepted by the application



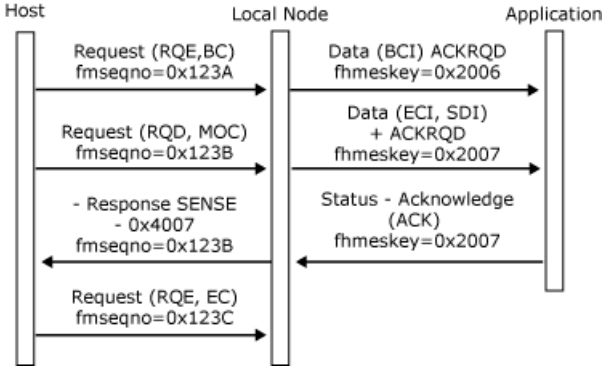
In the following figure, a complete outbound chain is received without error, but is rejected by the application. Note that even though the chain carried CD, the application does not have direction.

Outbound chain received without error, but is rejected by the application



In the following figure, the local node detects the invalid use of RQD without EC and converts the request to a **Data** message with the SDI application flag set, plus ACKRQD and appropriate sense codes. The application's **Status-Acknowledge(Ack)** drives the negative response to the host. This example assumes that the receive check 4007 has been specified in the CICB on the **Open (SSCP)**.

Local node detects invalid use and converts request



In the following figure, the host cancels the outbound chain.

Host canceling the outbound chain

Inbound Chaining

The division of application data into Data messages and the control of inbound chaining are the responsibility of the application.

The secondary maximum send request unit size for the session is a parameter in the **BIND** from the host and is available in the bind information control block (BICB) on the Open(PLU) OK Confirm message. The application should ensure that each inbound **Data** message corresponds to a single request unit. It does not contain more data than the maximum request unit size given in the BICB.

The application should use the begin chain indicator (BCI) and end chain indicator (ECI) application flags in the **Data** message headers to control chaining. (For more information, see Application Flags.) The chain is the unit of recovery, and if recoverable errors occur in the chain, the application should assume responsibility for recovery. (For more information, see Recovery.)

An inbound chain can terminate in the following ways:

- The complete chain is sent without errors. All the **Data** messages in the chain have been passed to the host. If the session allows the secondary to send definite-response chains, and the application sets the **ACKRQD** field in the last **Data** message of the chain, the application receives a Status-Acknowledge(Ack) from the local node when the host supplies a response.

- The local node detects a critical error in the format of a **Data** message from the application or in the state of the session. The local node rejects the **Data** message with a Status-Acknowledge(Nack-2) containing an error code and closes the PLU connection. Note that the local node will generate an inbound **CANCEL** request before closing the PLU connection. The local node will send a **TERM-SELF** request to the host to elicit an **UNBIND**.

- The host sends a negative response to a request in the chain. The local node sends a Status-Acknowledge(Nack-1) message to the application with the sense codes and sequence number from the negative response. If the host rejects a request that does not carry the ECI application flag, and the application does not specify the application cancel option in the PLU CICB, the local node also generates an inbound CANCEL request. When the application specifies application cancel, it must send EC or **Status-Control(CANCEL)** to terminate the chain. Any subsequent inbound chains are rejected with a noncritical **Status-Acknowledge(Nack-2)**, sense code 0x2002 or 0x2004 (chaining or direction). When the application receives the **Status-Acknowledge(Nack-1)** message, it should stop sending data after this chain for half-duplex flip-flop sessions because the direction has passed to the host. (For more information, see Direction.)

- The application cancels the chain while sending, by sending a **Status-Control(CANCEL)** message to the local node. The local node sends a CANCEL request to the host and sends a **Status-Control(CANCEL)** Acknowledge to the application on receiving a positive response from the host. Responses from the host to requests sent before the **CANCEL** will generate appropriate **Status-Acknowledge** messages to the application if the original Data messages had the **ACKRQD** field set.

- The application closes the PLU connection while sending the chain. The local node sends a **Close(PLU) Response** to the application. Responses from the host to requests sent before the **Close(PLU)** message will not generate **Status-Acknowledge** messages to the application. Note that the local node will also generate an inbound **CANCEL** request and a **TERM-SELF** request to elicit an **UNBIND**.

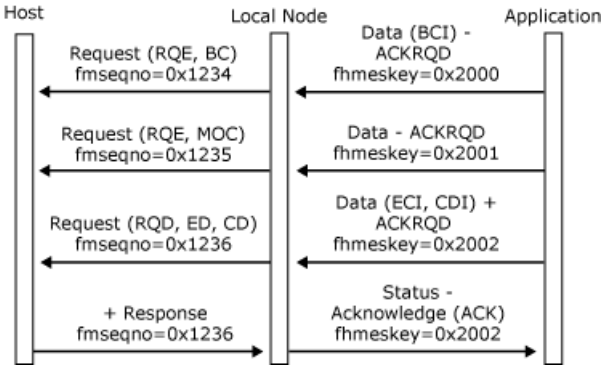
If the local node detects a noncritical error in the format of a **Data** message from the application or the state of the session, it does not close the PLU connection. Instead, it rejects the **Data** message in error with a **Status-Acknowledge(Nack-2)** containing an appropriate error code. No data is sent to the host.

If an inbound chain terminates with an error, when the session uses half-duplex protocols, the application must assume a receive state. (For more information, see Recovery.)

The following six figures illustrate inbound chaining protocols between the local node and the application, and how those protocols relate to the underlying SNA protocols.

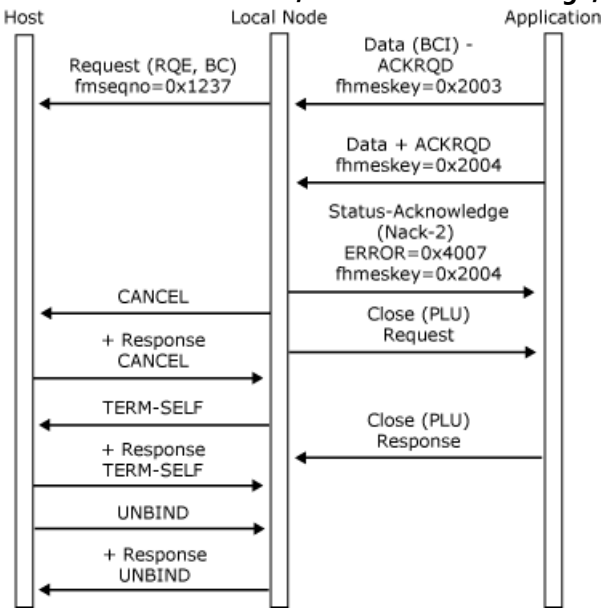
In the first figure, a complete inbound chain is sent without error and accepted by the host. Note that after receiving **Status-Acknowledge(Ack)** the application relinquishes direction to the host.

Inbound chain is sent without error and accepted by the host



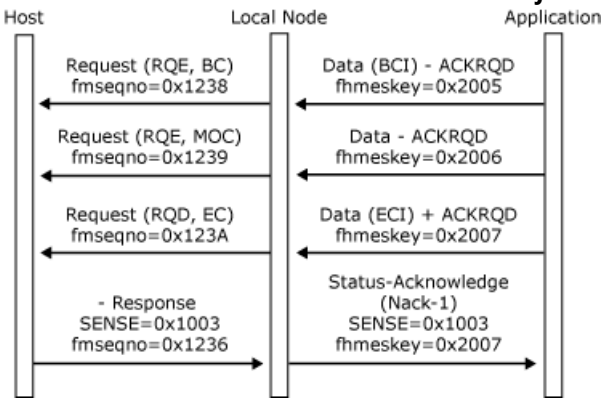
In the following figure, the local node detects a critical error in the format of the second **Data** message in the chain (**ACKRQD** without the ECI application flag), sends a **Status-Acknowledge(Nack-2)** to the application with the appropriate error code, and closes the PLU connection. Note that the local node only generates the **CANCEL** if the session's function management (FM) profile supports **CANCEL**.

Local node detects error, sends a Status message, and closes the PLU connection



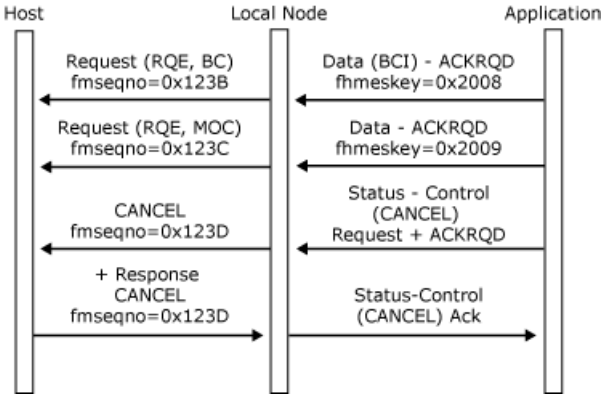
In the following figure, a complete inbound chain is sent without error, but is rejected by the host. After the negative response, the application must enter receive state, pending error recovery. (For more information, see Recovery.)

Inbound chain is sent without error but is rejected by host



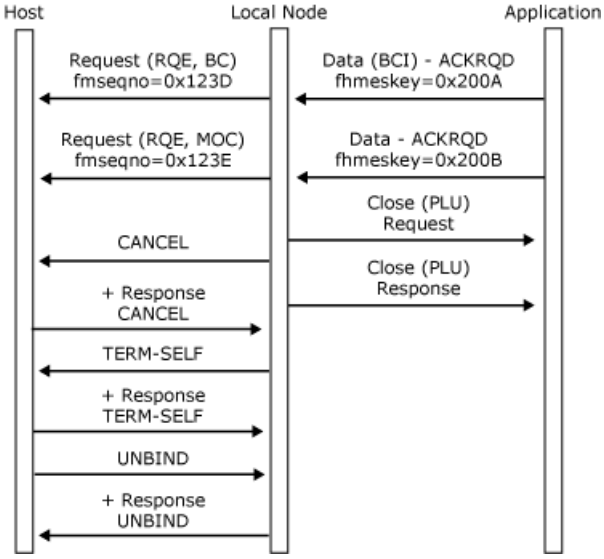
In the following figure, the application cancels the chain by sending **Status-Control(CANCEL)**. Note that the application still has direction and can start a new chain.

Application cancels the chain with a Status-Control(CANCEL)



In the following figure, the application closes the PLU session while sending the chain. The local node only generates the **CANCEL** if the session's FM profile supports **CANCEL**.

Application closes the PLU connection while sending the chain



In the following figure, the local node detects a noncritical error in the format of the second **Data** message in the chain and sends a **Status-Acknowledge(Nack-2)** to the application with the appropriate error code.

Local node detects a noncritical error and sends a Status-Acknowledge(Nack-2)

Segment Delivery

If the maximum request/response unit (RU) size for a session (supplied in the **BIND** parameters) allows RUs that are larger than the maximum size of a data link control transmission unit, for example, a Synchronous Data Link Control (SDLC) frame, the local node's path control is responsible for assembling outbound segments into RUs and segmenting inbound RUs where required.

However, certain IBM products (for example, SNA models of the 3270 controllers) do not perform outbound segment assembly, to improve perceived response times at display terminals by displaying each segment as soon as it is received. This feature is referred to as window shading.

The local node allows an application to specify a segment delivery option in the connection information control block (CICB) on the Open(PLU) OK Response. If an application specifies this option, the local node's path control does not assemble outbound segments into complete RUs, and the local node delivers the segments to the application in Data messages. This enables an application emulating a 3270 device to reproduce the perceived response characteristics of the IBM device. In cases where throughput is high, such as 3270 file transfer, segment delivery can give improved performance compared to RU delivery.

Note that there is no comparable feature for inbound data. The application must present **Data** messages containing complete RUs to the local node. Also, there is no support for segment delivery on the system services control point (SSCP) session and connection (where the maximum RU size is limited to 256 bytes).

The local node supports the segment delivery option in such a way that the constraints placed on an application receiving data in either form are identical. If complete RUs are required, the local node rebuilds the RUs from segments in path control. If segments are required, the local node handles all segmentation indicators and modifies processing within its SNA layers to cater for segmented RUs.

All **Data** messages delivered to the application contain application flags, whereas only the first segment in an RU contains a response header (RH). The local node delays the end chain (EC) and change direction (CD) indicators if they occur in the RH of the RU's first segment, and sets the corresponding ECI and CDI application flags in the **Data** message corresponding to the last segment of the RU. Therefore, the **Data** messages corresponding to RU segments have application flags set as if they corresponded to whole RUs. This considerably simplifies the handling of chaining, bracket, and half-duplex protocols for an application using the segment delivery option.

Note
EB is not delayed until end basic information unit (EBIU), because the application should use the Status-Session between-brackets message to determine when to enter the between-brackets state.

Brackets

This section primarily describes the bracket protocols between the local node and an application for a session supporting half-duplex flip-flop with brackets.

The local node enforces no bracket protocols for full-duplex sessions. Therefore, messages with begin bracket (BB) are not presented as **Status-Control(BID)** messages, and there are no **Status-Session(BETB)** messages.

The management of this protocol for a generalized application is complex, and there is a significant amount of code in the local node to simplify the application's perception of the protocol. An application is only aware of two states:

- In-bracket
- Between-bracket

The local node, in addition to the states of in-bracket and between-bracket, maintains transient states with a large state transition matrix, or finite-state machine, governing the half-session's state at a particular time.

In This Section

Bracket Initiation

While a session is in the between-bracket state, contention exists. Either the application or the host primary logical unit (PLU) can attempt to initiate a bracket, as follows:

- The application initiates a bracket by sending a Data message with the begin bracket indicator (BBI) application flag and **ACKRQD** set while in the between-bracket state. The local node sends a request corresponding to the **Data** message to the host PLU. The application has successfully initiated a bracket and is in the in-bracket state. Flip-flop protocols are now in force until the bracket is terminated.

- The application initiates a bracket by sending a **Status-Control(LUSTAT)** with the BBI application flag set while in the between-bracket state. The local node sends an **LUSTAT** request to the host PLU. The application has successfully initiated a bracket and is in the in-bracket state. Flip-flop protocols are now in force until the bracket is terminated.

- The host PLU sends a **BID** request while in the between-bracket state. The local node sends a **Status-Control(BID)** with **ACKRQD** to the application. (For more information, see Status-Control Message.) The application replies with a **Status-Control(BID) Acknowledge**, to indicate that it is willing to accept a bracket. The local node sends a positive response to the **BID** request. The host PLU has successfully initiated a bracket, and the application's state is in-bracket, with flip-flop protocols applying until the bracket is terminated.

- The host PLU sends data in an RU carrying the BB indicator in the RH while in the between-bracket state. The local node presents this method of initiating a bracket in the same way as if the host PLU had initiated the bracket with **BID**. The local node sends a **Status-Control(BID)** with **ACKRQD** to the application. The application replies with a **Status-Control(BID) Acknowledge** to indicate that it is willing to accept the bracket. The local node sends the Data message corresponding to the RU to the application and sends a positive response to the data RU. The host PLU has successfully initiated a bracket, and the application's state is in-bracket, with flip-flop protocols applying until the bracket is terminated.

- The host PLU sends an **LUSTAT** request carrying the BB indicator in the RH. The local node presents this method of initiating a bracket in the same way as if the host PLU had initiated the bracket with **BID**. The local node sends a **Status-Control(BID)** with **ACKRQD** to the application. The application replies with a **Status-Control(BID) Acknowledge** to indicate that it is willing to accept the bracket. The local node sends a **Status-Control(LUSTAT)** to the application, which requires an acknowledgment. The host PLU has successfully initiated a bracket, and the application's state is in-bracket, with flip-flop protocols applying until the bracket is terminated.

- The host attempts to initiate a bracket using a **BID** request or an RU carrying BB, which the local node sends to the application as a **Status-Control(BID)**, but the application cannot accept the bracket. The application should send a negative **Status-Control(BID)** response with an appropriate sense code. The local node sends a negative response to the BID carrying the sense code supplied by the application. The application's state is still between-bracket. The application should use one of the following sense codes:

    - 0x081B if it has already committed resources for an inbound transfer. For example, a terminal operator has begun typing.

    - 0x0814 if it currently cannot begin a bracket but will notify the host when resources become available. For example, a 3270 printer is being used for local copy in between-bracket printer sharing mode. At a later stage when the resources become available, the application should temporarily reserve the resources and send a **Status-Control(RTR)** to the local node. If the host rejects the **RTR**, the local node returns a **Status-Control(RTR) Negative-Acknowledge-1** response, and the application can release the resources. Otherwise, the host attempts to initiate a bracket that the application must now accept.

- If the application has successfully initiated a bracket, a bracket race may occur due to the host PLU attempting to initiate a bracket. The application gets a **Status-Control(BID) Request**, which it should reject with 0x080B or 0x0813. The application retains direction after race negative responses. (For more information, see Recovery.) The application's bracket state remains as in-bracket.

The application needs to be aware of one further complication in bracket initiation. All the cases relate to sessions whose bracket reset state is between-bracket. A state of contention exists, and either half-session can attempt to begin a bracket.

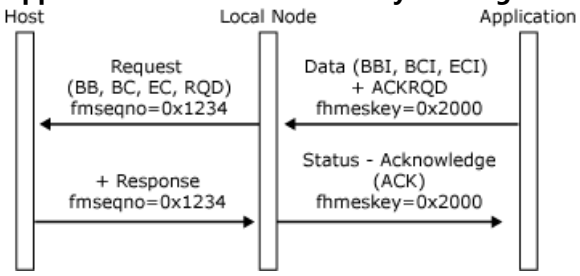
However, the **BIND** parameters for the session can specify a bracket reset state of in-bracket. If the bracket reset state is in-bracket, one half-session is considered to have already successfully initiated a bracket. Flip-flop protocols will then apply until a **Status-Session(BETB)** is received, at which time the session reverts to a contention state and bracket initiation proceeds as described earlier.

The application must set its bracket state when the PLU connection is opened (on receipt of the Open(PLU) OK Confirm message) and reset it each time the session is reset (after receipt of a **Status-Control(CLEAR) Request**). The appropriate bracket reset state for the session is supplied to the application in the BICB on the Open(PLU) OK Confirm message.

The following six figures illustrate bracket initiation protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

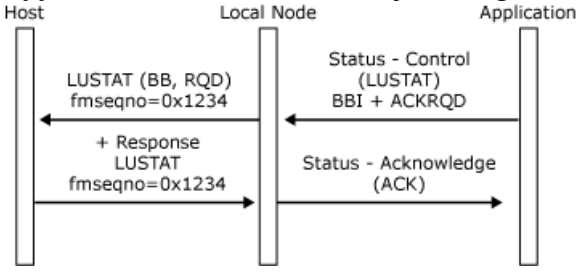
In the first figure, the application initiates a bracket by sending an inbound chain with the BBI application flag set when its state is between-bracket. The application's state is in-bracket until it receives a **Status-Session(BETB)**. (If the application can send RQE chains, a bracket can be opened by sending an RQE chain.)

Application initiates a bracket by sending an inbound chain



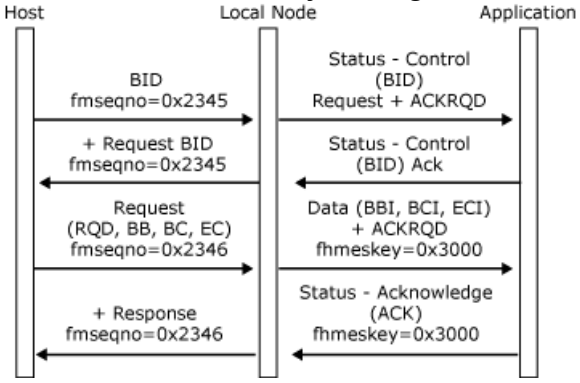
In the following figure, the application initiates a bracket by sending a **Status-Control(LUSTAT)** with the begin bracket indicator (BBI) application flag set when its state is between-bracket. The application's state is in-bracket until it receives a **Status-Session(BETB)**. The **LUSTAT** can be sent **NOACKRQD** (RQE) if required.

Application initiates a bracket by sending a Status-Control(LUSTAT)



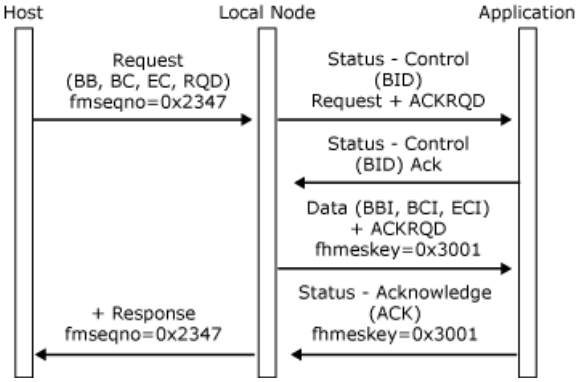
In the following figure, the host initiates a bracket by sending **BID**, which the application accepts. The application's state is in-bracket and the host can send.

Host initiates a bracket by sending BID



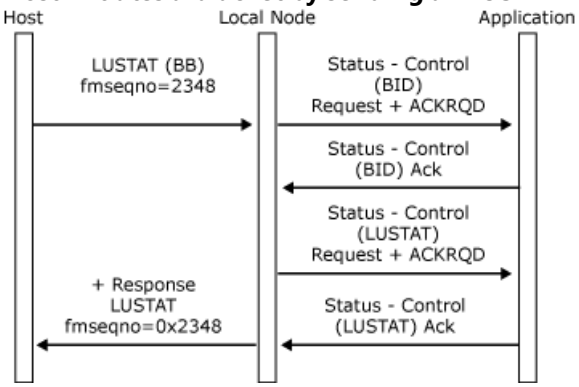
In the following figure, the host PLU initiates a bracket by sending a request with begin bracket (BB), which the application accepts. The application's state is in-bracket, and the host can send.

Host PLU initiates a bracket by sending a request with BB



In the following figure, the host initiates a bracket by sending an **LUSTAT** with BB, which the application accepts. The application's state is in-bracket, and the host can send.

Host initiates a bracket by sending an LUSTAT with BB



In the following figure, the host and application both attempt to initiate a bracket in between-bracket state. The application rejects the host bids with sense code 0x0813, and the local node delivers the application's data. After sending the data, the application's state is in-bracket, and the application can send.

Host and application both attempt to initiate a bracket in between-bracket state

Bracket Termination

The local node supports bracket termination rule one (conditional) and bracket termination rule two (unconditional), as specified in the **BIND** request. Some sessions only allow bracket termination by one session partner. This is a **BIND** option, supplied in the bind information control block (BICB) on Open(PLU) OK Confirm), and it is the application's responsibility to determine if (and when) it should request bracket termination.

If an application is allowed by its **BIND** to terminate brackets, it does so by setting the End Bracket Indicator (EBI) application flag in an inbound Data or **Status-Control(LUSTAT/CHASE/QC/CANCEL)** message. The bracket is only terminated when the application receives a Status-Session (BETB) from the local node.

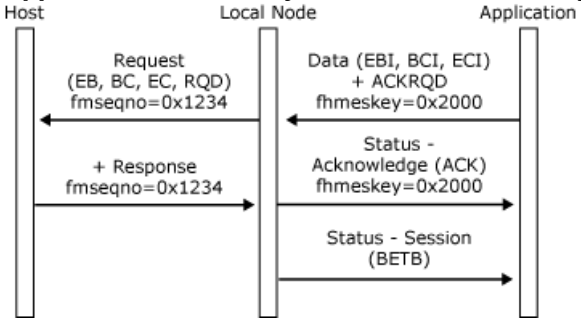
If the host terminates a bracket successfully, the local node sends a **Status-Session(BETB)** to the application. Note that the EBI application flag on outbound messages does not indicate bracket termination, but indicates that the corresponding request/response unit (RU) carried End Bracket (EB). The bracket is only terminated when the application receives **Status-Session(BETB)**.

Note that if the application queues data, it should also queue **Status-Session(BETB)** messages. They must not be processed as expedited.

The following two figures illustrate bracket termination protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the following figure, the application successfully terminates a bracket by sending an EBI data chain when the application's state is in-bracket, which the host accepts. The local node sends a **Status-Session(BETB)** to indicate that the application's state is now between-bracket.

Application successfully terminates a bracket by sending an EBI data chain



In the following figure, the host successfully terminates a bracket by sending an EBI data chain when the application's state is in-bracket, which the application accepts. The local node sends a **Status-Session(BETB)** to indicate that the application's state is now between-bracket.

Direction

When an function management interface (FMI) application is communicating on its primary logical unit (PLU) connection with a normal flow request mode other than full-duplex (that is, half-duplex flip-flop or half-duplex contention), it must obey the SNA direction protocol. These two modes are treated separately.

In This Section

- Half-Duplex Flip-Flop Direction
- Half-Duplex Contention

Half-Duplex Flip-Flop Direction

The **BIND** used to establish the session carries information about the initial state of the bracket and direction machines. This can be specified in the **BIND** if either of the following conditions are satisfied:

- Brackets are not used.
- Brackets reset state is in-bracket.

If neither of the conditions hold, the initial direction state is contention.

When the direction is specified in the **BIND**, the application should assume the direction state specified in the half-duplex reset state as soon as data can flow. This field can be obtained indirectly by using a **BIND** check index that only accepts a particular direction, or directly by reading the **HDXRSET** field in the bind information control block (BICB) on the Open(PLU) OK Confirm message or by reading the **BIND** on the Open(PLU) Request. For more information about opening the PLU connection, see Opening the PLU Connection.

When in contention state, either the PLU or the application can initiate a bracket. (For more information, see Brackets.) The successful initiator of the bracket obtains direction unless direction is relinquished when opening the bracket by sending Begin Bracket (BB), Begin Chain (BC), End Chain (EC), or Change Direction (CD). Because the secondary is assumed to be the contention winner, the application can assume send state from contention sending BB and rejecting any subsequent **Status-Control(BID) Request** from the local node before receiving **Status-Session(BETB)**. When the application accepts a S**tatus-Control(BID) Request** in contention state, it must assume receive state.

Half-duplex flip-flop direction can change through the following actions:

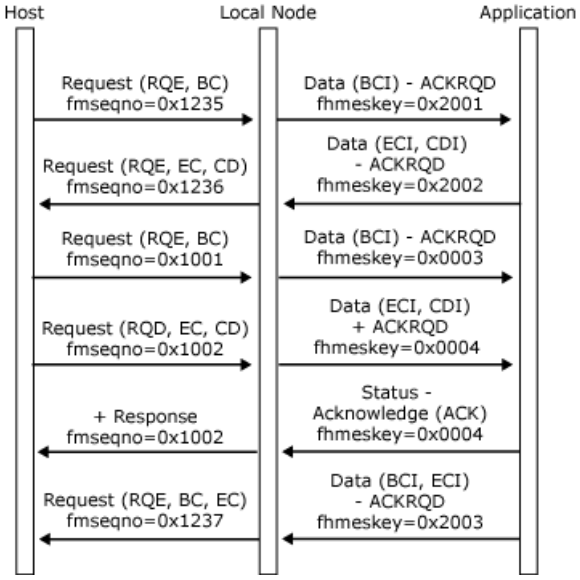
- Sending or receiving data with the change direction (CD) indicator in the RH, and the corresponding change direction indicator (CDI) flag on the **DATAFMI** and Status-Control messages. Note that CD is only used at the end of a chain (and for applications receiving segments that will be delivered with ECI, EBIUI). Also note that CD is valid on the following normal flow **Status-Control** requests: **LUSTAT**, **CANCEL**, **CHASE** and **QC**.
- Receiving a negative response when the application should assume receive state (error recovery pending state). For more information, see Recovery.
- If the application rejects data from the host carrying CDI, it must remain in receive state.

Providing the FM profile is correct (3, 4, or 7), the application can request direction from the host using a **Status Control(SIGNAL) Request** with CODE1 set to 0x0001. CODE2 is set to a user-defined value.

The following three figures illustrate the direction protocol for applications using the half-duplex flip-flop mode.

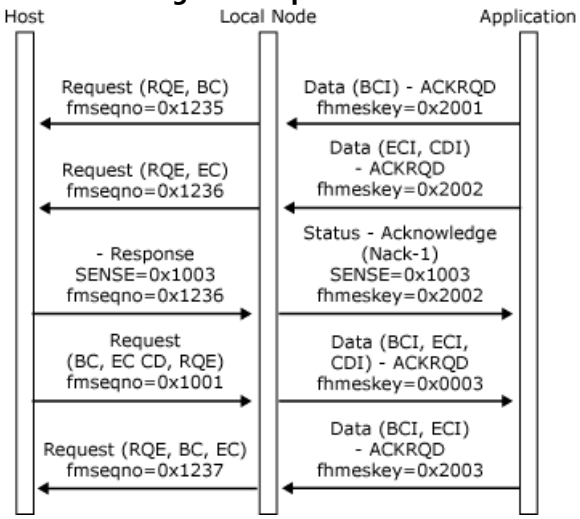
In the first figure, the application issues and receives the CD without error.

Application issues and receives the CD without error



In the following figure, the host sends a negative response to inbound data. The application assumes receive state, and then the host sends CD to give the application direction.

Host sends negative response to inbound data



In the following figure, a complete outbound chain is received without error, but is rejected by the application. Note that even though the chain carried CD, the application does not have direction.

Complete outbound chain received without error, but is rejected by application

Half-Duplex Contention

For half-duplex contention, the initial direction state is contention. Half-duplex protocol operates during a chain (only one partner can send), but the direction state normally returns to contention at the end of each chain. The change direction indicator (CDI) in the response header (RH) is thus not required. However, if the CDI is used, direction is reserved for the receiving half-session. Therefore, if the application receives change direction (CD), it should assume send state and not expect to receive data. Conversely, if the application sends CD, it cannot send again until it has received a chain from the host.

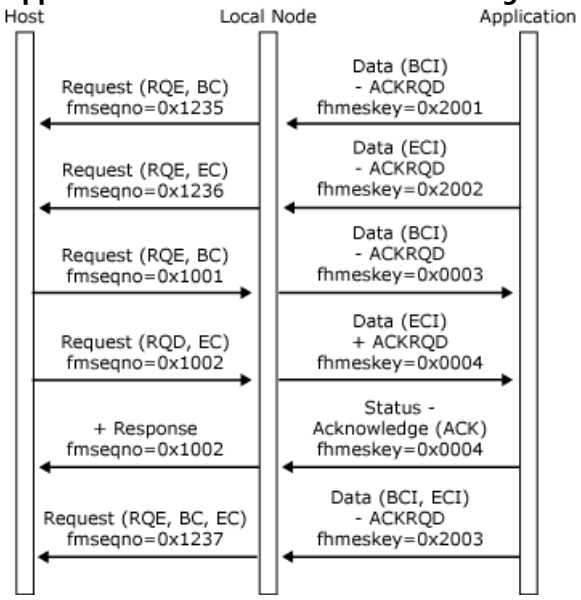
In the event of an error being discovered by either half-session, the application must assume receive state, because the host is responsible for recovery.

If both half-sessions attempt to start a chain when the direction state is contention, the race is resolved in favor of the secondary application using a sense code of 0x081B. However, the possible window between the local node and the application means that the local node cannot determine when outbound Request Exception (RQE) data is received by the application. Therefore, if the local node receives data from the application while it determines that the half-duplex contention state is receive, it will reject it with a noncritical NACK-2 (0x2004 direction).

The following two figures illustrate the direction protocol for applications using half-duplex contention mode. The three figures in the previous topic would also be valid although CD does not need to be specified.

In the following figure, the application issues and receives data using half-duplex contention protocol without error.

Application issues and receives data using half-duplex contention protocol without error



In the following figure, the half-duplex contention race is resolved in favor of the application.

Resolving half-duplex contention race in favor of the application

Pacing and Chunking

The local node supports session pacing inbound and outbound, according to the pacing values in the **BIND** parameters for the session. The application can be involved in outbound pacing through the use of the Status-Resource message. Inbound pacing is handled transparently by the local node and need not concern the application.

In This Section

- Outbound Pacing
- Chunking

Outbound Pacing

If the application has enough resources to handle outbound data as fast as the network can provide it (for example, a screen), or if a higher level protocol (for example, immediate request mode) constrains the data flow, the application need not be involved in pacing, and it is possible for the local node to handle outbound pacing transparently.

However, certain types of applications may require involvement in outbound pacing. If the application has limited resources (for example, a printer), the application should specify the application pacing option in the connection information control block (CICB) on the Open(PLU) OK Response. (For more information, see Opening the PLU Connection.) The application should also provide the local node with information about the state of these resources initially on the **Open(PLU) OK Response** and periodically using **Status-Resource** messages.

To assist the application in calculating the initial credit field in the **Open(PLU) OK Response**, the local node delivers the pacing window sizes and the primary and secondary maximum request/response unit (RU) sizes on the Open(PLU) Request. The initial credit must be at least as large as the primary to secondary pacing window size. Otherwise, the **BIND** will be rejected and the application will be sent an Open(PLU) Error Confirm message. The local node fills in a suggested initial credit value of one more than the pacing window (to try to avoid stop-start situations).

Note that the local node will also reject the **BIND** if the application specifies that it needs to be involved in pacing (of whatever initial credit), but the **BIND** specifies that there is no outbound pacing.

Only function management data (FMD) requests are part of the credit scheme, so the application must maintain space within its buffer for one Status-Control request per RU in addition to the number of RUs specified by the initial credit count. (A **Status-Control** message takes up 36 bytes.)

Each unit of credit that the application delivers to the local node allows the local node to give the application a single RU (or a single chunk if chunking is being used). Note that if the application is receiving segments, this may correspond to several **DATAFMI** messages. The application can count RUs for the purpose of outbound flow control by using the begin basic information unit (BBIU) and end basic information unit (EBIU) flags.

The application should maintain a credit-used count, which it should report to the local node on Status-Resource messages. The application needs to take the following actions:

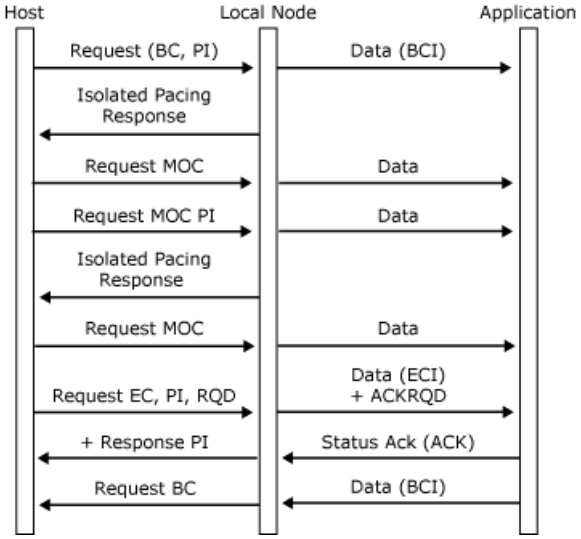
- On processing (not receiving) **DATAFMI** messages with EBIU set (corresponding to FMD requests), increment the credit-used count by one.
- On processing **Status-Control** messages and all other messages from the local node, do not increment the credit-used count.
- Periodically report the current credit-used count on a **Status-Resource** message.
- Report the credit-used count when its buffer becomes empty (whatever the last message processed was), unless the credit-used count is zero.
- When the credit-used count is reported to the local node, reset it to zero.

The frequency at which the application provides Status-Resource messages is not architected. However, the local node will only send the application as many Data messages as it has received credit for. When the application's credit-used count reaches the initial credit value, the local node will not send any more data. The application should attempt to send a **Status-Resource** message before this happens, because if the local node cannot send a **Data** message to the application and the host is still sending requests, the local node may not be able to send a pacing response to the host when required, with a consequent degradation of performance.

If the pacing window is small, such as one or two, the application should send a **Status-Resource** after processing each **DATAFMI** message to enable the local node to send the suitable pacing response.

The following figure shows the local node handling outbound pacing when the application is not involved (APPLPAC = 0x00). The pacing window is assumed to be two.

Local node handling outbound pacing



The following figure shows the local node and the application handling outbound pacing with the outbound pacing window assumed to be two and the initial credit from the local node to the application assumed to be four. Note that the local node can send an isolated pacing response (IPR) to the host to get another window full of data as soon as the application has sufficient credit for the rest of the present window and the next window.

Chunking

Chunking can be thought of as similar to segmentation. (For more information, see Segment Delivery.) The distinction is that segmentation is determined by the communications link between the local node and the remote system, whereas chunking is determined by the communications link between the application and the local node.

The application indicates on the Open(SSCP) Request whether it supports chunking, and, if so, the chunk size in bytes that it wants to use. The local node then uses the request/response unit (RU) size, the chunk size, and the segment size (if applicable) to determine whether chunking is necessary. It then specifies the chunk sizes used for inbound and outbound flow (which need not be the same) on the Open(PLU) Request. These values are specified in units of elements. (For more information, see Messages.) A value of zero for either of these sizes indicates that chunking is not necessary because the chunk size is not the limiting factor. Note that in chunking data, an RU will not be split in the middle of an element. This avoids data copying.

For example, assume that the local node is using an RU size of 8 kilobytes (KB) and segments of 2 KB, and the application's **Open(SSCP) Request** specifies segment delivery and a chunk size of 4 KB. Chunking will be used on inbound data flow (because the chunk size is smaller than the RU size), but is not necessary on outbound data flow (because data will be delivered in segments that are smaller than the chunk size).

If chunking is being used in either direction, all credit values specify the number of chunks that can be sent in that direction, not the number of RUs. Note that the segment delivery option is included on the **Open(SSCP) Request** to enable the local node to calculate the initial chunk credit values on the corresponding PLU connection. The application must also set this option on the **Open(PLU) Response**. If the **Open(SSCP) Request** and the **Open(PLU) Response** have different settings of this option, the setting from the **Open(PLU) Response** will be used. This can mean that the initial credit value used is not appropriate.

If session-level pacing is being used, the local node links this to the chunking credit. In particular, if the application withholds credit, the local node will delay sending a pacing response to the host, thereby applying back pressure to the host. This linkage is handled by the local node and need not concern the application.

Application flags on chunks of RUs are handled in the same way as those on segments. (For more information, see Application Flags and Segment Delivery.) In particular:

- FMHI, BCI, COMMIT, BBI, EBI, CODE, ENCRYP, ENPAD, QRI, and CEI are only set on the first chunk of an RU.
- ECI and CDI are only set on the last chunk of an RU.
- BBIUI is always set on the first chunk of an RU.
- EBIUI is always set on the last chunk of an RU.

Note that EBI is set on the first chunk of the last RU in a bracket and not on the last chunk as might be expected. This is the same behavior as for segment delivery. The application should use the **Status-Session(BETB)** message, not the EBI flag, to determine when a bracket has ended.

Chunks are identified using the segmentation flags BBIUI and EBIUI, and therefore the application cannot distinguish between chunks and segments if both segmentation and chunking are being used outbound. However, there is generally no need for the distinction. The application can perform window shading by displaying each unit of data as it is received, whether the unit of data is a segment or a chunk. (For more information, see Segment Delivery.)

Note
Previous versions of this document indicated this as a future feature. The support is enabled in Host Integration Server 2009. Applications can test the product version returned on a call to sepdgetinfo for version 1.2 or later before using the chunking system.

In some cases, the RU size used by the local node may be too large for the length of the path between the local node and an FMI application, for example, when using a 16 megabyte (MB) token-ring link, which can support 16 kilobyte (KB) frames. The local node allows an FMI application to specify that data transfer should be in smaller units, called chunks.

Confirmation and Rejection of Data

The following topics describe conditions under which inbound and outbound data is confirmed or rejected.

In This Section

- Confirmation and Rejection of Inbound Data
- Confirmation and Rejection of Outbound Data

Confirmation and Rejection of Inbound Data

For every SNA chain of data sent or received for which responses are outstanding, such as Request Exception (RQE) or Definite Response Required (RQD), the local node maintains a correlation table entry. If the table entries become depleted, the local node will terminate the session using the most table entries. A Status-Error message (code 0x46) and a Close(PLU) Request are sent to the application, and a **TERM-SELF** message is sent to the host. Table entry shortages (inbound) can be avoided by sending change direction (CD) (for half-duplex) data, or data **ACKRQD,** or any **Status-Control(CHASE)**, or **Status-Control(LUSTAT)** with **ACKRQD**. Outbound shortages can be avoided by sending courtesy acknowledge messages as described in Opening the PLU Connection.

The local node sends chains of data to the host with their chain response mode specified as follows:

1. Definite

   If the application sends a **Data** message to the local node with the **ACKRQD** field set, and the **BIND** parameters specified that the secondary uses definite or definite/exception response mode.

2. Exception

   If the application sends a **Data** message to the local node without the **ACKRQD** field set, and the **BIND** parameters specified that the secondary uses exception or definite/exception response mode.

3. No-Response

   If the application sends a **Data** message to the local node without the **ACKRQD** field set, and the **BIND** parameters specified that the secondary uses no-response mode.

If the setting of **ACKRQD** on a Data message from the application does not reflect the chain response mode specified in the **BIND** parameters, the local node returns a Status-Acknowledge(Nack-2) indicating a noncritical error code. For example, if the application specifies **ACKRQD** but the **BIND** parameters do not permit the local node to send definite response chains.

In case 1, the application receives an acknowledgment to all function management data (FMD) chains it sends to the local node:

- Positive responses from the host are returned to the application as Status-Acknowledge(Ack) messages.
- Negative responses from the host are returned as Status-Acknowledge(Nack-1) messages carrying the SNA sense codes.
- Errors detected by the local node when attempting to send the message are returned as Status-Acknowledge(Nack-2) messages carrying the equivalent error code.

In case 2, the application only receives an acknowledgment of an FMD chain it sends to the local node for:

- Negative responses from the host, which are returned as **Status-Acknowledge(Nack-1)** messages carrying the SNA sense codes.
- Errors detected by the local node when attempting to send the message, which are returned as **Status-Acknowledge(Nack-2)** messages carrying the equivalent error code.

In case 3, the application only receives an acknowledgment of an FMD chain it sends to the local node when the node detects an error in the message and sends the application a **Status-Acknowledge(Nack-2)**. The only dissent that the host can make is to send a subsequent LUSTAT 0x400A (no response not supported) with the sequence number of the request in the sense qualifier field. This is presented to the application as a **Status-Control(LUSTAT)** as usual.

Whenever an application receives a **Status-Acknowledge(Ack)** or **Status-Acknowledge(Nack-1)**, it implicitly confirms receipt by the partner half-session in the host of all previously sent chains.

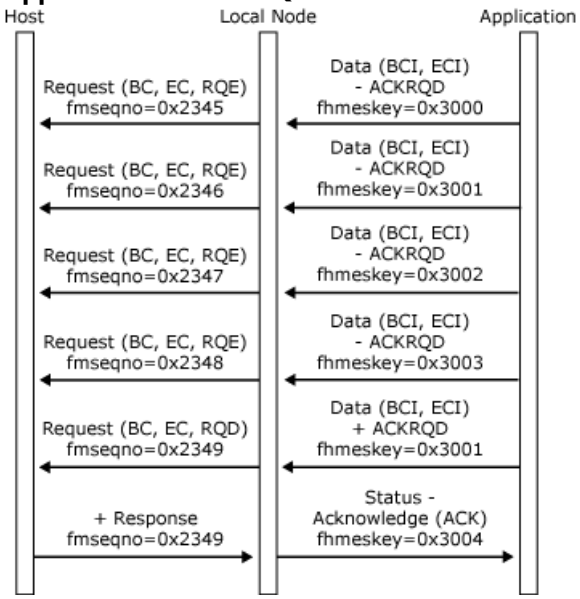
In case 2, the application does not usually receive such responses from the host to chains it has sent, and in case 3, the application never receives such responses. Therefore, to get the host to confirm receipt of all previously sent chains, the

application should issue a **Status-Control(CHASE) Request** with ACKRQD set. This causes the local node to generate an SNA **CHASE** request to the host. The receipt of the response to this CHASE confirms that the host has received this **CHASE** request and all previous chains sent by the application. The local node issues a **Status-Control(CHASE) Acknowledge** to notify the application that this is so.

The following three figures illustrate the inbound data confirmation and rejection protocols between the local node and the application, and how those protocols relate to the underlying SNA protocols.

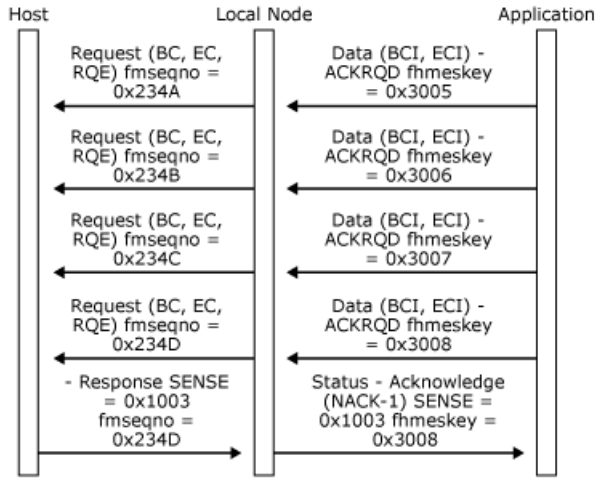
In the first figure, an application sets the **ACKRQD** field in an inbound data chain to get the host to confirm receipt of the chain and all previously sent chains.

Application sets ACKRQD field



In the following figure, the **Status-Acknowledge(Nack-1)** rejects the last chain, but confirms receipt by the host of all previously sent data chains.

Status-Acknowledge(Nack-1) rejects the last chain, but confirms receipt



In the following figure, the application uses a **Status-Control(CHASE)** to get the host to confirm receipt of the corresponding **CHASE** request and all previously sent chains.

Using a Status-Control(CHASE) to get the host to confirm receipt of the corresponding CHASE request

Confirmation and Rejection of Outbound Data

The local node sends chains of data from the host to the application with their **ACKRQD** field set as follows:

- **ACKRQD** set

  If the corresponding SNA request was received specifying definite response, and the **BIND** parameters specify that the primary uses definite or definite/exception chain response mode.

1. **ACKRQD** not set, response mode

   If the corresponding SNA request was received specifying exception response, and the **BIND** parameters specify that the primary uses exception or definite/exception chain response mode.

2. **ACKRQD** not set, no-response mode

   If the corresponding SNA request was received specifying no response, and the **BIND** parameters specify that the primary uses no-response chain response mode.

In case 1, the application should always send an acknowledgment as follows:

- If the application accepts the data, it should return a Status-Acknowledge(Ack) message.
- If the application wants to reject the data, it should return a **Status-Acknowledge(Nack-1)** message carrying the appropriate SNA sense codes.

In case 2, the application should only send an acknowledgment in the following cases:

- If the application wants to reject the data, it should return a **Status-Acknowledge(Nack-1)** message carrying the appropriate SNA sense codes.
- The application can send a courtesy acknowledgement to a Request Exception (RQE) message to clear up correlation data within the local node. (For more information, see Outbound Data.)

In case 3, the application should not send acknowledgments. However, the sending of a **Status-Acknowledge(Ack)** or **Status-Acknowledge(Nack-1)** by the application has no effect. It is discarded.

Whenever an application sends a **Status-Acknowledge(Ack)** or **Status-Acknowledge(Nack-1)** to a received Data message, it implicitly confirms receipt of this and all previously received Data messages.

In case 2, the host can issue a **CHASE** request. The local node sends a **Status-Control(CHASE) Request** with **ACKRQD** set to the application. When the application is in a position to confirm receipt of all outstanding data, it should issue a **Status-Control(CHASE) Acknowledge** message, which the local node converts into a positive response to **CHASE** for the host.

In cases 1 and 2, if the local node detects an error in a received request, it converts the request into a special Data message, which it passes to the application. Regardless of the chain response mode specified for the secondary in the **BIND** parameters, this **Data** message has the following characteristics:

- **ACKRQD** is set. The application must confirm receipt using a Status-Acknowledge(Ack) message.
- The Sense Data Indicator (SDI) application flag is set to indicate that this is a special Data message used to inform the application of an error detected by the local node.
- The End Chain Indicator (ECI) application flag is set to indicate that the received chain has now terminated.
- The first four bytes of the buffer element hold the SNA sense codes detected by the local node that caused the termination.

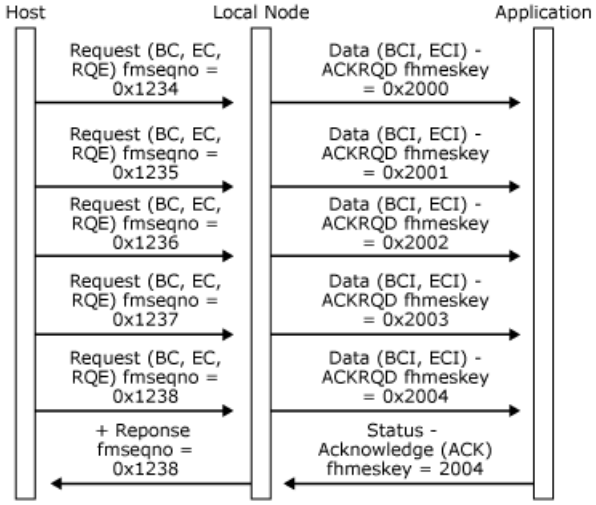
This mechanism enables:

- The application to reject any previously received **Data** messages.
- The local node to inform the application of any errors it detects in received requests.
- The local node to send negative responses in the correct order.

The following three figures illustrate the outbound data confirmation and rejection protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

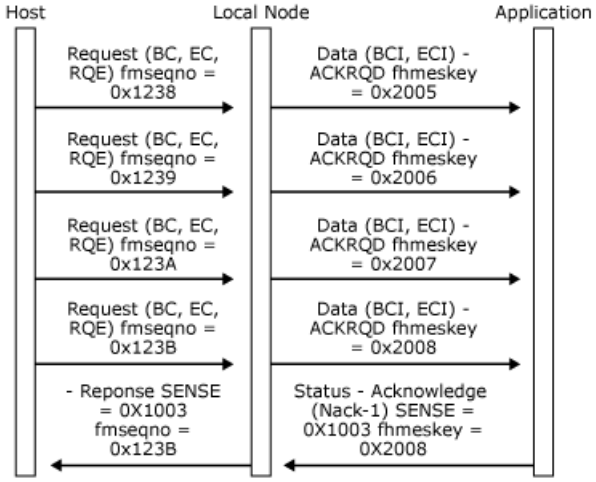
In the first figure, the host sends a definite response chain to get the application to confirm receipt of the RQD request and all previously sent RQE chains.

Host sends a definite response chain



In the following figure, a **Status-Acknowledge(Nack-1)** from the application rejects the last chain and confirms receipt of all previously sent data chains.

Status-Acknowledge(Nack-1) rejects the last chain and confirms receipt



In the following figure, the host sends a **CHASE** request to get the application to confirm receipt of the **CHASE** and all previously sent chains.

Host sends a CHASE request

Shutdown and Quiesce

Both shutdown and quiesce protocols involve a half-session entering a quiesced state, in which it cannot send any more normal flow requests, but must continue to receive and respond to requests from its session partner. The essential differences are that shutdown can only be initiated by the host and only requires that the secondary quiesce as soon as is convenient (usually at the end of a bracket). Quiesce can be initiated by both the host and the application and requires that the recipient quiesce at the end of the chain.

If the application has been quiesced but still attempts to send inbound Data messages, they will be rejected with Status-Acknowledge(Nack-2) messages. The application can, however, continue to generate status messages.

In This Section

- Shutdown
- Quiesce

Shutdown

The shutdown protocol provides a means for the host application to stop the application from sending any further normal flow requests. This protocol is used when the host application wants to end the session in an orderly manner and is only available for sessions using function management (FM) profile 3 or 4.

If the local node receives a **SHUTD** request from the host, it issues a **Status-Control(SHUTD) Request** (without **ACKRQD**) to request the application to enter a quiesced state at a convenient time. The application determines what is convenient. For example, it could be after a **Status-Session(BETB)** has been received.

When the application decides it is ready to quiesce, it should issue a **Status-Control(SHUTC) Request** (again without **ACKRQD**) to indicate this transition. The local node will notify the host of this change by sending a **SHUTC** request. The host can continue sending normal flow outbound requests and can subsequently take one of the following actions:

- The host terminates the primary logical unit (PLU) session by sending an **UNBIND** request. The local node closes the PLU connection by sending a Close(PLU) Request to the application. The system services control point (SSCP) session remains active.

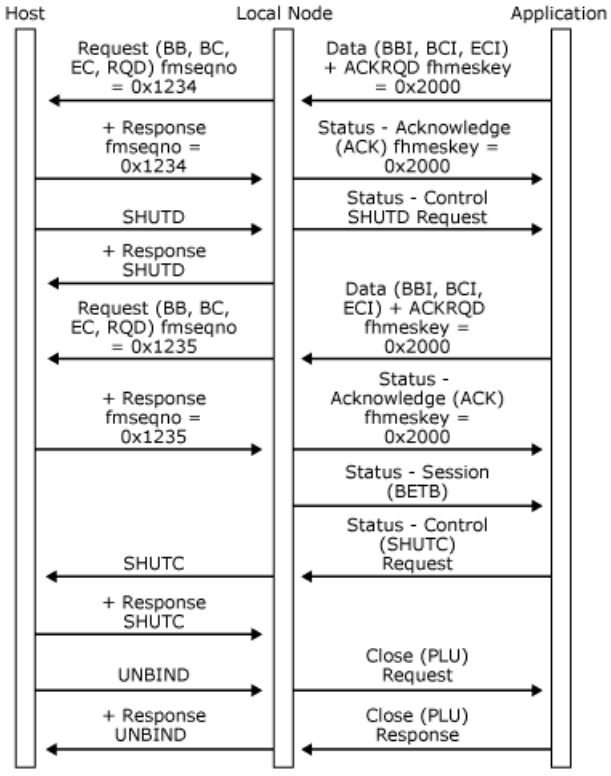
- The host abandons the shutdown procedure by sending an **RELQ** request. The local node sends a **Status-Control(RELQ) Request** (with **ACKRQD**) to the application to indicate that it can now resume sending on the PLU session. **RELQ** is only supported on sessions using FM profile 4.

- The host resets the session by sending **CLEAR**, a Transmission Service profile (TS profile) 3 or 4. One of the effects of this is to release the quiesced state. (For more information, see Recovery.)

The following two figures illustrate the shutdown protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

In the following figure, the host sends **SHUTD** while the application is sending in the in-bracket state. The application completes the bracket, sends **Status-Control(SHUTC) Request**, and the host terminates the PLU session by sending **UNBIND**. The local node closes the PLU connection.

Host sends SHUTD while the application is sending in the in-bracket state



In the following figure, the host sends **SHUTD** while the application is sending in the in-bracket state. The application completes the bracket, sends **Status-Control(SHUTC) Request**, and then the host releases the application from the quiesced state by sending **RELQ**. The local node sends a **Status-Control(RELQ) Request** to the application, which initiates a new bracket.

Host sends SHUTD while the application is sending in the in-bracket state

Quiesce

The quiesce protocol is only supported on sessions using function management (FM) profile 4. The quiesce protocol can be initiated by either half-session.

When an application wants to quiesce its partner half-session in the host, it sends a **Status-Control(QEC) Request** to the local node. The node generates a **QEC** request to the host, which asks the host to quiesce after completing the current outbound chain.

If the host quiesces, it sends a **QC** request, which the local node presents to the application as a **Status-Control(QC) Request** (with **ACKRQD**). The host remains in a quiesced state until the application sends a **Status-Control(RELQ) Request**. The local node sends the **RELQ** request to the host, and the host resumes communications on the primary logical unit (PLU) session.

If the attempt to quiesce the host fails, the host responds with a negative **QEC** response, which the local node presents to the application as a **Status-Control(QEC) Negative-Acknowledge-1**.

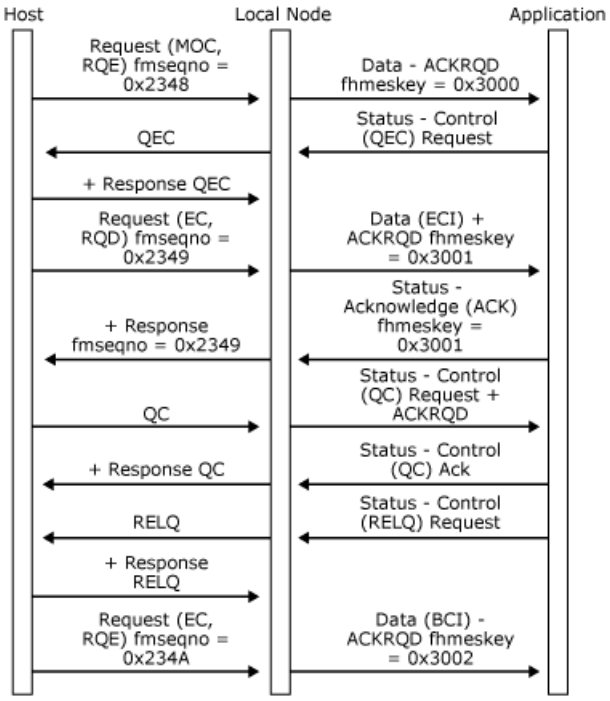
Conversely, a **Status-Control(QEC) Request** (without **ACKRQD**) is presented to the application if a **QEC** request is received from the host. In this direction, **QEC** cannot be rejected. The local node will always force the application to quiesce after presenting it with a **Status-Control(QEC) Request** by rejecting further attempts to send inbound data. When the application has quiesced, it should send a **Status-Control(QC) Request** to the local node, which sends a **QC** request to the host. The application can subsequently be released by an **RELQ** request from the host, which the local node presents to the application as a **Status-Control(RELQ) Request**.

The receipt of a **CLEAR** or **UNBIND–BIND** sequence, **Close(PLU)–Open(PLU)**, causes the quiesced state to be released.

The following three figures illustrate the quiesce protocols between the local node and the application and how those protocols relate to the underlying SNA protocols.

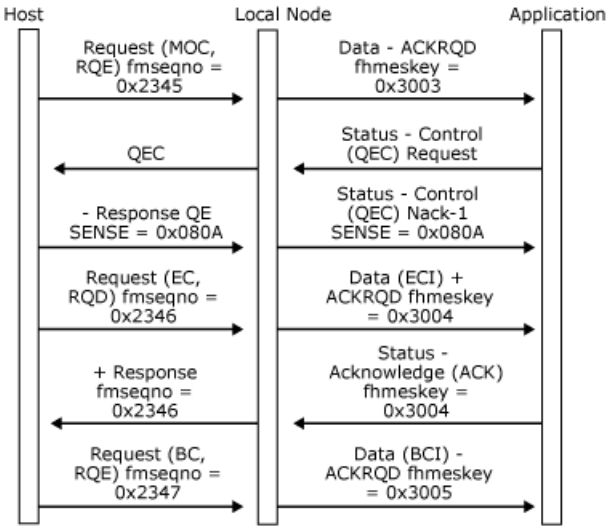
In the first figure, the application quiesces the host and then releases the quiesce.

Application quiesces the host and releases the quiesce



In the following figure, the application attempts to quiesce the host, but the host rejects the quiesce and continues with the next chain.

Application attempts to quiesce the host, but the host rejects and continues with the next chain



In the following figure, the host sends **QEC** while the application is sending a chain. The application completes the chain and sends a **Status-Control(QC) Request**. The host releases the quiesce by sending **RELQ**, and the local node sends a **Status-Control(RELQ) Request** to the application, which then initiates a new chain.

Host sends QEC while the application is sending a chain

Recovery

This section covers a variety of issues pertaining to error recovery.

In This Section

Application CANCEL

One of the parameters on the Open(PLU) OK Response, which the application sends to the local node, specifies whether the application generates **CANCEL** (or **EC**) to terminate an inbound chain that has received a negative response. If this option is not selected, the local node generates a **CANCEL** request when it receives a negative response from the host to an incomplete chain.

Concepts

Direction after Receiving a Negative Response

Direction after Sending a Negative Response

Critical Failure

Link Service Failure

Local Node Failure

Client Failure

Direction after Receiving a Negative Response

Within the local node, error recovery for a half-duplex application (as specified by byte 7 bit 2 of the **BIND**) is assumed to be the responsibility of the host. However, the application must be aware that an error recovery state has been entered to obey the direction protocol.

When an application using half-duplex protocols (flip-flop or contention) receives a negative response to an inbound chain that it sent that does not refer to a race, it must assume receive state. The sense codes used for race conditions that do not require the transition to receive state are listed in the following table.

Sense code	Description
0x080B	Bracket race error
0x081B	Receiver in transmit mode

Reference

RQR and CLEAR

STSN

Concepts

Application CANCEL

Direction after Sending a Negative Response

Critical Failure

Link Service Failure

Local Node Failure

Client Failure

Direction after Sending a Negative Response

When an application using half-duplex flip-flop protocol sends a negative response to an outbound chain (or sends a Status-Acknowledge(Ack) to a **DATAFMI** message with **SDI** set) that does not refer to a race, the application must assume an error recovery pending state. The sense codes used for race conditions that do not require the transition to error recovery pending state are listed in the following table.

Sense code	Description
0x080B	Bracket race error
0x0813	Bracket bid reject (no RTR forthcoming)
0x0814	Bracket bid reject (RTR forthcoming)
0x081B	Receiver in transmit mode

The application must therefore examine the sense code on an **SDI** message to detect such races.

Error recovery pending state differs from receive state only in one respect: The application can convey sense information to the host using **Status-Control(LUSTAT).** (For more information, see LUSTATs.) The **LUSTAT** must not have the change direction (CD) or end bracket (EB) flags set. (The host already has direction, and the bracket must not be terminated prematurely by the application.) Host Integration Server also enables the function management interface (FMI) application to send **Status-Control(LUSTAT)** in receive state.

An application using the half-duplex contention protocol does not have an error recovery pending state, and must enter contention state whenever it sends a negative response.

Note
If the chain is canceled by the host with CD on the **CANCEL** , the application must assume send state.

Application CANCEL

Direction after Receiving a Negative Response

Critical Failure

Link Service Failure

Local Node Failure

Client Failure

Critical Failure

When an application makes a protocol error in sending data, the local node rejects the data using a Status-Acknowledge(Nack-2) with a sense code indicating the reason for failure. This message has a critical failure flag that indicates whether the local node has marked the session as unrecoverable. The sense codes are listed in FMI Status, Error, and Sense Codes.

If the error is noncritical, the application can proceed as if the message that caused the error had not been sent. If the error is critical, the local node issues a Close(PLU) Request to the application (providing that the primary logical unit (PLU) connection is open), which means that the application cannot communicate on the PLU-SLU session until an **UNBIND–BIND** sequence is received from the host. The local node also sends a **TERM-SELF** request to the host to elicit an **UNBIND**. Therefore, the application does not need to issue a **LOGOFF** request on the system services control point (SSCP) session.

Direction after Sending a Negative Response

Link Service Failure

Local Node Failure

Client Failure

RQR and CLEAR

An application using Transmission Service profile (TS profile) 4 can request the session to be recovered by sending **Status-Control(RQR)**. The local node presents this to the host as an **RQR** request. Note that, if the application has received a critical Status-Acknowledge(Nack-2), this option cannot be taken because the local node will send a Close(PLU) Request immediately following the **Status-Acknowledge(Nack-2)** to the application, and the primary logical unit (PLU) connection will no longer be valid. The **RQR** message requests the host to reset the session by sending a **CLEAR** request, as shown in the following figure.

The receipt of **CLEAR** causes the application to reset its session state to that following the **BIND**, the **Open(PLU)**.

Another way for the application to deal with error conditions is to ask for an **UNBIND** by sending **Status-Control(RSHUTD)**. (For more information, see Application-Initiated Termination.) Note that this may not require the host to supply a new **BIND**, depending on the host configuration. A new SSCP request may be required (such as **LOGON**).

In the following figure, the application requests recovery by issuing **Status-Control(RQR)**. The host sends **CLEAR**, and the application must reset its session to state that it was following the **BIND (Open(PLU))**. In this case, the application is now between brackets and awaiting start data traffic (SDT).

Application requests recovery by issuing Status-Control(RQR)

Client Failure

STSN

Set and test sequence numbers (STSN) are used on sessions with Transmission Service profile (TS profile) 4 for applications to maintain transaction processing sequence numbers between sessions. This enables both partners on the session to discover the amount of data lost after a **CLEAR** or **UNBIND–BIND** sequence.

The **STSN** message is the only one that can reset such transaction processing sequence numbers. **BIND**, **UNBIND**, and **CLEAR** do not affect them.

If the application wants to maintain such transaction numbers, it must specify the **APPLTRAN** option in the Open(PLU) OK Response. The host can send **STSN** after a **BIND** or **CLEAR** before sending **SDT** to set or test the application's transaction numbers. The local node resets its internal session sequence numbers to zero on receipt of **BIND** or **CLEAR**. When the local node receives an **STSN** specifying **SET** (or **SET** and **TEST**) for one half-session, it resets the corresponding internal session sequence number.

Unless both half-session actions are ignore (the action byte is 0x00), the **STSN** request is passed to the application (provided that it specified **APPLTRAN**), with the action byte and the two sequence numbers from the request, as a **Status-Control(STSN)**. (For more information, see Status-Resource.) The application must examine the action byte to determine whether the action is ignore, set, test, or set and test. The application must send a positive response (**Status-Control(STSN) Acknowledge**) to the **STSN**, with the sensed sequence numbers if required (sense or set and test). The local node is responsible for generating the correct result code for the **STSN RSP**.

Note that the application should perform the sense part of **STSN** first (by examining bits 0 and 2 of the action byte for the secondary-to-primary flow and primary-to-secondary flow respectively). The set part of the **STSN** is then performed (by examining bits 1 and 3 of the action byte).

The application should increment its transaction numbers when sending and receiving normal flow request/response units (RUs) from the host. (Note that **Status-Control** messages corresponding to normal flow data flow control (DFC) requests cause the transaction numbers to be incremented.) The sequence number is reported on **DATAFMI** messages and **Status-Acknowledge** messages. The application should be aware that, if a message from the host fails receive checks (and is converted to an **SDI** message), sub-network access protocol (SNAP)-2.1 will purge the remainder of the chain from the host, and the application may miss some sequence numbers. Therefore, the application should reset its primary-to-secondary transaction number from the next outbound data after processing an **SDI** message.

Note that the second application flag byte is not valid for **Status-Control(STSN)**. It is used for the **STSN** control byte.

Link Service Failure

When the server running a link service fails, the local node is informed of this. It treats the problem as a link outage with outage code 0x0D. This is reported to any active 3270 emulation sessions as a communications check code (–+z_nnn). The local node will attempt periodically to reconnect to the link service.

Local Node Failure

Client Failure

Local Node Failure

If the local node fails, applications are informed of this by the path error return code from the Dynamic Access Module (DMOD) on the sbpurcvx call, or from the routing procedure. All connections that use the destination locality value for which the path error is reported are closed. The application must do the following:

- Clean up resources related to the closed connections, including resetting presentation spaces and displaying a communications check code

  (–+z_nnn) on the status line.

- Attempt to reestablish connection with a local node by reinitiating the resource location process.

Application CANCEL
Direction after Receiving a Negative Response
Direction after Sending a Negative Response
Critical Failure
Link Service Failure
Client Failure

Client Failure

If the client computer fails, the local node terminates the application's PLU-SLU session (if it is active) by sending **TERM-SELF**. The system services control point (SSCP) and primary logical unit (PLU) connections are both marked as closed and cannot be reused without being reopened. Internally, the local node treats such a failure in the same way as the receipt of a Close(SSCP) Request from the application.

Direction after Sending a Negative Response

Critical Failure

Link Service Failure

Local Node Failure

Application-Initiated Termination

An application on a session with function management (FM) profile 3 or 4 can request termination of the primary logical unit (PLU) session. It should only do so if it has previously ensured that it is in a state where the PLU session can be terminated, that is, between-chain and between-bracket. Terminating the PLU session does not affect the state of the system services control point (SSCP) session.

Note that an application can issue a character coded or field formatted **LOGOFF** command on the SSCP session or send a Close(PLU) Request to get the local node to send **TERM-SELF** on the application's behalf. All of these will elicit an **UNBIND**, either immediately or after session clean-up in the host.

The application requests termination of the PLU session by sending a **Status-Control(RSHUTD) Request** to the local node, which generates an SNA **RSHUTD** request to the host.

After sending the **Status-Control(RSHUTD) Request**, the application must remain capable of accepting and responding to all outbound data it receives. The application can now expect one of two messages, depending on whether the state of the PLU session allows it to be terminated and whether the host wants to terminate the PLU session:

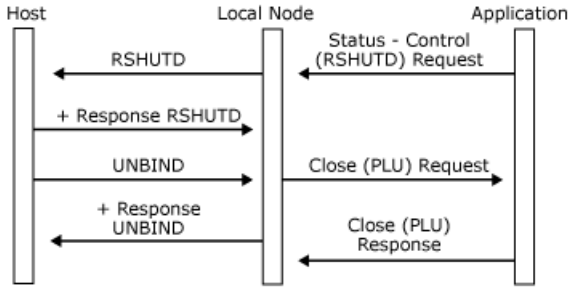
- If the state of the PLU session allows it to be terminated, and the host wants to terminate the PLU session, the host generates a positive response to the **RSHUTD** request, which can be followed by an **UNBIND** request. The local node closes the PLU connection. For more information, see Closing the PLU Connection.

- If the state of the PLU session does not allow it to be terminated (for example, if the session is in-bracket), or the host does not want to terminate the PLU session at this time, the host generates a negative response to the **RSHUTD** request, which the local node presents to the application as a **Status-Control(RSHUTD) Negative-Acknowledge-1** carrying the sense codes supplied on the negative response. This indicates that the request to terminate the PLU session has been rejected by the host, and communication on the PLU session continues unaffected.

The following two figures illustrate the application-initiated termination protocol between the local node and the application and how this protocol relates to the underlying SNA protocols.

In the first figure, the application requests termination of the PLU session, and the host sends **UNBIND**. The local node closes the PLU connection.

Application requests termination of the PLU session, and the host sends UNBIND



In the following figure, the application requests termination of the PLU session, but the session is not in an appropriate state. The host sends a negative response to the **RSHUTD** request, which the local node presents as **Status-Control(RSHUTD) Negative-Acknowledge-1**. Communication continues on the PLU session.

Application requests termination of the PLU session, but the session is not in an appropriate state

LUSTATs

The data flow control (DFC) logical unit status **LUSTAT** message is used within SNA to convey four bytes of sense data to the other session partner. It can also be used simply to send a response header (RH) to the other session partner (for example, to open a bracket). (For more information, see the figures in Bracket Initiation.) The message flows on the normal flow and so is subject to direction restrictions. However, it can be sent without end bracket (EB) or change direction (CD) on a half-duplex flip-flop session that is in error recovery pending state. (For more information, see Recovery.)

The local node allows the application to send **Status-Control(LUSTAT) Request** messages at any time that data traffic is active, except while sending data in chain. If the application is in a receiving state (using half-duplex protocol), the **LUSTAT** is queued up and used to provide the sense codes, which are filled into the next outbound request, and the SDI flag is set. The application can therefore present the sense codes for an error state without waiting for the next outbound data if required.

The first byte of sense data must be 0x08 to generate a **DATAFMI** message with **SDI** (to be converted to a negative response). Other **LUSTATs** are left queued on the session until they can be sent.

If multiple **Status-Control(LUSTAT)** messages are sent by the application while in a receive state, the local node queues them all. When outbound data has been delivered to the application with **SDI** set, as indicated earlier, and the application has converted it to a Status-Acknowledge(Ack), the local node sends the negative response and the remaining **LUSTATs** (which can now flow because the half-duplex flip-flop state is error recovery pending).

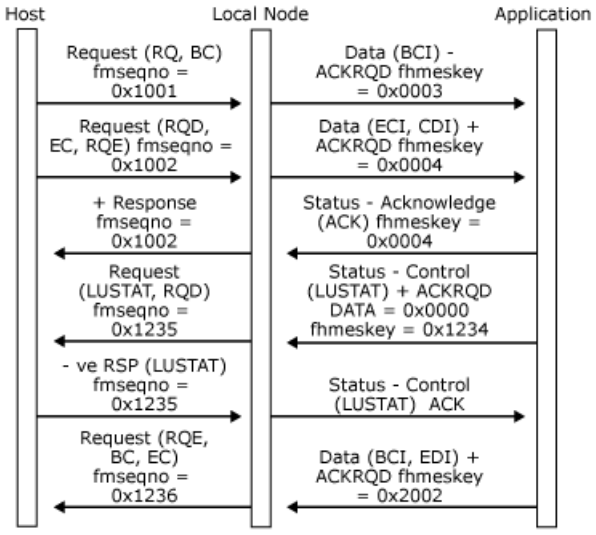
If the application intends to send multiple **Status-Control(LUSTAT)** messages to the host, it is possible that the host will attempt to initiate recovery before the last **LUSTAT** has been sent. In this case, the error recovery chain will be rejected by the next **LUSTAT**.

Note that the application can send **Status-Control(LUSTAT) Request** with or without **ACKRQD**. The local node will map these to **RQD** and **RQE LUSTATs** respectively.

The following three figures illustrate the use of **Status-Control(LUSTAT)** messages by an application using the half-duplex flip-flop mode.

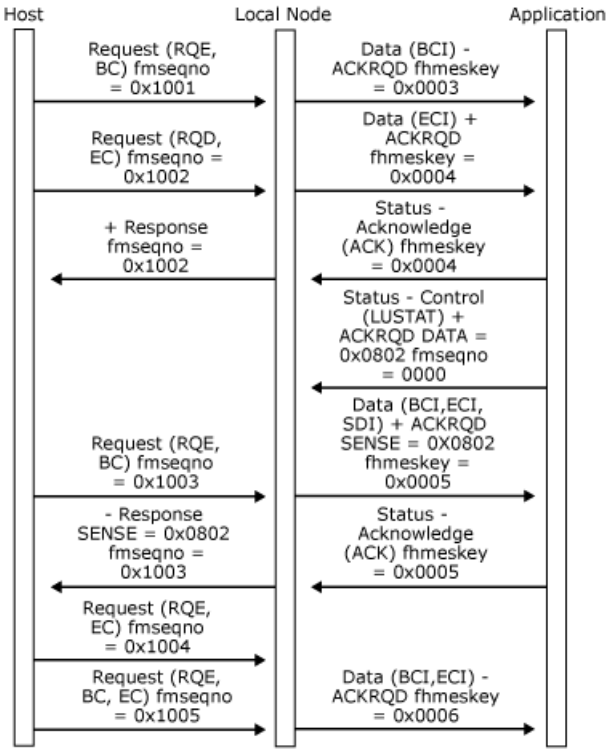
In the first figure, the application issues **Status-Control(LUSTAT)** when it has direction.

Application issues Status-Control(LUSTAT) when it has direction



In the following figure, the application sends **Status-Control(LUSTAT)** request when receiving data between chain. Next, outbound data is delivered with **SDI** set, which gets converted to negative **RSP**.

Application issues Status-Control(LUSTAT) request when receiving data between chain



In the following figure, the application sends several **Status-Control(LUSTAT)** requests when receiving data in chain. Next, outbound data is delivered with **SDI** set which gets converted to negative response. Subsequent **LUSTATs** are sent to host.

Application sends several Status-Control(LUSTAT) requests when receiving data in chain

Response Time Monitor Data

For a 3270 display application, the local node maintains statistics on host response times—the time it takes the host to respond after the 3270 user presses ENTER or an AID key to send data to the host. These statistics can then be sent to the host for analysis.

The Status-RTM message, sent by the local node to the application, informs the application of the Response Time Monitor (RTM) parameters specified by the host. (For more information, see RTM Parameters.) These parameters specify whether RTM data is to be collected, whether the application is permitted to display RTM statistics locally, the time boundaries by which response times are to be grouped, and the definition of response time. The time can be measured until the first character of the host response reaches the screen, until the keyboard is unlocked, or until the user can send further data (change direction (CD) or end bracket (EB) received by the application).

If the host specifies that response times are to be measured for this session, the application is responsible for measuring response times and for reporting them to the local node. This involves:

- Starting a timer when the user presses the ENTER key or an AID key to send data to the host.
- Stopping the timer when the host's response to the inbound data is received, as defined by the RTM definition specified on the **Status-RTM** message.
- Reporting the response time to the host on the Status-Acknowledge(Ack) message, which acknowledges the host's response. One of the fields on this message specifies the last response time measured by the application, or specifies that no response time is to be reported.
- Optionally displaying the most recent response time as a last transaction time indicator (LTTI) on the 3270 emulation status line.

If the application wants to provide a local display of RTM data, it is responsible for maintaining its own response time statistics. It should use the same definition and boundaries as those specified on the Status-RTM message to ensure that the local data matches the data sent to the host by the local node. Note that the **Status-RTM** message can indicate that a local display of response times is not permitted. In this case, the application should not display either the response times or the LTTI.

Data Flow

The following topics describe data flows between the application and the local node.

In This Section

- Outbound Data
- Inbound Data
- Inbound Data from LUA Applications

Outbound Data

This section describes the outbound data flows from the local node to the application. The overall structure of the protocols described applies to the system services control point (SSCP) and primary logical unit (PLU) connections, but certain features (such as the use of delayed request mode) are only applicable to the PLU connection.

The local node presents data originating at the host to the application on different connections, depending on the SNA session on which the data flows, as follows:

- Function management data network services (FMD NS) (session services) data and function management data (FMD) originating at the host SSCP and directed to the Host Integration Server logical unit (LU) is sent to the application on the SSCP connection.

- FMD data originating at the host PLU and directed to an SNA server LU is sent to the application on the PLU connection.

For all connections, only FMD requests are presented to the application as Data messages (with message-type = DATAFMI). DFC and session control requests are used to generate **Status-Control** messages. (For more information, see Status-Control Message.)

The local node performs the data flow control state changes required by the response header (RH) indicators in the request, before sending a **Data** message to the application.

The SNA request transmission header (TH) and RH indicators are not available to the application on outbound **Data** messages. Instead, the local node provides application flags in the **Data** message header that reflect the settings of a subset of the RH indicators, but are interpreted by the local node to shield the application from the more obscure aspects of chaining and bracket usage. For a description of the available flags and the way in which the local node uses them on outbound data, see Application Flags.

For outbound data, the first byte is RU[0] for standard function management interface (FMI), and TH[0] for the logical unit application (LUA) variant of FMI.

All Data messages from the local node to an application contain a message key. The local node maintains a unique message key sequence for each outbound data flow to an application. When the local node sends a **Data** message to an application on a particular connection, it places the next message key in the outbound sequence into the message header, sets the application flags, and sends the message to the application. This means that the message key uniquely identifies a **Data** message on a particular connection between the local node and the application. Note that the local node also places message keys on outbound **Status-Control Request** messages.

The acknowledgment protocol enforced by Host Integration Server reflects the chain response protocol and request mode in use on the SNA session, as follows:

- Outbound **RQD** requests generate Data messages with **ACKRQD** set in the message header.

- Outbound **RQE** requests generate **Data** messages without **ACKRQD** set.

- Outbound **RQN** requests generate **Data** messages without **ACKRQD** set.

- If the session uses primary immediate request mode, a **Data** message with **ACKRQD** set must be acknowledged by the application before further **Data** messages will be received.

- If the session uses primary delayed request mode, a **Data** message with **ACKRQD** set need not be immediately acknowledged by the application. **Data** messages will continue to be received.

Note that Host Integration Server enforces the equivalent of immediate response mode for the outbound data acknowledgment protocol for all connections. The application must send acknowledgments in order.

If the local node sets the **ACKRQD** field in the message header of a Data message to the application, it indicates that an acknowledgment to this **Data** message is required. The application acknowledges an outbound **Data** message by sending a **Status-Acknowledge** message to the local node on the same connection, which contains the same message key and sequence number fields as the **Data** message.

On receipt of a Status-Acknowledge(Ack), the local node correlates the message key with outstanding outbound messages and generates an SNA positive response to the appropriate SNA request.

The application should use the Status-Acknowledge(Nack-1) message as a negative acknowledgment. On receipt of a **Status-Acknowledge(Nack-1)**, the local node correlates the message with outstanding outbound messages and generates an SNA negative response plus sense data to the appropriate SNA request. The application supplies the sense data that should accompany the negative response as part of the **Status-Acknowledge(Nack-1)** message and must include the same message key, application flags, and sequence number fields as the **Data** message to which this is a negative acknowledgment.

Status-Control messages caused by expedited-flow requests can be sent at any time and do not affect the sending of positive or negative acknowledgment to normal flow outbound **Data** messages. The fact that they can occur between an outbound **Data** message and the matching **Status-Acknowledge** message is purely coincidental. For details about which **Status-Control** messages correspond to SNA requests, see Status-Control Message.

If errors are detected in the format of a normal flow request from the host or the request is inappropriate for the state of the session, the local node generates an error Data message for the application with the following characteristics:

- The SDI and ECI application flags are set.
- The sense code associated with the error occupies the first four bytes of the **Data** message. (For more information, see Status-Control Message.)
- **ACKRQD** is set.

The application should return a Status-Acknowledge(Ack), and the local node generates a negative response carrying the sense code appropriate to the detected error. This mechanism does the following:

- Informs the application of the detected error.
- Allows the application to respond to any previously received data before the local node sends the negative response to this Data message.

On sessions where the application is receiving a series of RQE chains, the local node will be retaining correlation information for each chain (in case the application wants to send negative responses to any of the chains). If the local node runs out of correlation table entries, it will attempt to allocate more entries and (if this fails) will be forced to terminate sessions. To prevent this, the application should provide **Status-Acknowledge(Ack)** messages for RQE data that it does not want to reject in this case. A response after five consecutive RQE chains should be sufficient. Such messages are referred to as courtesy acknowledgements and do not give rise to a response to the host, but merely free internal correlation data.

The following six figures illustrate the data acknowledgment protocol enforced between the local node and the application, and show the effects of the application generating positive and negative **Status-Acknowledg**e messages.

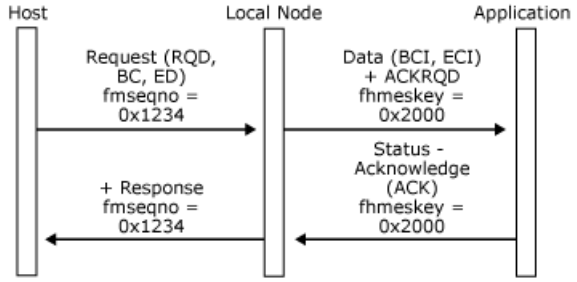
The figures show:

- The relevant RH flags in SNA requests/responses.
- The sequence number of SNA requests/responses.
- Any sense data (shown as "SENSE=...") on SNA requests/responses and **Status-Acknowledge** messages.
- The **ACKRQD** field in Data messages.
- The message key field in **Data** messages.

For simplicity, all messages are assumed to be FM data flowing on the same PLU session.

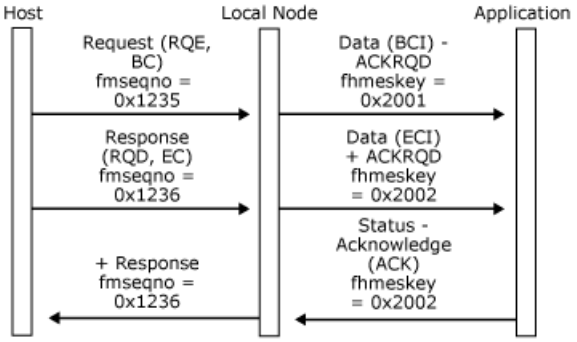
In the following figure, the application accepts a **Data** message corresponding to a definite-response RU.

Application sends a Data message corresponding to a definite-response RU



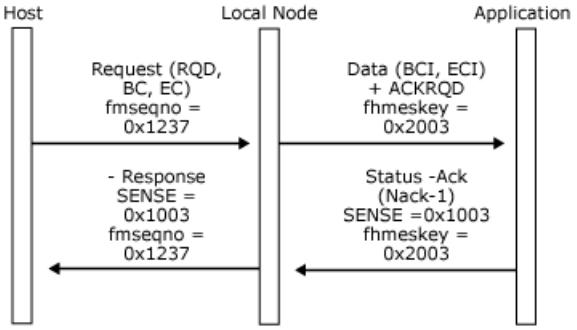
In the following figure, the application accepts a **Data** message corresponding to a multi-RU definite-response chain.

Application accepts a Data message corresponding to a multi-RU definite-response chain



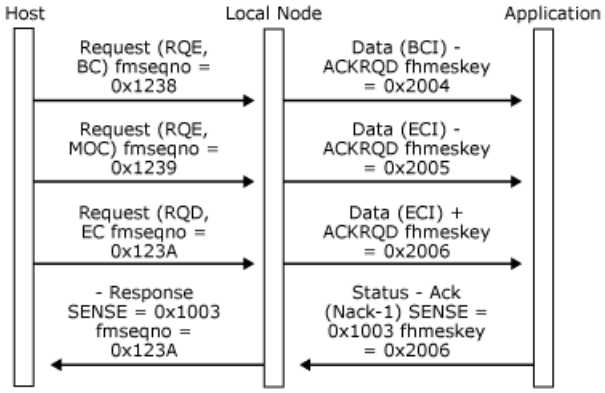
In the following figure, the application rejects a **Data** message corresponding to a definite-response chain.

Application rejects a Data message corresponding to a definite-response chain



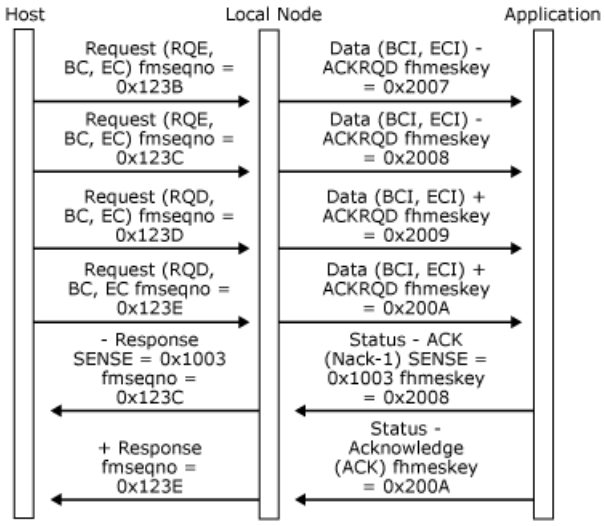
In the following figure, the application rejects a **Data** message corresponding to a multi-RU definite-response chain.

Application rejects a Data message corresponding to a multi-RU definite-response chain



In the following figure, the local node enforces immediate response mode. Responses must be sent in sequence. The application rejects the second exception-response chain and accepts the definite-response chain, which implies acceptance of the third exception-response chain.

Local node enforces immediate response mode



In the following figure, the local node detects a chaining error (RQD but not EC) in data destined for the application. (This example requires the receive check 0x4007 to be in force. For more information, see Opening the SSCP Connection.)

Inbound Data

Inbound Data from LUA Applications

Inbound Data

This section describes inbound data flows from the application to the local node. The overall structure of the protocols described applies to the system services control point (SSCP) and primary logical unit (PLU) connections, but more complex aspects (such as the use of delayed request mode) are only applicable to the PLU connection.

The application can send inbound data on any of the connections, as follows:

- Function management data network services (FMD NS) (session services) and function management data (FMD) character-coded data intended for the host SSCP should be sent to the local node on the SSCP connection.
- FMD data intended for the host PLU should be sent to the local node on the PLU connection.

The application cannot use Data messages to send data flow control (DFC) or session control request messages to the host. Instead it must use **Status-Control** messages. (For details, see Status-Control Message.)

For all connections, the application must fill in certain key fields in the **Data** message's header. In particular it must:

- Set the message-type to **DATAFMI**.
- Allocate a new message key for inbound **Data** messages on this connection.
- Set the **ACKRQD** field if required.
- Set the application flags. (For more information, see Application Flags.)

The **nxtqptr**, **hdreptr** and **numelts** fields in the message header, and the **elteptr** and **startd** fields in the message elements are set up by the Host Integration Server buffer management routines. (For more information, see DL-BASE/DMOD Interface.) The application is responsible for setting the **endd** field.

If the application does not have access to these routines (for example, when the operating environment does not support intertask procedure calls and shared memory), all the fields in the header must be set by the application.

The transmission header (TH) and response header (RH) indicators are not available to the application on inbound Data messages. The application should set the appropriate application flags in the message header to control chaining, direction, and so on. For a description of the available application flags for inbound data and later topics in this section for a description of how the flags are used to control inbound data flows, see Application Flags.

For inbound data, the first byte is RU[0] for standard function management interface (FMI).

The message key supplied by the application in the inbound **Data** message header is used by the local node to indicate which **Data** message on this connection an outbound **Status-Acknowledge** refers to. The application should maintain a unique message key sequence for the inbound data flow on each connection it has with the local node, so that the application can use the message key to correlate inbound **Data** messages and outbound **Status-Acknowledge** messages on the connection. Note that the application must also provide a message key on **Status-Control Request** messages to differentiate between multiple **RQE LUSTAT** messages.

The inbound data acknowledgment protocol reflects the secondary chain response protocol and request mode in use on the session, as follows:

- Inbound Data messages with **ACKRQD** set in the header generate **RQD** requests.
- Inbound **Data** messages without **ACKRQD** set in the header generate **RQE** or **RQN** requests depending on the chain response protocol.
- The application should only set **ACKRQD** on **Data** messages that have the end chain indicator (ECI) application flag set.
- If the session specifies that the secondary uses immediate request mode, the application can still send further **Data** messages after sending data with **ACKRQD** set, even though it has not received a **Status-Acknowledge** message for that **Data** message. The messages are queued within the local node and are progressively sent as positive responses are

received.

- If the session specifies that the secondary uses delayed request mode, after sending a **Data** message with **ACKRQD** set, the application can continue to send **Data** messages.

If the application sets the **ACKRQD** field in the message header of a Data message, it indicates that it requires an acknowledgment to this **Data** message. The local node acknowledges an inbound **Data** message by sending a **Status-Acknowledge** message to the application on the same connection and using the same message key as the **Data** message. (For an illustration, see the first figure at the end of this topic.)

The local node processes inbound **Data** messages from the application through its internal state computers, assigns the correct SNA sequence number or an identifier for this flow, and sends the data in a request to the host. The chain-response type of the request depends on whether **ACKRQD** was set in the **Data** message and the session parameters.

The local node maps a positive response from the host to a Status-Acknowledge(Ack) to the application. The application can use the message key in the **Status-Acknowledge** to correlate the acknowledgment with the original **Data** message. Therefore, receipt of a **Status-Acknowledge(Ack)** for a particular **Data** message implies that the local node has received a positive SNA response from the host to the inbound SNA request. (For an illustration, see the second figure at the end of this topic.)

Note that responses are absorbed on the SSCP-PU session.

Note that outbound Status-Acknowledge(Ack) messages contain application flags and a sequence number. The application flags reflect the RH indicators in the response. The sequence number is the SNA sequence number from the response, and provides a mechanism for applications using Transmission Service profile (TS profile) 4 to track the SNA secondary sequence number corresponding to a unit of work.

The local node maps a negative response from the host to a Status-Acknowledge(Nack-1) message to the application. The application can use the message key in the **Status-Acknowledge** to correlate the negative acknowledgment with the original **Data** message. The outbound **Status-Acknowledge(Nack-1)** message contains the SNA sense codes and sequence number from the negative response. (For an illustration, see the third and fourth figures at the end of this topic.)

If the local node detects an error in the format of an inbound **Data** message, or the **Data** message is not appropriate to the current state of the session, it sends a Status-Acknowledge(Nack-2) to the application containing an error code. (For a list of error codes, see Error and Sense Codes.) The local node does not send a request to the host corresponding to the **Data** message in error and does not advance the SNA sequence number for the session. The application can use any message key in its next inbound **Data** message (assuming the error does not cause a critical failure).

An example of a serious chaining error, where the application sends a **Data** message with **ACKRQD** but without ECI in the application flags, is shown in the last figure at the end of this topic. Note that after detecting this particular error, the local node marks the application's connection as critically failed, closes the connection, and sends a **TERM-SELF** request to the SSCP to elicit an **UNBIND**. (For more information, see Recovery.)

Inbound **Status-Control** messages, which cause the generation of expedited-flow requests, can be sent at any time and do not affect the sending of a positive or negative acknowledgment to inbound **Data** messages. For details about which **Status-Control** messages correspond to SNA expedited-flow requests, see Status-Control Message.

The following five figures illustrate examples of the inbound data acknowledgment protocols (and the underlying SNA protocols) for different chain-response types and secondary session request modes.

The figures show:

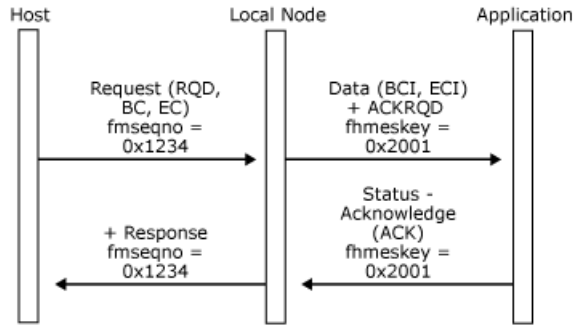
- The **ACKRQD** field on Data messages.
- The message key on **Data** messages.
- Any relevant application flags on **Data** messages.
- Error codes (shown as "ERROR=...") on **Data** messages.
- Relevant RH flags on SNA requests/responses.
- Sequence numbers on SNA requests/responses.

- Sense codes (shown as "SENSE=....") on SNA requests/responses.

For simplicity, all messages are assumed to be flowing on the same PLU session.

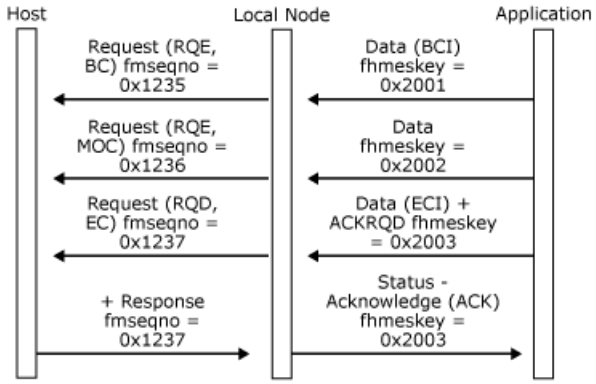
In the following figure, the application successfully sends a **Data** message.

Application successfully sends a Data message



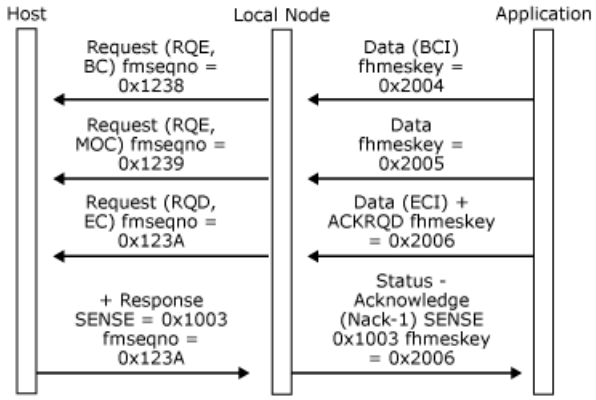
In the following figure, the application successfully sends a chain of **Data** messages.

Application successfully sends a chain of Data messages



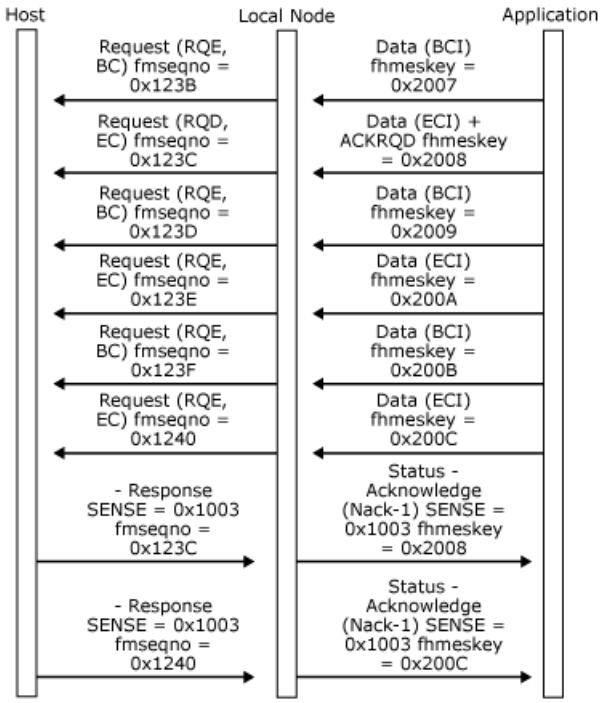
In the following figure, the host rejects a chain of **Data** messages.

Host rejects a chain of Data messages



In the following figure, the host rejects the first definite-response chain and rejects the third exception-response chain on a delayed request session. Note that the negative response to the third chain implies a positive response to the second chain.

Host rejects the first definite-response chain



In the following figure, the local node detects the application's invalid use of **ACKRQD** without the ECI application flag on a **Data** message. Note that no data is sent to the host. However, because the error is critical, the local node will send a **TERM-SELF** message to the SSCP.

Local node detects the application's invalid use of ACKRDQ without the ECI application flag on a Data message

Concepts

Outbound Data

Inbound Data from LUA Applications

Inbound Data from LUA Applications

The local node performs certain checks on data supplied by a client application before sending it to the host and rejects it with a Status-Acknowledge(Nack-2) message if the checks fail. It does not return any acknowledgment to the application if the data passes the checks (although the host may do so later).

If the client application is providing a logical unit application (LUA) API, the design of the API may require that an LUA verb sending data inbound to the application does not complete until the local node has checked the data. Because of this, the local node will always respond to a client application that uses the LUA variant of the function management interface (FMI), after it has completed its send checking of the inbound message. This allows the client application to complete processing of the LUA verb and return control to the LUA application program.

If the inbound message passed the local node's send checks and will be sent to the host, the local node sends a Status-Acknowledge(ACKLUA) message to the client application to indicate this. The client application can then complete the LUA verb processing with an OK return code. Note that the **Status-Acknowledge(ACKLUA)** message does not imply that the data was successfully sent to the host or that the host received it. It may later be followed by a Status-Acknowledge(Nack-1) message indicating that the host rejected the data.

If the inbound message fails the local nodes send checking, a Status-Acknowledge(Nack-2) message will be returned as for non-LUA client applications. The client application can then report this to the LUA application program by a non-OK return code to the LUA verb that sent the message.

If the client application is providing an LUA API, it should therefore wait for either **Status-Acknowledge(ACKLUA)** or **Status-Acknowledge(Nack-2)** to determine whether to return an OK or error return code to the LUA send verb. If this dependence on the local node's send checks is not required, the client application can ignore the **Status-Acknowledge(ACKLUA)** message.

Note that there are certain race conditions in which the local node cannot complete its send checks before replying to the client application. In these cases, the local node returns a Status-Acknowledge(ACKLUA), but may subsequently send a Status-Acknowledge(Nack-2) if it detects an error during the remaining send checks. The client application may therefore receive a **Status-Acknowledge(ACKLUA)** followed by a **Status-Acknowledge(Nack-2)** for the same inbound message.

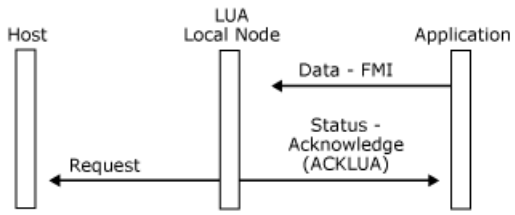
In the transmission header (TH) for the LUA variant of FMI, the expedited flow indicator (EFI), the destination-address field (DAF), and the origin-address field (OAF) are used. Other fields (including the sequence number field) are ignored. In the RH for the LUA variant of FMI, all fields except the queued-response indicator (QRI) and pacing indicator (PI) are used.

For inbound data, the first byte is TH[0] for the LUA variant of FMI.

The following three figures illustrate the **Status-Acknowledge(ACKLUA)** acknowledgment protocol for different messages that the application can send.

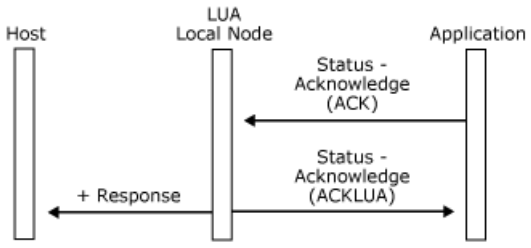
In the first figure, the application sends a **Data** message that passes the local node's send checks.

Application sends a Data message that passes the local node's send checks



In the following figure, the application sends a **Status-Acknowledge(Ack)** message that passes the local node's send checks.

Application sends a Status-Acknowledge(Ack) message that passes the local node's send checks



In the following figure, the application sends a **Status-Acknowledge(Nack-1)** message that passes the local node's send checks.

Application sends a Status-Acknowledge(Nack-1) message that passes the local node's send checks

Status Messages

The local node uses status messages to provide the application with information about the state of its sessions and to give the application control, in association with the host system services control point (SSCP) and primary logical unit (PLU), over the progress of the session. The status messages are designed to allow the application to use all the protocols allowed in the function management (FM) and Transmission Service profiles (TS profiles) supported by the Microsoft® Host Integration Server local node.

Most applications only need to use a subset of the available status messages. For example, a 3270 device emulator would not require the status messages used in quiesce protocols.

In This Section

Status-Acknowledge Message

Status-Acknowledge messages are the basic mechanism used to enforce inbound and outbound data acknowledgment protocols on all connections. For details about the use of **Status-Acknowledge** messages, see Outbound Data and Inbound Data.

For a 3270 emulation application, **Status-Acknowledge** messages sent from the application to the local node (acknowledging outbound data from the host) can also carry information about host response times. This allows the local node to maintain response time statistics for sending to the host when required. For details, see Response Time Monitor Data.

Status-Control Message

Status-Control Message

Status-Control messages provide access to session control and data flow control protocols on the primary logical unit (PLU) session using the PLU connection. They are not used on the other connections. **Status-Control** messages map directly to the equivalent SNA session control and data flow control request/response units (RUs).

All **Status-Control** messages that correspond to SNA requests on the normal flow with the exception of LUSTAT-sent Request Exception (RQE), and **Status-Control** messages corresponding to **CLEAR** and **STSN** request on the expedited flow, have the **ACKRQD** (acknowledgment required) field set. **Status-Control** messages that correspond to SNA requests on the expedited flow (with the exception of **CLEAR** and **STSN**) do not have the **ACKRQD** field set by the local node. However, the application can set **ACKRQD** when sending these **Status-Control** messages. The last figure in this topic summarizes which **Status-Control** requests always have **ACKRQD** set.

If a **Status-Control** request has **ACKRQD** set in the message header, the recipient must supply a **Status-Control** response (**Acknowledge, Negative-Acknowledge-1** or **Negative-Acknowledge-2**) before the sender sends further Data messages or further **Status-Control** requests on the flow. The sender can still send **Status-Control** responses, **Status-Acknowledge**, **Status-Error**, and **Status-Resource** messages on the flow. This applies to both normal and expedited flows and all request modes (including delayed-request mode). The message key received on the request must be returned on the response. (This is to allow multiple **RQE LUSTAT** messages to be outstanding.) The local node increments the message key on **Status-Control** requests and **DATAFMI** messages that it sends to the application on the PLU connection.

For the logical unit application (LUA) variant of the function management interface (FMI), the message key field is used in a different way, as follows:

- For inbound expedited flow requests, the local node sets the SNA sequence number to the value supplied by the application in the message key field. The application must ensure that this field is set to the correct sequence number.

- For inbound **Status-Control** responses, the local node sets the SNA sequence number to the value supplied by the application in the message key field. The application must ensure that this field is set to the sequence number of the request for which a response is being sent.

Except in the case of **Status-Control(LUSTAT)**, if a **Status-Control** request does not have **ACKRQD** set, the application should not reply, because a positive response has already been sent by the local node.

For example, if the application sends a **Status-Control(QC) Request** with **ACKRQD** set (corresponding to an SNA request on the normal flow), this blocks further data and **Status-Control** requests corresponding to the inbound normal flow until the **Status-Control(QC)** response is received. It does not block other messages on the normal flow, or messages on the expedited flow. For example, the application could still send **Status-Control(SIGNAL)**.

The receipt of the **Status-Control** response implies an acknowledgment to all outstanding messages (including **Data** messages) on the flow.

The use of **ACKRQD** on **Status-Control** messages effectively enforces definite-response and immediate request mode. This is appropriate for:

- **Status-Control** messages that correspond to the SNA requests **CLEAR** and **STSN** (because the expedited flow is **RQD**).

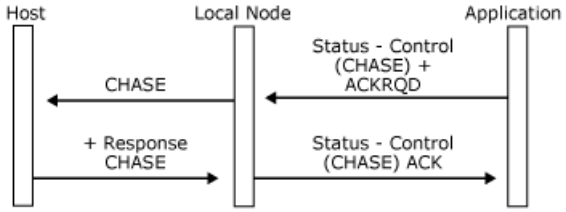
- **Status-Control** messages corresponding to all the **DFC** requests (which are **RQD**) except **LUSTAT** (which can be **RQE**).

The application can set **ACKRQD** on **Status-Control** requests that correspond to SNA requests on the expedited flow, even where **ACKRQD** is not required. For example, when an application is signaling for direction (for example, a 3270 emulator with a terminal operator repeatedly pressing the ATTN key), it can generate multiple **Status-Control(SIGNAL) Request** messages, which would adversely affect the performance of other users. The application can set **ACKRQD** on the first **Status-Control(SIGNAL) Request** and ignore events that would cause further **Status-Control(SIGNAL) Request** messages until the **Status-Control(SIGNAL) Response** is received from the local node.

The message flows in the following six figures show outbound and inbound **Status-Control** sequences with and without **ACKRQD** and the corresponding SNA RUs.

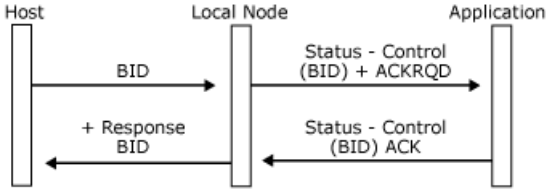
In the first figure, the application sends **Status-Control(CHASE)**.

Application sends Status-Control(CHASE)



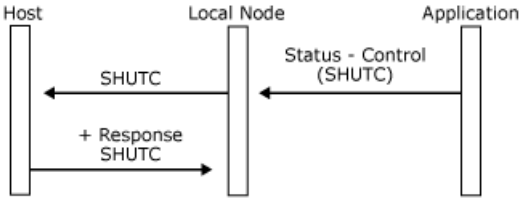
In the following figure, the host sends **BID** request.

Host sends BID request



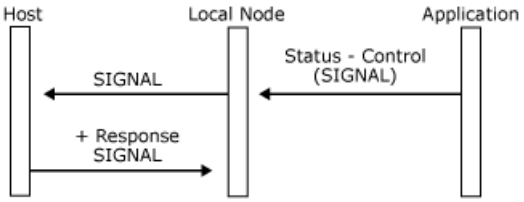
In the following figure, the application sends **Status-Control(SHUTC)**.

Application sends Status-Control(SHUTC)



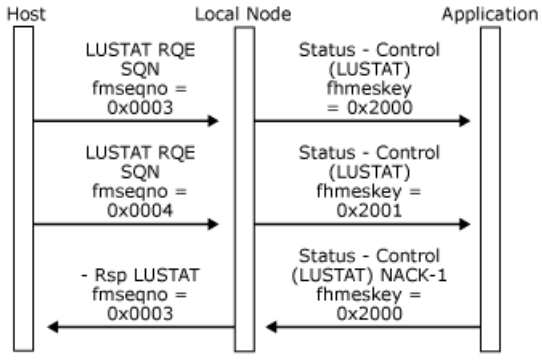
In the following figure, the host sends SNA **SIGNAL** request.

Host sends SNA SIGNAL request



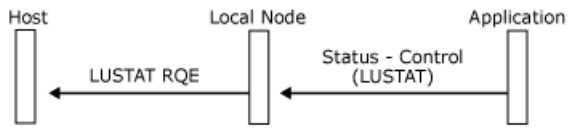
In the following figure, the host sends multiple **RQE LUSTAT** requests, and the application rejects the first one.

Application rejects the first RQE LUSTAT request



In the following figure, the application sends **Status-Control(LUSTAT) NOACKRQD**.

Application sends Status-Control(LUSTAT) NOACKRQD



The following table summarizes the **Status-Control** requests supported by the local node and SNA session control (SC) and data flow control (DFC) requests. For each **Status-Control** request, the table gives:

- The SNA category of the corresponding SNA request (SC or DFC).
- The flow used by the corresponding SNA request (normal or expedited).
- The TS or FM profiles on which the corresponding SNA request is supported.
- The directions for which it is valid (NODE <–> APPL).
- Whether it requires **ACKRQD**. Note that the application can set ACKRQD on a Status-Control request that does not require it.
- The hexadecimal code used in the control-type field of the Status-Control message. (For more information, see FMI Message Formats.)

Status-Control	SNA RQ flow	TS profile	FM profile	Direction node–appl	ACKRQD	Code
CLEAR	SC,Exp	2,3,4	–	–>	ACKRQD	CCLEAR (0x01)
SDT	SC,Exp	3,4	–	–>	–	CSDT (0x02)
RQR	SC,Exp	4	–	<–	–	CRQR (0x03)
STSN	SC,Exp	4	–	–>	ACKRQD	CSTSN (0x04)
CANCEL	DFC,Norm	–	3,4,7	<–>	ACKRQD	CCANCEL (0x10)
LUSTAT	DFC,Norm	–	3,4,7	<–>	–	CLUSTAT (0x11)
SIGNAL	DFC,Exp	–	3,4,7	<–>	–	CSIGNAL (0x12)
RSHUTD	DFC,Exp	–	3,4,7	<–	–	CRSHUTD (0x13)
BID	DFC,Norm	–	3,4	–>	ACKRQD	CBID (0x14)
CHASE	DFC,Norm	–	3,4	<–>	ACKRQD	CCHASE (0x15)
SHUTC	DFC,Exp	–	3,4	<–	–	CSHUTC (0x16)
SHUTD	DFC,Exp	–	3,4	–>	–	CSHUTD (0x17)
RTR	DFC,Norm	–	3,4	<–	ACKRQD	CRTR (0x18)
QC	DFC,Norm	–	4	<–>	ACKRQD	CQC (0x20)
QEC	DFC,Exp	–	4	<–>	–	CQEC (0x21)
RELQ	DFC,Exp	–	4	<–>	–	CRELQ (0x22)

The requests in the following table are used only with LUA. (For more information, see FMI Concepts.)

Status-Control	SNA RQ flow	TS profile	FM profile	Direction node–appl	ACKRQD	Code
CRV	SC,Exp	3,4	–	–>	ACKRQD	CCRV (0x05)
BIS	DFC,Norm	–	18	<–>	ACKRQD	CBIS (0x19)

SBI	DFC,Exp	–	18	<–>	ACKRQD	CSBI (0x1A)

The use of particular **Status-Control** messages is described in following topics of this section, in the context of PLU session protocols such as chaining, brackets, recovery, and so on.

For the formats of **Status-Control** messages, see Status-Control.

In This Section

- Status-Control (ACKLUA) Message

Status-Control (ACKLUA) Message

When a logical unit application (LUA) application sends a **Status-Control** message inbound to the local node, the LUA verb used to send the message cannot complete until the local node acknowledges the message. Because of this, the local node will always respond to the LUA application after it has completed its send checking of the inbound message. If the inbound message passes the local node's send checks, and the corresponding SNA message will be sent to the host, the local node sends a Status-Control(...) ACKLUA message to the application to indicate this. Note that the **ACKLUA** message does not imply that the SNA message was successfully sent to the host, or that the host received it.

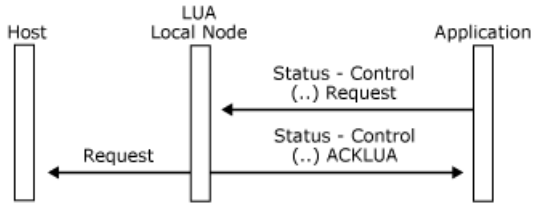
The format of the **Status-Control(...) ACKLUA** message is explained in Status-Control(...) ACKLUA. Note that the use of the message key field in **Status-Control(...) ACKLUA** is different from other **Status-Control** messages. It contains the sequence number from the transmission header (TH) of the **Status-Control** message sent by the LUA application, not the message key.

If the inbound message fails the local nodes send checking, a Status-Control(...) Negative-Acknowledge-2 message will be returned as for non-LUA applications. (This is then reported to the LUA application by a non-OK return code to the LUA verb that sent the message.)

The following three figures illustrate the **ACKLUA** acknowledgment protocol for different messages that the application can send.

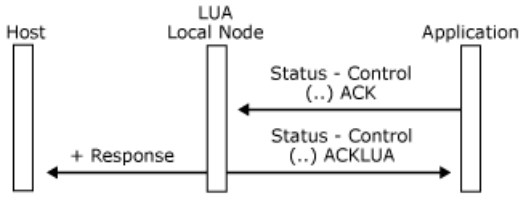
In the first figure, the application sends a **Status-Control(...) Request** message that passes the send checks of the local node.

Application sends a Status-Control() Request message



In the following figure, the application sends a **Status-Control(...) Acknowledge** message that passes the send checks of the local node.

Application sends a Status-Control(...) Acknowledge message



In the following figure, the application sends a **Status-Control(...) Negative-Acknowledge-1** message that passes the send checks of the local node.

Application sends a Status-Control() Negative Acknowledge-1 message

Status-Error Message

Status-Error messages flow from the local node to the application to report request reject and response header (RH) usage error conditions for:

- Errors in outbound expedited data flow control (DFC) requests.
- Errors in outbound session control (SC) requests.
- Errors in inbound responses.

The **Status-Error** message contains four bytes of error code information that contain the appropriate SNA sense codes for the detected error. For a list of error codes, see Error and Sense Codes.

Other Resources

Status-Acknowledge Message
Status-Control Message

Status-Resource Message

Status-Resource messages flow between an application and the local node to enable the local node to pace the primary logical unit (PLU) session of the application. They provide the local node with an indication of the buffer resources available at the application to receive outbound messages. With this information, the local node can determine when to send a pacing response. (For more information, see Pacing and Chunking.)

Note
Flow control is an option. Inbound pacing is handled by the local node, transparently to the application, and outbound pacing can be handled similarly. This is appropriate when only a limited number of messages flows from end-to-end of the SNA session between definite responses, such as with a 3270 screen.

Status-Acknowledge Message

Status-Control Message

Status-Session Message

Status-Session messages always flow from the local node to the application and provide information about changes in the state of the session. There are separate **Status-Session** flows for each connection between the application and the local node.

The local node uses only one **Status-Session** message on the primary logical unit (PLU) connection. This is the **Status-Session(BETB)** message, used to report when the PLU session returns to the between-bracket state after the application or the PLU initiated a bracket. (For more information, see Brackets.)

The local node reports the activation and deactivation states of the system services control point (SSCP) session and PU-SSCP session using **Status-Session** messages. For example, it reports the receipt of an **ACTLU** request from the host SSCP using a **Status-Session (LU-Active)** message on the SSCP connection. (For more information, see SSCP Connection.)

By providing **Status-Session** messages rather than requiring the application to interpret the relevant information in the SNA request, the local node shields the application from decisions affecting conditional state transitions and from the necessity for a detailed understanding of SNA protocols.

A **Status-Session** message contains a status code, and for some status codes, an additional status code that qualifies the meaning of the primary status code. For example, the Link-Error status code, which occurs on the SSCP connection, is qualified by a status code that reports the link outage code supplied by the data link control layer of the local node. Applications such as 3270 device emulators use the qualifying status codes to display communications check codes (–+z_nnn) on the status line of the display.

The **Status-Session** codes are summarized in Status-Session Codes.

Status-RTM Message

The Status-RTM message is used by the local node to inform the application of the Response Time Monitor (RTM) parameters being used by the host. It flows from the local node to the application on the system services control point (SSCP) connection and is sent only for 3270 display logical units (LUs), or LUs in a pool of display LUs.

The **Status-RTM** message is sent at the following times:

- After the OK response to the Open(SSCP) Request message, to inform the application of the initial RTM parameters.
- When the RTM counters are reset, either due to a request from the host or when the local node sends unsolicited RTM data to the host.
- When any of the RTM parameters are changed by the host.

For more information about the use of the **Status-RTM** message, see RTM Parameters. For more information about how the application supplies RTM data to the local node, see Response Time Monitor Data.

FMI Message Summary

This section lists each of the messages used at the function management interface (FMI) and gives a reference to a topic in the section where each message is described. The formats of the messages are given in FMI Message Formats.

For each message the direction of flow is indicated. IN means from the application to the local node, and OUT means from the local node to the application. The connection on which the message flows is also given.

Message	Direction	Connection	Reference
Open(SSCP) Request	IN	SSCP	Opening the SSCP Connection
Open(SSCP) Response	OUT	SSCP	Opening the SSCP Connection
Open(SSCP) Error Response	OUT	SSCP	Opening the SSCP Connection

Status Messages

FMI Status, Error, and Sense Codes

This section lists the function management interface (FMI) status codes, error codes, and sense codes used on **Open** messages, **Status** messages, and **Data** messages with the system detected error indicator (SDI) set.

This section contains:

Status-Session Codes

For the status codes used on Status-Session messages, the following table lists:

- The value for the status code.
- The valid qualifying codes (if any) and their values.
- On which sessions the combinations of primary and qualifying status codes can occur.

For an overall description of the role of the **Status-Session** message, see Status-Session Message. The individual codes are discussed in SSCP Connection and PLU Connection.

Status code	Value	Qualifying code	Value	Usage
STNOSESS (no session)	0x01	STPUINAC STPUACT STPUREAC STLUINAC	0x10 0x03 0x04 0x11	SSCP SSCP SSCP SSCP
STLINERR (link error)	0x02	DLC ERROR	(See Note 1)	SSCP
STLUACT (LU active)	0x05	-	-	SSCP
STLUREAC (LU reactivated)	0x06	-	-	SSCP
STBETB (between brackets)	0x07	-	-	PLU

Note

The qualifying status code supplied on a **Status-Session** link error is the error code supplied by the data link control layer of the local node.

Note

Status-Session link error code 20 is generated by the node rather than by the link service. It indicates that the link service is not yet available, but is being activated. Ignore this error code during session activation. Otherwise, all **Status-Session** link errors (including 20) will cause the emulator to send a **Close(SSCP)**. When the emulator receives the Close(SSCP) Response, it will start again and send a new **Open(SSCP)**.

Note

The session status identifier is obsolete. It was used by the Microsoft® SNA Server OS/2 and Microsoft MS-DOS®-based 3270 emulators. Its value was obtained by adding 484 (decimal) to the qualifying status code shown in the preceding table.

Error and Sense Codes

This section describes the error and sense codes that are reported to the application in the following messages:

- Error Codes for Open(SSCP) Error Response
- Error Codes for Open(PLU) Error Confirm
- Error Codes for Nack-2 Messages
- Error Codes for Status-Error Messages
- Sense Codes for SDI Messages

Where the reported codes are SNA sense codes, a more complete description is given in Chapter 8 of the IBM document *Systems Network Architecture: Reference Summary* (GA27-3136). These SNA sense codes are also documented in Host Integration Server 2009 Help.

In addition, the local node delivers negative responses from the host as **Status-Acknowledge(Nack-1)** and **Status-Control(...) Negative-Acknowledge-1**, which can have any SNA sense code.

Application designers should note that error codes listed here that are specific to Host Integration Server always have an initial byte value of 0x00, and therefore can be easily distinguished from SNA sense codes, which have nonzero initial bytes.

The error codes are listed in topics for each type of message with an indication of the reason for the error.

This section contains:

- Error Codes for Open Messages
- Error Codes for Nack-2 Messages
- Error Codes for Status-Error Messages
- Sense Codes for SDI Messages

Error Codes for Open Messages

The possible error codes for **Open(SSCP) Error Response** and **Open(PLU) Error Confirm** are shown in the following topics.

This section contains:

- Error Codes for Open(SSCP) Error Response
- Error Codes for Open(PLU) Error Confirm

Error Codes for Open(SSCP) Error Response

The following table gives the values for error code 1 and error code 2 that can be returned on the **Open(SSCP) Error Response**.

Error code 1	Description	Error code 2	Description
0	No servers found.	CSRENOSR (0)	No servers found.
0x0053	Logical unit (LU) not verified.	CSRECBSH (3)	LU not verified.
0x0055	System services control point (SSCP) connection already open.	CSRECBSH (3)	Control block / resource shortage.
0x0057	No LU in group free.		
0x0812	No free session control block available.		
0x1001	A connection activation failed recently.		
0x1002	The connection is inactive.		
0x1008	The link service is active remotely. This error return code is not supported by this level of Host Integration Server.		
0x1009	The SNA server is active, but the connection on which the requested LU is defined is not active.		
0x100B	The connection is in the process of activating as the result of another **Open(SSCP)** or operator activation or recovery from an outage.		
0x1010	The connection is active, but an activate physical unit (ACTPU) has not yet been received.		
0x1011	The connection is active, but an activate logical unit (ACTLU) has not yet been received.		
0x0063	Unrecognized Open request.	CSRESERV (1)	Service not present.
0x0A0E	LU/LU group not found in configuration.		

Note

The error code 1 values 0x1001 to 0x1011 are returned when the Open(SSCP) Request specifies a nonforced Open. They do not indicate errors, but indicate that the LU-SSCP session is not active. The application can retry the **Open(SSCP) Request** specifying a forced Open, in which case the local node will attempt to activate the connection if possible.

Error Codes for Open(PLU) Error Confirm

The following table gives the values for error code 1 that can be returned on the Open(PLU) Error Confirm message. Error code 2 is zero, except when error code 1 is 0x0821. In this case it contains the byte offset in the **BIND** where the **BIND** failed to match the **BIND** check table.

Error code	Description
0x0051	Fewer than two buffer elements were present on **Open(PLU) Response**.
0x0052	System services control point (SSCP) connection is no longer active.
0x0821	**BIND** checking failed: error code 2 gives byte offset in **BIND** at which the error occurred.

Error Codes for Nack-2 Messages

The possible error codes delivered to the function management interface (FMI) application on Status-Acknowledge(Nack-2) and Status-Control(...) Negative-Acknowledge-2 messages are tabulated in the following table. A **Nack-2** is delivered to the application in response to data that is sent in error (or a Status-Control(...) Request that is in error). The data has not been sent to the host. The table indicates whether the error is critical, applying to the primary logical unit (PLU) connection only. If the error is critical, the critical failure indicator will be set in the message, and the application will receive a Close(PLU) Request as the next message.

All Nack-2 messages have the second word of information as 0x0000.

Error / Sense code	Critical YES/NO	Description
0x0040	YES	No buffer element on DATAFMI message.
0x0042	YES	DATAFMI message sent when no credit.
0x0043	YES	Invalid status-control for Transmission Service profile (TS profile).
0x0044	YES	Invalid status-control from application.
0x004A	YES	Half-duplex (HDX) contention and -QR,-BB,EB, or BKTFSM in pending-term-session.
0x0809	YES	Mode inconsistency.
0x1002	YES	Request/response unit (RU) length error.
0x1003	YES	Function not supported, invalid function management (FM) profile.
0x2002	NO	Chaining error.
0x2003	NO	Bracket error.
0x2004	NO	Direction error.
0x2005	YES	Data traffic reset.
0x2006	YES	Data traffic quiesced.
0x200D	YES	Response owed before sending request (half-duplex).
0x4003	YES	Begin bracket (BB) not allowed.
0x4004	YES	End bracket (EB) not allowed.
0x4006	YES	Exception response not allowed.
0x4007	YES	Definite response not allowed.
0x4009	YES	Change direction (CD) not allowed.
0x400A	YES	No-response not allowed.
0x400B	YES	Chaining not supported.

0x400C	YES	Brackets not supported.
0x400D	YES	CD not supported.
0x400F	YES	Incorrect use of FI.
0x4014	YES	Incorrect use of DR1, DR2, ER.
0x8005	NO	System services control point (SSCP) data sent when logical unit (LU) inactive.

Error Codes for Status-Error Messages

The possible error codes delivered to the function management interface (FMI) application on Status-Error messages are tabulated in the following table. A **Status-Error** message is delivered to the application in one of several cases, as shown in the following list:

- The local node detects an error in a response sent from the application (as a **Status-Acknowledge** or **Status-Control Ack/Nack-1** message).
- The local node detects an error in some data from the host that will not be delivered to the application as an system detected error indicator (SDI) message (such as an expedited flow request).
- The application sends an invalid **Status** message.

For inbound responses, the **Status-Error** codes have first byte 0x00. When the application is in error, the table indicates whether the error is critical, applying to the primary logical unit (PLU) connection only. If the error is critical, the application will receive a Close(PLU) Request as the next message.

The sense codes beginning with 0x40 will only be delivered if the corresponding receive check has been enabled in the connection information control block (CICB) on the Open(SSCP) Request from the application.

Where the sense code is marked with the * symbol, the second word of sense information carries the request code of the expedited flow request that was in error (for example 0x00C9 for SIGNAL).

Error / Sense code	Critical YES/NO	Description
0x0008	NO	Negative response already sent to this chain.
0x0040	YES	Invalid **Status** message from application.
0x0046	YES	Session failure due to correlation table shortage.
0x0050	YES	Invalid sequence number on Status-Ack.
0x0053	YES	Application may not send status control (**STSN**) negative acknowledge if it supports transaction numbers.
0x0056	YES	**Status-Ack** sent when previous RQD chains are outstanding. (For more information, see Outbound Data.)
0x0801	NO	Message received when pacing count is zero.
0x0805	NO	**BIND** from another PLU when already bound.
0x0809 *	NO	Mode inconsistency (**QEC** or **SHUTD**).
0x0815	NO	**BIND** from same PLU when already bound.
0x0821	NO	Incorrect **ACTLU** type (SSCP connection).
0x1003 *	NO	Wrong profile/network control request/invalid session control message.
0x2005	NO	Data traffic reset.
0x2007	NO	Data traffic not reset (**STSN** after **SDT**).
0x4009 *	NO	Change direction (CD) not allowed.
0x400B *	NO	Chaining not supported.
0x400C *	NO	Brackets not supported.

0x400F *	NO	Incorrect use of FI.
0x4011 *	NO	Incorrect use of request/response unit (RU) category.
0x4014 *	NO	Incorrect use of definite response 1 (DR1), definite response 2 (DR2), exception response (ER) .

Sense Codes for SDI Messages

When the local node detects an error in a normal flow request from the host, the message is converted into a **DATAFMI** message with the system detected error indicator (SDI) set to inform the application and to allow data to be processed serially. The application must convert the message to a Status-Acknowledge(Ack) to allow the local node to send the required negative response to the host. The possible error codes delivered to the function management interface (FMI) application on such SDI messages are tabulated in the following table.

The sense codes beginning with 0x40 will only be delivered if the corresponding receive check has been enabled in the connection information control block (CICB) on the Open(SSCP) Request from the application. If a receive check has been disabled, the message can still be converted to an SDI message. For example, a message with begin bracket (BB), -begin chain (BC) would fail as 2002 or 2003 if 4003 were disabled.

When the application uses a **Status-Control(LUSTAT) Request** to reject outbound data, the sense codes supplied by the application will be present on the SDI message generated by the local node. For more information, see LUSTATs.

Sense code	Description
0x0809	Mode inconsistency.
0x080B	Bracket race error.
0x081B	Contention race condition.
0x1003	Incorrect FM profile for request.
0x2001	Sequence number error.
0x2002	Chaining error.
0x2003	Bracket error.
0x2004	Direction error.
0x2006	Data traffic quiesced.
0x4003	BB not allowed.
0x4004	End bracket (EB) not allowed.
0x4006	Exception response not allowed.
0x4007	Definite response not allowed.
0x4009	Change direction (CD) not allowed.
0x400B	Chaining not supported.
0x400C	Brackets not supported.
0x400D	CD not supported.
0x400F	Incorrect use of FI.
0x4011	Incorrect use of RU category.
0x4014	Incorrect use of definite response 1 (DR1), definite response 2 (DR2), exception response (ER).

Configuration Information

To obtain information about the Microsoft® Host Integration Server 3270 configuration, the application uses the calls listed in the following table.

Function	Description
sepdcrec	Returns a data structure that contains the 3270 user record for this user and the diagnostics record from the running configuration file.
sepdgetinfo	Returns general information about the version of Host Integration Server currently running, such as the release level, the network operating system, and the directory of the running configuration file.

If the return code from **sepdcrec** indicates that no 3270 user record was found for this user, the emulation program should terminate and not allow the user to use 3270 emulation. The Host Integration Server error message COM0438 is provided to log this error.

In This Section

- 3270 User Record Format
- Diagnostics Record Format
- Creating NetView User Alerts

3270 User Record Format

Two structures make up the 2370 user record:

Tecwrksd, a logical unit (LU)/session information record, which includes details of a 3270 LU.

Tecwrkus, a 3270 user record, which includes a number of Tecwrksd LU/session information records.

Note that the user record is not a fixed length, because the number of LU/session information records in the remap list is variable. The structures described in the following sections are provided simply as a template to allow you to map to the correct offset in the record.

In This Section

tecwrksd

Tecwrksd is a logical unit (LU)/session information record, which includes details of a 3270 LU.

Syntax

```
typedef struct tecwrksd {
    UCHAR   cwshost[9];
    USHORT  cwsestyp;
    USHORT  cwsmodov;
    USHORT  cwspad;
} TECWRKSD;
```

Members

cwshost[9]

LU/pool name accessed.

cwsestyp

Session type (M2, M3, M4, M5, printer).

cwsmodov

Whether the user has override permission.

cwspad

Two bytes of padding.

Remarks

For Windows 2000

The following "Members" list explains the meaning of each field in the structures and indicates how the application should use each field. For more information about Host Integration Server 3270 configuration, see Configuration Information.

Members

cwshost

The name (up to eight characters) of the LU or LU pool that this session is configured to use. The application specifies this name on the Open(SSCP) Request.

cwsestyp

The LU type (display or printer) of the LU used by this session and (if it is a display LU or a pool of display LUs) the screen model. The possible values are:

- CERTMOD2 (0) Model 2 display (24 by 80)
- CERTMOD3 (1) Model 3 display (32 by 80)
- CERTMOD4 (2) Model 4 display (43 by 80)
- CERTMOD5 (3) Model 5 display (27 by 132)
- CERTPRNT (4) Host printer

The application should use this value to distinguish between display and printer sessions and to set the appropriate screen model for display sessions.

cwsmodov

TRUE if the user has permission to override the screen model for display sessions—that is, to change the session to use a different screen model from the one configured. If this value is **FALSE**, the user should not be permitted to change the screen model. This field is not used for printer sessions and should not be checked.

tecwrkus

Tecwrkus is a 3270 user record, which includes a number of Tecwrksd LU/session information records.

Syntax

```
typedef struct tecwrkus {
    USHORT   cwlen;
    USHORT   cwtype;
    UCHAR    cwname[21];
    UCHAR    cwremark[26];
    UCHAR    cwstylef[9];
    USHORT   cwvewrtm;
    USHORT   cwalert;
    USHORT   cwchghan;
    USHORT   cwmaxses;
    USHORT   cwnumrec;
    TECWRKSD cwsesdat[10];
    USHORT   cwmodisf;
    UCHAR    cwstatus;
    UCHAR    cwpad;
    USHORT   cwnumrmp;
    TECWRKSD cwremap[1];
} TECWRKUS;
```

Members

cwlen

Length of record.

cwtype

Type of record.

cwname[21]

User name.

cwremark[26]

Comment field.

cwstylef[9]

Initial style file name.

cwvewrtm

Whether user can view Response Time Monitor (RTM) information.

cwalert

Whether user has ALERT permission.

cwchghan

Whether user can change LU/pool name accessed.

cwmaxses

Maximum number of active sessions (1–10).

cwnumrec

Number of sessions for user.

cwsesdat[10]

Session information records.

cwmodisf

Permission to modify initial style.

cwstatus

Status byte: user or group.

cwpad

One byte of padding.

cwnumrmp

Number of LUs/pools in remap list.

cwremap[1]

LU/pool remap list.

Remarks

For Windows 2000

Microsoft® Host Integration Server permits configuration of more than 10 sessions per user when used with clients running Microsoft Windows® 2000. The first 10 sessions are placed in the **cwsesdat** array with **cwnumrec** set to 10 and the remainder are placed in the location of the remap list. The **cwnumrmp** member indicates the number of Tecwrksd structures in the remap list. Note that this permits **cwmaxses** to be greater than **cwnumrec**.

The following "Members" list explains the meaning of each field in the structures and indicates how the application should use each field. For more information about Host Integration Server 3270 configuration, see Configuration Information.

Members

cwlen

The length of the 3270 user record (this is variable because it contains a variable number of LU/session records in the remap list). The application should use this value to locate the start of the next 3270 user record when searching for the correct record.

cwtype

Identifies this as a 3270 user record.

cwname

The Local Area Network (LAN) Manager user name, or other identifying name, of the 3270 user (up to 20 characters). The application uses this to search for the correct 3270 user record.

cwremark

An optional comment field (up to 25 characters), used in the configuration program to give more information about the user (for example, the user's full name).

cwstylef

The name (up to eight characters) of the default style file used by this user (a file containing the user's 3270 customization settings, used by the Host Integration Server 3270 emulation programs). This field can be used to identify the equivalent file for your 3270 emulator, if appropriate.

If this field is blank, no style file is used and the 3270 emulator should revert to its default settings (unless overridden by a style file specified by the user).

cwvewrtm

TRUE if this user is permitted to view a display of RTM statistics for his or her 3270 sessions. If this field is **FALSE**, the application should not display RTM statistics and should not display a last transaction time indicator (LTTI) on the status line of display sessions. For more information about the use of Response Time Monitor (RTM), see Diagnostics Record Format.

cwalert

TRUE if the user is permitted to send NetView user alerts. If this field is **FALSE**, the user should not be permitted to send alerts. For more information about the use of alerts, see Diagnostics Record Format.

cwchghan

TRUE if the user is permitted to remap a 3270 session to use a different LU (in which case it can be changed to use any LU in the remap list—see **cwremap**). If this field is **FALSE**, the application should not allow the user to remap sessions.

cwmaxses

The maximum number of active sessions permitted to this user. If the number of sessions configured (see **cwnumrec**) is greater than this, the user must not be allowed to activate more sessions at a time than this field specifies.

cwnumrec

The total number of sessions configured for this user. The user record always contains 10 LU/session records (see **cwsesdat**), but only this number of the records will be used—the remainder will be filled with zeros.

cwsesdat

Ten LU/session records. Some of these records can be filled with zeros, indicating that they are unused (**cwnumrec** gives the number of sessions that are used). The application should list, and allow the user to use, only the sessions that have valid session records here.

cwmodisf

TRUE if the user is permitted to modify the initial 3270 customization. If this field is **FALSE**, the application should use the customization defined by **cwstylef** (if specified); the user should not be allowed to make changes to this style, or to override it by loading a different style file.

cwstatus

Indicates whether the user name in this record is a LAN Manager user name or group name. The least significant bit of this byte is **CERTGRUP (1)** for a group, and **zero** for a user. Other bits are not used.

cwpad

Pad byte—not used by the application.

cwnumrmp

The number of LU/session records in the remap list (see **cwremap**).

cwremap

The list of LU/session records, which indicates the LUs to which the user can remap sessions (if any). If the user is not permitted to remap sessions (see **cwchghan**), this list is not used and should not be checked by the application.

Diagnostics Record Format

Two structures make up the Diagnostics record:

The Alert information record tedalert, which includes details of a 3270 NetView user alert, and tediagns, the diagnostics record, which includes a number of tedalert information records.

In This Section

- tedalert
- tediagns

Tedalert

The alert information record tedalert includes details of a 3270 NetView user alert.

Syntax

```
typedef struct tedalert {
    UCHAR    dalrtnam[53];
    UCHAR    daparam1[33];
    UCHAR    daparam2[33];
    UCHAR    daparam3[33];
} TEDALERT;
```

Remarks

The following "Members" list explains the meaning of each field in the structures that is relevant to the application and indicates how the application should use each field. Fields that are not included in the list are used by other Microsoft® Host Integration Server components and need not concern the application; in particular, the network management connection name and the times at which RTM data is sent to the host are handled by the local node on behalf of the application.

Note that the application should determine whether the user is permitted to send NetView user alerts and/or view RTM data (see 3270 User Record Format). It should not display the appropriate information, as described below, if the user does not have permission to use that information. The host can also override whether the application is permitted to send and/or to display RTM data (for more information, see RTM Parameters).

For more information about how the application uses the RTM parameters, see RTM Parameters, Response Time Monitor Data, and Status-RTM.

Members

dalrtnam[53]

The description (up to 52 characters) of the alert corresponding to a particular alert number. The application should display this information to help the user determine which alert to send.

daparam1[33]

The descriptions (each up to 32 characters) of up to three parameters.

daparam2[33]

Required for the alert; depending on the specific alert.

daparam3[33]

One or more of these descriptions can be blank, indicating that the parameter is not used. For each of these descriptions that is not blank, the application should display this string to prompt the user for the appropriate parameter.

tediagns

The diagnostics record tediagns includes a number of tedalert information records.

Syntax

```
typedef struct tediagns {
    USHORT   dilen;
    USHORT   ditype;
    UCHAR    dinetmgt[9];
    USHORT   disrtmco;
    USHORT   disrtmub;
    USHORT   diwruldr;
    USHORT   dirtmth1;
    USHORT   dirtmth2;
    USHORT   dirtmth3;
    USHORT   dirtmth4;
    TEDALERT dialerts[20];
    UCHAR    diaudit[128];
    UCHAR    dierror[128];
    USHORT   diaudlev;
    UCHAR    dipad[16];
} TEDIAGNS;
```

Members

dilen

Length of record.

ditype

Type of record.

dinetmgt[9]

Network management connection name.

disrtmco

Send Response Time Monitor (RTM) data at counter overflow.

disrtmub

Send RTM data at UNBIND.

diwruldr

The definition by which response times are to be measured. The application should measure the response time from the time the user presses ENTER or an AID key to send data to the host, until one of the following events as defined by this field:

CERTWRIT (0)

The first host data reaches the 3270 display.

CERTUNLK (1)

The host unlocks the user's keyboard.

CERTDIRE (2)

The host gives the application direction so that the user can send further data.

Note that the host can override these definitions; for more information, see RTM Parameters.

dirtmth1

The thresholds that define the bands into which response times are to be classified. Note that the host can override these definitions; for more information, see RTM Parameters.

dirtmth2

RTM threshold #2.

dirtmth3

RTM threshold #3.

dirtmth4

RTM threshold #4.

dialerts[20]

Up to 20 alert records that define the alerts that Host Integration Server users can send to a host. There are always 20 records, but some of these can be blank, indicating that they are not used. The application should display the descriptions of any nonblank alerts together with the alert number (from 1 to 20) defined by the position of the alert record in this array.

diaudit[128]

Audit log file name.

dierror[128]

Error log file name.

diaudlev

Default audit level.

dipad[16]

16 bytes of padding.

Creating NetView User Alerts

You can create NetView user alerts for users to send. Users identify the alerts by number. Each number corresponds to a specific collection of information or requests that the user wants to send through NetView to a host operator.

Microsoft® Host Integration Server leaves blank fields for the user alert information in the structure that is returned from sepdcrec. To create specific user alerts, create appropriate data structures and call the TRANSFER_MS_DATA common service verb to send the user alert to NetView.

Compiling and Linking 3270 Client Applications

This section describes the 3270 client samples included with Host Integration Server 2009. The samples are located in the \SDK\Samples\SNA folder on the Host Integration Server CD.

This section lists and explains the header files and libraries needed to develop 3270 client applications for use with Host Integration Server client applications. It also provides information about compiling and linking the 3270 client applications.

In This Section

Building the 3270 Client Samples

When installed from the Microsoft Host Integration Server 2009 CD, all the 3270 client samples are built in a similar way, as described in this section. First, set the environment variables listed in the following table.

Variable	Description
ISVLIBS	The directory containing the Host Integration Server LIB files for Microsoft Windows 2000.
ISVINCS	The directory containing the Host Integration Server header files.
SAMPLEROOT	The root directory where the sample code provided as part of the SDK has been installed on a local hard disk.

For example, after copying the contents of the SDK folder on the Host Integration Server 2009 CD to C:\SNASDK, use the following lines to set the variables:

```
ISVLIBS=C:\SNASDK\Lib
ISVINCS=C:\ SNASDK\Include
SAMPLEROOT=C:\SNASDK\Samples\SNA
```

Next, run NMAKE on the .mak file in each subdirectory below this root directory containing the actual sample source code. For example, for APING and APINGD, change to the Samples\aping directory and type the following:

nmake -f makeping.mak

Client Interface Files for 3270 Applications

The files listed in the following table are required to build 3270 client applications for use with Microsoft® Host Integration Server.

File	Description
FMI.H	Main header file containing the definitions of buffer and message formats, function prototypes for the DL-BASE/DMOD interface calls, and constant definitions.
TRACE.H	Definitions of the logging and tracing macros.
FMISTR32.LIB	Function Management Interface (FMI) string library for use with Microsoft Windows® 2000.
SNACLI.LIB	Main interface library for developing 3270 client applications on Windows 2000.

3270 Include Files

To compile the application, the header files FMI.H and TRACE.H are required. In addition, one of the standard operating system header files may be required. To include the required files, use the following lines in your application:

```
#include <fmi.h>
#include <trace.h>
```

Compiler Options for 3270 Applications

When compiling the 3270 client application, the compiler options listed in the following table are required.

Option	Explanation
/c	Compile only, without linking. Linking is normally done as a separate phase to include the required Microsoft® Host Integration Server libraries.
/D NOTRC	The NOTRC macro specifies that internal tracing should not be compiled into the application. The **/D NOTRC** option should be used for building a final system (internal tracing should not be included because it will degrade performance and require more memory and resources). For a development system, you may want to compile with internal tracing; if so, remove the **/D NOTRC** option.
/D WIN32_SUPPORT /D MSWIN_SUPPORT, /D OS2_SUPPORT, /D DOS_SUPPORT	These macros are used in the header files FMI.H and TRACE.H supplied with SNA services to support variants of the client interface for the different operating systems supported. One of these options must be defined, depending on the operating system for which the application is intended.

/Gzs	c:	Use **stdcall** calling conventions on i386/i486 and Pentium class processors.
	S:	Remove stack check calls.

The compiler flags listed in the following table are required, but any of the valid options for each flag may be used, as appropriate to your application.

Flag	Description
/A	Compiler model (Does not apply to Microsoft Windows® 2000)
/O	Optimization
/W	Warning level

Linking 3270 Client Applications

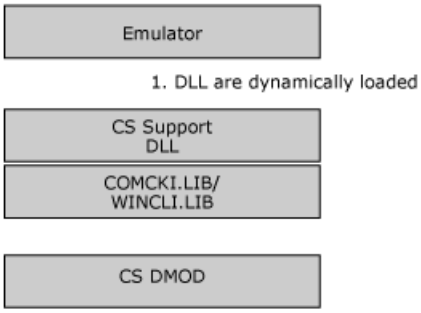
This topic describes how to link 3270 client applications using different platforms.

The SNACLI.LIB library must be linked with the application.

The DMOD is implemented as a DLL. SNACLI.LIB contains import definitions for the APIs in the DLL, and some global variables required for the logging and tracing macros.

It is possible to create a DLL that is dynamically loaded when the user starts a session for an LU. In this case, to make the log and trace macros available, the application structure needs to be as shown in the following figure.

Application Structure



Support for 3270 Single Sign-On

This section describes the support for Single Sign-On for 3270 display sessions that is available in Microsoft Host Integration Server 2009.

Over 3270 LUs, a Single Sign-On feature is supported to automate the overall logon process. When configured for this feature, Host Integration Server automatically replaces special keywords in the data stream with the actual host user name and password at appropriate points in the session.

This section contains:

Prerequisites for 3270 Single Sign-On

In preparation for using 3270 Single Sign-On, the system administrator must define a host security domain containing host connections. This host security domain must be initially created or modified to enable the Single Sign-On feature. The system administrator must enable a user's Microsoft® Windows Server™ 2003 or Microsoft Windows® 2000 account in the host security domain and either the administrator or the user must establish a mapped host account for the Microsoft® Windows Server™ 2003 or Windows 2000 domain user name.

The user must be logged on to a Microsoft® Windows Server™ 2003 or Windows 2000 domain with a user name and password. Note that this Single Sign-On feature is only supported over 3270 LUs.

Registry Settings Used for 3270 Single Sign-On

The 3270 Single Sign-On feature depends on Microsoft® Host Integration Server scanning 3270 logical units (LUs) used in the logon process for special keywords that are defined in the registry on the computer running Host Integration Server. The values for these special keywords can be defined by the system administrator on the computer running Host Integration Server.

The registry settings used by the 3270 Single Sign-On process are located under the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services** registry node. The following entries are installed under the **SNASERVR\PARAMETERS** subkey:

3270SSOPadByte
This entry should be set to an ASCIIZ string to use as the character for padding replacement text in the user name or password if these strings are shorter than the length of the special tag strings defined below. The default value for this pad character is the ASCII space character.

3270SSOPostReplaceCount
This entry should be set to a DWORD that represents the number of message chains of RUs to scan after replacement of text for user name or password. The default value for this number is 10.

3270SSOPrefix
This entry should be set to an ASCIIZ string to use as the special prefix tag string in combination with the user name and password tags. The default value of this string is MS$.

3270SSOPwdTag
This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special host password string that will be replaced. The default value of this string is SAMEP, so the default host password string that is scanned for and replaced is MS$SAMEP. Note that length of the password string that is scanned for (MS$SAMEP, for example) determines the maximum length of the password string that can sent to the host using Single Sign-On. This limit occurs because the password substitution cannot change the length of the data message. Note that the value of this string must be different from the value of the **3270SSOUserTag** entry for Single Sign-On to function properly.

3270SSOReplaceCount
A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceCount** registry entry is defined and the **3270SSOReplaceTimer** registry entry is not defined, the node counts this number of RUs (on PLU-SLU session only) before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined and the node defaults to a time-out of 30 seconds.

3270SSOReplaceTimer
A DWORD value that affects the time-out value for password substitution. User IDs and passwords will be substituted in each chain on the LU-SSCP and PLU-SLU sessions until the timer expires. By default the timer will be set to 30 seconds, but this behavior can reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node.

If the **3270SSOReplaceTimer** registry entry is defined and **3270SSOReplaceCount** is not defined, the node uses this value in seconds before time-out occurs. If both the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries are defined, the value for **3270SSOReplaceCount** will be used to determine when a time-out will occur. By default, this key is not defined and the node defaults to a time-out of 30 seconds.

3270SSOUserTag
This entry should be set to an ASCIIZ string to use as the special tag string in combination with the **3270SSOPrefix** tag in defining the special user name string that will be replaced. The default value of this string is SAMEU, so the default user name string that is scanned for and replaced is MS$SAMEU. Note that length of the user name string that is scanned for (MS$SAMEU, for example) determines the maximum length of the username string that can sent to the host using Single Sign-On. This limit occurs because the user name substitution cannot change the length of the data message. Note that the value of this string must be different from the value of the **3270SSOPwdTag** entry for Single Sign-On to function properly.

3270 User Name and Password Replacement

The SNA node on the host monitors the inbound session for a replacement sequence consisting of the **3270SSOPrefix** string immediately followed by one of the strings **3270SSOUserTag** or **3270SSOPwdTag**. Thus, the default user name string that would be scanned for and replaced is MS$SAMEU. When this string is found in the inbound session data, the node looks up the corresponding information (host user name in the current host security domain) and overwrites MS$SAMEU with this information. The same process occurs for the password string that would be scanned for and replaced, which defaults to MS$SAMEP.

Note that this operation cannot change the length of the data message. If the actual user name or password that is retrieved from the current host security domain is shorter than the replacement sequence, it is padded out with the first character of the **3270SSOPadByte** string used as a padding character. If the actual host user name or password string is longer than the string that is scanned for, these strings are truncated to the length of the scanned string so that the data message length is not affected.

Note that since the user name and password can be sent in any order, the registry string values for the **3270SSOUserTag** and **3270SSOPwdTag** entries must be different for Single Sign-On to function properly.

The SNA node monitors the SSCP-LU session for these special tag strings at all times and replaces all occurrences of these strings with corresponding looked-up data. On the LU-LU session, the node starts monitoring at start of session (BIND). The node stops monitoring when it has received **3270SSOPostReplaceCount** chains of request/response units (RUs) without seeing a substitution tag. The node will not restart monitoring until it receives an UNBIND–BIND sequence for that session.

Note that the node considers the sequence:

```
BIND, data, UNBIND(BIND FORTHCOMING), BIND
```

As a continuation of the same LU-LU session and does not restart monitoring on receipt of the second BIND. This sequence is often used by host session managers handing off a session to an application system, and is considered a single terminal session.

User IDs and passwords will be substituted in each chain on the system services control LU-SSCP and PLU-SLU sessions until the node has received **3270SSOPostReplaceCount** chains of RUs without seeing a substitution tag or a timer expires. By default the timer is set to 30 seconds, but this behavior can reconfigured in the registry using the **3270SSOReplaceCount** and **3270SSOReplaceTimer** registry entries. The timer is started when the OPEN SSCP is received by the node. After the timer expires, the node will stop scanning messages for the 3270 replacements strings for the user ID and password. If the replacement strings arrive after the timer expires, the replacement strings will be sent to the host unmodified causing the Single Sign-On to fail. The application will not receive any notification that the timer has expired. The only indication of a problem will likely be that the Single Sign-On to the host session has failed.

Note that all strings are specified in the registry in ASCII, but the node translates them to Extended Binary Coded Decimal Interchange Code (EBCDIC) through AE character mapping before scanning for a match.

SNA Internationalization Programmer's Guide

This section describes the features available in Host Integration Server 2009 for supporting international languages and different national language character sets.

The SNANLS API uses the language support features provided with Microsoft Windows 2000 and Microsoft Windows XP. SNANLS supports European languages that use single-byte encoding, as well as East Asian languages that use double-byte or Unicode encoding.

For API references and other technical information about SNA Internationalization, see SNA Internationalization Programmer's Reference.

In This Section

- SNA National Language Support Programmer's Guide

SNA National Language Support Programmer's Guide

The SNA National Language Support (SNANLS) API standardizes the way in which national languages and locales are supported. SNANLS handles string conversion necessary for supporting a wide range of host and code pages. Components such as the Host Print service and Shared Folders service use SNANLS API to convert strings from EBCDIC to ANSI and from ANSI to EBCDIC.

The SNANLS API is the standard means to convert strings in Host Integration Server 2009. SNANLS presents a single interface to applications that need strings converted from one code page to another. These conversions may be EBCDIC-to-ANSI, ANSI-to-EBCDIC, EBCDIC-to-OEM code pages, OEM-to-EBCDIC, EBCDIC-to-ISO code pages, and ISO-to-EBCDIC. Additionally, SNANLS supports the broadest possible range of host and PC code page conversions.

SNANLS provides a uniform interface for programmers, hiding the details and difficulties of string conversion. SNANLS supports both SBCS and DBCS conversions. Two other lower-level APIs handle the actual string conversion. For SBCS conversions, SNANLS uses the system-provided Win32 NLS API that is resident on Microsoft Server 2003, Windows XP, and Windows 2000.

For DBCS conversions, SNANLS uses the **TrnsDT** API. The **TrnsDT** API is installed with Host Integration Server.

SNANLS is supported on Windows Server 2003, Windows XP, and Windows 2000.

In This Section

National Language Support in Windows Server 2003, Windows XP, and Windows 2000

National Language Support (NLS) provides a standardized method of supporting multiple international locales, code pages, input methods, sort orders, and number/currency/time/date formats.

The Win32 NLS API provides developers with a way to access system-provided Unicode-to-ANSI and ANSI-to-Unicode conversion services. Microsoft Windows Server 2003, Windows XP, and Windows 2000 supply EBCDIC-to-Unicode and Unicode-to-EBCDIC translation tables for all of the popular host code pages.

The SNANLS API leverages the existing work done to support the NLS API on Windows Server 2003, Windows XP, and Windows 2000. Host Integration Server 2009 takes advantage of these EBCDIC-to-Unicode-to-ANSI and ANSI-to-Unicode-to-EBCDIC code page conversion services.

Currently, the Win32 NLS API only supports SBCS EBCDIC code pages. However, future versions of the NLS API will support DBCS EBCDIC. SNANLS currently uses TrnsDT for DBCS conversions.

SNA Print Server Data Filter Programmer's Guide

The Host Print service of Microsoft® Host Integration Server 2009 provides server-based 3270 and 5250 printer emulation, enabling host applications to print to Local Area Network (LAN) printers supported by Microsoft Windows Server™ and Novell NetWare. This section introduces the SNA Print Server Data Filter API (sometimes referred to as the Print Exit API). This API can be used to extend the capabilities of the Host Print service in Host Integration Server 2009.

The user can provide a print data filter DLL that will be called by Host Print service when a print job is initiated, when data is sent to the printer, and when the print job is completed. This print data filter DLL can:

- Send data to the printer when a job starts (print a banner page, for example).
- Perform special processing on the data to be printed.
- Send data to the printer upon print job completion (print a trailer page, for example).

SNADIS Programmer's Guide

This section enables original equipment manufacturers (OEMs) and adapter vendors who are developing their own SNALink software to work with Host Integration Server 2009 SNA Services.

SNALink software must be written as a Microsoft Windows 2000 device driver. For information about writing Windows 2000 device drivers, see the Windows 2000 Device Driver Kit (DDK).

This section provides the following information:

- Internal concepts of Host Integration Server 2009 that are required to integrate new communications adapters into the server environment.
- Definitions of the interfaces used by Host Integration Server 2009 to communicate with SNALinks.
- Information about using the configuration and diagnostics features included in Host Integration Server 2009.
- Instructions for compiling and linking the SNALink support software.

The network operating systems currently supported by Host Integration Server 2009 include Microsoft LAN Manager (as implemented in Microsoft Windows 2000) and TCP/IP. Future versions of Host Integration Server may support other network operating systems. Because of this, it is recommended that you develop link support that is independent of the network operating system.

For API references and other technical materials for programming SNALink applications, see the SNADIS Drivers Programmer's Reference section of the SDK.

This section contains:

SNALink Concepts in Host Integration Server

This section describes key concepts used in the SNALink feature of Host Integration Server 2009. Because the purpose of this section is to enable original equipment manufacturers (OEMs) and adapter vendors to develop link support software to integrate their hardware adapters into a Host Integration Server 2009 system, only the relevant parts of the Host Integration Server 2009 architecture are described.

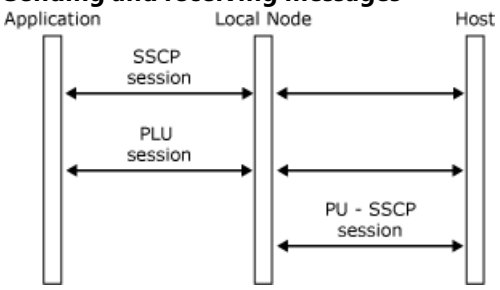
In This Section

Overview of SNALink

A Host Integration Server 2009 SNALink must implement an SNA-compatible data transport mechanism capable of connecting the local type 2.1 node to remote host (PU4/5) or peer (PU2.1) systems.

The local node provides the SNA layers of path control, transmission control, data flow control, and logical unit (LU) services. The following figure shows an example of a Host Integration Server 2009 system.

Sending and receiving messages



The local node uses the data link control (DLC) interface to communicate with a SNALink. This interface is defined in The Data Link Control Interface. The SNALink and the DLC driver are responsible for transferring data between the path control layer of the node and the DLC adapter.

The routing of messages that flow between Host Integration Server components is handled by the SnaBase and Dynamic Access Module (DMOD) components. For details about how to send and receive messages, see The SNALink Interface.

SNALink Configuration and Management

The configuration information for a Host Integration Server 2009 system is stored in two forms:

- A centralized configuration file containing details of logical units (LUs), physical units (PUs), and connections.
- Entries in the Microsoft Windows Server 2003 or Windows 2000 registry containing configuration information for the SNALinks supported on that computer. This information contains parameters required by Host Integration Server 2009, and any other parameters that independent hardware vendor (IHV) code may require.

A Host Integration Server SNALink is defined when a Host Integration Server system is installed. A SNALink can support only one physical connection from the server. If a single adapter is capable of supporting multiple physical connections, Host Integration Server requires multiple SNALinks to be configured.

To reconfigure a server's SNALink support (for example, after installing a new adapter), the administrator uses either the Windows Network Control Panel applet or the Host Integration Server setup program. For further information about how this operates, see Setup Information.

All other configuration of a Host Integration Server system is performed using SNA Manager. As part of the configuration process, logical connections to remote PUs are associated with one or more SNALinks.

All configured SNALinks are automatically started when the Host Integration Server system is started. At this stage, the SNALink performs any initialization required, and then waits for instructions from local nodes.

When a connection is activated, either from SNA Manager or automatically (for example, in response to a 3270 user's request for a session with a remote host), the SNALink receives an Open(LINK) message from the local node. The SNALink should then perform whatever action is required to initiate that connection. This can involve dialing a telephone number for a switched Synchronous Data Link Control (SDLC) connection or bringing up level 2 on an X.25 link and sending a CALL packet.

If the IHV wants the same physical adapter to be available for use by multiple SNALinks (for example, a dumb SDLC card can be used to communicate using SDLC or X.25 protocols), the SNALink should not attempt to access the hardware until it has received an **Open(LINK)** message from the local node.

Structure of SNALink Components

The components of SNALink are:

- Local nodes
- SNALinks
- 3270 emulators

This section introduces the structure of these components and explains terms used to refer to the structure.

In This Section

Role of the Base

TheBase is a part of each Host Integration Server 2009 component, such as the local 2.1 node or a link service that provides the operating environment for that component. It passes messages between components and provides functions common to all components, such as diagnostic tracing.

The Link Base is the type of Base used by Host Integration Server SNALink. The Base has entry points for initialization, sending messages, receiving messages, and termination.

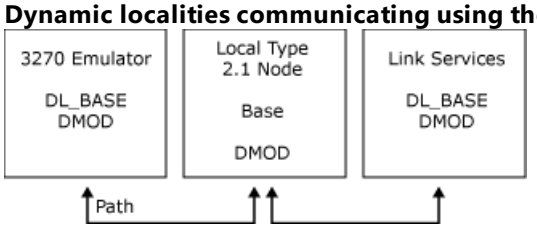
Localities and DMODs

A Base and its components (that is, a Host Integration Server 2009 executable program) is called a **locality**. The Host Integration Server system therefore consists of one or more communicating localities (all the running Host Integration Server 2009 executable programs within the LAN Manager domain). For each Host Integration Server system, there is a central configuration file. In addition, each Host Integration Server computer maintains configuration information about the SNALinks it supports.

In a system such as Host Integration Server, where the number of localities and their types are not configured in advance, the relationships between the localities are set up dynamically as individual localities come and go. Localities that can enter and leave a system in this way are called **dynamic localities**.

Dynamic localities communicate using the Dynamic Access Module (DMOD) component, which provides the communications facilities needed to pass messages between the Bases. This is illustrated in the following figure.

Dynamic localities communicating using the DMOD component



This figure shows a system consisting of three dynamic localities. Dynamic localities can enter or leave this system at any time.

Component Localities

SNALinks can enter dynamically into a Host Integration Server 2009 system. The SNALink, in conjunction with the Base, acts as a whole locality and communicates with the other localities in the system using a Dynamic Access Module (DMOD).

SNALink Interface describes the interface to the Base and the DMOD that allows a SNALink (or any other Host Integration Server component) to participate in a Host Integration Server system.

Partners

For Host Integration Server 2009 components and applications to communicate with each other, it must be possible to identify a partner within a locality. A partner is an addressable component of a locality; that is, code to which messages can be sent. In a Host Integration Server system, there is generally only one partner within a locality (such as an SNALink or the 3270 emulation program). However, separate functions within the local 2.1 node (such as the 3270 and Advanced Program-to-Program Communications (APPC) functions) can be considered to be separate partners.

SNALink Structure

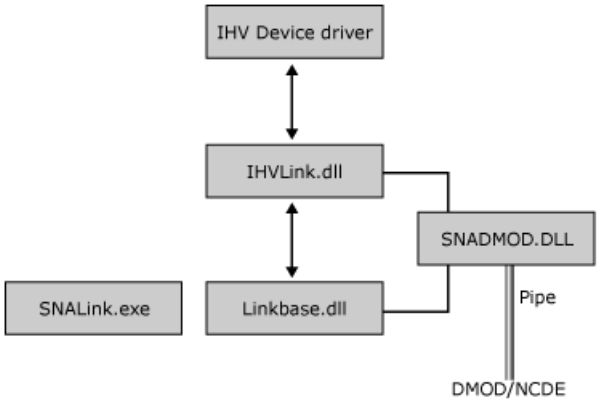
A Host Integration Server 2009 SNALink consists of the following:

- The link-specific protocol code provided by the independent hardware vendor (IHV)
- A Base
- A Dynamic Access Module (DMOD)

The DMOD, Base, and the IHV link-specific component of a Host Integration Server SNALink are implemented as dynamic-link libraries (DLLs). The executable component SNALINK.EXE is used to start a SNALink. SNALINK.EXE determines (from the Host Integration Server configuration) which link support DLL (for example, IHVLINK.DLL) is required and dynamically loads it before entering the Base scheduler.

The following figure shows the executable structure of a SNALink.

Executable structure of an SNALink



Messages

Messages are used to pass data between partners in the Host Integration Server 2009 system. This section provides information about message structure and formats.

In This Section

- Overview of Message Formats
- Buffer Header Format
- Buffer Element Format

Overview of Message Formats

A message always contains fixed-format header information such as a message type and addressing information. It can also contain other header information specific to a particular message type (such as the message subtype) and an indefinite amount of extra data.

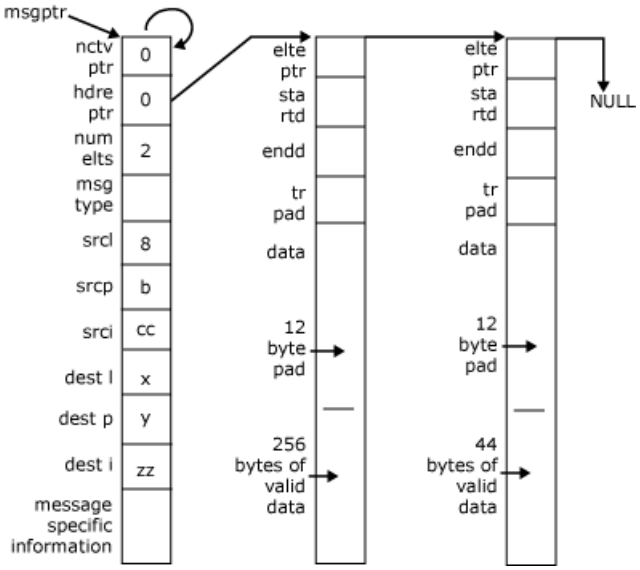
Messages are saved in buffers that consist of one header and zero or more elements:

- The header contains the fixed-format information and a pointer to an element. (This pointer will be NULL if there are no elements associated with the message.)
- An element contains any extra data for a message and a pointer to another element if the data continues into another element.

Buffer headers and elements are regarded as contiguous (8-bit) byte sequences. Messages of any length can be built up by chaining sufficient elements to a header.

The following figure shows a typical message with two elements.

Typical message with two elements



Buffer Header Format

This topic lists the common fields that always occur at the start of a buffer header. These are followed by further fields specific to the particular message. For details about individual message formats, see SNADIS Message Formats.

Field	Type	Description
PTRBFHDR	nxtqptr	When the buffer is in a queue, this field points to the header of the next buffer in the queue (NULL if it is the last buffer in the queue). When the buffer is not in a queue, this field points to itself. The Host Integration Server 2009 buffer management routines use this to check for buffer corruption.
PTRBFELT	hdrptr	Pointer to the first buffer element in the associated chain of buffer elements; NULL if the message consists only of a buffer header.
CHAR	numelts	Number of buffer elements chained from the header. Zero if the message consists only of a buffer header.
CHAR	msgtype	Message type. For more information, see individual message descriptions in SNADIS Message Formats.
CHAR	srcl	Source locality. For more information, see LPI Addresses.
CHAR	srcp	Source partner. For more information, see LPI Addresses.
INTEGER	srci	Source index. For more information, see LPI Addresses.
CHAR	destl	Destination locality. For more information, see LPI Addresses.
CHAR	destp	Destination partner. For more information, see LPI Addresses.
INTEGER	desti	Destination index. For more information, see LPI Addresses.

Note

Fields that occupy two bytes, such as **opresid** in the Open(LINK) request, are normally represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. However, the following fields are exceptions:

- The **srci** and **desti** fields in buffer headers are stored in the local format of the application that assigns them (only the assigning application needs to interpret these values).
- The **startd** and **endd** fields in elements are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).

Buffer Element Format

This topic lists the common fields that always occur at the start of a buffer element. The **dataru** field contains information specific to the particular message. For details about individual message formats, see SNADIS Message Formats.

Field	Type	Description
PTRBFELT	hdrptr–>elteptr	Pointer to next buffer element in the chain. NULL if this element is the last or only element in the chain.
INTEGER	hdrptr–>startd	Start of valid data in this element. The index into *dataru* of the first byte of valid data.
INTEGER	hdrptr–>endd	End of valid data in this element. The index into *dataru* of the last byte of valid data.
CHAR	hdrptr–>trpad	Pad byte (reserved).
CHAR[SNANBEDA]	hdrptr–>dataru	An array of characters that contains the data for this element. Note that the valid data might not occupy the whole of the element. The **startd** and **endd** fields give the indexes into this array of the start and end of the valid data. The constant SNANBEDA is defined in SNA_DLC.H as 268.

The following information will help you to interpret the message formats:

- Fields that occupy two bytes are represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. The exceptions to this are the **startd** and **endd** fields in elements, which are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).

- The offsets indicated by the **startd** and **endd** fields are expressed in terms of the first byte of dataru being offset 1; the first byte of valid data is at **dataru(startd–1)**. For example, if **startd** is 11 and **endd** is 18, **dataru** begins with 10 bytes that are not valid data, followed by 8 bytes of valid data.

In the example message format illustrated in Overview of Message Formats, each element has a **startd** of 13, indicating 12 bytes of padding before the start of the valid data. This leaves room for 256 bytes of data, and hence the element data (300 bytes long in this example) requires two elements.

LPI Connections

Partners communicate by passing messages to each other. If two partners want to communicate with each other, a locality, partner, index (LPI) connection is set up between the two partners. Messages then flow between the partners over this connection. The term *LPI connection* is explained in LPI Addresses. Note that this is not related to the Microsoft Host Integration Server 2009 concept of a connection between the local node and a remote system.

In This Section

- Paths and DMODs
- LPI Addresses
- Making Connections

Paths and DMODs

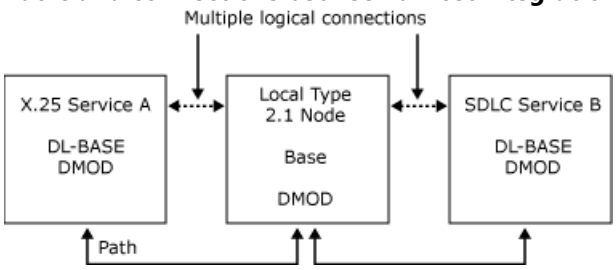
Dynamic Access Modules (DMODs) are responsible for the communication between localities. When the DMODs in two localities can successfully pass messages between them, a path is said to exist between the two localities. A path must exist between two localities before a connection can exist between partners in those localities.

In Host Integration Server 2009, a path is implemented using reliable LAN connections (named pipes, SPX, TCP, VINES IP)—one LAN connection for each path. When the two localities are on the same computer, a local pipe is used. This is implemented using shared buffers to increase performance, but is used by the application in exactly the same way as communication with a remote locality.

The DMOD provides communication between dynamic localities and provides guaranteed in-order delivery of messages flowing over paths between localities. If the DMOD loses its path to another locality, it informs the Base.

The following figure illustrates the paths and connections between a Host Integration Server local node and two SNALinks. X.25 service A has two connections to the local node (one for each of two virtual circuits); SDLC service B has one connection to the local node.

Paths and connections between a Host Integration Server local node and two SNALinks



LPI Addresses

A locality, partner, index (LPI) address is used to identify each end of a connection. It has three components: locality (L), partner (P), and index (I).

- **Locality** is a 1-byte identifier that uniquely identifies a locality within a system. This locality corresponds to a Host Integration Server 2009 component (local node, SNALink, 3270 emulator, and so on).

- **Partner** is a 1-byte identifier for the type of service. Each type of service has a unique value. A Host Integration Server local type 2.1 node has a defined value of 0x11. A Host Integration Server emulator has a defined product identifier of 0x12. A Host Integration Server link service (X.25. SDLC, Token Ring, Ethernet, or Channel, for example) has a defined value of 0x16.

- **Index** is a 2-byte identifier that uniquely identifies a logical entity within the product. The meaning and use of this field is defined by the communicating services. It is used to distinguish multiple connections between the same services (for example, to identify one of many virtual circuits available from an X.25 SNALink). The value of zero should not be used as an index. Applications must assign unique index values for every active LPI connection within the node.

A message flowing over a connection carries a pair of LPIs, identifying the source and destination of the message. These are the source LPI and destination LPI of the message. Together they identify the connection on which the message is flowing.

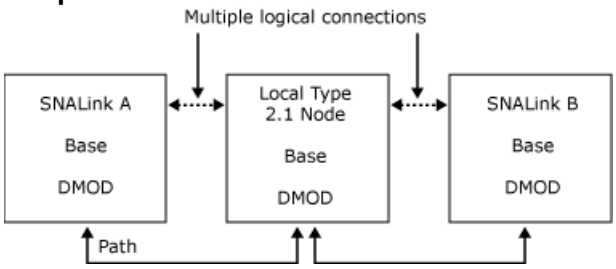
Note that more than one connection can exist between any pair of services. The Index values are then used to distinguish the connections. For example, in communications between the local node and a SNALink, the L and P values identify the message as being data link control (DLC) data for that local node, and the I value indicates which connection the data is intended for.

The LPIs are assigned by a combination of the products and the Dynamic Access Modules (DMODs) when the connection is opened, as described in Making Connections.

Because they are assigned dynamically for each component, the L values are not the same across a whole system. For example, a local 2.1 node locality could be known as locality 4 to one SNALink locality and locality 6 to a second SNALink locality. However, from the viewpoint of any locality, there exists a unique L value for each remote locality within which a path exists. This L value is used as an index into an internal table that identifies the path to that locality.

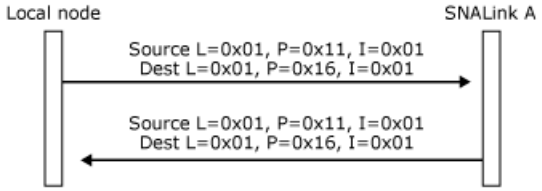
The following three figures show an example of the L values that could be used between the components shown in Paths and DMODs, and examples of the LPI values that would be used by the local node on messages flowing between the components.

Sample L values



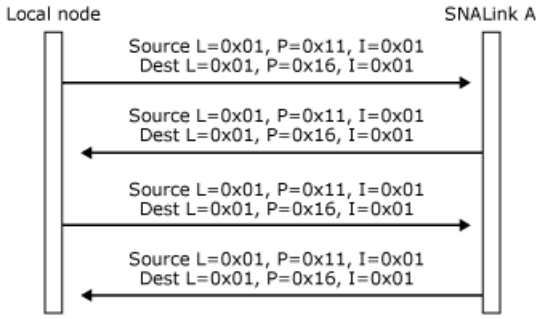
The following figure shows L values specified on messages between the local node and SNALink A.

L values specified on messages between the local node and SNALink A



The following figure shows LPI values specified on messages flowing on two different connections between the local node and SNALink A.

LPI values specified on messages flowing on two different connections



The Base is called by any piece of code that wants to send a message. It uses the destination L value on the message to determine where to send it. When the message gets to the remote locality, the Base in that locality routes it to the appropriate service if the locality contains more than one service.

Making Connections

Before messages can flow across connections, the connections must be established, or opened. This is necessary because a service does not initially know the locality, partner, index (LPI) address of the service with which it wants to communicate. There may not even be a suitable service for it to communicate with.

When a local node wants to communicate with an SNALink, it attempts to open a connection by sending an **Open(LINK)** request to the SNALink. This message will have LPI values already set up by the Base, which the SNALink should save for referencing the connection in the future.

The data link control (DLC) interface does not permit the SNALink to issue an Open request.

SNALink Interface

The SNALink interface specifies how an Independent Hardware Vendor (IHV) link DLL fits into the SNA link service architecture provided by the Base/DMOD interface. This section describes the SNALink interface, the entry points that an IHV link DLL can call, and those functions that a link service must provide to the Base/DMOD interface. These entry points allow messages to be sent to and received from the local 2.1 node.

In This Section

Process Structure and Scheduling

The primary thread of execution within a Host Integration Server 2009 SNALink is under the complete control of the Base. The Base schedules the SNALink by calling predefined entry points, which the IHV link support code must provide.

The IHV link support code can spawn extra threads of execution; however, the Base is not reentrant. The IHV code must ensure that only a single thread is executing within the Base at any moment in time.

The recommended SNALink structure uses the dispatcher to handle messages received from the local node and the work manager to process data received from the link. These routines and the way in which they are scheduled are described in The Dispatcher and The Work Manager respectively.

SNALink Initialization

When the SNALink is loaded into memory, the Base/DMOD performs all initialization required by the Host Integration Server 2009 system, including announcing availability of the new SNALink to other Host Integration Server components.

When this has been completed, the Base/DMOD calls the SNALinkInitialize function, which must be provided by the IHV link support code.

SNALinkInitialize is called with a parameter that is a handle to the global Base event. This handle should be saved by the SNALink and used to signal the Base when an event occurs (for example, when data is received from the link).

The **SNALinkInitialize** function should also:

- Read in the Host Integration Server configuration information for the SNALink. For details, see SNALink Configuration Information.
- Set up any required data structures.
- Register with the driver that provides the support for the hardware adapter, initializing this if necessary.

If initialization fails for any reason (for example, if an associated driver is not installed), the function should report the failure to the administrator by calling **SNAReportStatus**.

SNALink Termination

When a critical error occurs, forcing abnormal termination of the SNALink, the IHV code must ensure that all active connections are cleanly terminated, using whatever protocols are appropriate for the link type in use. For example, an X.25 SNALink would send a CLEAR packet on all active VCs and possibly take down level 2.

This should be performed using the process detach facility of the Win32® API function **DLLEntryPoint** .

Sending Messages

The SNALink should build a message in a buffer, and then call the Base to send it. The message contains source and destination LPIs, which are set up when the connection is opened. For more information, see LPI Connections.

The SNALink can either obtain a new buffer to contain the message to be sent (using SNAGetBuffer) or reuse one in which it has previously received a message. The application is responsible for any buffer that it has obtained or in which it has received a message. It must either use (or reuse) the buffer to send a message or release it (using SNAReleaseBuffer). If a buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using SNAGetElement) or release existing ones (using SNAReleaseElement). It is the applications responsibility to maintain the **numelts** field in the message header.

The function used to send a message to the node is SNASendMessage.

Dispatcher

Whenever a Base event occurs, the Base calls the link support code dispatcher function SNALinkDispatchProc to handle the event. The term Base event in this context means:

- A message arriving from a local 2.1 node.
- A Base timer tick occurring—this relatively slow event happens approximately every five seconds.
- Losing contact with a local 2.1 node (for example, the machine being powered down).

The **SNALinkDispatchProc** function should examine parameters passed to it by the Base to determine why it has been called (for details, see Sample Code for SNALinkDispatchProc) and call an appropriate function to handle the event. When the event has been processed, control returns to the Base scheduler.

Receiving Messages

The Base calls the SNALink dispatcher function SNALinkDispatchProc when a message is available for it.

Note that after the application receives a message, it is responsible for the buffer in which the message was received. It must either reuse the buffer to send a message (using SNASendMessage) or release it (using SNAReleaseBuffer). If the buffer to be reused does not contain the correct number of elements for the message to be sent, the application can obtain additional elements (using SNAGetElement) or release existing ones (using SNAReleaseElement).

Work Manager

When no work is currently outstanding, the Base thread of execution sleeps, waiting for an event or for a maximum period of five seconds. SNALinks should signal the Base when an event occurs (such as data arriving on the link) by setting the Base global event. A handle to this event is passed on the SNALinkInitialize call.

When the Base is rescheduled, it calls the SNALink work manager function SNALinkWorkProc. This function should handle any link events that have occurred.

A common use of this function is in an SNALink where there is a single thread that handles the protocol of the link and also multiple threads suspended on synchronous calls to a driver read function. When data is received from the link, it is placed on an internal queue, and the driver sets the global Base event. This causes the Base to be scheduled, and **SNALinkWorkProc** is called. **SNALinkWorkProc** then removes messages from the queues and passes them to the Base to be sent to the local node.

Base/DMOD and SNALink Entry Point Summary

The following tables show entry points divided into the categories SNALink, buffer management, and Base/DMOD, and listed in alphabetic order within each category.

SNALink entry points

Entry point	Description
SNALinkDispatchProc	Dispatcher.
SNALinkInitialize	Initialize SNALink.
SNALinkTerminate	Terminate SNALink.
SNALinkWorkProc	Work manager.

Buffer management entry points

Entry point	Description
SNAGetBuffer	Get buffer.
SNAGetElement	Get buffer element.
SNAReleaseBuffer	Release buffer.
SNAReleaseElement	Release buffer element.

Base/DMOD entry points

Entry point	Description
SNAGetLinkName	Get the name of the SNALink.
SNASendAlert	Send a preformatted NMVT alert to NetView.
SNASendMessage	Send a message to the node.

The following functions are defined in SNALink Configuration Information:

Entry point	Description
SNAGetConfigValue	Get a named item of configuration information.
SNAGetSystemInfo	Get Host Integration Server 2009 system information.

Note
Standard calling conventions [WINAPI] are used for all entry points including those provided by the IHV SNALink.

The format of buffer headers and elements is described in Messages. The formats of individual messages contained in buffers are defined in SNADIS Message Formats.

Sample Code for SNALinkDispatchProc

This section contains outline source code for the link dispatcher function SNALinkDispatchProc.

```
/*********************************************************************/
/* First, include the SNA service header files                       */
/*********************************************************************/
#include <sna_dlc.h>
#include <sna_cnst.h>
#include <trace.h>

/*********************************************************************/
/* The link dispatcher routine - SNALinkDispatchProc                 */
/*********************************************************************/
VOID SNALinkDispatchProc (msgptr, function, locality)
PTRBFHDR msgptr;
INTEGER  function;
INTEGER  locality;
{
  INTEGER     discard_buff;
  COM_ENTRY("Ldisp");
  if (msgptr != NULL)
  {
    TRACE4()"received message from local node"));
    discard_buff = FALSE;
    switch (msgptr->msgtype)
    {
      case OPENMSG:
             /* process the OPEN message */
             break;
      case CLOSEMSG:
             /* process the CLOSE message */
             break;
      case DLCDATA:
             /* Data to be sent on link */
             break;
      case DLCSTAT:
             /* Switch on the subtype of the message */
             switch (msgptr->dshdr.dstype)
             {
               case STRESRCE :
                      /* call flow control processor */
                      break;
               case DLCSDXID:
                      /* call XID processor */
                      break;
               default:
                      discard_buff = TRUE;
                      break;
             }
             break;
      default:
             discard_buff = TRUE;
             break;
    }
    if (discard_buff)
    {
      /* message has not been processed, so simply discard */
      SNAReleaseBuffer(msgptr);
      msgptr = NULL;
    }
  }
  else if (function == SBLOST)
  {
    /* Lost contact with local node 'locality'  */
    /* Terminate all connections on this node (matching destl-value) */
```

```
    }
    else if (function == SBTICK)
    {
      /* 5 second timer tick */
    }
    COM_EXIT;
  }
```

SNALink Configuration Information

The configuration information for all SNALinks on a computer is stored hierarchically, referenced by the SNALink name.

The entry for each SNALink must include certain fields that are required by the Host Integration Server 2009 system. These are listed in the following table.

Required field	Description
TYPE	The type of the SNALink. Acceptable values for TYPE are: SDLC, X25, TOKENRING, TCPIP, FRAMERELAY, CHANNEL, ISDN, ETHERNET.
LINKMODULE	The name of the IHV DLL that provides the protocol code.

The remainder of the configuration information consists of entries of the form PARAMETER = VALUE. Parameters can be set to either an integer or a string.

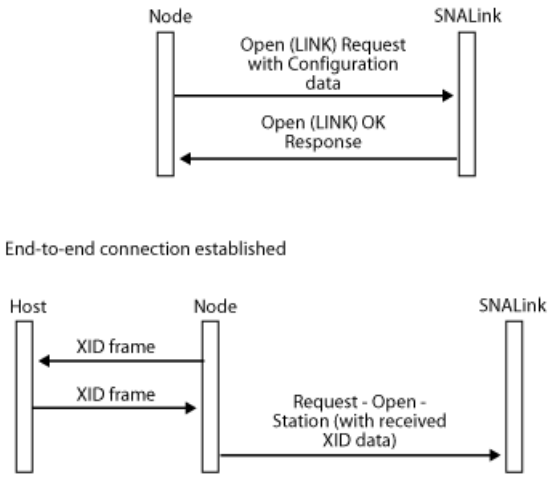
Examples of possible parameters that may be required by an SNALink are as follows:

- PortNumber = 3
- LineType = SWITCHED
- L3PacketSize = 128
- T1Timeout = 30

Note that to support more than one port on a multiport adapter, you must define multiple SNALinks. It is not possible to configure a single SNALink to support more than one physical link.

The following figure shows a sample configuration for a computer with two SNALinks—SDLC1 and X25HOST.

Sample configuration for a computer with two SNALinks



The configuration information is accessed using API calls that Host Integration Server provides.

The IHV Setup utility must write the configuration information for each SNALink supported. See Setup Information for information about how this should be performed.

In This Section

Accessing Configuration Information

Accessing Configuration Information

The following table lists the calls the SNALink uses to obtain its configuration information.

Call	Description
SNAGetConfigValue	Returns the value of a named configuration parameter.
SNAGetSystemInfo	Returns general information on the version of SNA server currently running, such as the release level, and the network operating system.

If the return code from **SNAGetConfigValue** indicates that the specified configuration parameter is not available, or if the information returned is invalid, it is the SNALink's responsibility to decide what action to take. If appropriate, an error message could be logged.

It is strongly recommended that the SNALink read all required configuration parameters at initialization time (when SNALinkInitialize is called by the Base). This safeguards against the configuration information changing while the link service is running.

Note
Standard calling conventions (WINAPI) are used for all entry points, including those provided by the IHV SNALink.

Data Link Control Interface

The data link control (DLC) interface defines the interface between the local 2.1 node and an SNALink. The DLC interface is defined in terms of the messages that are sent across the interface. Note that this is logically distinct from the definition of the Base/Dynamic Access Module (DMOD) interface, which defines the API used to send messages between two components in Host Integration Server 2009 (for example, between the local node and an SNALink).

DLC messages are exchanged between the local node and an SNALink across LPI connections. For details, see Structure of SNALink Components.

The local node uses the DLC interface to:

- Activate DLC connections.
- Exchange format 0 or format 3 XIDs for station activation.
- Exchange DLC information frames.
- Handle DLC error notification.

In This Section

Supported Configurations

The 2.1 node supports the full range of station roles:

- Primary data link control (DLC) stations
- Secondary DLC stations
- DLC station role negotiation

For Synchronous Data Link Control (SDLC) connections, the node allows:

- Leased lines configured as:
    - Secondary point-to-point
    - Primary point-to-point or multipoint
    - Negotiable point-to-point
- Switched lines (point-to-point only) with:
    - Remote physical unit (PU) identification through XID exchange
    - Auto dial (with suitable hardware support)
    - Incoming call support

For X.25 and 802.2, the node also supports:

- Multiple connections over one physical link
- Incoming calls with validation of caller's address

In addition, for X.25, the node supports permanent virtual circuits (PVCs) and switched virtual circuits (SVCs).

Opening a Connection

The 2.1 node is capable of supporting multiple connections through one or more SNALinks. For each connection, the node opens two Locality Partner Index (LPI) connections to the SNALink:

- LINK LPI connection to handle activation and deactivation of the connection.
- STATION LPI connection to transfer data to and from the remote station.

The one exception to this rule is the case of primary multipoint connections where there is a single LINK LPI connection and multiple STATION LPI connections. This special case is described in SDLC Multipoint Connections.

The following messages flow over the data link control (DLC) interface and are used to activate a connection to a remote station.

Message	Description
Open(LINK) Request	• Flows from node to DLC over LINK connection. • Opens the LINK LPI connection between the node and the SNALink. • Provides configuration data for the SNALink. • Provides link connection data such as Token Ring address for the remote station.
Open(LINK) Response	• Flows from DLC to node over LINK connection. • Reports whether the SNALink has accepted the **Open(LINK) Request**. • Returns certain link-specific configuration parameters to the local node. • Can be an OK Response or an Error Response.
Request-Open-Station	• Flows from DLC to node over LINK connection. • Passes an XID received from the SNALink up to the node. • Indicates that the SNALink has received a mode setting command, such as SNRM over S DLC, or SABME over 802.2.
Send-XID	• Flows from node to DLC over LINK connection. • Passes an XID from the node to the SNALink to be sent out over the link to the remote s tation.
Open(STATION) Request	• Flows from node to DLC over STATION connection. • Opens the STATION LPI connection between the node and the SNALink. • Specifies certain station-specific configuration information.

Open(STATION) OK Response –or– Open(STATION) Error Response	• Flows from DLC to node over STATION connection. • Acknowledges **Open(STATION) Request**.
Station-Contacted	• Flows from DLC to node over STATION connection. • Informs the local node that the link is now ready for data transfer.

The use of these messages in activating various types of connections is described throughout the rest of this section. For information about the format of the messages, see SNADIS Message Formats.

The name of the Request-Open-Station message is historical. In earlier versions of the DLC interface, the higher-level software (such as the local node) always sent an **Open(STATION) Request** in response to this message—hence the name Request-Open-Station. However, now that multiple XIDs can be exchanged before the link is activated, the **Open(STATION) Request** is only sent at the end of the XID exchange.

The Request-Open-Station message now has two distinct semantic meanings:

- A Receive-XID
- A Receive-Set-Mode

In This Section

- Opening the LINK LPI Connection
- Activating a Host Connection
- Activating a Peer Connection
- Opening the STATION LPI Connection
- Node Identification and Signaling Information
- XID Retries
- Multiple Connections

Opening the LINLPI Connection

The local node attempts to activate a connection:

- During system initialization if the connection is configured as initially active.
- If the system administrator manually activates the connection.
- If a 3270 or logical unit (LU) 6.2 session is requested when there is no active connection to support the LU, and the connection is configured to be activated on demand.

For each connection to be activated, the local node opens a LINK Locality Partner Index (LPI) connection by sending an Open(LINK) Request to the SNALink. This message contains configuration data such as:

- Synchronous Data Link Control (SDLC) line type: leased, switched.
- Operational role: primary, secondary, or negotiable.
- Time-out values.
- Retry limit values.
- Line speed.
- Half-duplex/full-duplex.
- 802.2 remote service access point (SAP) address.
- X.25 facility data.

For incoming calls, the local node primes the SNALink by opening the LINK LPI connection, but does not perform an activation sequence at this stage. For details, see Incoming Call Support.

The local node also inserts the first XID frame to be used (where applicable) and link connection data to be used on a switched link. The link connection data can be:

- A telephone number for a manual or autodial modem (in this case, the SNALink software could dial the required number or send a message to the operator specifying the number to be dialed).
- The media access control (MAC) address of the remote station.
- The X.25 remote data terminal equipment (DTE) address.

Finally, the **Open(LINK)** contains various time-out values that should be used by the SNALink when setting up protocol timers. For more information, see Open(LINK) Request and Open(LINK) Response.

The SNALink should return an **Open(LINK) OK Response** if:

- Its internal control blocks are successfully initialized.
- Its device driver has installed correctly.
- Its link hardware is successfully initialized.

The SNALink should not wait for an end-to-end connection before giving an **Open(LINK) Response**.

If the SNALink has successfully initialized, it should return an **Open(LINK) OK Response** immediately, supplying the required link-specific configuration information to the node (such as the maximum BTU size it can support). The local node uses this information during XID negotiation with the remote station.

If the SNALink cannot initialize successfully, it responds with an **Open(LINK) Error Response** containing an error code. The error is logged and the local node notifies the system operator before retrying the link activation.

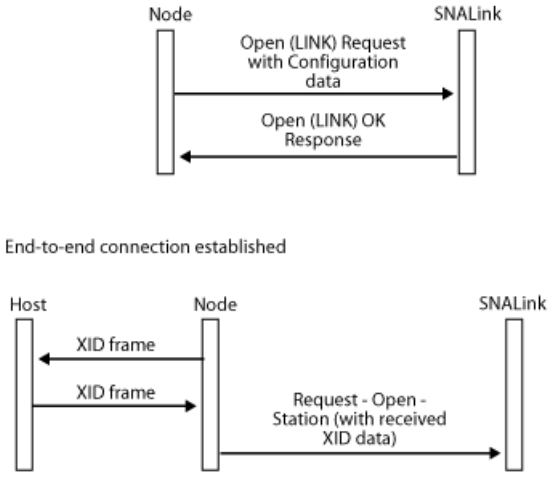
If an XID is supplied on the **Open(LINK) Request**, this should be sent when the end-to-end connection is established for a primary or negotiable link. Note that the supplied XID can be a NULL XID, which has a zero length. Hence, it is important that the XID field is examined rather than checking for a zero XID length. An XID will be supplied for all connections except primary leased connections (which could be multipoint).

When an SNALink receives an XID frame from the remote station, it is passed to the local node in a Request-Open-Station message on the LINK LPI connection.

If the SNALink fails to receive any frames from the remote station, it generates an Outage message as described in Closing a Connection.

The following figure shows the **Open(LINK) Request** and **Open(LINK) Response**, followed by an exchange of XIDs.

Open(LINK) Request and Open(LINK) Response, followed by an exchange of XIDs



Activating a Host Connection

A host connection can be activated over a leased synchronous data link control (SDLC) line, X.25, 802.2, or a switched SDLC line. This section describes the activation procedures for each type of connection.

In This Section

Leased SDLC Line (No XIDs Exchanged), Channel Adapter

For a connection to a host computer using a leased synchronous data link control (SDLC) line, the SNALink receives a set normal response mode (SNRM) when the end-to-end connection is established. The SNALink responds with an unnumbered acknowledgement (UA) and informs the local node that the connection is ready for data transfer. This is done with the Request-Open-Station message with the Rcv-Set-Mode flag set.

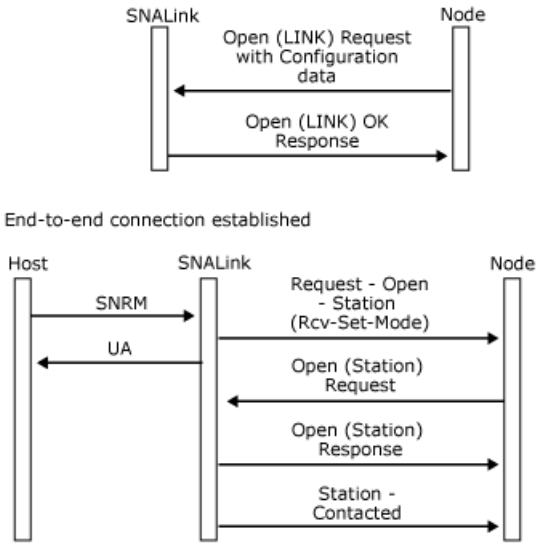
The node then opens the STATION Locality Partner Index (LPI) connection with the Open(STATION) message. If the SNALink has an available control block, it responds with an **Open(STATION) OK Response**. This is followed by a Station-Contacted message.

A channel connection is treated the same way as a leased secondary SDLC connection. Each channel connection is associated with a channel subaddress in the range 0x00 to 0xFF. The SNA service node sends the channel link service an Open(LINK) Request for each configured channel connection when the connection is activated. The link service should expect to receive multiple Open(LINK) Requests, one for each supported subchannel address.

Note that the Request-Open-Station message flows on the LINK LPI connection, whereas the Station-Contacted message flows on the STATION LPI connection.

The message flow for a leased line is shown in the following figure.

Message flow for a leased line



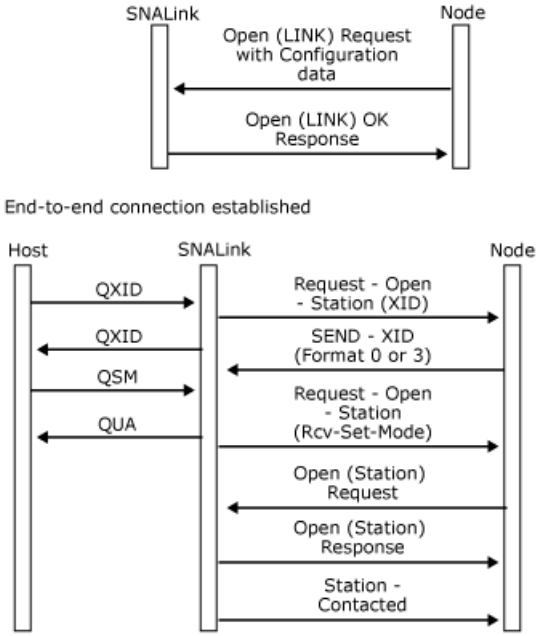
X.25, 802.2, or Switched SDLC Line (XIDs Exchanged)

The initial sequence for a host connection over X.25, 802.2, or a switched synchronous data link control (SDLC) line is similar to the sequence over a leased line. The only difference is that exchange identifications (XIDs) are exchanged before the host (or front-end processor) sends a mode-setting command such as set mode (QSM) on an X.25 qualified logical link controlQLLC) link.

When the SNALink receives an XID, it is passed to the local node on a Request-Open-Station message (on the LINK Locality Partner Index (LPI) connection). The local node then passes the data link control (DLC) a Send-XID message (also on the LINK LPI connection) containing the XID to be sent to the host. The host typically checks the node identifier in this XID and, if it is valid, sends the mode-setting command.

The sequence is shown in the following figure.

Sequence for passing an XID



For switched connections using SDLC modems, the Open(LINK) Request contains dial digits for manual or auto-dial modems. It is the responsibility of the SNALink to handle the management of these devices. For X.25 and 802.2 connections, the **Open(LINK) Request** contains the address of the remote station.

The SNALink should initiate the dialing procedure when it receives the **Open(LINK) Request**.

Activating a Peer Connection

For a peer connection, there is an activation sequence that involves the two stations exchanging format 3 exchange identification (XID) frames. As part of this sequence, the two stations agree on their link roles. They also exchange information relating to the link level connection, such as the maximum frame size supported.

The node passes XIDs to the SNALink over the LINK LPI connection using the Send-XID message. The SNALink returns received XIDs to the local node over the LINK LPI connection using the Request-Open-Station message.

Fixed Link Roles and Negotiable Link Roles show examples of XID exchange for the two cases:

- The link roles are explicitly configured for the two stations.
- The link roles of both stations are negotiable.

Points to note are:

- The Open(LINK) Request is supplied with a NULL XID that is sent when the end-to-end connection is established.
- After the first NULL XID, all XIDs are format 3.
- If both stations are set up to be negotiable, the station with the higher node identifier becomes the primary.
- If both stations are negotiable and have the same node identifier, both stations produce randomized node identifiers that are compared as before.

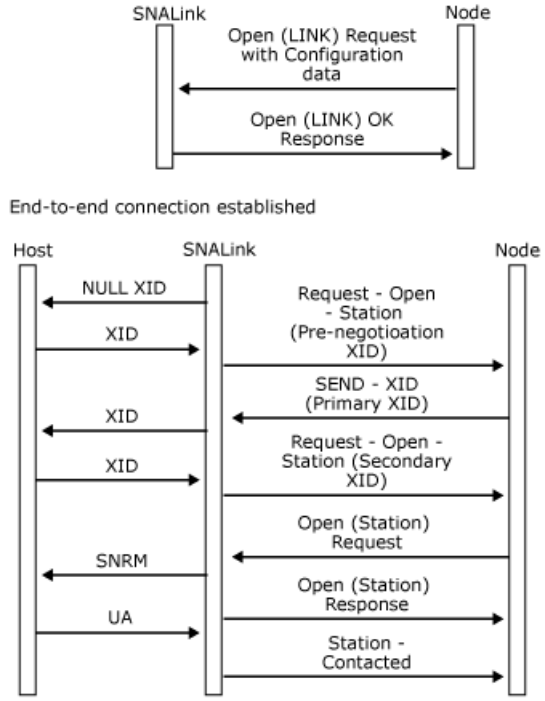
In This Section

- Fixed Link Roles
- Negotiable Link Roles

Fixed Link Roles

The following figure shows the sequence of messages for a peer connection where the local end is configured as the primary station and the remote end is configured as the secondary.

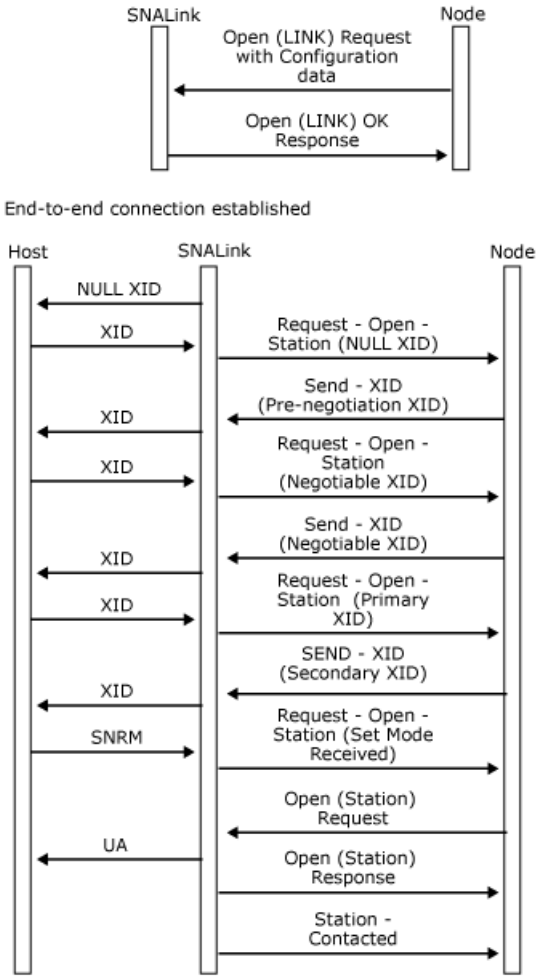
Sequence of messages from a peer connection where the local end is configured as the primary station



Negotiable Link Roles

The following figure shows the sequence of messages for a peer connection where both the local and remote ends are configured as negotiable. Because the remote node identifier is larger (numerically) than the local node identifier, the remote station will become primary.

Sequence of messages for a peer connection where both ends are configured as negotiable



local node identifier	= 0x05D11111
remote node identifier	= 0x05D22222

The following summaries the rules that the SNALink must follow when supporting exchange identification (XID) exchange, and in particular XID role negotiation:

- If an XID is supplied in the Open(LINK) Request, it must be transmitted as soon as the end-to-end connection is established for primary or negotiable links.
- All XIDs received from the remote station must be passed to the local node in a Request-Open-Station message.
- An XID received from the local node in a Send-XID message must be transmitted immediately.
- XID transmissions must be retried until an XID is received from the remote station. For half-duplex links, the retry time-out should be randomized to prevent repeated XID clashes.
- When a mode-setting command, such as set normal response mode (SNRM), QSM, or set asynchronous balanced mode extended (SABME), is received before the station has been opened, a Request-Open-Station must be sent to the local node with the Rcv-Set-Mode flag on.
- When the local node sends an Open(STATION) message, the link should examine it to determine its link role (that is, primary or secondary).

- A secondary station should send a Station-Contacted message after receiving and responding to the **Open(STATION)** message.

- For a primary station, the mode-setting command should be sent when the **Open(STATION)** message is received. The Station-Contacted message should be sent to the local node when this command has been acknowledged by the secondary station (for instance, an unnumbered acknowledgement (UA) received on an Synchronous Data Link Control (SDLC) link).

If the local node detects an error during role negotiation, such as both physical units (Pus) configured as primary, it sends out an XID containing an error vector. The vector is appended to the end of the normal XID data. The vector number specified is 0x22, and the vector data specifies that the data link control (DLC) role field is in error.

After sending the error XID, the local node sends a **Close(LINK)** message to terminate the connection (see Closing a Connection).

The following table is a matrix of the possible combinations of station link roles and shows the eventual role of the local station.

	Local Station			
Remote Station		**Primary**	**Secondary**	**Negotiable**
	Primary	Fail	Secondary	Secondary
	Secondary	Primary	Fail	Primary
	Negotiable	Primary	Secondary	Either*

*The station with the higher node identifier becomes the primary.

Opening the STATION LPI Connection

After receiving a Request-Open-Station (RQOS) message, the local node sends an Open(STATION) message to the SNALink when:

- The station is configured as secondary (or has negotiated to secondary), and the RQOS message has the Rcv-Set-Mode flag on, indicating that the SNALink has received a mode-setting command such as set normal response mode (SNRM).

- The station is configured as primary (or has negotiated to primary), the RQOS message contains a secondary exchange identification (XID), and the local station has sent at least one negotiation-proceeding XID.

The Open(STATION) Request contains the link index that was on the Open(LINK) Request. This field is used to correlate the LINK and STATION LPI connections for SNALinks that support multiple connections, such as X.25, 802.2, and channel.

This **Open(STATION) Request** contains configuration data for the link station, such as the Synchronous Data Link Control (SDLC) address of the adjacent link station (0x00 for secondary stations, 0x01 to 0xFE for primary stations).

The SNALink should use this address field for determining the local station's role. If it is set to 0x00, the local station is a secondary station. Otherwise, the local station is the primary station. This field has this meaning even when the address is not used because of the link type (such as 802.2).

See Open(STATION) Request for the format of this message.

If the station cannot be initialized (perhaps due to a lack of resources), the SNALink responds with an Open(STATION) Error Response containing the appropriate error code.

Node Identification and Signaling Information

For information about the role an SNALink plays in node identification, see Incoming Call Support.

When exchange identifications (XIDs) are exchanged, there are two mechanisms for identifying the remote station:

- The node identifier on received XIDs.
- The data link control (DLC) defined address; for example, the media access control (MAC) address. This is known as signaling information.

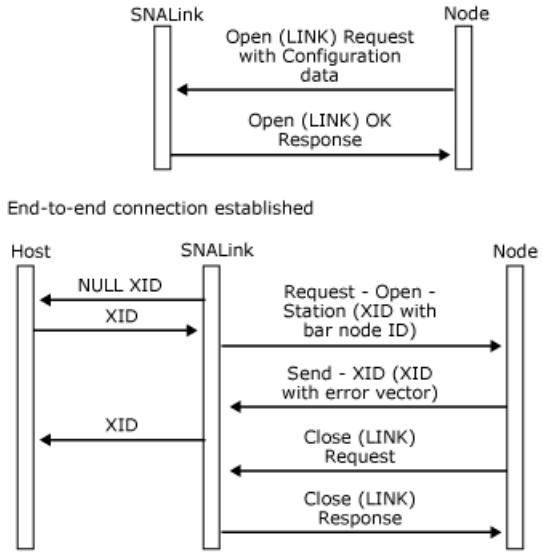
The presence of signaling information depends on the type of the SNALink. For instance, there is no signaling information over a Synchronous Data Link Control (SDLC) link, but there is signaling information over X.25 and 802.2. The SNALink passes signaling information to the local node on the Request-Open-Station message by appending it after the XID.

If signaling information is present, the local node checks it against the configured value in the dial-digits record of the Host Integration Server 2009 configuration file. For incoming call support, this allows the local node to determine the connection that is to be activated. For a fuller description of incoming calls, see Incoming Call Support.

If there is no signaling information, the local node compares the control point (CP) name on the received XID with the remote control point name in the configuration.

If the remote station is identified correctly, XID exchange proceeds as detailed in Activating a Peer Connection. However, if there is a mismatch, the local node sends an XID (in the Send-XID message) containing an error vector followed by a Close(LINK) Request, as shown in the following figure.

Local node sending an XID containing an error vector, followed by a Close(LINK) Request



XID Retries

When the local node specifies that the SNALink is to send an exchange identification (XID), either by supplying it on the Open(LINK) Request or by sending it on a Send-XID message, it is the responsibility of the SNALink to perform any retries.

XIDs need to be retried because:

- The remote station has not been started yet.
- Frames may be lost on the line due to noise.

Synchronous Data Link Control (SDLC) SNALinks should implement a contact time-out and a retry limit—values for these are provided on the Open(LINK) message. The time-out specifies how often the XID should be retried, and the retry limit specifies how many XIDs should be sent before abandoning the connection activation and sending an Outage message to the local node. The SNALink should stop retrying the XID when one of the following occurs:

- It receives an XID from the remote station.
- An Open(STATION) message is received from the node.
- A mode-setting command is received on the link.

Multiple Connections

For 802.2 and X.25 links, multiple connections can use the same physical link supported by a single instance of the SNALink software.

For each connection to a remote station, there is a LINK LPI connection and a STATION LPI connection (this is different from Synchronous Data Link Control (SDLC) multipoint as described in SDLC Multipoint Connections). Hence, there can be multiple pairs of LPI connections between a local node and an SNALink. For each connection, the local node issues an Open(LINK) Request and, after exchange identification (XID) exchange, an Open(STATION) Request.

The local node is configured with a maximum number of connections that can be active at any one time. In addition, each potential connection is configured with the address of the remote station. This information is required when activating a connection, and is included in the **Open(LINK) Request** for an outgoing connection.

DLC Information Transfer

When the local node has opened the LINK and STATION LPI connections and received a Station-Contacted message from the SNALink for a remote station, it can exchange data using the data link control (DLC) interface with the physical unit (PU) and associated logical units (LUs) at the remote station.

Data messages are contained within buffers. The transmission header (TH) of the SNA path information unit is contained within the buffer header. The request/response header (RH), if present, and request/response unit (RU) are contained within one or more buffer elements. The TH is contained in the buffer header for historical reasons. Typically, this will be copied by the SNALink into the element before **startd**, to keep the entire frame in contiguous memory locations. For a description of the DLC-Data message format, see DLC-Data.

Note that all data messages to a specified remote station flow on the associated DLC STATION LPI connection, and not on the controlling DLC LINK LPI connection.

In This Section

- DLC Flow Control

DLC Flow Control

The flow of data messages at the data link control (DLC) interface for each link station is flow controlled. For each direction of flow, there is an initial credit of messages that can be transmitted.

Flow control is maintained by initial specification on the Open(STATION) Request and Open(STATION) OK Response messages, and by the sending of DLC Status-Resource messages to give more credit periodically.

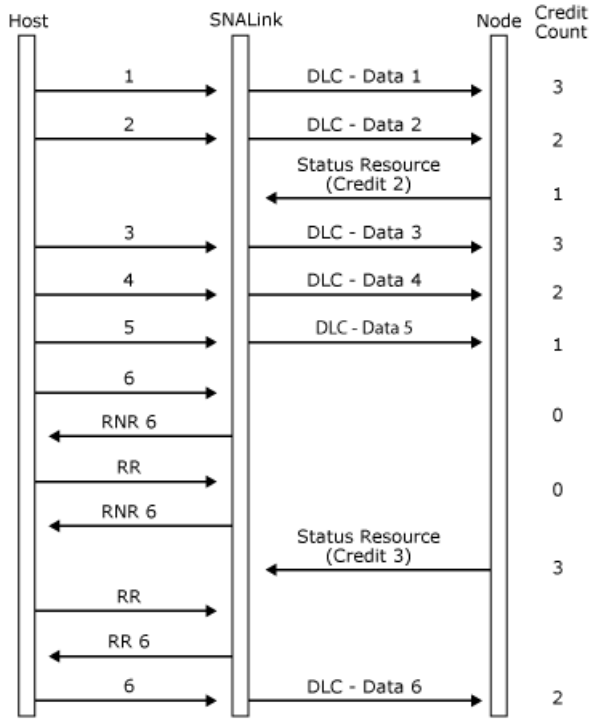
The sender maintains a count of credit, starting at the initial value set on the **Open(STATION)**, which is decremented for each DLC-Data message sent. When the credit count reaches zero, no more DLC-Data messages can be sent until more credit is received.

For flow in a given direction, the amount of credit is specified by the recipient of the data, because the recipient has to do any queuing. The initial credit values are passed on the Open(STATION) message (on the request for flow from the SNALink to the local node and on the response for flow from the local node to the SNALink).

The initial credit for the flow from the SNALink to the local node is determined by the node. The initial credit for the flow from the local node to the SNALink is set by the SNALink software—a suggested value is 16.

If the SNALink runs out of credit to send to the local node, it should either queue the data or discard it and send no acknowledgment. It should also start sending receive not ready (RNR), for example, when polled by a primary station. An example message flow with an Synchronous Data Link Control (SDLC) SNALink is shown in the following figure with an initial credit of 3. When the SNALink runs out of credit, it does not acknowledge any further frames and starts sending RNR.

Message flow with an SDLC SNALink with an initial credit of 3



For flow control from the local node to the SNALink, when the node runs out of credit, it queues the data and applies back pressure on sessions using that station. There is thus end-to-end flow control in this direction, independent of any SNA pacing that may be in force.

The SNALink gives credit to the local node for the messages that have been transmitted, not for the messages for which acknowledgments have been sent. The amount of data queuing in the SNALink is kept down most of the time because frames will usually be acknowledged.

Flow control for the flow of data from the local node to the SNALink is shown in the following figure, where the initial credit is assumed to be 2.

Closing a Connection

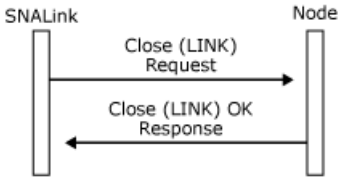
The local node closes a connection to a remote station:

- If the system administrator manually deactivates the connection.
- If the connection is configured as on-demand and no 3270 or LU 6.2 sessions are active.
- If an outage has been reported by the SNALink.

The local node closes a connection by sending a Close(LINK) message. The SNALink then takes some action, such as lowering Data Terminal Ready (DTR) on an Synchronous Data Link Control (SDLC) link or issuing a DLC_CLOSE_STATION on a 802.2 connection. It then replies with a **Close(LINK) OK Response** as shown in the following figure.

The case of multipoint connections is slightly different and is considered in SDLC Multipoint Connections. The following topics discuss point-to-point connections.

Local node receiving a Close(LINK) and replying with a Close(LINK) OK Response



In This Section

- Outages
- Connection Retries

Outages

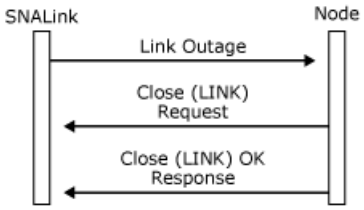
If the SNALink detects a link or station failure, it reports the failure by sending an Outage message to the node on either the LINK or STATION LPI connection depending on whether it is a link or station outage. Generally, a station outage indicates a problem at the remote station, and a link outage indicates a local or line problem.

When the local node receives an Outage message, it:

- Logs an error containing the outage code.
- Cleans up each session using the connection and informs applications of the failure (for instance, with a Comm Check code on a 3270 emulator).
- Sends a Close(LINK) Request to the SNALink.

On receipt of the **Close(LINK) Request**, the SNALink should clear up its internal resources for the connection and send back a Close(LINK) Response.

Local node receiving an Outage message and sending a Close(LINK) Request and a Close(LINK) response



There is a special case when the node loses contact with the SNALink software. In this case, the node is notified of this event (a lost locality) and performs outage processing apart from sending messages to the SNALink.

The outage codes are not distinguished by the node, but they are logged. For the sake of consistency across SNALink implementations, the values listed in the following topics should be used.

In This Section

- SDLC Outage Codes
- 802.2 Outage Codes
- X.25 Outage Codes

SDLC Outage Codes

The following table describes Synchronous Data Link Control (SDLC) outage codes.

Outage code	Description
0x0D	Internally generated for SNALink lost locality.
0x11	Data set ready (DSR) failure.
0x12	Clear to send (CTS) failure.
0x14	Data carrier detect (DCD) failure.
0x24	Nonproductive receive retry limit exceeded.
0x25	Idle time-out retry limit exceeded.
0x29	Connection problem. subqual = 0x00I-frame retransmission subqual nonzeroXID retransmission
0x2D	Abnormal modem response.
0x2E	Write time-out retry exceeded.
0xA0	Exchange identification (XID) exchange failed on multidrop line. Subqual is address of secondary station.
0x15	Discontact (DISC) received.
0x23	Receive buffer overrun.
0x2C	Invalid command received. subqual = 0x03invalid N(R) subqual = 0x04invalid or unsupported command/response s ubqual = 0x05excess I-field
0x80	Disconnect mode (DM) received in information transfer state.
0x81	Discontact retry limit exceeded.
0x82	Contact retry limit exceeded.
0x83	Poll retry limit exceeded.
0x84	No response retry limit exceeded.
0x85	Remote busy retry limit exceeded.
0x86	Frame reject (FRMR) received. subqual = 0x00no reason given subqual = 0x03invalid N(R) subqual = 0x04invalid or unsupported command/response subqual = 0x05excess I-field
0x87	Invalid frame received. subqual = 0x03invalid N(R) invalid or unsupported command/response subqual = 0x05exces s I-field
0x88	Request Initialization Mode (RIM) received.
0x89	Request Disconnect (RD) received.

802.2 Outage Codes

The following table describes 802.2 outage codes.

Outage code	Description
0x29	Remote node not active.
0xAB	The set asynchronous balanced mode extended (SABME) received while connection active.
0xAC	Frame reject (FRMR) sent.
0xAD	FRMR received.
0xAE	Discontact (DISC)/disconnect mode (DM) received.
0xAF	Link lost.

X.25 Outage Codes

The following table describes X.25 outage codes.

Outage code	Description
0x37	Loss of a virtual circuit.
0x60	Switched virtual circuit (SVC) cleared down by remote station or network.
0x61	Permanent virtual circuit (PVC) has been reset by remote station or network.
0x62	Attempt to connect to remote station through SVC failed.

Connection Retries

If an initially active or operator-started connection is closed because of an outage, the node periodically tries to reopen the connection. This can be stopped by manually deactivating the connection. This retry mechanism is also used when the node attempts to open a connection but the SNALink software has not yet been started. On-demand connections are not retried automatically by the node, but will be retried if the user attempts to reactivate a session using the connection.

Note that this connection retry timer is totally separate from the timers specified on the Open(LINK) Request.

Incoming Call Support

The local node allows an SNALink to be set up to support incoming calls. In this mode of operation, the node primes the SNALink by sending an Open(LINK) Request, but the SNALink does not attempt to activate the link until it receives an exchange identification (XID) from a remote station.

The SNALink recognizes an **Open(LINK) Request** for an incoming call by the absence of a connection name in the destination name field (this field is filled with ASCII blanks).

For incoming calls, **Open(LINK) Request** requires an immediate response from the SNALink, just as in the case of an **Open(LINK) Request** for an outgoing call.

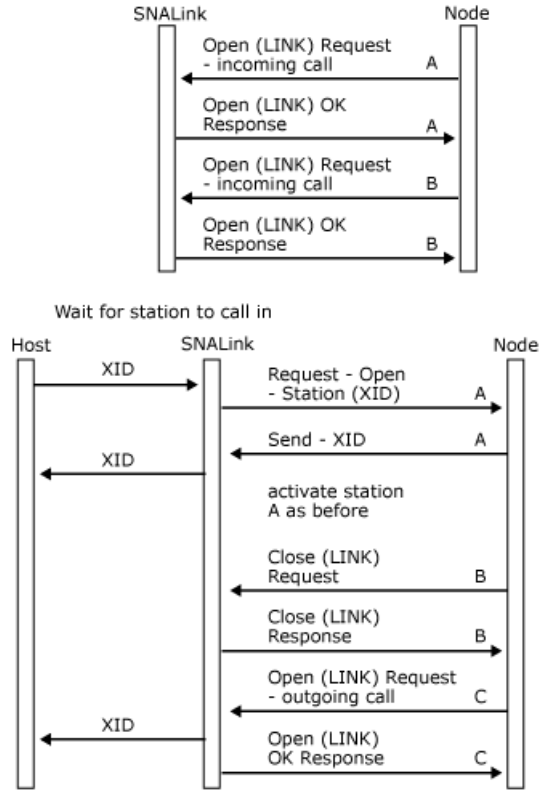
For a Synchronous Data Link Control (SDLC) SNALink, there can be only one **Open(LINK)** outstanding. However, 802.2 and X.25 allow the possibility of multiple connections being handled through a single SNALink. In these cases, for each configured connection that is primed to await incoming calls, the local node will send an **Open(LINK)** with a blank connection name to the SNALink.

When an incoming call is received by the SNALink, the received XID should be passed to the local node on any LPI connection that is primed for incoming calls. The LPI connection selected must then be used for all future messages relating to that incoming call.

It is not necessary for the SNALink to perform validation of incoming calls—this will be performed by the local node. However, if required, the SNALink can choose to validate calls before passing them to the node. A common example of this is to ensure that only X.25 calls with a specific local address are passed through to the local node.

The following figure shows incoming call support with an SNALink that supports two connections. A remote station calls in and uses connection A. The node sets up connection B for incoming calls but then needs to open connection C. Because the SNALink only supports two connections, connection B is closed.

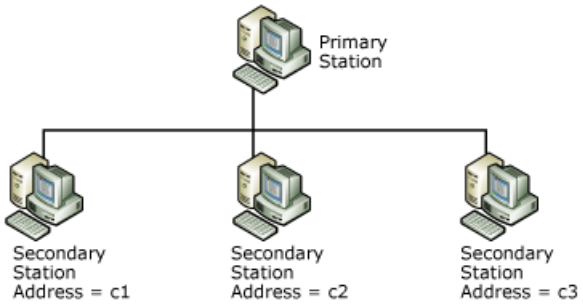
Call support with an SNALink that supports two connections



SDLC Multipoint Connections

The node can support primary multipoint (also known as multi-dropped) links, at both the primary and secondary end. Multipoint is a special configuration for a synchronous data link control (SDLC) leased link where a single SDLC line at the primary station can be used to communicate with up to 16 secondary stations. Special hardware is required to fan out the primary line so that there is a physical connection to each secondary station. The following figure shows an example with three secondary stations.

Primary station with three secondary stations



The SDLC address of the secondary station is used to route frames to and from the individual secondary stations. Hence, the SNALink at the secondary station needs to check the SDLC address as the primary sends all frames to all secondary stations. The SNALink at the secondary station should only accept frames with its SDLC address—the other frames should be ignored.

From the viewpoint of the node at a secondary station, the message flow at the data link control (DLC) interface is as for a point-to-point connection (described in Opening a Connection). The node need have no knowledge that this is a multipoint connection.

The primary end has to handle the special processing required for multipoint connections. The remainder of this section concentrates on the primary station.

At the primary end, there are the following LPI connections:

- One LINK LPI connection.
- A STATION LPI connection for each active secondary station.

Because the exchange identification (XID) exchange is carried out using the single LINK LPI connection, the Request-Open-Station and Send-XID messages always specify the station address of the secondary station that the XID has arrived from or is going to. Note that no XID is supplied on the Open(LINK) Request.

Each STATION LPI connection has different values of I, the index. After the station has been activated, data messages flow on the STATION LPI connection rather than the LINK LPI connection.

If the XID exchange fails because the secondary is failing to reply to the XID, the SNALink generates a special variant of link Outage message. Ideally, the SNALink would give a station Outage message, but this is not possible because the STATION LPI connection is not yet open. Instead, the SNALink generates a link Outage message with code 0xA0 and a subqualifier that is the SDLC address of the station.

When the stations are activated on a multipoint link, the majority of messages flow across the STATION LPI connections. If a connection to a particular secondary station is to be closed (because the operator deactivates it, for instance), the node issues a Close(STATION) Request. The SNALink replies with a Close(STATION) Response to the node and sends a Discontact (DISC) frame to the secondary station.

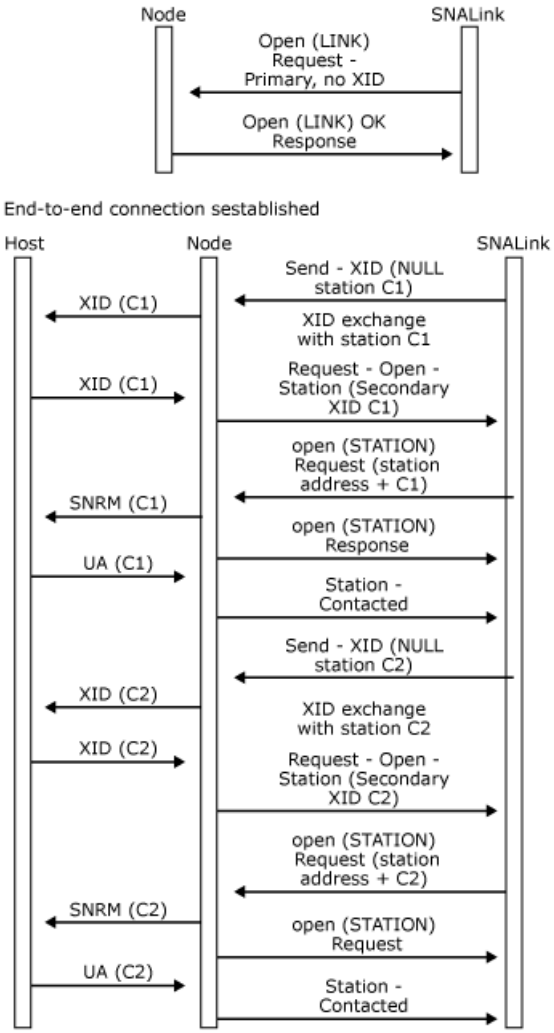
The SNALink can generate both station and link Outage messages. If the problem only affects a particular station, such as not responding to polls, the link generates a station Outage message and the node closes the station with a **Close(STATION) Request**. The SNALink responds with a **Close(STATION) Response**.

If the problem affects the link as a whole, such as the line being disconnected from the primary SDLC adapter, the SNALink generates a link Outage message and the node sends a Close(LINK) Request. The SNALink responds with a Close(LINK) Response.

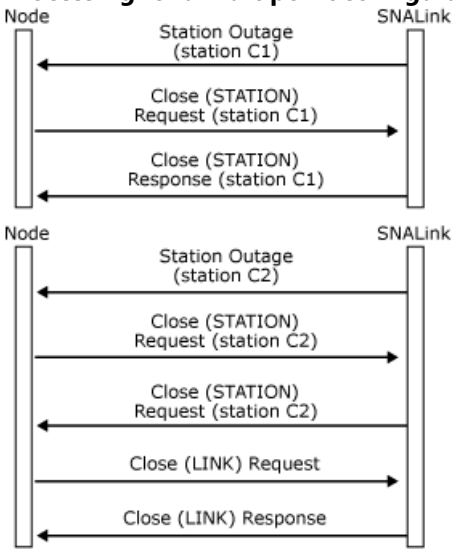
Whenever the node receives a **Close(STATION) Response**, it checks to see if any stations are still active on the multipoint link. If not, a **Close(LINK) Request** is sent. The SNALink responds with a **Close(LINK) Response**. The following figure shows the message flows for outage processing. It shows a multipoint connection with two secondary stations (the full XID exchange is

not shown).

Message flow for outage processing



Processing for a multipoint configuration with two secondary stations



Note that the station messages are labeled in the figure with station addresses. In fact, the node and SNALink use the LPI addresses to identify the two stations.

Setup Information

This section describes the integrated link service installation provided with Host Integration Server 2009.

In Host Integration Server, SNA Manager is used to install and configure link services. Host Integration Server uses the Microsoft System Installer (MSI) and MSI packages for the installation of the Host Integration Server software. Link services from independent hardware vendors (IHVs) are not included in the main Host Integration Server MSI packages. IHV link services are installed using a separate IHV-provided MSI package.

A sample IHV link service using the generic Synchronous Data Link Control (SDLC) link service that illustrates IHV link service installation is included in the Host Integration Server software development kit (SDK). The SDK samples are installed on your computer when the SDK option is selected during installation of Host Integration Server software. These sample files are also located on the Host Integration Server CD under the SDK\Samples\IHVLInks subdirectory. Host Integration Server does not support the earlier .inf-based link service setup procedure.

In This Section

Setup Registry Architecture

There are two main subtrees in the Microsoft Windows® 2000 registry where information is kept relevant to Host Integration Server 2009: the **SOFTWARE** tree and the **SYSTEM** tree. Both of these are subtrees of **HKEY_LOCAL_MACHINE**. The **SOFTWARE** tree contains generic information about independent hardware vendor (IHV) link services, and the **SYSTEM** tree contains information about the individual components of those services. While reading the following topics, it may be helpful to view examples of what is being discussed by inspecting the registry of an existing system with several of the built-in link services installed.

In This Section

Product Entries

All of the information relevant to the product as a whole resides in the registry under the key **SOFTWARE\Microsoft**. Each product or link support has an entry whose name consists of the product name and version separated by an underscore. This key contains most of the information about the product, such as the script name and option name that control it and the service name for that particular instance.

Each instance key must also have a NetRules key. This key contains all of the information for the Network Control Panel Applet bindings.

The Host Integration Server Setup writes the path of the root directory of the computer's Host Integration Server tree into the key:

SOFTWARE\Microsoft\SNA Server\CurrentVersion\Setup\RootDir

Service Entries

Each instance of a component appears to the system as a unique service. These services must be created using the Service Control Manager (SCM). The SCM creates a registry entry for each service under **SYSTEM\CurrentControlSet\Services**. This key contains all of the service-specific information.

The top-level service key contains information that the SCM uses to control the service. This includes the type of service that this key represents, how it should be started, what sort of error handling should be used, the path to the executable image, and so on. All information in this key should be handled by the SCM. Each service key also contains two subkeys—the Linkage key and the Parameters key.

The Linkage key is used by the Network Control Panel Applet to store binding information. The Parameters key contains information that is relevant to Host Integration Server 2009 Setup, such as the name of the DLL responsible for handling a link service. All information in this key should be handled by Host Integration Server 2009 Server Setup. The Parameters key contains another key, ExtraParameters, which is used for any IHV-specific information, including component-specific parameters and other information not required by the main SNA Server Setup program.

Integrated Link Service Setup on Host Integration Server

In Host Integration Server 2009, the SNA Manager supports installation and configuration of link services. Host Integration Server uses the Microsoft System Installer (MSI) and MSI packages for the installation of the Host Integration Server software. Link services from independent hardware vendors (IHVs) are not included in the main Host Integration Server MSI packages. IHV link services are installed using a separate IHV-provided MSI package. For an example of this process, install the DLC, 802.2, or IBM Synchronous Data Link Control (SDLC) link service in Host Integration Server.

IHV MSI Packages contain two types of features:

- Features that can be installed and used independently of Host Integration Server.
- Features that require Host Integration Server to function.

Features that can be installed and used independently of Host Integration Server include drivers, utilities, and applications that can run without Host Integration Server support. These features should be represented in the package as one or more features in the MSI Select Features dialog box. (For more information, see the Generic Link Service sample feature "Generic Link Service" from the Generic.msi Featuretable.) Generic.msi can be found in the Host Integration Server SDK on the CD and in the install directory at the following address: SDK\Samples\IHVLinks\Packages\Generic.msi.

Features that require Host Integration Server include drivers, utilities, and applications that require Host Integration Server to function. These features should be represented in the package as one or more features in the MSI Select Features dialog box. These features should be hidden if Host Integration Server is not installed on the computer. (For more information, see the Generic Link Service sample feature "Host Integration Server Support" from the Generic.msi feature table.)

Properties can be equated to a variable (either global or local) in a high-level programming language such as C or C++. Properties can be used as a placeholder for informational text, or as values used during an installation. (For more information, see the property SERVER_INSTALLED in the custom action source code GenSet.cpp, and the Condition table entry in the Generic.msi package.)

Custom Actions provide a method of extending the capabilities of MSI. Functions not supported in MSI, can be custom written, and invoked from within a sequence table or directly from a dialog control event. (For more information, see the Custom Actions SetHISPath and GetHISData in the GenSet.cpp source file.)

Launch Conditions provide a method of preventing an install from launching. The sample MSI package included with the Host Integration Server SDK does not use a launch condition, however, if your package requires Host Integration Server to be installed for your features to function, you should include a launch condition that fails the installation if Host Integration Server is not detected.

The Condition table provides a method of controlling the layout of the features listed in the select feature dialog box. The sample MSI package uses the Condition table to hide the "Host Integration Server Support" if Host Integration Server is not detected in the installation.

For Host Integration Server to control the installed state of IHV features that require Host Integration Server to be installed, the following registry keys must be included in the package for each separate feature which requires Host Integration Server to be installed.

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\IHVSupport\<ihv key>
<feature table entry 1> : REG_SZ : <product code 1>
<feature table entry 2> : REG_SZ : <product code 2>
.
.
.
<feature table entry n> : REG_SZ : <product code n>
```

Where:

<feature table entry x> specifies an entry in the feature table (not title).

<product code x> specifies the package product code.

Note that feature table entries must be unique. Product codes may or may not be unique depending on the number of packages provided by an IHV. One package may have several Host Integration Server dependent features and therefore should list each feature separately.

These registry keys should be installed by the feature rather than globally by the package.

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\LinkServicesInstalled
<Link Service Name> : REG_SZ : <Link Service Configuration Dll name>
```

Target paths specify a directory where files will be installed. An MSI package will contain one or more target paths.

The sample package contains two features:

- Generic Link Service
- Host Integration Server Support

The Generic Link Service is not dependent on Host Integration Server. This feature installs the following:

- gencfg.exe into the <Generic Link Service> directory.
- generic.sys driver into the %windir%\system32\drivers directory.
- generic.inf into the %windir%\inf directory

Host Integration Server Support is dependent on Host Integration Server. This feature installs the following:

- gendtct.dll into the HIS\system directory.
- generic.dll into the HIS\system\hwsetup\i386 directory.

This feature contains the following entry in the condition table to hide the feature if Host Integration Server is not detected

```
HIS_RELATED_FEATURE  0  SERVER_INSTALLED="NO"
```

See dialog snapshots later in this topic for layout of features with and without Host Integration Server installed:

Adds:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\LinkServicesInstalled
Generic Link Service : REG_SZ : GENERIC.DLL

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SnaBase\IHVSupport\GenericLinkService
HIS_RELATED_FEATURE : REG_SZ : {FDF11E0E-3BFF-4B0F-89BD-E4E1FB979E4D}
```

The sample package uses one custom action DLL with two entry points:

```
SetHISPath
GetHISData
```

The **SetHISPath** entry sets the target path to the Host Integration Server installation directory.

The **GetHISData** entry sets the MSI property SERVER_INSTALLED to "YES" if Host Integration Server is installed and sets the MSI property SERVER_INSTALLED to "NO" if Host Integration Server is not installed.

The sample contains two target paths:

```
INSTALLDIR
INSTALLDIR1
```

The INSTALLDIR target path specifies the installation directory for the features that are not dependent on Host Integration Server. It can be set using the **browse** button in the **Select Features** dialog box when the Generic Link Service feature is currently selected.

The INSTALLDIR1 target path specifies the directory where Host Integration Server is installed. This target path is set by the custom action SetHISPath.

The IHVUtil.exe tool can be used to verify the Host Integration Server dependent interfaces. If the tool is launched after the IHV package is installed, all Host Integration Server dependent features should show up in the dialog box. Executing Remove from the dialog box should remove the Host Integration Server dependent feature as well as remove it from the dialog box.

Note that the sample provided can also be tested using the SNA Manager. While the sample does not actually function, it will appear as an installed link service.

Integrated Link Service Configuration and Reconfiguration on Host Integration Server

Constructing an Integrated Link Service DLL on Host Integration Server

Integrated Link Service Configuration and Reconfiguration on Host Integration Server

In Host Integration Server 2009, the initial configuration functions are performed by your configuration DLL running in the context of SNA Manager.

After your link service has been created, SNA Manager must be able to locate its configuration DLL when the operator wishes to reconfigure the link service. To support this feature, when your configuration DLL initially creates the link service, it must put a new value in the registry of the target server as follows:

SYSTEM\CurrentControlSet\Services\<yourLinkService>\Parameters

DLLName: REG_SZ: <configDllName>

where:

<*configDllName*> is the file name and extension of the configuration DLL, for example, IBMSDCFG.DLL. No path is specified in the value.

This value replaces **InfName**, which was used in SNA Server 2.*x* to name the path to the .inf file.

Since SNA Manager can be running on a management workstation remote from the target server, the configuration DLL must be able to create configuration information on the target server. Host Integration Server loads the appropriate configuration DLL over the network from \<snaRoot>\SYSTEM\HWSETUP\<cpu> on the target server as needed.

Note
There is an alternate way of locating the link service configuration DLL (linkcfg) if the link services from the vendor were not i ncluded with the released Host Integration Server CD.

Note
Depending on the setup tool used by the vendor, the vendor's setup software may not be able to read the registry and locate the directory where link services should be installed. To resolve this problem, the SNA Manager scans the **LinkServicesInsta lled** key prior to making the call to the link service configuration DLL. The SNA Manager checks for a % character in the *confi gDllName* and if it exists, *configDllName* will be interpreted differently than just the name of the configuration DLL. The follo wing example illustrates this case:

Note
Under the **SYSTEM\CurrentControlSet\Services\<yourLinkService>\Parameters key**

Note
DLLName: REG_SZ: "share\%s\<relative path and DLL Name>

Note
If a %s string is found, \\ServerName will be prepended and the CPU architecture string (i386) will be substituted for %s.

Constructing an Integrated Link Service DLL on Host Integration Server

Microsoft Host Integration Server 2009 provides an enhanced method for installing integrated link services that allows for remote setup and administration of new link services, as well as support for setup and configuration using a command-line tool. This feature is based on the link service provider supplying a setup and configuration DLL exporting a specific list of functions. A developer must follow certain standards for using this SNA link service configuration DLL (linkcfg) and set various keys and values as registry settings to be used by Host Integration Server for link service configuration.

To support vendors using these setup and configuration features, Host Integration Server includes the source code for a sample generic Synchronous Data Link Control (SDLC) link service configuration DLL. Also included for use by developers is the source code to a library of utility functions (lnktools) that are commonly useful when implementing the linkcfg DLL. This sample code and the documentation that follows can be used as a guideline for vendors developing similar link service configuration DLLs for their hardware. This sample source code is located on the Host Integration Server CD in the \SDK\SAMPLES\IHVLinks subdirectory. Sample include files, C++ files, resource files, makefiles, and project files are included for use with Microsoft Visual C++ version 6.0 and later.

In This Section

Components of an Integrated Link Service Configuration DLL on Host Integration Server

The link service configuration DLL (linkcfg) must export the following functions.

Exported function	Purpose
CommandLineAdd	Called from **LinkCfg** to parse command-line input.
ConfigureLinkService	Called from SNA Manager to add or modify a link service.
ConfigureLinkServiceEx	Called from SNA Manager to add or modify a link service, returning a configuration buffer to be added to the configuration file.
DisplayHelpInfo	Returns a buffer containing command-line syntax for this type of link service.
RemoveLinkService	Called from SNA Manager to remove a link service.
RemoveAllLinkServices	Called from Setup to remove all instances of this link service.

The sample linkcfg.cpp DLL is written in C++ using the Microsoft Foundation Classes (MFC) and uses a single property sheet with two property pages as follows:

- The card configuration property page implementation is in the cardcfg.cpp and cardcfg.h files. This property page is concerned with configuring various hardware properties (interrupt, DMA channel, and I/O address, for example) of the link service hardware.

- The connection mode property sheet implementation is in the mode.cpp and mode.h files. This property page is concerned with configuring mode information (link service name, link service title, Synchronous Data Link Control (SDLC) line type, for example) for the link service.

The two property pages are linked to the link service property sheet in linkcfg.cpp within the **ConfigureLS** routine. This function is called by the exported **ConfigureLinkService** and **ConfigureLinkServiceEx** routines in linkcfg.cpp. An actual link service configuration DLL developed from these sources may require more property pages depending on the information needed to configure the actual link service DLL.

The registry.h include file used by linkcfg.cpp contains a global definition of the registry entries required for the sample generic SDLC link service. The values in this structure will be modified to contain the actual information specified by the user. This structure is added to the registry when a new link service is configured, and this structure is removed when a link service is deleted. The registry values that a developer must modify include the Link Registry Base entry (LINKSERVICE is used in the sample include file), the name of the device driver root (GenSdlc is used in the sample include file and source code), and various software and service registry settings appropriate for the target link service.

Several of the exported link service DLL functions use a configuration buffer, the CONFIG_BUFFER structure defined in linkcfg.h. The format of any CONFIG_BUFFER used by developers must match the structure format of this sample file for the first three parameters. Other parameters may differ for a developer's version of the CONFIG_BUFFER structure based on the target link service.

The sample link service configuration DLL calls a set of general utility functions that are not specific to any target link service. These utility functions are included in the lnktools library (lnktool.cpp) that is linked in as an OBJ file. This lnktools library includes the following utility functions that are useful in developing link service configuration DLLs.

Utility function	Purpose
AddPerfmonCounters	Add Perfmon counters for this link service.
bCreateService	Create a service on a computer.
bDeleteService	Delete a service on a computer.
bStopService	Stop a service running on a computer.

CheckForExistingLinkService	Check to see if a link service of this type exists with this title.
ConvertHexStringToDWORD	Convert a hexadecimal string to a DWORD value.
ExtractNextParameter	Get the next parameter from a buffer.
fAddRegistryEntry	Add a new registry value to the registry.
fCanWeAdministerRemoteBox	Determine if the user has administrative privileges on the remote computer.
fConnectRegistry	Connect to a remote computer's registry and return a handle to the remote registry.
fDisconnectRegistry	Disconnect from a remote computer's registry.
fFindAndReplaceString	Find and replace a substring within a string.
fFindString	Determine if a string exists within a string buffer.
fFindStringInMultiSZ	Find a string in a REG_MULTI_SZ string list and return entire string.
fQueryRegistryValue	Query a value from the registry.
fRegistryKeyExists	Test whether a registry key exists.
fRemoveRegistryEntry	Remove a registry key.
fRemoveRegistryValue	Remove a registry value.
fStringCompare	Determine if two strings compare.
LoadStringResource	Load a string from the string resource.
ParseNextField	Return the next field from a string.
RemovePerfmonCounters	Remove Perfmon counters for this link service.
ReturnString	Return a pointer to a string resource string.

The sample source code for a generic SDLC link service configuration DLL (linkcfg) includes several functions that may be useful as sample code when developing link service configuration DLLs for other hardware. The following functions are included in the linkcfg.cpp source code that may be of use as examples.

Utility function	Purpose
bDetectNetworkCard	Detect the remote network card and return the card settings buffer for the sample generic SDLC link service.
bLastGenericDFTLinkService	Check for the last generic SDLC link service for the sample generic SDLC link service. This routine is used to determine if the GENSDLC Device Driver (if one exists) can be removed.
ConfigureLS	The common link service configuration function used by the sample generic SDLC link service.
fAddAllRegistryValues	Add all registry values for the sample generic SDLC link service.
fAddClassAndBindformRegistries	Add the class and bindform registry entries for the sample generic SDLC link service. The bindform and class registry entries can only exist for the first link service of this type.
fEnumerateEventLogSources	Enumerate the Event Log sources registry value for the sample generic SDLC link service.
fRemoveAllRegistryValues	Remove all registry values for the sample generic SDLC link service.
fReplaceAllRegistryValues	Replace all user-provided information in the registry data for the sample generic SDLC link service.

fReplaceRegistryData	Replace global registry data for the sample generic SDLC link service.
fReplaceRegistryKeyName	Replace global registry structure strings for the registry key name for the sample generic SDLC link service.
fSetupGlobalValues	Create or update all user-provided information in the registry data structure for the sample generic SDLC link service.
InitializeGlobalStructure	Initialize link service data contained in the global data structure for the sample generic SDLC link service.

Contents of IHVLinks Sample Kit on Host Integration Server

The sample source code for a generic Synchronous Data Link Control (SDLC) integrated link configuration MSI package that illustrates an integrated independent hardware vendor (IHV) link service installation are included on the Host Integration Server 2009 CD. These sample programs are located in the \SDK\Samples\IHVLinks subdirectory on the Host Integration Server CD. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit (SDK) option is selected. These samples are installed in the SDK\Samples\IHVLinks subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Microsoft Host Integration Server\SDK, by default).

These sample files include the following directories.

Directory	Description
LinkServ	Directories used in creating the IHVLinks sample generic SDLC link service configuration and detection DLLs.
LinkServ\Build	A file containing the normal COFF base address for a link service configuration DLL (linkcfg).
LinkServ\Detect	The source code to the sample generic SDLC link service detection DLL.
LinkServ\Linkcfg	The source code to the sample generic SDLC link service configuration DLL. The link service configuration DLL must export specific functions. A definitions (.DEF) file must be used so that exported function names are not decorated by the compiler and linker.
LinkServ\LnkTools	The source code to a collection of library routines used by the generic SDLC link service configuration DLL.
LinkServ\NT5INF	An INF file that can be used with the generic SDLC link service.
Setup	Directories used in creating the IHVLinks sample generic SDLC link service setup and setup test tools.
Setup\Bins	The compiled generic MSI package containing the generic SDLC link service driver, configuration and detection DLLs, and configuration tool.
Setup\CASource	This directory contains the source code used for the custom actions in setup. The GetHISData custom action sets the MSI property SERVER_INSTALLED to "YES" if Host Integration Server is installed, otherwise the property is set to "NO". This custom action is used to disable Host Integration Server dependent features from the installation directory if not installed. The SetHISPath custom action sets the target directory INSTALLDIR1 to the installation directory where Host Integration Server was installed. This custom action is used to set the destination directory for the link service configuration DLLs.
Setup\Package	The sample GENERIC.MSI SDLC link service package ready for installation and testing.

Setup\Tools	The source code for various utility functions and tools that can be used to test your integrated link service MSI package.

This sample source code is included for your reference. The communication between workstation management station and Host Integration Server is performed by RPCSVC.EXE, the SNA remote procedure call (RPC) service.

Compiling and Linking a SNALink

This section provides information about compiling and linking a SNALink for use with Host Integration Server 2009. This section also lists and explains the header files and libraries need to build a SNALink.

In This Section

Host Integration Server DLC Header Files

The following files are required to build a Host Integration Server 2009 SNALink:

File	Description
SNA_DLC.H	Main header file containing the definitions of buffer and message formats.
SNA_CNST.H	Function prototypes for the Base/DMOD interface calls and constant definitions.
TRACE.H	Definitions of the logging and tracing macros.
IHVLINK.LIB	Main library for the SNADIS interface.

Included Files

To compile a SNALink, the header files SNA_DLC.H, SNA_CNST.H and TRACE.H are required. In addition, one of the standard operating system header files may be required. To include the required files, the following lines should be used in your application:

```
#include <sna_dlc.h>
#include <sna_cnst.h>
#include <trace.h>
```

Note

The TRACE.H include file is required to enable SNA tracing and use of the Host Integration Server 2009 Trace viewer utility.

Required Exports

The IHV link support DLL must export the following entry points:

- SNALinkInitialize
- SNALinkWorkProc
- SNALinkDispatchProc

These are called by the Base scheduler when the SNALink is invoked.

Compiler Options

When compiling the SNALink DLL, the following compiler options are required:

Option	Explanation
/c	Compile only, without linking. Linking is done as a separate phase to include the required Microsoft Host Integration Server 2009 libraries.
/D NOTRC	The NOTRC macro specifies that internal tracing should not be compiled into the application. The /D NOTRC option should be used for building a final system (internal tracing should not be included because it will degrade performance and occupancy). For a development system, you may want to compile with internal tracing; if so, remove the /D NOTRC option.
/D WIN32_SUPPORT	The macro WIN32_SUPPORT is used in the header files SNA_DLC.H, SNA_CNST.H, and TRACE.H to support variants of the DLC interface for Microsoft Windows 2000.
/Gzs	**z**: Use stdcall conventions .**s**: Remove stack check calls.

The following compiler flags are required, but any of the valid options for each flag may be used, as appropriate to your application:

/O	Optimization
/W	Warning level

Linking

The IHVLINK.LIB library must be linked with the application. It contains the Base, DMOD imports, and diagnostics routines. The DMOD and the Base are implemented as DLLs.

Note
The Host Integration Server 2009 library only contains the external references for the corresponding DLLs, which are part of t he main Host Integration Server product.

Synchronous Dumb Card Interface

This section describes the interface to the synchronous dumb card device driver used by the Synchronous Data Link Control (SDLC) and X.25 SNALinks that Microsoft Host Integration Server 2009 supplies. The interface provides a simple but flexible mechanism for transferring frames of data through a dumb synchronous communications card (such as the IBM MPCA card).

This interface is intended primarily for independent hardware vendors (IHVs) who want to provide drivers for their own dumb cards that are directly compatible with SDLC and X.25 SNALinks. It can also be used by Independent Hardware Vendors (IHVs) who intend to write their own SNALinks and want to ensure that their drivers conform to the standard Host Integration Server 2009 model.

In This Section

Driver Interface

Application software running on Microsoft Windows Server 2003 or Windows 2000 normally does not interact directly with device drivers. Usually, the operating system itself controls the interface to underlying device drivers on behalf of the application. For example, Disk I/O consists of sequences of driver requests generated by a file system, as a result of an application making file system requests.

By contrast, in the Microsoft Host Integration Server 2009 device driver model, synchronous dumb cards are controlled directly by the SNALink using input and output control (IOCTL) commands. This mechanism enables the SNALink to pass raw control packets to the driver without any intervention from the operating system.

This is achieved by issuing an Open request with a file name that identifies the device driver. The operating system detects the fact that this file is a driver and passes an OPEN I/O request packet to the driver. The user application is returned a handle that can be used to reference the driver.

The IBMSYNC driver creates various device names. During setup, the configuration for adapters in the computer is saved in the registry. When the driver starts, it reads this data and creates the device names for all the adapters that are found.

The following table lists the device names that the IBMSYNC driver can create.

Device name	**Description**
\Device\IBMSDLC	Standard IBM Synchronous Data Link Control (SDLC) adapter.
\Device\MPCA_1	IBM MPCA 1 adapter. This adapter has a switch set on it to enforce MPCA 1 operation. This adapter is the primary MPCA adapter in the computer and supports direct memory access (DMA) interrupt mode.
\Device\MPCA_2	IBM MPCA 2 adapter. This adapter has a switch set on it to enforce MPCA 2 operation. This adapter is the secondary MPCA adapter in the computer and supports only interrupt mode.
\Device\SYNC_*x*	Generic adapter (for example, Microgate). The letter *x* is 1 (for the primary adapter) or 2 (for the secondary adapter).
\Device\MPAA_S*x*	IBM MPAA adapter, where *x* represents the number of the MCA slot where the adapter is installed in the computer. This number is a value from 1 through 8.
\Device\SYNC_S*x*	Generic MPAA adapter (for example, the Microgate MPAA adapter). The letter *x* represents the number of the MCA slot where the adapter is installed in the computer. This number is a value from 1 through 8.

Subsequent IOCTL calls using **DeviceIOControl** made by the SNALink using the driver handle cause the operating system to pass an IOCTL I/O request packet to the driver. The driver therefore sees IOCTL requests from the SNALink as a series of I/O request packets passed to it by the operating system.

The Host Integration Server 2009 dumb card interface uses the following operating system calls:

- **OpenFile**
- **DeviceIOControl**
- **CloseFile**

DeviceIOControl allows free-format information to be passed to the driver. The dumb card interface uses its own format of information to pass all requests to the driver (with the exception of Open and Close requests, which are handled differently by the operating system).

In This Section

- Architecture Overview

Architecture Overview

This section describes how information is transferred between the driver and the SNALink.

In This Section

- Interface Record
- Event Signaling
- Link Characteristics

Interface Record

Status information is transferred between the driver and the SNALink using a buffer known as the interface record.

The driver allocates this buffer when it starts and maintains the information in it while it is running. The contents of this buffer are copied to an SNALink buffer by using an IOCTL call of type **READ_INTERFACE_RECORD**.

Event Signaling

The device driver notifies the SNALink whenever an event occurs (such as a frame being received from the line) by setting an event.

The SNALink provides the driver with a handle to this event (or semaphore) at the start of day by issuing an IOCTL call of type **SET_EVENT_HANDLE**.

Link Characteristics

Before the driver can transfer any data, it needs information about the link. This includes the following:

- The frame size.
- The station address to listen on (if required).
- Details of hardware selectable options, such as SDLC/HDLC, Internal/External clocking, and so on.

For more details of these options, refer to the topic Function 0x42: Set Link Characteristics.

I/O Request Packets

All I/O requests are passed to the driver by Microsoft® Windows Server™ 2003 or Windows® 2000 using the standard IRP structure. For more details about this, refer to the Windows Server 2003 or Windows 2000 Device Driver Kit.

I/O request packets are defined in terms of C structures. The relevant fields are accessed as follows:

Field name	Description
IRP.CurrentStackLocation -> MajorFunction	Defines the IRP as an IOCTL.
IRP.IoStatus	Status codes upon completion of request.
IRP.CurrentStackLocation -> IoControlCode	The IOCTL function code.

IoControlCode identifies the function to be performed and **IoStatus** is the mechanism for returning result codes to the SNALink. The structure **IoStatus** is defined as follows:

IoStatus.Status

A standard Windows Server 2003 or Windows 2000 result code (for example, STATUS_INVALID_PARAMETER) as defined in the Windows Server 2003 or Windows 2000 header file NTSTATUS.H.

IoStatus.Information

For successful read-frame IOCTLs, the length of the received buffer (can be zero if no data available). Additional error information, as defined in the header file SECLINK.H.

In This Section

Initialization

Device drivers under Windows Server 2003 or Windows 2000 should perform all initialization required at the start of day when they are loaded by Windows Server 2003 or Windows 2000. Configuration information for device drivers is stored in the Configuration Registry under Windows Server 2003 or Windows 2000. For more details, refer to the documentation supplied with the Windows Server 2003 or Windows 2000 Device Driver Kit.

The SNALinks for dumb cards are implemented by the following files:

SDLC SNALink
SNAroot\SYSTEM\IBMSDLC.DLL

X.25 SNALink
SNAroot\SYSTEM\IBMX25.DLL

To bind to one of these, an installation script should mention the appropriate DLL in the IHVDLL registry entry that the script creates for the link service.

OPEN Call

The **OPEN** call has no parameters. It grants access to the driver from a particular process. The driver ensures that only one **OPEN** is accepted by the link at any one time. When **OPEN** is processed, the driver attempts to reserve access to hardware resources such as interrupt vectors. The **OPEN** is rejected if this fails.

After a successful **OPEN** request, the driver expects to receive the following IOCTL commands:

- **SET_EVENT_HANDLE**
- **SET_INTERFACE_RECORD**
- **SET_LINK_CHARACTERISTICS**

Of these, the first two can be performed in any order, but both should be issued before calling **SET_LINK_CHARACTERISTICS**.

When these three calls have been successfully performed by the SNALink, the driver is ready for information transfer.

CLOSE Call

The **CLOSE** call has no parameters. It performs the logical converse of **OPEN**. Resources are released back to the operating system when a **CLOSE** is performed.

IOCTL Command Summary

The parameters to the IOCTL request packet are stored in the following fields in the associated I/O request packet (IRP).

IRP.CurrentStackLocation -> IOControlCode	**Function code**
IRP.SystemBuffer	Address of parameter buffer (if used)
IRP.CurrentStackLocation -> InputBufferLength	Length of parameter buffer
IRP.UserBuffer	Address of data buffer
IRP.CurrentStackLocation -> OutputBufferLength	Length of data buffer

Note that under Windows Server 2003 or Windows 2000, the operating system reserves the lower four bits of the IOCTL function codes to determine the method used to map the various buffers passed on the **DeviceIoControl** function call into the driver address space. The various options available to device driver writers are:

Low nibble	**IOCTL definition**
0	METHOD_BUFFERED
1	METHOD_IN_DIRECT
2	METHOD_OUT_DIRECT
3	METHOD_NEITHER

For further details of the memory mapping performed by these various options, refer to the Windows Server 2003, Windows 2000, or Windows DDK documentation.

For a driver function code of ZZ, using memory mapping code M, the IOCTL code passed on the **DeviceIoControl** function call is 0xZZM.

The function codes are set out as shown in the table later in this topic. Note that all other function codes will be returned with the error ERROR_INVALID_DEVICE_REQUEST in the field **IoStatus.Status**. The Windows Server 2003 or Windows 2000 I/O System validates the address and length of the areas passed as parameter and data packets. If the address validation fails, an exception will be raised.

All requests must return immediately. In general, they are simple, immediate operations, but in the case of Transmit Frame and Receive Frame, the driver must not suspend the calling SNALink thread while waiting for I/O to complete—a relevant return code should be sent instead, allowing the SNALink to retry.

The complete list of functions is as follows.

Function	**Function code**	**Windows Server 2003 or Windows 2000 IOCTL code**
Function 0x41: Set Event/Semaphore Handle	0x41	0x410
Function 0x42: Set Link Characteristics	0x42	0x420
Function 0x43: Set V24 Output Status	0x43	0x430
Function 0x44: Transmit Frame	0x44	0x441
Function 0x45: Abort Transmitter	0x45	0x450
Function 0x46: Abort Receiver	0x46	0x460
Function 0x47: Off-Board Load	0x47	0x470
Function 0x61: Get/Set Interface Record	0x61	0x613
Function 0x62: Get V24 Status	0x62	0x622
Function 0x63: Receive Frame	0x63	0x632

Function 0x64: Read Interface Record	0x64	0x642

In the function descriptions in the following topics, the bit-numbering convention is: The bits in a byte are numbered 0 through 7, where bit 0 is the least significant and bit 7 is the most significant.

Note

There is no function for the controlling autodialer across the synchronous dumb card interface. This autodial feature is implemented in the link service itself. The Microsoft link services that support the synchronous dumb card interface first perform the dial operation by sending the dial string containing the server-stored number to a COM port rather than the SDLC chip, and then sending a command to the device driver to raise DTR through a Set V24 Output Status IOCTL.

Equates and Structure Layouts

Many standard operating system device driver error codes are used (for example, "invalid function"), together with a new set of device driver-specific errors. Return codes below 0x80 reflect serious failures.

SNA Modem Status Interface

This section describes the interface to the modem status used by Synchronous Data Link Control (SDLC) and X.25 SNALinks that Host Integration Server 2009 supplies. This interface provides a set of simulated modem lights to show modem status. The modem status interface is intended primarily for the Microgate cards with internal modems, but can be used with any SDLC or X.25 link service to show the modem status.

This interface is intended primarily for independent hardware vendors (IHV) who want to provide drivers for their own dumb cards that are directly compatible with SDLC and X.25 SNALinks that Host Integration Server provides. It can also be used by IHVs who intend to write their own SNALinks but who want to ensure that their drivers conform to the standard Host Integration Server model.

In This Section

SNA Device Driver Interface to Modem Status

There are three interfaces from which modem status can be gathered:

- The SNADIS Dumb Card Interface **GetV24Status** IOCTL call that reports the status of the Ring Indicator (DRI), Carrier Detect (DCD), Clear To Send (CTS), and Data Set Ready (DSR) signal lines.

- The SNADIS Dumb Card Interface **SetV24Status** IOCTL call that sets the status of the Data Terminal Ready (DTR) and Request To Send (RTS) signal lines.

- The SNADIS Dumb Card Interface receive and transmit IOCTL calls, used to set the operating mode of the device driver.

Whenever one of the first two interfaces indicates a modem line is high, the corresponding light in the display is lit. However, the transmit and receive IOCTL calls cannot provide a definitive statement as to whether the card is receiving data, only that it is ready to receive data. To work around this limitation and to have the modem lights give a reasonable indication of ordinary data throughput, the following mechanism is recommended:

Simulate the receive and transmit lights with counters and track the number of frames received and transmitted for each link service. The display application uses this information to control the flashing of the receive and transmit lights.

The other topics in this section describe the changes that must be made to the link service for supporting the modem status interface and the interface provided to the display application. Microsoft Host Integration Server 2009 comes with an application that displays the modem status.

Supporting Modem Status in an SNA Link Service

The implementation of a link service that supports the modem status requires the following:

- A call to the SNA Modem interface to initialize the SNA Modem data structures.
- Modification of the SNA Modem structures as the status changes, as reported by the **DevIoctl** calls.

Independent hardware vendors (IHVs) who use the MicrosoftHost Integration Server 2009 SDLC link service and who fully implement the SNADIS interface do not need to make any changes to use the modem status feature. However, IHVs should check that the status returned by **DevIoctl** calls from their device driver conforms to the requirements described later.

IHVs who provide both the device driver and link service need to implement the code in their link service that initializes the SNA Modem API and updates the modem status information.

Modem API Summary

To simplify the task for independent hardware vendors (IHVs) who want to use this feature, four new entry points have been added to SNALINK.DLL. An IHV who uses these must be linking with IHVLINK.LIB, a stub library that contains the exports library for SNALINK.DLL. This API enables the IHV to simply maintain the contents of a MODEM_STATUS structure. The underlying SNALINK library code handles the communication of this information to the modem lights application.

The modem status functions are as follows.

Function	Description
SNAModemInitialize	Initializes the communication path to the SNA Modem application.
SNAModemAddLink	Adds an SNA link.
SNAModemDeleteLink	Deletes the resources associated with a link.
SNAModemTerminate	Terminates an SNA link.

DevIoctl Definitions to Support SNA Modem Status

The **SNA DevIoctl** interface is modified to update the MODEM_STATUS structure for a link each time a modem status change is detected or caused by a **GetV24** or **SetV24** IOCTL call. Code is manually added to the link service to track the number of frames received and transmitted.

The **DevIoctl** changes are highlighted as follows.

```
#define SETV24STATUS                                                \
         NtDeviceIoControlFile(seldrvrh,NULL,NULL,NULL,&IoStatus,  \
                               IoctlCodeSetV24,NULL,0L,             \
                               &pInterfaceRecord->V24Out,1L);       \
         if (SavedIROut != (InterfaceRecord.V24Out &                \
                            (MASK_DTR | MASK_RTS)    ))            \
         {                                                          \
           SavedIROut = (pInterfaceRecord->V24Out &                 \
                         (MASK_DTR | MASK_RTS)    );                \
           pSharedMem->V24Out = pInterfaceRecord->V24Out;           \
         }

#define GETV24STATUS(rc)                                            \
         rc |= NtDeviceIoControlFile(seldrvrh,NULL,NULL,NULL,       \
             &IoStatus,IoctlCodeGetV24,NULL,0L,NULL,0L);            \
         rc |= READINTERFACERECORD;                                 \
         if (SavedIRIn != (InterfaceRecord.V24In &                  \
                     (MASK_CTS | MASK_DSR | MASK_DCD| MASK_DRI))) \
         {                                                          \
             SavedIRIn = (InterfaceRecord.V24In &                   \
                     (MASK_CTS | MASK_DSR | MASK_DCD| MASK_DRI)); \
             pSharedMem->V24In = InterfaceRecord.V24In;             \
         }
```

pSharedMem is a pointer to the MODEM_STATUS structure for this link service.

V24In and *V24Out* are of type char and are used to notify the display application when status changes, not each time it is read or set.

SNA Performance Monitor Interface

This section describes the interface for performance monitoring (Perfmon) used by SNADIS links that Microsoft Host Integration Server 2009 supplies. This interface is provided to simplify the integration of SNADIS-compliant link services with the Microsoft Windows 2000 System Monitor applications. It provides a common look-and-feel to all link service performance counters exported by SNADIS links, independent of the vendor and link transport (channel, Twinax, SDLC, X.25, TR, E/Net, and so on).

The performance monitoring statistics maintained for an SNA link service are stored in a series of ADAPTERCOUNTER structures that are members of an ADAPTERPERFDATA structure. These structures are defined in the SEMFPERF.H header file.

Three API entry points are exported from IHVLINK.DLL (and the IHVLINK.LIB import library) that are used by the Perfmon API. These functions should be called in the order noted below at link service initialization time.

To support performance monitoring, an SNA Link driver first calls SNAInitLinkPerfmonto initialize data structures used by the Perfmon application. This call should be followed with a call to the function SNAGetLinkPerfArea, which returns a shared mutex handle and a pointer to the shared data area for the **ADAPTERPERFDATA** structure used by the Perfmon application to store the link statistics. This handle and shared memory data area parameter are the returned values from **SNAInitLinkPerfmon**. Finally, the SNAGetPerfValues function is called to fill in the *ServiceNameIndex* and *FirstCounterIndex* fields so that the Perfmon application knows where to get the descriptions of the performance counters from the registry.

After these three calls have been made, the SNA link driver simply maintains the count members in the **ADAPTERCOUNTER** structures that make up the **ADAPTERPERFDATA** structure, incrementing the count member whenever data is received, connections fail, and other events occur. The Perfmon application accesses these counters to display Host Integration Server performance monitoring data statistics.

Network Integration Security Guides

The network integration features of Microsoft Host Integration Server 2009 fall into several areas. Each area has a Security guide.

This section contains:

- APPC Programmer's Security Guide
- CPI-C Programmer's Security Guide
- LUA Programmer's Security Guide
- SNA Print Server Data Filter Programmer's Security Guide

APPC Programmer's Security Guide

The following topics discuss security as it applies to the APPC section of the Microsoft Host Integration Server 2009 SDK.

About APPC security for developers

This section discusses security practices and issues that apply to C-language applications that you write to use Advanced Program-to-Program Communications (APPC) to exchange data in a Systems Network Architecture (SNA) environment.

Conversation Security

- Owners of APPC transaction programs may want to allow only a limited set of users to start the program. APPC provides a mechanism, called APPC conversation security, where the client transaction program supplies credentials to the server to gain access to the program. You can find more information on conversation security in the section: APPC Security.

Several APPC verbs create a connection with a remote LU. When creating a connection with a remote LU, credentials may be required to establish access. The **security** parameter controls conversation security, and the **pwd** and **user_id** parameters specify the information used to validate the user on the host.

Conversational security is documented in the topic Conversation Security, and in the reference pages for the following APPC verbs:

- ALLOCATE
- MC_ALLOCATE
- SEND_CONVERSATION
- MC_SEND_CONVERSATION

Session Security configuration using SNACFG

You can use the utility SNACFG to set session security for a remote LU. Possible values are none, use a plaintext key, and use a scrambled key.

Automatic Login

The configuration of Host Integration Server to support automatic login is discussed in the topic Support for CPI-C Automatic Logon.

Setting the service key with CNOS

You can specify a master or service key using the **key** parameter when changing the number of sessions with the CNOS verb. This is a plaintext parameter, and is valid if the keylock feature has been secured.

CPI-C Programmer's Security Guide

The following topics discuss security as it applies to the CPI-C section of the Host Integration Server 2009 SDK.

About CPI-C Security for Developers

The Common Programming Interface for Communications (CPI-C) is a platform-independent API designed to simplify the use APPC verbs, and has many of the same issues and features as APPC.

This section discusses security practices and issues that apply to C-language applications that you write to use CPI-C to exchange data between a Host Integration Server system and a computer or computers in a Systems Network Architecture (SNA) environment.

Session Security Configuration Using SNACFG

You can use the utility SNACFG to set session security for a remote LU. Possible values are none, use a plaintext key, and use a scrambled key.

Conversation Security in CPI-C

Conversation security in CPI-C controls who can connect to a remote LU. You can find more information in the topic Conversation Security.

A programmer controls conversation security using the Set_Conversation_Security_Type call and sets user credentials using the Set_Conversation_Security_User_ID and Set_Conversation_Security_Password call from the CPI-C SDK.

LUA Programmer's Security Guide

The following topics discuss security as it applies to the LUA section of the Host Integration Server 2009 SDK.

About LUA security for developers

LUA presents a simple API that enables programmatic control over the SNA messages. LUA has a simple structure, but exposes a complex data stream, that associated with SNA messages.

Since LUA is a low-level interface, the programmer must be especially vigilant on security issues.

Threats and mitigations for LUA

Programmers who use this feature should be aware of the following security practices and issues.

The data stream between Host Integration Server and the Mainframe is not encrypted.

LUA provides no encryption for the data stream between Host Integration Server and the Mainframe.

SNA Print Server Data Filter Programmer's Security Guide

The following topics discuss security as it applies to the APPC section of the Host Integration Server 2009 SDK.

Threats and mitigations for SNA Print Server Data Filter

Programmers who use the SNA Print Server Data Filter should be aware of the following security issue.

Store DLLs in a secure location

The DLLs which support the SNA Print Server Data Filter API can be configured by an administrator or developer. Because of this, the DLLs should be stored in a secure location, such as the default installation directory. If this location is customized by an administrator or developer the new location should also be secured.

Session Integrator Programmer's Guide

This section describes how to create applications that interact with a remote server using LU0 and LU2 protocols.

In This Section

Session Integrator

Using Session Integrator

Reference

Microsoft.HostIntegration.SNA.Session

Session Integrator

An enterprise organization might run the bulk of their daily operations on an IBM host system, such as the zSeries IBM mainframe. Many host-based applications use session-based termination emulation and other client-server programs that use either Logical Unit type 0 (LU0) or Logical Unity type 2 (LU2). LU0 programs, common in retail banking, are based on the Logical Unit for Applications (LUA) programming model. In contrast, the LU2 programs, common in many vertical markets, are based on terminals and terminal emulation using a 3270 data stream.

Session Integrator provides COM and .NET Framework access to LU0 and LU2 sessions, using Host Integration Server as the gateway and platform for IBM interoperability.

Session Integrator Programming Interfaces

Session Integrator provides a COM and a .NET Framework interface to grant programmatic access to an SNA network using LU0 and LU2 protocols. The following tables describe the relationships between the COM and the .NET Framework interfaces.

LU0 Interfaces

COM	.NET	Description
IcomLU0	SessionLU0	The primary interface for connecting, sending, and receiving information over an LU0 session.
	SessionConnectionLU0	Represents the LU0 connection. **SessionLU0** uses **SessionConnectionLU0** to contain the relevant connection and initialization information.
	SessionLU0Data	Encapsulates the information you want to send and receive over LU0. **SessionLU0** uses **SessionLU0Data** in the **Send** and **Receive** methods to send and receive data.
	SessionLU0InitType	Contains initialization information. **SessionLU0** uses this class during the initialization process to pass initialization information to the host.
	SessionLU0ReceiveIndication	Represents the current state of a session associated with a receive call.
	SessionLU0SendIndication	Contains values used by the **Send** method of **SessionLU0**.

LU2 Interfaces

COM	.NET	Description
	SessionDisplay	Provides the connection interface for the **SessionDisplay** class.
	ScreenPosition	Provides access to a position on the LU2 screen.
	ScreenCursor	Provides access to the cursor on the screen.
	ScreenPartialField	Provides access to a part of a screen field.
	ScreenField	Provides access to a particular area of the LU2 screen including the data and attributes.
	ScreenFieldCollection	Contains a collection of **ScreenField** classes.
	ScreenPartialFieldCollection	Contains a collection of **ScreenPartialFields** classes.
	ScreenFieldAttributeData	Provides all of the attributes about the **ScreenField** data.
Icom3270	**SessionDisplay**	Primary interface for accessing the network over a 3270 connection.
	ScreenData	Provides access to a particular area of the raw 3270 data representations.
	SessionDisplayScript	Enables users to take a script created in the Host Integration Server 3270 client and play it programmatically.

	SessionDisplayVariableCollection	Used with the **SessionDisplayScript** class to provide variables that can be replaced in the script.

Session Integrator

Using Session Integrator

What You Should Know Before Using Session Integrator

Session Integrator is designed to communicate between a Windows-based enterprise and an IBM network. Therefore, you should be familiar with the following concepts and technologies before attempting to use Session Integrator:

- Programming with the .NET Framework or COM
- Windows Networking
- SNA Networking

See Also

Other Resources

Session Integrator

Using Session Integrator

Supported Platforms for Session Integrator

Session Integrator is designed to be used with Host Integration Server 2009, and is therefore supported on all platforms that support Host Integration Server 2009.

Other Resources

Session Integrator

Using Session Integrator

COM Security Requirements for Session Integrator

When using Session Integrator in an environment where the Client application and the Service component are running under two different user accounts, special configuration of COM security should be performed.

To configure COM security in Component Services

1. Click Start, then click Run, then type **DCOMCNFG**, and then click **OK**.
2. In Component Services, expand **Component Services**, expand **Computers**, right-click My **Computer**, and then click **Properties**.
3. In **My Computer Properties**, in the **COM Security** tab, under **Access Permissions**, click **Edit Default**.
4. In **Access Permission** dialog box, click **Add** to add the Server user context. If the Server is not on the same computer as the client, you must allow Remote Access to the user.
5. Click **OK** twice.

Using Session Integrator

The topics in this section describe how to create Session Integrator applications.

LUA Programmer's Guide

How to Initialize a Session Integrator Session for LU0

The first action you must perform when you connect to an LU0 session for Session Integrator is to create and initialize the SessionLU0 object. As the name implies, **SessionLU0** represents the LU0 session to your application, and is the primary interface that you will use to access the SNA network.

After you initialize the connection, you can begin to send and receive information over the LU0 session.

To initialize a Session Integrator session for LU0

1. Determine what type of session you will connect to.
2. If necessary, create a new session connection by using SessionConnectionLU0.

   You can create the **SessionConnectionLU0** directly if you have all the relevant information. However, you do not need to perform this step. More likely, you will just pass in the LU connection string in step 3.
3. Create a new session by using **SessionLU0**.
4. Pass the connection information to Connect.

   Connect contains several overloads: you can choose to connect with an already-created SessionConnection object, a **SessionConnection** object and additional initialization information, or with a connection string and initialization information.

   If you choose to call **Connect** with a connection string, Session Integrator creates a new **SessionConnectionLU0** for you. You can directly access the **SessionConnectionLU0** object through Connection.
5. If necessary, confirm that you connected by using IsConnected.

Example

The following code example demonstrates how to create a session, using a connection string received from the user.

```
private void CreateSession_Click(object sender, EventArgs e)
 {
   try
     {
      LUName.Text = LUName.Text.Trim();
      if (LUName.Text.Length == 0)
       {
       MessageBox.Show("You must fill out the LU or Pool Name");
       return;
       }
    _session = new SessionLU0();
    _session.Connect("LogicalUnitName=" + LUName.Text, SessionLU0InitType.SSCP);
                // Receive the logon screen.
    SessionLU0Data receivedData = _session.Receive(20000, true);
                // Trace out the received data.
    TraceData(false, receivedData.Data, receivedData.Indication);
                // Disable every button and text box.
    DisableEverything();
                // Insert User/Password.
    EnableInsertUserId();
   }
catch (Exception ex)
 {
  MessageBox.Show(ex.Message);
 }
}
```

Note that the primary purpose of this code example is to create a new session and connect to the LU using a connection string. However, the example also receives data back over the LU0 session. The example also sends password information using the **EnableInsertUserId** function.

Using Session Integrator for LU0

How to Send a Message Using Transaction Integrator for LU0

After you initialize and connect to the logical unit (LU), you can send information over the LU0 connection. The primary tool that Session Integrator exposes for sending LU0 information is the **SessionLU0Data** object and the **SessionLU0.Send** method.

In addition to sending information, you probably will want to receive information too.

To send a message using Transaction Integrator for LU0

1. Collect your data into the format your LU uses.
2. Place your data into a **SessionLU0Data** object.
3. Send the data with **SessionLU0.Send**.

Example

The following code example demonstrates how to send data over an LU0 session using Session Integrator.

```
private void InsertUserId_Click(object sender, EventArgs e)
 {
  try
   {
    // Disable every button and text box.
     DisableEverything();
     // Enter UserName (SNA200 is what is in the script).
     // AID = 7D - Enter.
     byte AID = 0x7D;
     // Cursor address.
     byte ca1 = 0x5B;
     byte ca2 = 0x6B;
     // SBA
     byte SBA = 0x11;
     byte fa1 = 0x5B;
     byte fa2 = 0xE5;
     byte[] sna200 = HostStringConverter.ConvertUnicodeToEbcdic("SNA200");
     byte sixD = 0x6D;
     byte [] message = new byte [8 + sna200.Length ];
     message[0] = AID;
     message[1] = ca1;
     message[2] = ca2;
     message[3] = SBA;
     message[4] = fa1;
     message[5] = fa2;
     Array.Copy(sna200, 0, message, 6, sna200.Length);
     message[6 + sna200.Length] = sixD;
     message[7 + sna200.Length] = sixD;
     // Send the data.
     SessionLU0Data data = new SessionLU0Data();
     data.Data = message;
     // Trace out the data to send.
     TraceData(true, message, 0);
     _session.Send(data);
     // Allow entering director.
     EnableEnterDirector();
     }
    catch (Exception ex)
    {
     MessageBox.Show(ex.Message);
    }
   }
```

Most of this code example is about formatting the data so that the LU can correctly interpret the information; the call to **SessionLU0.Send** is relatively simple. For more information about the code sample, see Session Integrator for LU0 Code Example.

Using Session Integrator for LU0

How to Receive a Message Using Transaction Integrator for LU0

After you create and initialize your connection, you can receive information from the specified logical unit (LU). The primary way of receiving information with Session Integrator is with the **SessionLU0.Receive** method.

After sending and receiving messages, you must disconnect from your Session Integrator session.

To receive information using Session Integrator for LU0

1. Use SessionLU0.Receive and **SessionLU0data** to wait for data from the LU.

   Receive allows you to pass the maximum length of time to wait for information, as well as whether you want to send an automatic acknowledgement. **Receive** returns a **SessionLU0Data** object.

Example

The following code example demonstrates how to receive information with Session Integrator for LU0.

```
private void CreateSession_Click(object sender, EventArgs e)
 {
   try
     {
      LUName.Text = LUName.Text.Trim();
      if (LUName.Text.Length == 0)
       {
       MessageBox.Show("You must fill out the LU or Pool Name");
       return;
       }
    _session = new SessionLU0();
    _session.Connect("LogicalUnitName=" + LUName.Text, SessionLU0InitType.SSCP);
                // Receive the logon screen.
    SessionLU0Data receivedData = _session.Receive(20000, true);
                // Trace out the received data.
    TraceData(false, receivedData.Data, receivedData.Indication);
                // Disable every button and text box.
    DisableEverything();
                // Insert User/Password.
    EnableInsertUserId();
   }
catch (Exception ex)
 {
  MessageBox.Show(ex.Message);
 }
}
```

Using Session Integrator for LU0

How to Terminate a Connection with Session Integrator for LU0

After you finish sending and receiving information over the LU0 session, you must terminate your connection. Ending a session with Session Integrator consists primarily of calling **SessionLU0.Disconnect**.

To terminate a connection with Session Integrator for LU0

1. End the connection by using **SessionLU0.Disconnect**.

   After you call **Disconnect**, you must call **Connect** in order to re-establish a connection. This is true even if the call fails to complete successfully.

2. If necessary, ensure that you have released all relevant data objects.

Example

The following code example shows how to terminate a Session Integrator session for LU0.

```
private void Disconnect_Click(object sender, EventArgs e)
 {
 // Disable every button and text box.
  DisableEverything();
  _session.Disconnect();
// Go back to the original state of buttons.
  SetOpeningState();
  }
```

Using Session Integrator for LU0

Using Pre-Recorded Scripts with Session Integrator

The **SessionDisplayScript** class allows users to use a script created in the Host Integration Server 3270 client and play it programmatically.

The script can implement variables using a double percent sign on each end of the name, for example, %%MYVARIABLE%%. These variables are resolved using the SessionDisplayVariableCollection class provided in this class. In addition, the script file can contain environment variables using the standard notation which this class will translate.

SessionDisplayScript Class

The input script must be a normal text file with one command per line. The Script file supports the following commands:

Command	Description
SETTIMEOUT {timeout},{label}	Sets the default timeout for all commands and the label where processing should continue. If no default is set, 30 seconds is assumed.
WAITSESSION {wait}	Waits for the session to be in the input wait state before returning. The accepted values are: SSCP; LULU; UNOWNED
WAIT {seconds}	Waits the input number of seconds and then moves to the next command. The WAIT command can be replaced by the WAITSTRING command to wait for a specific string on the screen.
SETCURSOR {ROW},{COLUMN}	Moves the cursor to the desired position on the screen. If the position is not found on the screen, the script is aborted and a ScriptError Exception is returned with an InnerException of the actual Exception when running the script.
SEND {string}, {%environmentvariable%}, {%%sessiondisplayvariable%%}	Causes the string to be sent to the screen using the SendKeys method. Variables can be input that are matched against the SessionDisplayVariablesCollection passed into the class. If a variable is not located in the script, the script is aborted and a ScriptError Exception is returned with a InnerException of Variable {name} not located in collection.
GOTO {label}	Allows for scripts to jump to labels below the current line. If the label is not found, the script will abort with a ScriptError exception and an InnerException of “Label {name} not found”. {label} = A way to define a freeform label in the script that can be used in branching scenarios.

Session Integrator for LU0 Code Example

The following code example shows how to use the primary techniques for creating an LU0 connection, logging on to the LU0 session, sending and receiving information, and terminating the connection.

For the complete code sample, see the \\Microsoft Host Integration Server\SDK\Samples\AppInt\COMLU0 directory.

Example

The following example is from the CSClient.Form1 file in the COMLU0 sample.

```
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Text;
using System.Windows.Forms;
using Microsoft.HostIntegration.SNA.Session;

namespace CSClient
{
    public partial class Form1 : Form
    {
        private SessionLU0 _session = null;

        // As the LU0 managed wrapper does no tracing
        // we will trace the data contents to the provided text box.
        private TextBox m_TextBox = null;
        private Font m_FixedFont;

        public Form1()
        {
            InitializeComponent();
        }

        private void SetOpeningState()
        {
            DisableEverything();

            // Only the LU Name and Create Session are enabled.
            this.CreateSession.Enabled = true;
            this.LUName.Enabled = true;

            m_TextBox = this.ScreenText;

            // If we should trace, we need a fixed width font.
            FontFamily fontFamily = new FontFamily("Courier New");
            m_FixedFont = new Font(fontFamily, 10, FontStyle.Regular, GraphicsUnit.Pixel);

            // Set up some things.
            m_TextBox.WordWrap = false;
            m_TextBox.Multiline = true;

            // Find a fixed font.
            m_TextBox.Font = m_FixedFont;
        }

        private void DisableEverything()
        {
            // All buttons are disabled.
            this.CreateSession.Enabled = false;
            this.InsertUserId.Enabled = false;
            this.EnterDirector.Enabled = false;
            this.Disconnect.Enabled = false;

            // All text boxes are disabled.
```

```
            this.LUName.Enabled = false;
        }

        private void EnableDisconnect()
        {
            // Just allow the Disconnect.
            this.Disconnect.Enabled = true;
        }

        private void EnableInsertUserId()
        {
            // Enable the cics name / connect.
            this.InsertUserId.Enabled = true;

            // Enable the disconnect.
            EnableDisconnect();
        }

        private void EnableEnterDirector()
        {
            // Enable clear screen.
            this.EnterDirector.Enabled = true;

            // Enable the disconnect.
            EnableDisconnect();
        }

        private void Form1_Load(object sender, EventArgs e)
        {
            // Enable only the LU Name and Create.
            SetOpeningState();
        }

        private void CreateSession_Click(object sender, EventArgs e)
        {
            try
            {
                LUName.Text = LUName.Text.Trim();
                if (LUName.Text.Length == 0)
                {
                    MessageBox.Show("You must fill out the LU or Pool Name");
                    return;
                }

                _session = new SessionLU0();
                _session.Connect("LogicalUnitName=" + LUName.Text, SessionLU0InitType.SSCP)
;

                // Receive the logon screen.
                SessionLU0Data receivedData = _session.Receive(20000, true);

                // Trace out the received data.
                TraceData(false, receivedData.Data, receivedData.Indication);

                // Disable every button and text box.
                DisableEverything();

                // Insert User/Password.
                EnableInsertUserId();
            }
            catch (Exception ex)
            {
                MessageBox.Show(ex.Message);
            }
        }

        private void InsertUserId_Click(object sender, EventArgs e)
        {
```

```
        try
        {
            // Disable every button and text box.
            DisableEverything();

            // Enter UserName (SNA200 is what is in the script).
            // AID = 7D - Enter
            byte AID = 0x7D;
            // Cursor address.
            byte ca1 = 0x5B;
            byte ca2 = 0x6B;
            // SBA
            byte SBA = 0x11;
            byte fa1 = 0x5B;
            byte fa2 = 0xE5;

            byte[] sna200 = HostStringConverter.ConvertUnicodeToEbcdic("SNA200");

            byte sixD = 0x6D;

            byte [] message = new byte [8 + sna200.Length ];
            message[0] = AID;
            message[1] = ca1;
            message[2] = ca2;
            message[3] = SBA;
            message[4] = fa1;
            message[5] = fa2;

            Array.Copy(sna200, 0, message, 6, sna200.Length);

            message[6 + sna200.Length] = sixD;
            message[7 + sna200.Length] = sixD;

            // Send the data.
            SessionLU0Data data = new SessionLU0Data();
            data.Data = message;

            // Trace out the data to send.
            TraceData(true, message, 0);

            _session.Send(data);

            // Allow entering director.
            EnableEnterDirector();
        }
        catch (Exception ex)
        {
            MessageBox.Show(ex.Message);
        }
    }

    private void EnterDirector_Click(object sender, EventArgs e)
    {

            SessionLU0Data receivedData = _session.Receive(20000, true);

            // Trace out the received data.
            TraceData(false, receivedData.Data, receivedData.Indication);

            EnableDisconnect();
        }
        catch (Exception ex)
        {
```

```
                MessageBox.Show(ex.Message);
            }
        }

        private void Disconnect_Click(object sender, EventArgs e)
        {
            // Disable every button and text box.
            DisableEverything();

            _session.Disconnect();

            // Go back to the original state of buttons.
            SetOpeningState();
        }

        // Print out the Data to a provided text box.
        private void TraceData(bool sent, byte[] data, int indication)
        {
            if (m_TextBox == null)
                return;

            // Was the last thing sent or received?
            if (sent)
                m_TextBox.Text += "====>> Sent to Host" + Environment.NewLine;
            else
                m_TextBox.Text += "<<==== Received from Host" + Environment.NewLine;

            // How much is there to trace.
            int traceLength = data.Length;

            m_TextBox.Text += "Size = " + traceLength.ToString();

            if (!sent)
                m_TextBox.Text += String.Format(", Indication = {0:X}", indication);

            m_TextBox.Text += Environment.NewLine;

            int numberTraced = 0;
            while (numberTraced < traceLength)
            {
                string hexLine = "";
                for (int i = 0; i < 16; i++)
                {
                    if (numberTraced + i >= traceLength)
                        hexLine += "   ";
                    else
                        hexLine += String.Format("{0:x2} ", data[numberTraced + i]);
                }

                m_TextBox.Text += hexLine + Environment.NewLine;

                numberTraced += 16;
            }
        }
    }
}
```

Using Session Integrator

How to Initialize a Session Integrator Session for LU2

The first action that you must perform when you are connecting to an LU2 session for Transaction Integrator is to create and initialize the SessionDisplay object. As the name implies, **SessionDisplay** represents the 3270 display to your application, and is the primary interface that you will use to access the SNA network.

After you initialize your connection, you can begin to send and receive information over your LU2 session.

Procedure Title

1. If necessary, create a new session connection with SessionConnectionDisplay.

   You can create the **SessionConnectionDisplay** directly if you have all the relevant information. However, you do not need to perform this step. More likely, you will simply pass in the LU connection string in step 2.

2. Create a new session with **SessionDisplay**.

3. Pass the connection information to Connect.

   Connect contains several overloads: you can choose to connect with an already-created **SessionDisplay** object, a **SessionDisplay** object and additional initialization information, or with a connection string and initialization information.

   If you choose to call **Connect** with a connection string, Transaction Integrator will create a new **SessionConnectionDisplay** for you. You can directly access the **SessionConnectionDisplay** object through Connection.

4. If necessary, confirm that you connected using IsConnected.

Example

The following code is from the COM3270 application in the SDK sample directory.

```
private void CreateSession_Click(object sender, EventArgs e)
        {
            try
            {
                LUName.Text = LUName.Text.Trim();
                if (LUName.Text.Length == 0)
                {
                    MessageBox.Show("You must fill out the LU or Pool Name");
                    return;
                }
                m_Handler = new SessionDisplay();

                m_Handler.Connect("TRANSPORT=SNA;LOGICALUNITNAME=" + LUName.Text);
                m_Handler.Connection.HostCodePage = 37;

                FontFamily fontFamily = new FontFamily("Courier New");
                m_FixedFont = new Font(fontFamily, 10, FontStyle.Regular, GraphicsUnit.Pixe
l);
                ScreenText.Font = m_FixedFont;
                TraceScreen();

                // Disable every button and text box.
                DisableEverything();

                m_Handler.WaitForContent("TERM NAME", 20000);
                TraceScreen();

                // Enable Connect to CICS and Disconnect Session.
                EnableCICSElements();
            }
            catch (Exception ex)
            {
                MessageBox.Show(ex.Message);
            }
        }
```

How to Send a Message Using Session Integrator for LU2

After you create a connection, you can send information over the LU2 connection to the remote display.

To send a message using Transaction Integrator for LU2

1. If necessary, move the cursor to the position that you want to write to on the screen by calling one of the **SessionDisplay.Move** methods.

   SessionDisplay contains a variety of MoveCursor, MoveNextField, MovePreviousField, and MoveToField overloads. These overloads enable you to move the cursor to different parts of the screen, depending on what information you provide.

   The **SessionDisplay.Move** methods are mirrored by a similar set of **SessionDisplay.Get** methods, which enable you to retrieve the location of the cursor, as well as the information contained in different fields on the screen.

2. Send information to the current cursor position using a call to **SessionHandler.sendKey**.

   sendKey sends a specified string to the location on the screen marked by the cursor. If no cursor location is available, **sendKey** sends the information to the default location.

Example

The following code is from the 3270 application in the SDK sample directory. In this sample, the developer assumes that the cursor is in the default location on the screen, and therefore does not confirm the cursor location.

```
private void ConnectCICS_Click(object sender, EventArgs e)
        {
            try
            {
                CICSName.Text = CICSName.Text.Trim();
                if (CICSName.Text.Length == 0)
                {
                    MessageBox.Show("You must fill out the CICS Name");
                    return;
                }
                // Disable every button and text box.
                DisableEverything();
                m_Handler.SendKey(CICSName.Text + "@E");
                TraceScreen();
                m_Handler.WaitForSession (SessionDisplayWaitType.PLUSLU, 5000);
                TraceScreen();
                m_Handler.WaitForContent(@"DEMONSTRATION", 20000);
                TraceScreen();
                // Enable clear screen.
                EnableClearScreen();
            }
            catch (Exception ex)
            {
                MessageBox.Show(ex.Message);
            }
```

How to Receive a Message Using Session Integrator for LU2

After you create an LU2 session, you can retrieve information and messages from the 3270 console through the ScreenData and SessionDisplay objects.

To receive information over an LU2 connection

1. If necessary, retrieve the entire screen as a screen dump using **ScreenData**.

   For most circumstances, retrieving all the information on the screen is not necessary. Instead, you can use the **SessionDisplay** object for most applications.

2. Get the location of the cursor with a call to ScreenCursor.

3. Optionally, you can get the location and information contained within different fields on the screen with a call to one of the GetField or GetFields methods, or the CurrentField property.

   GetField and **GetFields** both contain multiple overloads, allowing you to retrieve field information from the screen, depending on what information you provide. In contrast, **CurrentField** represents only the field the cursor is currently in.

4. Finally, you can receive field update information with a call to the various **SessionDisplay.Wait** methods.

Example

The following code is from the 3270 application in the Host Integration Server SDK. The sample uses **SessionDisplay.CurrentField.Data** to access the screen data.

```
private void PerformTX_Click(object sender, EventArgs e)
        {
            try
            {
                // Disable every button and text box.
                DisableEverything();

                m_Handler.SendKey("@E");
                TraceScreen();

                // Wait for screen to calm down.
                m_Handler.WaitForSession(SessionDisplayWaitType.NotBusy, 5000);
                TraceScreen();

                // See if the Balance Field is filled out.
                m_Handler.Cursor.Row = m_row;
                m_Handler.Cursor.Column = m_column;
                TraceScreen();
                // Tab to the Account Number field.
                m_Handler.SendKey("@T");
                TraceScreen();
                // Move to the Next Field (Empty Stuff after 123456).
                m_Handler.MoveNextField();
                TraceScreen();
                // Move to the Next Field (Title, Account Balance).
                m_Handler.MoveNextField();
                TraceScreen();
                // Move to the Next Field (Account Balance).
                m_Handler.MoveNextField();
                TraceScreen();

                // Extract Data from this field.
                string accountBalance = m_Handler.CurrentField.Data;

                // Trim the string.
                accountBalance = accountBalance.Trim();

                // Only things to do now are clear screen or disconnect.
                EnableClearScreen();
```

```
                // If we failed (not Abended) then this field will be blank.
                if (accountBalance.Length == 0)
                    throw new Exception("Failed to get Account Balance");
                else
                    MessageBox.Show(accountBalance, "Account Balance");
            }
            catch (Exception ex)
            {
                MessageBox.Show(ex.Message);
            }
        }
```

How to Terminate a Connection with Session Integrator for LU2

After you have finished sending and receiving information on your LU2 connection, you must shut your connection down with a call to Disconnect.

To shut an LU2 connection down

1. When you are finished with your connection, call **SessionDisplay.Disconnect** to disconnect.

Example

The following code example is from the 3270 application in the Host Integration Server SDK.

```
private void Disconnect_Click(object sender, EventArgs e)
        {
            // Disable every button and text box.
            DisableEverything();

            m_Handler.Disconnect();

            // Go back to the original state of buttons.
            SetOpeningState();
        }
```

```

Using Session Integrator for TN3270

Session Integrator can be used to interact with TN3270 sessions. The behavior for Session Integrator using the TN3270 protocol is the same as Session Integrator for LU2 except for a different connection string.

Connection string for TN3270 sessions.

```
TRANSPORT=TN3270;TN3270SERVER="{IP address or
hostname}";TN3270PORT="{default=23}";DEVICETYPE="{default=IBM-3278-2}"
```

Client-Based BizTalk Adapter for WebSphere MQ Programmer's Guide

This section discusses how to use the client-based BizTalk Adapter for WebSphere MQ.

Network Integration Programmer's Guide

Correlating Messages using Request-Reply

There are two ways to correlate messages in BizTalk Server orchestrations for MQSeries request-reply scenarios. The first is to supply the correlation identifier by setting both the MessageID (MQMD_MsgID) and the CorrelationID (MQMD_CorrelationID) to the same value. The second is to use the BizTalk_CorrelationId context property.

When sending the message to an MQSeries Queue Manager, you can set the message identifier (MQMD_MsgID) and the correlation identifier (MQMD_CorrelationID) to the same value in the outgoing message. The MQSeries Queue Manager copies the MessageID to the CorrelationID for the reply message. You can initialize the correlation sets for the outgoing message and follow the correlation sets for the incoming message using the value of MQMD_CorrelationID.

Alternately, instead of setting the MessageID and CorrelationID to the same value in the outgoing message, you can use the BizTalk_CorrelationID context property with a solicit-response send port of BizTalk Adapter for MQSeries.

To use identifiers provided by MQSeries Server for correlations in your BizTalk orchestration, BizTalk Server must first obtain the identifier. Your application does this through a solicit-response request. BizTalk Server sends a solicit-response request using MQSC Adapter to the MQSeries Server. In return, it receives a response with the message identifier (MQMD_MsgId) and the correlation identifier (MQMD_CorrelationId).

For the outgoing message in a solicit-response send port, the adapter copies the MQMD_MsgID generated by MQSeries to the MQSeries.BizTalk_CorrelationId context property.

When receiving messages, the adapter copies the MQMD_CorrelationId to the MQSeries.BizTalk_CorrelationId. In this case, using correlation sets, you can initialize the correlation sets for the outgoing message and follow the correlation sets for the incoming message using the MQSeries.BizTalk_CorrelationId.

Note
In the pre-release, the second mechanism is not supported.

Administration and Management Programmer's Guide

This section describes how to use Windows Management Instrumentation (WMI) to programmatically manage different tasks for Host Integration Server.

In This Section

WMI and Host Integration Server

Using WMI with Host Integration Server

WMI and Host Integration Server

Windows Management Instrumentation (WMI) is a component of the Microsoft Windows operating system that provides management information and control in an enterprise environment. In the context of Microsoft Host Integration Server, WMI provides a programming and scripting interface for four major administrative tasks: configuration, run-time control, health monitoring, and trace capturing.

In This Section

WMI and the Host Integration Server Architecture

The architecture of the Windows Management Instrumentation (WMI) technology includes management applications, managed objects, providers, and the management infrastructure.

Management Applications

A management application is a Microsoft Windows-based application or service that processes or displays data from a managed object. A management application can perform a variety of tasks in a Host Integration Server 2009 environment, such as configuring servers running Host Integration Server, measuring performance, reporting outages, and correlating data. The management application is what you will probably be creating using this programmer's guide.

Managed Objects

A managed object represents a logical or physical enterprise component. A managed object is modeled in WMI using the Common Information Model (CIM), and is accessed by a management application through the WMI programming interface. A managed object in the Host Integration Server 2009 environment can be any component of the system, from a link service device driver communicating with hardware to software configuration information about users and connected logical units (LU).

WMI Providers

A WMI provider is a COM object that exposes an interface to a managed object. The WMI providers supplied with Host Integration Server 2009 use the WMI COM API to supply the WMI repository with data from Host Integration Server managed objects, to handle requests on behalf of Host Integration Server management applications, and to generate notifications of events.

Management Infrastructure

The management infrastructure is made up of WMI and the CIM repository. WMI lets users handle communications between management applications and providers. Users store their static data in the CIM repository. Applications and providers communicate through WMI using a common application programming interface (COM API). The COM API, which supplies event notification and query processing services, is available in the C and C++ programming languages.

The CIM repository holds static management data. Static data is data that does not regularly change. WMI also supports dynamic data, which is data that must be generated on demand because it changes frequently. Data can be placed in the CIM repository by WMI or network administrators. Information can be placed in the CIM repository using either the managed object format (MOF) language and the MOF Compiler or the WMI COM APIs. The WMI providers supplied with Host Integration Server 2009 use both mechanisms.

Management applications can access the COM API directly to interact with WMI and the CIM repository to make management requests of Host Integration Server. applications can also use other access methods such as Open Database Connectivity (ODBC) and HTML to make these requests. An ODBC driver for WMI is included with Windows 2000. The protocol used for communication between local and remote components is Distributed Component Object Model (DCOM).

WMI and Host Integration Server

What You Can Do to Administer Host Integration Server Using WMI

The Windows Management Instrumentation (WMI) providers for Host Integration Server are designed as programming and scripting administration interfaces. As such, these providers are optimized to perform get and set information, and to start and stop services. The following section describes what components of Host Integration Server you can administer with WMI, and what tasks you can perform on those components.

In This Section

Administrative Tasks That You Can Perform on Host Integration Server Using WMI

Using the Windows Management Instrumentation (WMI) providers for Host Integration Server, you can administer a variety of components on Host Integration Server. However, any administration you perform on Host Integration Server through WMI is performed through the following tasks:

- Logging on to WMI

  Like most providers, you must first log on to the WMI provider to use it. Therefore, the WMI providers expose the logon and security interfaces. For more information, see Logging on to Host Integration Server Through a WMI Provider.

- Getting and setting information

  Most of the tasks you will do through WMI will be checking information about different Host Integration Server services. You can also set information. For more information, see Accessing a Host Integration Server Property through WMI.

- Calling methods

  The methods exposed on the WMI providers for Host Integration Server are designed mainly to administer various Host Integration Server services. You can administer these services by calling the relevant **Start**, **Stop**, **Pause**, or **Cancel** method through the relevant provider. For more information, see
  Calling a Host Integration Server Method through WMI.

Sections of Host Integration Server That You Can Administer with WMI

Host Integration Server 2009 is included with Windows Management Instrumentation (WMI) providers that grant administrative access to the following areas:

- Rolling out, configuring, and restoring services

  The SNA Provider WMI Programmer's Reference and SNA Trace Provider WMI Programmer's Reference providers expose information regarding the Setup and rollout procedures for Host Integration Server 2009. You can use instances of classes such as **MsSna_LinkService** to set up and administer link services, and the classes derived from **MsSna_Config** to configure your system. For more information, see Configuring Host Integration Server with WMI.

- Starting and stopping services and connections

  The **WmiSna** provider exposes the **MsSna_Server**, **MsSna_Service**, and **MsSna_Connection** classes. These classes and their derived classes let you add an SNA service, start and stop services, pause services, and start and stop connections. For more information, see Controlling Services and Connections with WMI.

- Health monitoring

  The **WmiSnaStatus** provider exposes information regarding the SNA service status. **WmiSnaStatus** uses a variety of classes derived from **MsSnaStatus_Event** to describe changes in different parts of your system. For more information, see How to Monitor the Health of Host Integration Server with WMI.

- Trace capturing

  The **WmiSnaTrace** provider supports classes and instances derived from the **MsHisTrace_Config** class, which displays information regarding different configuration files. **WmiSnaTrace** also supports the **MsHisTrace_Event**, which describes an event that occurs whenever a trace is triggered. For more information, see How to Capture a Trace with WMI.

Additionally, Microsoft Windows 2000 includes several standard WMI providers, such as a registry provider, for accessing information from the system registry. Windows 2000 also supplies a Windows 2000 Event Log provider that enables applications to receive notifications of Windows 2000 and Host Integration Server 2009 events and to access the information stored in the Windows 2000 event log. Third-party vendors can create custom providers to interact with managed objects specific to their environment.

What You Should Know Before Programming for WMI and Host Integration Server

To use this guide effectively, you should be familiar with the following:

- Microsoft Host Integration Server 2009
- SNA concepts
- Windows Management Instrumentation (WMI)
- Microsoft Windows Server 2003 operating systems, Windows XP Professional, Windows 2000 Server

Depending on the API and development tools used, you should also be familiar with the following languages:

- WMI COM/DCOM APIs
- WMI Query Language
- WMI schema and MOF file syntax
- Windows Script Host
- Microsoft Visual Basic .NET
- Visual Basic for Applications
- Visual Basic Scripting Edition
- JScript
- Microsoft ODBC
- Microsoft ADO
- Active Server Pages

See Also
Other Resources
WMI and Host Integration Server

Supported Platforms for Administering with WMI

Microsoft Windows Management Instrumentation (WMI) is included as part of Microsoft Windows Server 2003, Windows XP, and Windows 2000. For use with Host Integration Server, the WMI Software Development Kit version 1.1 or later can be installed on one of the following operating systems:

- Windows Server 2003
- Windows XP Professional
- Windows 2000 Server
- Windows 2000 Advanced Server
- Windows 2000 Datacenter Server

Windows Script Host (WSH) is installed by default with Windows 2000.

Complete information about WSH is available as part of the Windows 2000 MSDN Platform SDK.

Using WMI with Host Integration Server

There are two main types of programming tasks described in this section: basic tasks and advanced tasks. A basic task is one of the tasks common to most every Windows Management Instrumentation (WMI) application: logging on to WMI, getting and setting properties, and calling methods. The advanced tasks are those built on the basic tasks, and describe the tasks for which the developers incorporated WMI into Host Integration Server. Additionally, this section discusses common problems that you may experience when installing and programming WMI for Host Integration Server, and solutions to those problems.

In This Section

Installing WMI on Host Integration Server

Host Integration Server 2009 should automatically install the relevant files for you to use the relevant Windows Management Instrumentation (WMI) interfaces. However, you may have to modify the location of certain managed object format (MOF) files if you want to use WMI on remote servers, and you may have to modify certain security settings if you want to have WMI work correctly as well.

In This Section

Installing WMI Providers on a Host Integration Server

Microsoft Host Integration Server 2009 provides several Windows Management Instrumentation (WMI) providers. The managed object format (MOF) files used by Host Integration Server are installed in the System directory below where Host Integration Server 2009 is installed. The default location for these files is in the following subdirectory:

C:\Program Files\Microsoft Host Integration Server\System

To use or view these MOF files on other computers (a computer with the Administration client or end-user client, for example) to develop applications, these MOF files must be copied from the Host Integration Server 2009 computer. These MOF files document the WMI providers supplied with Host Integration Server 2009 and the class identifiers (CLSIDs), classes, properties, and methods supported by these providers.

How to Upgrade to Windows Server 2003 with Host Integration Server and WMI

Windows Server 2003 interacts with Windows Management Instrumentation (WMI) providers differently than previous versions of the operating system. One change is how the operating system handles the credentials under which the provider is hosted. If you upgraded your Host Integration Server computer to Windows Server 2003, you may have to recompile the Host Integration Server WMI namespace using updated Windows Server 2003 MOF files. Recompiling with the new MOF files should let you use WMI on Windows Server 2003.

To recompile the Host Integration Server WMI namespace for Windows Server 2003

- Use the following syntax on the command prompt:

  Mofcomp -class:forceupdate mof filename

  The following examples show how to recompile each MOF file:

```
Mofcomp -class:forceupdate  wmiHIS_xp.mof
Mofcomp -class:forceupdate wmiHIS_xp.mof
Mofcomp -class:forceupdate wmisnastatus_xp.MOF
Mofcomp -class:forceupdate wmisnatrace_xp.mof
Mofcomp -class:forceupdate wmisna_xp.mof
```

How to Set ASP Security for Host Integration Server and WMI

WMI scripting using Active Server Pages (ASP) is enabled automatically on Microsoft Windows 2000. For the correct security setting for ASP on Windows 2000, it is recommended that you set **Anonymous Authentication** to **Off** and enable **Integrated Windows Authentication** in the Internet Information Services (IIS) configuration for directories with ASP files used with Host Integration Server. To access Host Integration Server configuration and status information, an application or user must have the appropriate administrative rights, which are not available with anonymous authentication. Use the following procedure on Windows 2000 to correctly configure security using ASP.

To configure security using ASP

1. To open IIS, click **Start**, point to **Administrative Tools**, point to **Services**, and then click **IIS Admin Service**, or click **Start**, point to **Settings**, click **Control Panel**, click **Administrative Tools**, click **Services**, and then click **IIS Admin Service**).
2. Move to the directory where the ASP files reside.
3. Right-click the directory, and then click **Properties**.
4. When the next dialog box appears, on the **Directory Security** tab, in the **Anonymous Authentication** section, click **Edit**.
5. When the next dialog box appears, clear the **Anonymous Authentication** check box, select **Integrated Windows Authentication**, and then click **OK** to save these settings.

This sets that particular directory to use **Integrated Windows Authentication** instead of **Anonymous Authentication** without affecting any of your other directories. If there are other ASP files that require or allow **Anonymous Authentication** you may want to create a new directory in which you can turn off **Anonymous Authentication** and store the WMI ASPs there. Any script that calls **ExecMethod** from an ASP page should be set up to use **Integrated Windows Authentication** to verify the user trying to run the script.

Additionally, when using a "REFRESH" variable on a Web page and the page is being used to start and stop SNA service through ASP scripting, the Web browser client (Internet Explorer, for example) should set the **Every visit to the page** option, as shown in the following procedure.

To use a Web browser client to start and stop SNA services through ASP scripting

1. Click **Start**, point to **Programs**, and then click **Internet Explorer**.
2. In Internet Explorer, on the **Tools** menu, click **Internet Options**.
3. In the **Internet Options** dialog box, on the **General** tab, in the **Temporary Internet file** section, click **Settings**.
4. In the **Settings** dialog box, in the **Check for newer versions of stored pages** section, make sure that the option **Every visit to the page** is selected.
5. Click **OK**.

If this change is not made on the Web browser client, some ASP scripts do not run correctly because Internet Explorer is caching older results.

Basic WMI Tasks for Host Integration Server

Regardless of what you may want to do with Windows Management Instrumentation (WMI), most actions you will perform with it are one of the following: logging on to WMI, getting or setting WMI properties, or calling WMI methods.

In This Section

Logging on to Host Integration Server Through a WMI Provider

The first step that you must perform when you create a WMI application or script is to log on to WMI and set the security for your application. You can perform this action either by using the **SWbemLocator** locator object, or with a moniker.

To connect to WMI using SWbemLocator

1. Retrieve a locator object with a call to **CreateObject**.
2. Log on to the namespace with a call to **ConnectServer**.
3. Set the impersonation level with a call to **Security._ImpersonationLevel**.
4. Implement your task.

The following code sample shows how to connect to WMI using **SWbemLocator**:

```
    Set WmiLocator = CreateObject("WbemScripting.SWbemLocator")
    Set WmiNameSpace = WmiLocator.ConnectServer("","root\MicrosoftHIS","", "","", "",0,Noth
ing)

    if Err = 0 then
        'Retrieve the SNA_LU_Lua class
        Set ServerClass = WmiNamespace.Get("MsSNA_LuLua")
        Set Path = ServerClass.Path_
        ServerClass.Security_.impersonationLevel = 3
        Set LU3270 = ServerClass.Instances_
```

Another way you can connect to WMI is by using a moniker. A moniker is essentially a compact version of the above lines of code, and contains the WMI namespace and other connection information.

To connect to WMI using a moniker

1. Call **GetObject** with a moniker in the input parameter.
2. Implement your task.

The following example shows how to connect to WMI using a moniker:

```
    set objService = GetObject("winmgmts:root/microsofthis")
```

Accessing a Host Integration Server Property through WMI

Getting and setting an instance is one of the most common retrieval procedures you are most likely to perform on Host Integration Server using Windows Management Instrumentation. You can retrieve an instance using the **GetObject** method, and modify it using the various **Put_** methods.

In This Section

How to Retrieve an Instance

You can retrieve a local copy of the instance with a call to **GetObject** with the object path of the instance. The following example shows how to retrieve an IPDLC connection using WMI:

```
Set ObjClass = Namespace.Get("MsSna_ConnectionIpDlc")
```

Besides retrieving a single instance, you can also retrieve collections of WMI instances by querying the WMI database with a **SELECT** statement.

How to Retrieve Multiple Instances

You can retrieve a local copy of the collection with a call to **ExecQuery**. After you have retrieved an instance, you can modify and update the instance. The following example shows how to retrieve a collection:

```
Set colItems = objWMIService.ExecQuery("Select * from MSSnaStatus_Connection")
```

How to Modify or Update an Instance

After you have retrieved an instance, you can modify your local copy and update your changes to the server.

To modify or update an instance

1. Retrieve a local copy of the object with a call to **GetObject**.
2. If necessary, view the properties of the object with a call to the **Properties_** method.

   Although not required, you may want to know the value of the property before you change it.
3. Make any changes to the object properties with a call to the **SWbemProperty.Value** method.

   The **Value** method changes only the local copy. To save your changes to WMI, you must put the complete copy back in the WMI repository.
4. Put the object back in the WMI repository with a call to the **SWbemObject.Put_** or **SWbemObject.PutAsync_** methods.

   As the names imply, **Put_** updates synchronously while **PutAsync_** updates asynchronously. Either method copies over the original instance with your modified instance. However, to take advantage of asynchronous processing, you must create a **SWbemSink** object.

   The following example shows how to update an instance:

```
    Set ObjClass  = Namespace.Get("MsSna_LinkService_IpDlc")
' Create new link service instance
    Set NewInst   = ObjClass.SpawnInstance_
    ' Set instance properties
    NewInst.NetworkName = Left(strComputerName, 8)
    NewInst.CPName = "IPDLCLS"
    NewInst.NodeID = "05D.FFFFF"
    NewInst.AddressType = 2
    NewInst.LocalAddress = Trim(strLocalAddress)
    NewInst.LENNode = strLenNode
    NewInst.PrimaryNNS = strPrimaryNNS
    if (strBackupNNS <> Empty) then
        NewInst.BackupNNS = strBackupNNS
    end if
    ' Commit the instance
    NewInst.Put_
```

Calling a Host Integration Server Method through WMI

You have two options when calling methods through WMI: you may call a WMI method, or a provider method. A WMI method is supported by the WMI infrastructure, and provides general services such as query support or log on access. For example, Logging on to Host Integration Server Through a WMI Provider and Accessing a Host Integration Server Property through WMI describe calling the **GetObject** and **ExecQuery** WMI methods. In contrast, a provider method is supported by the provider, and is unique to each service. Most HIS provider methods deal with controlling services. For example, the **WmiSna** provider supports the **MsSna_ServiceSNA** class, which in turn supports the **Start**, **Stop**, **Pause**, and **Resume** methods. The actual process of calling a WMI method or a provider method is the same as calling any other COM or scripting interface.

Advanced WMI Tasks for Host Integration Server

An advanced Windows Management Instrumentation (WMI) task is a task that uses the basic WMI programming tasks to perform an activity specific to Host Integration Server. Generally, an advanced task deals with setting up Host Integration Server on a server, controlling a service or connection, or monitoring an aspect of your enterprise.

In This Section

Configuring Host Integration Server with WMI

One of the reasons Windows Management Instrumentation (WMI) is implemented in Host Integration Server is to help in configuring and updating different technologies in your enterprise. As an extended sample, this section describes how to configure an IPDLC link service. This sample is a command prompt script that takes as input the host you want to go against and configures an IPDLC link service and independent session connection to the host.

In This Section

How to Configure an IPDLC Link Service

To configure an IPDLC link service

1. Retrieve the command prompt instructions.
2. If necessary, retrieve the adapter name.
3. Create the link service.
4. Create the independent session.

The following code sample describes how to configure an IPDLC link service. The following table describes the relevant command prompt switches:

Command line switch	Description
-p	PrimaryNNS: the Primary Network Node Server
-b	(Optional) BackupNNS: Backup Network Node Server
-d	(Optional) device: Overrides the adapter name discovered
-l	(Optional) LenNode: Used to configure the LEN node (default is 1st)

```
    On Error Resume   Next
'Declarations and Constants
    Dim strPrimaryNNS
    Dim strBackupNNS
    Dim strLocalAddress
    Dim strLenNode
    Dim strComputerName
    Dim wshEnvProc
'Defaults
    strPrimaryNNS = ""
    strBackupNNS = ""
    strLocalAddress = ""
    strLenNode = "SNA Service"
'Get the command line
    Set objArgs = WScript.Arguments
    For I = 0 to objArgs.Count - 1
       select case objArgs(I)
        Case "-p"
            I = I + 1
            strPrimaryNNS = objArgs(I)
        case "-b"
            I = I + 1
            strBackupNNS = objArgs(I)
        case "-d"
            I = I + 1
            strLocalAddress = objArgs(I)
        case "-l"
            I = I + 1
            strLenNode = objArgs(I)
        case else
            Wscript.Echo "Script Usage: "
            Wscript.Echo " -p Primary NNS (Required)"
            Wscript.Echo " -b Backup NNS (Optional)"
            wscript.echo " -d Device Name (Optional)"
            wscript.echo " -l Len Node (Optional)"
            return
       end select
    Next
'NNS parameter is required
    if strPrimaryNNS = "" then
```

```
        Wscript.Echo "Please supply the -p (PrimaryNNS) parameter"
        return
    end if
'See if we need to get a device
    if strLocalAddress = "" then
        GetAdapterName()
    end if
' Two methods for creating the link service and independent session connection
    CreateIPDLCLinkService
    CreateIndependentSession
```

How to Retrieve an Adapter Name

One of the tasks you must perform when setting up an IPDLC connection is to retrieve the name of the adapter you are connecting with.

To retrieve an adapter name

1. Connect to the namespace on the local computer using **GetObject**.
2. Retrieve the name of the adapter using **ExecMethod** with **GetAllNetworkAdapters** as the method to execute.

The following example shows how to retrieve the name of the first adapter on a system:

```
Private Sub GetAdapterName()
   Dim objService, outParam, objSD, MyArray, nArray
   set objService = GetObject("winmgmts:root/microsofthis")
   set outParam = objService.Execmethod("MsSna_LinkService_IPDLC",
"GetAllNetworkAdapters")
   objSD = Join(outParam.Adapters, ",")
   MyArray = Split(objSD, ",")
   nArray = Ubound(MyArray)
   if nArray < 0 then
      strLocalAddress = ""
   else
      strLocalAddress = MyArray(0)  'default to first one
   end if
End Sub
```

How to Create a Link Service

Another task you may want to perform when setting up an IPDLC connection is to create the link service.

To create a link service

1. Connect to the namespace on the local computer using **GetObject**.
2. Create the new link service instance using **SpawnInstance**.
3. Set the properties of the new link service.
4. Commit the new instance to memory using the **Put_** method.

The following example shows how to create a new link service:

```
private Sub CreateIPDLCLinkService
    on error resume next
' Connect to the namepsace on the local machine
    Set Namespace = GetObject("Winmgmts:root\MicrosoftHIS")
    Set ObjClass  = Namespace.Get("MsSna_LinkService_IpDlc")
' Create new link service instance
    Set NewInst   = ObjClass.SpawnInstance_
    ' Set instance properties
    NewInst.NetworkName = Left(strComputerName, 8)
    NewInst.CPName = "IPDLCLS"
    NewInst.NodeID = "05D.FFFFF"
    NewInst.AddressType = 2
    NewInst.LocalAddress = Trim(strLocalAddress)
    NewInst.LENNode = strLenNode
    NewInst.PrimaryNNS = strPrimaryNNS
    if (strBackupNNS <> Empty) then
        NewInst.BackupNNS = strBackupNNS
    end if
    ' Commit the instance
    NewInst.Put_
    if Err.Number <> 0 then
        PrintWMIErrorThenExit Err.Description, Err.Number
        Wscript.Echo "Link Service Creation Failed " & Err.Description
    Else
        Wscript.Echo "Link Serice Created Successfully"
    end if
End Sub
```

How to Create an Independent Session

After you have created the link service, you need to create an independent session to use.

To create an independent session

1. Create the "Independent Sessions Connection" record.
2. Validate that the session was created.
3. Define the properties of the new connection.

The following code sample shows how to create an independent session:

```
 Private Sub CreateIndependentSession
     On error resume next
 'Create the Independent Sessions Connection record.
     Set Namespace = GetObject("Winmgmts:root\MicrosoftHIS")
 'Validate that the instance was created
     strQuery = "select * from MsSna_LinkService_IpDlc"
     ' this is our instance
     Set instset = Namespace.ExecQuery(strQuery)
     if ( instset.Count<>1) Then
         wscript.echo "No instances found for the link service query " & strQuery
     End If
     For each inst_ in instSet
         Set Inst = inst_ ' This is our new instance
     Next ' end of query workaround
     ' define independent sessions connection
     Set ObjClass = Namespace.Get("MsSna_ConnectionIpDlc")
     Set IndepConn = ObjClass.SpawnInstance_
     IndepConn.Activation = 0
     IndepConn.Adapter = "SNAIP1"
     IndepConn.AllowIncoming = TRUE
     IndepConn.BackupDLUSCPName = ""
     IndepConn.BackupDLUSNetName = ""
     IndepConn.BlockId = "05D"
     IndepConn.Comment = ""
     IndepConn.CompressionLevel = 0
     IndepConn.DLURRetryDelay = 0
     IndepConn.DLURRetryLimit = 0
     IndepConn.DLURRetryType = 0
     IndepConn.DynamicLuDef = TRUE
     IndepConn.IndepSess = TRUE
     IndepConn.LocalControlPoint = ""
     IndepConn.LocalNetName = ""
     IndepConn.Name = Inst.Name
     IndepConn.NodeId = "FFFFF"
     IndepConn.PartnerConnectionName = ""
     IndepConn.PeerRole = 1
     IndepConn.PrimDLUSCPName = ""
     IndepConn.PrimDLUSNetName = ""
     IndepConn.RemoteAddress = ""
     IndepConn.RemoteBlockId = ""
     IndepConn.RemoteControlPoint = ""
     IndepConn.RemoteEnd = 1
     IndepConn.RemoteNetName = ""
     IndepConn.RemoteNodeId = ""
     IndepConn.RetryDelay = 0
     IndepConn.RetryLimit = 0
     IndepConn.Service = strComputerName
     IndepConn.XIDFormat = 1
     IndepConn.Put_
     if Err.Number <> 0 then
         PrintWMIErrorThenExit Err.Description, Err.Number
     End If
 End Sub
```

Creating a Link Service

How to Handle Errors While Creating a Link Service

As with most scripts, you need to write functions to handle any errors. This error handler scans the Windows Management Instrumentation (WMI) error queue for any relevant error information and posts and displays the error to the user.

The following sample shows how to handle errors while you are creating a link service:

Syntax

```
Sub PrintWMIErrorThenExit(strErrDesc, ErrNum)
    On Error Resume Next
    Dim objWMIError : Set objWMIError =    CreateObject("WbemScripting.SwbemLastError")
    wscript.echo TypeName(objWMIError)

    If ( TypeName(objWMIError) = "Empty" ) Then
    wscript.echo strErrDesc & " (HRESULT: " & Hex(ErrNum) & ")."
    Else
    wscript.echo "Extended error information:"
    wscript.echo objWMIError.Description
    Set objWMIError = nothing
    End If
    Exit sub
End Sub
```

Controlling Services and Connections with WMI

Another task that Windows Management Instrumentation (WMI) can perform is accessing services and connections throughout Host Integration Server. Two common procedures in this realm are displaying the status of all current connections, and retrieving information about a specified connection.

In This Section

How to Display Connection Status

Retrieving the status of a connection is a common task that you might want to perform with WMI.

To display the status of a connection

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Enumerate **MsSnaStatus_Connections** using **ExecQuery**.
3. Display error codes if necessary.

The following example shows how to display the status of all the connections defined in Host Integration Server (HIS):

```
Private Function DisplayConnectionStatus ()
'Variables
   Dim objWMIService, colItems, iCounter, objItem, _
       strReport
'Connect to the namespace
   Set objWMIService = GetObject("winmgmts:\\" & strComputer & "\root\microsofthis")
'Enumerate the Class
   Set colItems = objWMIService.ExecQuery("Select * from MSSnaStatus_Connection")
   iCounter = colItems.Count
   if Err.Number = 0 then
      For Each objItem in colItems
         strReport = "Connection " & objItem.Name & " status is " & objItem.StatusText
         Wscript.Echo strReport
         strReport = ""
      Next
   else
      Wscript.Echo "An error occurred enumerating instances for status " & Err.Number & " "
& Err.Description
   End If
   DisplayConnectionStatus = true
End Function
```

How to Retrieve Connection Information

Another common task you may want to perform with Windows Management Instrumentation (WMI) for Host Integration Server is retrieving information regarding a connection.

To retrieve connection information

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Retrieve all connection information objects using **ExecQuery**.
3. Display the information as appropriate.

The following code sample shows how to retrieve information about an SDLC connection:

```
On Error Resume Next
strComputer = "."
Set objWMIService = GetObject("winmgmts:\\" & strComputer & "\root\MicrosoftHIS")
Set colItems = objWMIService.ExecQuery("Select * from MsSna_ConnectionSdlc",,48)
For Each objItem in colItems
    Wscript.Echo "Activation: " & objItem.Activation
    Wscript.Echo "Adapter: " & objItem.Adapter
    Wscript.Echo "AllowIncoming: " & objItem.AllowIncoming
    Wscript.Echo "BlockId: " & objItem.BlockId
    Wscript.Echo "Comment: " & objItem.Comment
    Wscript.Echo "CompressionLevel: " & objItem.CompressionLevel
    Wscript.Echo "DialData: " & objItem.DialData
    Wscript.Echo "DynamicLuDef: " & objItem.DynamicLuDef
    Wscript.Echo "LocalControlPoint: " & objItem.LocalControlPoint
    Wscript.Echo "LocalNetName: " & objItem.LocalNetName
    Wscript.Echo "MaxBtu: " & objItem.MaxBtu
    Wscript.Echo "Name: " & objItem.Name
    Wscript.Echo "NodeId: " & objItem.NodeId
    Wscript.Echo "PartnerConnectionName: " & objItem.PartnerConnectionName
    Wscript.Echo "PeerRole: " & objItem.PeerRole
    Wscript.Echo "RemoteBlockId: " & objItem.RemoteBlockId
    Wscript.Echo "RemoteControlPoint: " & objItem.RemoteControlPoint
    Wscript.Echo "RemoteEnd: " & objItem.RemoteEnd
    Wscript.Echo "RemoteNetName: " & objItem.RemoteNetName
    Wscript.Echo "RemoteNodeId: " & objItem.RemoteNodeId
    Wscript.Echo "RetryDelay: " & objItem.RetryDelay
    Wscript.Echo "RetryLimit: " & objItem.RetryLimit
    Wscript.Echo "SdlcContactLimit: " & objItem.SdlcContactLimit
    Wscript.Echo "SdlcContactTO: " & objItem.SdlcContactTO
    Wscript.Echo "SdlcDataRate: " & objItem.SdlcDataRate
    Wscript.Echo "SdlcDuplex: " & objItem.SdlcDuplex
    Wscript.Echo "SdlcEncoding: " & objItem.SdlcEncoding
    Wscript.Echo "SdlcIdleLimit: " & objItem.SdlcIdleLimit
    Wscript.Echo "SdlcIdleTO: " & objItem.SdlcIdleTO
    Wscript.Echo "SdlcLeasedLine: " & objItem.SdlcLeasedLine
    Wscript.Echo "SdlcMultiPrimary: " & objItem.SdlcMultiPrimary
    Wscript.Echo "SdlcPollAddress: " & objItem.SdlcPollAddress
    Wscript.Echo "SdlcPollLimit: " & objItem.SdlcPollLimit
    Wscript.Echo "SdlcPollRate: " & objItem.SdlcPollRate
    Wscript.Echo "SdlcPollTO: " & objItem.SdlcPollTO
    Wscript.Echo "SdlcStandby: " & objItem.SdlcStandby
    Wscript.Echo "SdlcSwitchTO: " & objItem.SdlcSwitchTO
    Wscript.Echo "Service: " & objItem.Service
    Wscript.Echo "StatusText: " & objItem.StatusText
    Wscript.Echo "XIDFormat: " & objItem.XIDFormat
Next
```

How to Monitor the Health of Host Integration Server with WMI

Health monitoring refers to viewing the current status of different aspects of Host Integration Server through the **WmiSnaStatus** provider. You can access **WmiSnaStatus** provider in the same manner as you would any other instance and method provider. You use **ExecQuery** to query for the relevant information, and then display the information to screen or write the information to a log file. Some **WmiSnaStatus** classes also have methods that let you start and stop related services.

To monitor the health of Host Integration Server with WMI

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Retrieve the object representing the SNA Status provider using **ExecQuery**.
3. Use the information gathered from the **ExecQuery** as appropriate.

You can see an example of health monitoring in How to Display Connection Status.

How to Capture a Trace with WMI

Trace capturing refers to the process of viewing trace logs. For Host Integration Server, this typically refers to collating data stored in trace log objects into a single file and saving it to a specified location. You can capture SNA trace information in the same manner as you would retrieve any other information from Windows Management Instrumentation (WMI). You use **ExecQuery** to make a call to the relevant object, and then write the information to the location you want.

To capture a trace

1. Connect to the namespace using **GetObject** with a moniker in the parameter.
2. Retrieve the objects representing the SNA Application using **ExecQuery**.

   The core functionality of capturing a trace can be described in the following code:

   ```
   Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNAApplication",,48)
   Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNABase",,48)
   ```

   Everything else in this sample is to support logging to a file.

The following code example shows how to capture a trace:

```
On Error Resume Next
strComputer = "."
Dim iCounter
'Initialize
    CreateLogFile
    Set objWMIService = GetObject("winmgmts:\\" & strComputer & "\root\MicrosoftHIS")

'Validate TraceSnaApplication
    iCounter = 0
    Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNAApplication",,48)
For Each objItem in colItems
    Wscript.Echo "APPCTrace: " & objItem.APPCTrace
    Wscript.Echo "CPICTrace: " & objItem.CPICTrace
    Wscript.Echo "CSVTrace: " & objItem.CSVTrace
    Wscript.Echo "EnabledTraces: " & objItem.EnabledTraces
    Wscript.Echo "InternalMessageTrace: " & objItem.InternalMessageTrace
    Wscript.Echo "LU62Trace: " & objItem.LU62Trace
    Wscript.Echo "LUATrace: " & objItem.LUATrace
    Wscript.Echo "T3270Trace: " & objItem.T3270Trace
    iCounter = iCounter + 1
Next

if iCounter > 0 then
    Wscript.Echo "Number of Instances found " & iCounter
else
    Wscript.Echo "No Instances Found"
End If

    iCounter = 0
    Set colItems = objWMIService.ExecQuery("Select * from MsHisTrace_SNABase",,48)
For Each objItem in colItems
    Wscript.Echo "EnabledTraces: " & objItem.EnabledTraces
    Wscript.Echo "InternalMessageTrace: " & objItem.InternalMessageTrace
    Wscript.Echo "LU62Trace: " & objItem.LU62Trace
    Wscript.Echo "T3270Trace: " & objItem.T3270Trace
    iCounter = iCounter + 1
Next

if iCounter > 0 then
    Wscript.Echo "Number of Instances found " & iCounter
else
    Wscript.Echo "No Instances Found"
End If
```

Programming Considerations When Using WMI with Host Integration Server

The following section discusses various issues that you need to know about when programming Windows Management Instrumentation (WMI) with Host Integration Server.

In This Section

Using Host Integration Server and WMI on a Backup Server

There are some restrictions on using Windows Management Instrumentation (WMI) and Host Integration Server 2009 regarding connections to backup servers. The Snabase works to synchronize the information in the COM.CFG configuration file on the primary server across all backup servers. Each backup server has a local copy of the COM.CFG file from this synchronization process. WMI has a limitation that it will not attempt to read the local backup server's copy of COM.CFG if the primary server is alive. This request will always be forwarded to the primary server.

A client that connects to a WMI provider running on a backup server cannot retrieve any information or make configuration changes. This is a limitation of DCOM which does not permit impersonation outside the local computer. When a client on one computer connects to a WMISNA provider on another computer that is a backup server, the client is using DCOM to connect to the backup Host Integration Server computer. When the WMI provider on the backup server tries to access the COM.CFG file from the primary server, this is not allowed by DCOM because the application is trying to impersonate the user across the computer boundary.

You can work around this limitation on Windows 2000 using delegation.

The limitation against accessing a remote COM.CFG file does not apply when the primary server is down. In this case the server will fail-over to a backup and use replicated copies.

Using Duplicate LU Pools with Host Integration Server and WMI

A VBScript ImportExport sample program written in Microsoft Visual Basic Scripting Edition (VBScript) is provided as part of the Host Integration Server SDK. This tool enables configuration information from Host Integration Server to be exported and saved to a text file using Windows Management Instrumentation (WMI) in MOF format. This text file can also be changed and imported using this sample program to change configuration information.

A potential problem using WMI can occur with duplicate LU pools that can be illustrated using this sample program. Typically, exporting and re-importing the MOF file would not create duplicates. However, the Host Integration Server WMI provider allows pool-to-workstation association instances to be duplicated because, by design, duplicates of this type of object are allowed. You can associate the same pool to the same workstation or user multiple times. This is used by emulators to create more sessions for clients. Therefore, you cannot identify one such association from another. The WMISNA provider, WMISNA.DLL, always creates new associations of these types, even if an association with the same pair (Pool, Wks) already exists. This object type is allowed only in this specific case. However, this can create a problem for applications developed using WMI (the Import/Export sample, for example) if the application does not know not to create the duplicates.

The follow sequence illustrates this issue using the ImportExport sample:

1. Use SNA Manager to create a pool workstation association.
2. Export the SNA configuration to a MOF file using the ImportExport utility.
3. Import that same MOF file again using the ImportExport utility.
4. Duplicate pool-workstation associations are created.

The result is that if a client uses the import/export sample or a similar application developed using WMI on a Host Integration Server configuration that has pool-to-workstation associations, then the number of associations will effectively double after running the sample. The workaround using the ImportExport sample would be as follows:

1. Export the configuration to a MOF file.
2. Remove the pool to workstation associations from the MOF file that was just created.
3. Re-import the MOF file.

When importing the configuration from one domain to another using the ImportExport sample or a similar application developed using WMI, then step 2 should be ignored. Typically, WMI applications should copy an existing configuration to a blank configuration file so this condition does not occur.

Messaging Programmer's Guide

This section of the Host Integration Server 2009 SDK describes the extensions and components that make up Microsoft MSMQ-MQSeries Bridge.

For general information about developing for MSMQ-MQSeries Bridge, see Messaging Programmer's Reference.

For sample programs illustratating MSMQ-MQSeries Bridge, see Messaging Samples.

In This Section

MSMQ-MQSeries Bridge Programmer's Guide

MSMQ-MQSeries Bridge Programmer's Guide

The MSMQ-MQSeries Bridge provides the ability to send and receive messages between Message Queuing (also known as MSMQ) and IBM MQSeries easily and efficiently. The MSMQ-MQSeries Bridge Extensions enable a programmer to develop and control how these message transfers will occur and how properties of a message are translated.

The main programming issues when using the MSMQ-MQSeries Bridge Extensions fall into three areas:

- Queue addressing
- Message conversion
- Limitations to specific API functions

Queue addressing deals with how to specify the name of an MQSeries destination queue in a Message Queuing API call, or the name of an MSMQ destination queue in an MQSeries API call. Message conversion deals with how the MSMQ-MQSeries Bridge converts MSMQ message properties to MQSeries message data structures, and how the MSMQ-MQSeries Bridge converts MQSeries message data structures to MSMQ properties. These topics are covered in detail in separate sections. Limitations to the MSMQ-MQSeries Bridge Extensions are discussed in detail in the section on programming considerations.

In This Section

Platforms Supported by MSMQ-MQSeries Bridge Extensions

The MSMQ-MQSeries Bridge Extensions can access message queues on IBM MQSeries systems through SNA LU 6.2 or TCP/IP using Host Integration Server 2009 and MSMQ-MQSeries Bridge:

On Windows 2000, The MSMQ-MQSeries Bridge requires that Message Queuing (also known as MSMQ) be set up as a Message Queuing server, not a workgroup, with routing enabled. MSMQ-MQSeries Bridge Manager, which is used to configure and manage MSMQ-MQSeries Bridge, can be installed on any of the platforms supported by Host Integration Server 2009.

Queue Addressing Using MSMQ-MQSeries Bridge

This section explains how to specify the name of an MQSeries destination queue in a Message Queuing (also known as MSMQ) call, or the name of a Message Queuing destination queue in an MQSeries call. This information is needed to specify the destination queue where you are sending a message.

In This Section

Addressing an MQSeries Queue in Message Queuing

In Message Queuing, address MQSeries queues as if they are on the Message Queuing network. For the Message Queuing computer name, specify the MQSeries Queue Manager name. For the Message Queuing queue name, specify the MQSeries queue name.

For example, if the MQSeries Queue Manager is MQS1, and the queue name is **MQS_QUEUE4**, the Message Queuing path name is **MQS1\MQS_QUEUE4**.

Sending a Message Queuing Message to an MQSeries Queue

To send a message to an MQSeries queue, you follow the normal Message Queuing (also known as MSMQ) procedure, which is to determine the Message Queuing format name corresponding to the path name. More precisely, you must determine the format name of the Message Queuing foreign queue representing the MQSeries queue. If the foreign queue does not already exist, you can create it and determine its format name by calling **MQCreateQueue**. If the foreign queue already exists, you can call **MQPathNameToFormatName**, or you can determine the format name in Message Queuing Explorer.

Call **MQOpenQueue** with the format name argument to open the queue for send access.

Call **MQSendMessage** and specify the destination queue handle returned by **MQOpenQueue**.

In the MSMQ-to-MQSeries direction, MSMQ-MQSeries Bridge sends transacted messages using the MSMQ to MQS message pipe and untransacted messages using the MSMQ to MQS transactional message pipe.

Addressing a Message Queuing Queue in MQSeries

There are two ways to address a Message Queuing (also known as MSMQ) queue from MQSeries:

- By the Message Queuing format name
- By the Message Queuing path name

By either method, you specify the name in the object descriptor (MQOD structure) of the MQSeries message.

Note

MSMQ-MQSeries Bridge supports the following types of format names:

```
PUBLIC=<GUID>
PRIVATE=<machine GUID>\<file number>
DIRECT=OS:<Path name>
```

Note

For detailed addressing syntax and examples, see the section on Object Descriptors under Converting Messages Sent from MQSeries to Message Queuing.

Sending a Message to a Message Queuing Queue in MQSeries

To send a message from MQSeries to Message Queuing (also known as MSMQ), you specify the Message Queuing format or path name of the destination queue in the object descriptor. Call **MQOPEN** to open the queue. Call **MQPUT** or **MQPUT1** to send the message.

The addressing syntax enables you to send a message by either MQS->Message Queuing message pipe or MQS->Message Queuing transactional message pipe.

Converting Messages Using MSMQ-MQSeries Bridge

This section describes how the MSMQ-MQSeries Bridge converts Message Queuing (also known as MSMQ) message properties to MQSeries message data structures and how MQSeries data structures are converted to Message Queuing message properties.

When the MSMQ-MQSeries Bridge transmits a message, it converts the message properties between the Message Queuing and MQSeries formats. When equivalent properties exist in the two systems, the MSMQ-MQSeries Bridge assigns the property values directly. For example, the Message Queuing **messagebody** property is converted to the MQSeries **messagebuffer**. The Message Queuing **messagebodylength** is converted to the MQSeries **messagebufferlength**.

When partially equivalent properties exist in the two systems, the MSMQ-MQSeries Bridge assigns the properties according to conversion rules. For example, the MQSeries property **MQMD.Report** is converted to the Message Queuing properties **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL**.

When a property has no equivalent, the MSMQ-MQSeries Bridge either ignores the property or assigns a default value. For example, the Message Queuing property **PROPID_M_AUTH_LEVEL** refers to a specific Message Queuing authentication method that is not supported by MQSeries. In a message sent from Message Queuing to MQSeries, this property is ignored. In a message received by Message Queuing from MQSeries, the MSMQ-MQSeries Bridge assigns the Message Queuing default value to the property.

You can supplement or override the conversions described here using the Message Queuing message extension property (**PROPID_M_EXTENSION**). For information about overriding the default conversions, see Using Message Extensions.

When you send a message from Message Queuing to IBM MQSeries, MSMQ-MQSeries Bridge converts the Message Queuing message properties to an MQSeries data structure. To do this, MSMQ-MQSeries Bridge maps the various message properties of the Message Queuing message as nearly as possible to equivalent MQSeries fields. The following sections describe the conversion rules by which this is done.

In This Section

Converting Messages Sent from Message Queuing to MQSeries

The information in this section applies to messages that you send from Message Queuing (also known as MSMQ) to MQSeries. For messages sent from MQSeries to Message Queuing, see Converting Messages Sent from MQSeries to Message Queuing.

This section contains two main subsections, which provide essentially the same information but from complementary points of view.

The first section describes the conversion rules from the sender's point of view, and explains how MSMQ-MQSeries Bridge converts each Message Queuing property that you include in a message.

The second section explains the rules from the receiver's point of view. This section describes how MSMQ-MQSeries Bridge builds a complete MQSeries message containing all the needed fields, whether or not they have exact Message Queuing equivalents.

You can supplement or override the conversions described in this section by using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

In This Section

- Converting Message Queuing Properties
- Building an MQSeries Message

Converting Message Queuing Properties

This topic explains how MSMQ-MQSeries Bridge converts the Message Queuing (also known as MSMQ) properties that you include in a message to MQSeries. For information about MQSeries fields that have no Message Queuing equivalents, see Building an MQSeries Message.

In This Section

Message Body (PROPID_M_BODY)

The Message Queuing (also known as MSMQ) message body is equivalent to the MQPUT or MQGET message buffer of MQSeries. The length of the MQPUT buffer is the Message Queuing message body size.

The following table lists the Message Queuing properties and the MQSeries fields to which they are converted.

Message Queuing property	Converted to MQSeries field
PROPID_M_BODY	Message buffer
PROPID_M_BODY_SIZE	Message buffer length

Queue Format Names (PROPID_M_..._QUEUE)

Each Message Queuing (also known as MSMQ) message contains the format name of a destination queue, and optionally the format names of response or administration queues. The MSMQ-MQSeries Bridge converts the names to the equivalent MQSeries object and Queue Manager names.

If a message contains both a response queue and an administration queue, MSMQ-MQSeries Bridge ignores the administration queue.

The following table lists the Message Queuing properties and the MQSeries fields to which they are converted.

Message Queuing properties	**Converted to MQSeries fields**
PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN	MQOD.ObjectName and MQOD.ObjectQMgrName
PROPID_M_RESP_QUEUE and PROPID_M_RESP_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr
PROPID_M_ADMIN_QUEUE and PROPID_M_ADMIN_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr

Message Class (PROPID_M_CLASS)

MSMQ-MQSeries Bridge converts the Message Queuing (also known as MSMQ) message class (PROPID_M_CLASS) to the MQSeries message type and feedback. It translates the message class values according to the following table.

Value of Message Queuing property	**Converted to MQSeries value**	
PROPID_M_CLASS	MQMD.MsgType	MQMD.Feedback
MQMSG_CLASS_NORMAL	MQMT_REQUEST or MQMT_DATAGRAM	MQFB_NONE
MQMSG_CLASS_ACK_REACH_QUEUE	MQMT_REPORT	MQFB_COA
MQMSG_CLASS_ACK_RECEIVE		MQFB_COD
MQMSG_CLASS_NACK_RECEIVE_TIMEOUT		MQFB_EXPIRATION
MQMSG_CLASS_NACK_REACH_QUEUE_TIMEOUT		MQFB_EXPIRATION
MQMSG_CLASS_NACK_Q_EXCEED_QUOTA		MQRC_Q_FULL
MQMSG_CLASS_NACK_ACCESS_DENIED		MQRC_NOT_AUTHORIZED
MQMSG_CLASS_NACK_ERROR		MQFB_APPL_TYPE_ERROR
Any other value		MQFB_NONE

MQMSG_CLASS_NORMAL is converted to **MQMD_REQUEST** if the message includes a response queue (**PROPID_M_RESP_QUEUE**) or if **PROPID_M_RESP_QUEUE** is missing, NULL, or an empty string.

Message Expiration (PROPID_M_TIME...)

Message Queuing (also known as MSMQ) provides two message expiration properties, **PROPID_M_TIME_TO_REACH_QUEUE** and **PROPID_M_TIME_TO_BE_RECEIVED**, both in units of seconds. MQSeries provides a single expiration field, **MQMD.Expiry**, whose units are tenths of a second.

MSMQ-MQSeries Bridge converts the values as listed in the following table.

Value of Message Queuing properties PROPID_M_TIME_TO_REACH_QUEUE and PROPID_M_TIME_TO_BE_RECEIVED	**Converted to MQSeries value of MQMD.Expiry**
Both values are INFINITE	MQEI_UNLIMITED
One or both values are not INFINITE	Ten times the smaller of the two Message Queuing values

Note

Message Queuing typically interprets **INFINITE** as 90 days. In practice, the MSMQ-MQSeries Bridge does not apply the **INFINITE** conversion because Message Queuing decrements the values slightly during transmission. If you need an **MQMD.Expiry** value of exactly **MQEI_UNLIMITED**, you should send this value in the message extension.

Message Acknowledgment (PROPID_M_ACKNOWLEDGE)

MSMQ-MQSeries Bridge supports the Message Queuing (also known as MSMQ) and MQSeries acknowledgment mechanisms. You can send a Message Queuing message to MQSeries and receive an automatic acknowledgment from the MQSeries Queue Manager.

To do this, set the Message Queuing acknowledgment property (**PROPID_M_ACKNOWLEDGE**) to a value that requests an acknowledgment. Also specify the administration or response queue name (**PROPID_M_ADMIN_QUEUE** or **PROPID_M_RESP_QUEUE**), to which the acknowledgment is sent. For more information about queue format names, see Queue Format Names (PROPID_M_..._QUEUE).

MSMQ-MQSeries Bridge converts the acknowledgment property to the MQSeries **MQMD.Report** field, as listed in the following table. When MQSeries receives the message, it returns the appropriate acknowledgment through MSMQ-MQSeries Bridge.

Value of Message Queuing property PROPID_M_ACKNOWLEDGE	**Converted to MQSeries value of MQMD.Report**
MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE	MQRO_EXCEPTION | MQRO_COA
MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE	MQRO_EXCEPTION | MQRO_EXPIRATION | MQRO_COD
MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE	MQRO_EXCEPTION
MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE	MQRO_EXCEPTION | MQRO_EXPIRATION
MQMSG_ACKNOWLEDGMENT_NONE	MQRO_NONE

If both PROPID_M_ACKNOWLEDGE and PROPID_M_JOURNAL are included in a Message Queuing message, the value of the MQSeries **MQMD.Report** field is computed by a bitwise or of the values converted from the two Message Queuing properties. For more information about other Message Queuing properties, see Other Message Queuing Properties with Equivalent Properties.

If the **MSMQ_PROPID_M_ACKNOWLEDGE** property has a value of **MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE**, the value of MQSeries **MQMD.Report** field is computed by a bitwise or **of MQRO_EXCEPTION** and **MQRO_COA**.

If the **MSMQ_PROPID_M_ACKNOWLEDGE** property has a value of **MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE**, the value of MQSeries MQMD.Report field is computed by a bitwise or of **MQRO_EXCEPTION**, **MQRO_EXPIRATION**, and **MQRO_COD**.

If the Message Queuing **PROPID_M_ACKNOWLEDGE** property has a value of **MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE**, the value of MQSeries MQMD.Report field is computed by a bitwise or of **MQRO_EXCEPTION** and **MQRO_EXPIRATION**.

Other Message Queuing Properties with Equivalent Properties

The following Message Queuing (also known as MSMQ) properties have MQSeries equivalents. The MSMQ-MQSeries Bridge converts the values of each property as listed in the table.

Note

To save space in the table, the prefixes PROPID_M_ and MQMD are omitted from the Message Queuing property names and the MQSeries field names, respectively. For example, the first row of data means that **PROPID_M_BODY_TYPE** is converted to MQMD.Format.

Message Queuing property		**Converted to MQSeries**	
PROPID_M_	**Value**	MQMD	**Value**
BODY_TYPE	VT_BSTR Any other value	Format	MQFMT_STRING MQFMT_NONE
CORRELATIONID	Value (20 bytes)	CorrelId	"FQ2Q" + value
DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS	Persistence	MQPER_ PERSISTENT NOT_PERSISTENT
JOURNAL	MQMSG_ DEADLETTER MQMSG_JOURNAL MQMSG_JOURNAL_NONE	Reporta	MQRO_ DEAD_LETTER_Q (Ignored) DISCARD_MSG
LABEL LABEL_LEN	Value	ApplIdentityData	Value (MQCHAR32)
MSGID	Value (20 bytes)	MsgId	"FQ2Q" + value
PRIORITY	0 1 2 3 4 5 6 7	Priority	1 3 4 5 6 7 8 9
SENTTIME	Seconds since Jan. 1, 1970	PutDate PutTime	YYYMMDD format HHMMSSTH format

If both **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL** are included in a Message Queuing message, the **MQSeries MQMD.Report** field is computed by a bitwise or of the values converted from the two Message Queuing queuing properties.

Unconverted Properties

The following Message Queuing (also known as MSMQ) properties have no equivalents in MQSeries. The MSMQ-MQSeries Bridge ignores these properties and does not transmit them to MQSeries:

- **PROPID_M_APPSPECIFIC**
- **PROPID_M_ARRIVEDTIME**
- **PROPID_M_AUTH_LEVEL**
- **PROPID_M_AUTHENTICATED**
- **PROPID_M_CONNECTOR_TYPE**
- **PROPID_M_DEST_SYMM_KEY**
- **PROPID_M_DEST_SYMM_KEY_LEN**
- **PROPID_M_ENCRYPTION_ALG**
- **PROPID_M_HASH_ALG**
- **PROPID_M_PRIV_LEVEL**
- **PROPID_M_PROV_NAME**
- **PROPID_M_PROV_NAME_LEN**
- **PROPID_M_PROV_TYPE**
- **PROPID_M_SECURITY_CONTEXT**
- **PROPID_M_SENDER_CERT**
- **PROPID_M_SENDER_CERT_LEN**
- **PROPID_M_SENDERID**
- **PROPID_M_SENDERID_LEN**
- **PROPID_M_SENDERID_TYPE**
- **PROPID_M_SIGNATURE**
- **PROPID_M_SIGNATURE_LEN**
- **PROPID_M_SRC_MACHINE_ID**
- **PROPID_M_TRACE**
- **PROPID_M_VERSION**

Transaction Properties

The following Message Queuing (also known as MSMQ) properties are not converted to MQSeries fields or values:

- **PROPID_M_XACT_STATUS_QUEUE**
- **PROPID_M_XACT_STATUS_QUEUE_LEN**

For more information about transactions, see Transaction Support Using MSMQ-MQSeries Bridge.

Building an MQSeries Message

This section explains how the MSMQ-MQSeries Bridge builds a complete MQSeries message, including all needed fields whether or not they have Message Queuing (also known as MSMQ) equivalents. The conversion to MQSeries fields from Message Queuing properties is listed from the MQSeries perspective.

For information about these same conversion rules from the Message Queuing perspective, see Converting Message Queuing Properties.

In This Section

- Message Buffer
- Object Descriptor (MQOD)
- Message Descriptor (MQMD)

Message Buffer

The MQPUT or MQGET message buffer of MQSeries is equivalent to the message body property of Message Queuing (also known as MSMQ). The length of the MQPUT buffer is the Message Queuing message body size.

The following table lists the MQSeries fields and the Message Queuing properties from which they are converted.

MQSeries fields	Converted from Message Queuing property
Message buffer	PROPID_M_BODY
Message buffer length	PROPID_M_BODY_SIZE

Object Descriptor (MQOD)

The MSMQ-MQSeries Bridge retrieves the MQSeries object descriptor fields from the Message Queuing (also known as MSMQ) format name of the destination queue.

The following table lists the MQSeries fields and the Message Queuing properties from which they are converted.

MQSeries fields	Converted from Message Queuing property
MQOD.ObjectName and MQOD.ObjectQMgrName	PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN

Message Descriptor (MQMD)

Some fields of the MQSeries message descriptor have no equivalent in Message Queuing (also known as MSMQ). The MSMQ-MQSeries Bridge assigns default values to these fields. Alternatively, you can pass explicit values of the MQMD fields using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

The following table lists the MQSeries fields and the default value assigned by MSMQ-MQSeries Bridge.

MQSeries MQMD fields	Default value assigned by MSMQ-MQSeries Bridge
MQMD.AccountingToken	MQACT_NONE
MQMD.CodeCharSetId	MQCCSI_Q_MGR
MQMD.Encoding	MQENC_NATIVE
MQMD.PutApplName	NULL
MQMD.PutApplType	NULL
MQMD.StrucId	MQMD_STRUC_ID
MQMD.Version	MQMD_VERSION_1

Some fields of the MQSeries message descriptor have no equivalent in Message Queuing and the MSMQ-MQSeries Bridge does not assign default values to these fields. You can assign explicit values for these MQMD fields using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

The following table lists the MQSeries fields for which no default value is assigned by MSMQ-MQSeries Bridge.

MQSeries MQMD fields	Default value assigned by MSMQ-MQSeries Bridge
MQMD.UserIdentifier	No default value is assigned

Many of the MQMD fields are equivalent to one or more Message Queuing properties. The conversion rules are listed in the following table.

You can override the conversion rules by passing explicit MQMD values in the Message Queuing message extension property.

To save space in the table, the prefix MQMD. is omitted from the MQSeries field names. For example, the first row of data means that MQMD.ApplIdentityData is built from the Message Queuing properties **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN**.

MQSeries MQMD field	MQSeries MQMD field value	Converted from Message Queuing property
ApplIdentity	Value (MQCHAR32)	The value of PROPID_M_LABEL and PROPID_M_LABEL_LEN
CorrelId	"FQ2Q" + value	The value of PROPID_M_CORRELATIONID (20 bytes)
Expiry	MQEI_UNLIMITED	Both PROPID_M_TIME_TO_BE_RECEIVED and PROPID_M_TIME_TO_REACH_QUEUE have value of INFINITE
Expiry	10 times the smaller of the two Message Queuing values	PROPID_M_TIME_TO_BE_RECEIVED or PROPID_M_TIME_TO_REACH_QUEUE have a value that is not INFINITE
Feedback	MQFB_EXPIRATION	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_RECEIVE_TIMEOUT
Feedback	MQFB_APPL_TYPE_ERROR	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_REACH_QUEUE_TIMEOUT
Feedback	MQRC_Q_FULL	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_Q_EXCEED_QUOTA
Feedback	MQRC_NOT_AUTHORIZED	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_ACCESS_DENIED
Feedback	MQFB_COA	PROPID_M_CLASS has a value of MQMSG_CLASS_ACK_REACH_QUEUE

Feedback	MQFB_COD	PROPID_M_CLASS has a value of MQMSG_CLASS_ACK_RECEIVE
Feedback	MQFB_NONE	PROPID_M_CLASS has any other value
Format	MQFMT_STRING	PROPID_M_BODY_TYPE has a value of VT_BSTR
Format	MQFMT_NONE	PROPID_M_BODY_TYPE has any other value
MsgId	"FQ2Q" + value	The value of PROPID_M_MSGID (20 bytes)
MsgType	MQMT_DATAGRAM	PROPID_M_CLASS has a value of MQMSG_CLASS_NORMAL
MsgType	MQMT_REQUESTREPORT	PROPID_M_CLASS has any other value
Persistence	MQPER_PERSISTENT	PROPID_M_DELIVERY has a value of MQMSG_DELIVERY_RECOVERABLE
Persistence	MQPER_NOT_PERSISTENT	PROPID_M_DELIVERY has a value of MQMSG_DELIVERY_EXPRESS
Priority	1	PROPID_M_PRIORITY has a value of 0
Priority	3	PROPID_M_PRIORITY has a value of 1
Priority	4	PROPID_M_PRIORITY has a value of 2
Priority	5	PROPID_M_PRIORITY has a value of 3
Priority	6	PROPID_M_PRIORITY has a value of 4
Priority	7	PROPID_M_PRIORITY has a value of 5
Priority	8	PROPID_M_PRIORITY has a value of 6
Priority	9	PROPID_M_PRIORITY has a value of 7
PutDate	YYYMMDD format	The date from the Message Queuing PROPID_M_SENTTIME property which has a value of seconds since January 1, 1970
PutTime	HHMMSSTH format	The time from the Message Queuing PROPID_M_SENTTIME property which has a value of seconds since January 1, 1970
ReplyToQ	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_RESP_QUEUE if this property is included and is not NULL or an empty string
ReplyToQ	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_ADMIN_QUEUE if PROPID_M_RESP_QUEUE is not included or is NULL or an empty string
ReplyToQMgr	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_RESP_QUEUE if this property is included and is not NULL or an empty string
ReplyToQMgr	Retrieved from Message Queuing format name	The Message Queuing format name from PROPID_M_ADMIN_QUEUE if PROPID_M_RESP_QUEUE is not included or is NULL or an empty string
Report	MQRO_EXCEPTION|COA	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
Report	MQRO_EXCEPTION|EXPIRATION|COD	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE
Report	MQRO_EXCEPTION	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
Report	MQRO_EXCEPTION|EXPIRATION	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE

Report	MQRO_NONE	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NONE
Report	MQRO_DEAD_LETTER_Q	PROPID_M_JOURNAL has a value of MQMSG_DEADLETTER
Report	The Message Queuing value is ignored	PROPID_M_JOURNAL has a value of MQMSG_JOURNAL
Report	MQRO_DISCARD_MSG	PROPID_M_JOURNAL has a value of MQMSG_JOURNAL_NONE

In practice, the MSMQ-MQSeries Bridge does not assign **MQEI_UNLIMITED** as value for MQMD.Expiry because Message Queuing interprets INFINITE values typically as 90 days and decrements them slightly during transmission. To assign an MQMD.Expiry value of exactly **MQEI_UNLIMITED**, send this value in the message extension.

The MSMQ-MQSeries Bridge assigns **MQMT_DATAGRAM** as value for MQMD.MsgType if the Message Queuing **PROPID_M_RESP_QUEUE** is missing, NULL, or an empty string. Otherwise a value of **MQMT_REQUEST** is assigned to MQMD.MsgType.

If both **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL** are included in a Message Queing message, MQMD.Report is computed by a bitwise or of the values converted from the two Message Queuing properties.

Converting Messages Sent from MQSeries to Message Queuing

When you send a message from IBM MQSeries to Microsoft® Message Queuing (also known as MSMQ), the MSMQ-MQSeries Bridge converts the message from an MQSeries data structure to a Message Queuing message property. o do this, MSMQ-MQSeries Bridge maps the various data fields of the MQSeries message as nearly as possible to equivalent Message Queuing message properties.

This section describes the conversion rules by which this is done. The information in this section applies to messages that you send from MQSeries to Message Queuing. For messages sent from Message Queuing to MQSeries, see Converting Messages Sent from Message Queuing to MQSeries.

The section contains two main subsections, which provide essentially the same information, but from complementary points of view. The first section describes the conversion rules from the sender's point of view, and explains how the MSMQ-MQSeries Bridge converts each MQSeries field that you include in a message. The second section explains the rules from the receiver's point of view. Use this section to learn how MSMQ-MQSeries Bridge builds a complete Message Queuing message containing all the needed properties, whether or not they have exact MQSeries equivalents.

Besides the conversions described in this section, the MSMQ-MQSeries Bridge transmits the original MQSeries message descriptor fields in the Message Queuing message extension property (**PROPID_M_EXTENSION**).

In This Section

- Converting MQSeries Fields
- Building a Message Queuing Message

Converting MQSeries Fields

This section explains how the MSMQ-MQSeries Bridge converts the fields of an MQSeries message to Message Queuing (also known as MSMQ). For information about Message Queuing properties that have no MQSeries equivalents, see Building a Message Queuing Message.

In This Section

Message Buffer

The MQGET or MQPUT buffer of MQSeries is equivalent to the message body property of Message Queuing (also known as MSMQ).

The following table lists the MQSeries fields and the Message Queuing properties to which they are converted.

MQSeries fields	Converted to Message Queuing property
Message buffer	PROPID_M_BODY
Message buffer length	PROPID_M_BODY_SIZE

Object Descriptor (MQOD)

The MSMQ-MQSeries Bridge converts the MQSeries remote Queue Manager and queue names to the Message Queuing (also known as MSMQ) destination queue name. The MQSeries fields are interpreted as a Message Queuing format name or path name.

The following table lists the MQSeries fields and the Message Queuing properties that they are converted to.

MQSeries fields	**Converted to Message Queuing property**
MQOD.ObjectName and MQOD.ObjectQMgrName	PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN

Character Substitutions in Object Descriptor Conversion

Certain characters are supported in Message Queuing (also known as MSMQ) format names, but not in MQSeries names. When you assign the MQSeries MQOD.ObjectName, the MSMQ-MQSeries Bridge performs character substitutions to the Message Queuing format names. The following table lists special characters in MQSeries names and what MSMQ-MQSeries Bridge converts these characters to in Message Queuing format names.

Characters in MQSeries MQOD field names	**Characters substituted in Message Queuing format names**
/ (forward slash))	: (colon) or \ (backslash)
_ (underscore)	- (hyphen) or = (equal)
P_ (at start of MQOD.ObjectName)	PRIVATE=

The MSMQ-MQSeries Bridge converts the characters back when it transmits the MQSeries message to Message Queuing. The characters are interpreted according to context to generate a legal Message Queuing name. For example, MSMQ-MQSeries Bridge converts the format name:

```
DIRECT_OS/MACHINE2/QUEUE4
```

to the following:

```
DIRECT=OS:MACHINE2\QUEUE4.
```

Note that this character substitution is only for format names, not for computer or path names. If you want to address Message Queuing path names, do not include hyphens or other characters not supported by MQSeries. For example, the path name:

```
MACHINE2\MY-QUEUE
```

is legal in Message Queuing, but you cannot specify the hyphen character in MQSeries.

Format Name Method of Object Descriptor Conversion

Subject to the following conditions, the MSMQ-MQSeries Bridge interprets the MQSeries MQOD.ObjectName field as the format name of the Message Queuing (also known as MSMQ) destination queue:

- The MQOD.ObjectQMgrName is an MQSeries alias for a Message Queuing computer.
- The MQOD.ObjectName begins with PUBLIC_, P_, or DIRECT_OS/.

If these conditions apply, the MSMQ-MQSeries Bridge converts the MQSeries MQOD.ObjectName to the Message Queuing format name of the destination queue using one of the following methods based on the value of **MQOD.ObjectName**:

```
PUBLIC=<GUID>
PRIVATE=<machine GUID>\<file number>
DIRECT=OS:<path name>.
```

If you know the globally unique identifier (GUID) of the destination queue, the PUBLIC=<GUID> syntax gives better performance than the DIRECT=OS:<path name> syntax. Also note that nontransacted private queues are supported only on the computer running the MSMQ-MQSeries Bridge.

Path Name Method of Object Descriptor Conversion

If the conditions for the format name method do not hold, the MSMQ-MQSeries Bridge interprets MQOD.ObjectQMgrName\MQOD.ObjectName as a Message Queuing (also known as MSMQ) path name. The remote Queue Manager name must be an alias for a computer running Message Queuing that you have previously defined in MQSeries.

For example, if MQOD.ObjectQMgrName is MACHINE2 and MQOD.ObjectName is QUEUE4, the MSMQ-MQSeries Bridge sends the message to a Message Queuing queue having the path name MACHINE2\QUEUE4.

The MSMQ-MQSeries Bridge determines the Message Queuing format name corresponding to this path name to forward the message.

Note
The MQSeries name fields are limited to 48 characters each. If the path name is longer than this, use the format name method instead.

Queue Alias Method of Object Descriptor Conversion

Optionally, you can address a Message Queuing (also known as MSMQ) queue using an MQSeries queue alias. If you use this method, set MQOD.ObjectName to the queue alias. Leave MQOD.ObjectQMgrName blank, or set it to the MQSeries Queue Manager where the transmission queue is located.

Examples of Object Descriptor Conversion

In the following examples, you want to send a message to a Message Queuing (also known as MSMQ) destination having the following identifiers:

```
Machine name = MACHINE2
Queue name = QUEUE4
GUID = A56F41B4-9869-11D0-AF8F-0000E8D1C3A7
```

MSMQ-MQSeries Bridge is installed on a computer called BRIDGEMQ1. You have defined the aliases BRIDGEMQ1 and BRIDGEMQ1% for this computer in MQSeries. In the MSMQ-MQSeries Bridge Manager, you have configured BRIDGEMQ1 for MQS->Message Queuing message pipe and BRIDGEMQ1% for MQS->Message Queuing transactional message pipe.

You may address a message to this queue in any of the following ways:

Format name method

Using the format name method and MQS->Message Queuing message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "BRIDGEMQ1"
MQOD.ObjectName = "PUBLIC_A56F41B4_9869_11D0_AF8F_0000E8D1C3A7"
```

- or -

```
MQOD.ObjectQMgrName = "BRIDGEMQ1"
MQOD.ObjectName = "DIRECT_OS/MACHINE2/QUEUE4"
```

Using the format name method and MQS->Message Queuing transactional message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "BRIDGEMQ1%"
MQOD.ObjectName = "PUBLIC_A56F41B4_9869_11D0_AF8F_0000E8D1C3A7"
```

- or -

```
MQOD.ObjectQMgrName = "BRIDGEMQ1%"
MQOD.ObjectName = "DIRECT_OS/MACHINE2/QUEUE4"
```

Optionally, you can define the MQSeries aliases MACHINE2 and MACHINE2% for the Message Queuing destination computer. You now have two additional ways to address the queue.

Using the path name method and MQS->Message Queuing message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "MACHINE2"
MQOD.ObjectName = "QUEUE4"
```

Using the path name method and MQS->Message Queuing transactional message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "MACHINE2%";
MQOD.ObjectName = "QUEUE4"
```

In yet another option, you can define the MQSeries aliases QUEUE4 and QUEUE4% for the Message Queuing destination queues. If you do this, you can address the queue using the following syntax.

Using the queue alias method and normal service, the MQSeries name would become:

```
MQOD.ObjectQMgrName = ""
MQOD.ObjectName = "QUEUE4"
```

Using the queue alias method and high service, the MQSeries name would become:

```
MQOD.ObjectQMgrName = ""
MQOD.ObjectName = "QUEUE4%"
```

Message Descriptor (MQMD)

The MSMQ-MQSeries Bridge converts most of the MQSeries field values to Message Queuing (also known as MSMQ) property values.

MQMD.Report Field

The MSMQ-MQSeries Bridge supports the MQSeries and Message Queuing (also known as MSMQ) acknowledgment mechanisms. You can send a Message Queuing message to MQSeries and receive an automatic acknowledgment from the Message Queuing Queue Manager.

To do this, set the MQMD.Report field of the MQSeries message to a value that requests an acknowledgment. Also set the MQMD.ReplyToQ and MQMD.ReplyToQMgr fields, which specify where the acknowledgment is sent.

The MSMQ-MQSeries Bridge converts MQMD.Report to the Message Queuing acknowledgment property. When Message Queuing receives the message, it returns the appropriate acknowledgment thorough the MSMQ-MQSeries Bridge.

The MSMQ-MQSeries Bridge also supports the MQSeries and Message Queuing dead letter mechanism. For this purpose, MSMQ-MQSeries Bridge converts the MQMD.Report values to the Message Queuing journaling property.

The conversions are listed in the following table.

Value of MQSeries field MQMD.Report	**Converted to Message Queuing property and value**
MQRO_NONE	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NONE
MQRO_EXCEPTION	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXCEPTION_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXCEPTION_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXPIRATION	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_EXPIRATION_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_EXPIRATION_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_COA	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_COA_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_COA_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_DEAD_LETTER_Q	The value of PROPID_M_JOURNAL is set to MQMSG_DEADLETTER
MQRO_DISCARD_MSG	The value of PROPID_M_JOURNAL is set to MQMSG_JOURNAL_NONE
MQRO_NEW_MSG_ID	(Not converted)
MQRO_PASS_MSG_ID	(Not converted)
MQRO_COPY_MSG_ID_TO_CORREL_ID	(Not converted)
MQRO_PASS_CORREL_ID	(Not converted)

Note

For these report values, the MSMQ-MQSeries Bridge duplicates part or all of the message buffer in the Message Queuing message extension (**PROPID_M_EXTENSION**). The increased message size may degrade performance.

MQMD.MsgType and MQMD.Feedback Fields

The values of the MQSeries MQMD.MsgType and MQMD.Feedback fields are converted to the Message Queuing (also known as MSMQ) message class property.

The conversions are listed in the following table based on the value of MQMD.MsgType when MQMD.Feedback is MQFB_NONE.

Value of MQSeries MQMD.MsgType	Converted to value of Message Queuing PROP_M_CLASS
MQMT_SYSTEM_FIRST	MQMSG_CLASS_NORMAL
MQMT_SYSTEM_LAST	MQMSG_CLASS_NORMAL
MQMT_DATAGRAM	MQMSG_CLASS_NORMAL
MQMT_REQUEST	MQMSG_CLASS_NORMAL
MQMT_REPLY	MQMSG_CLASS_NORMAL
MQMT_APPL_FIRST	MQMSG_CLASS_NORMAL
MQMT_APPL_LAST	MQMSG_CLASS_NORMAL

The conversions are listed in the following table based on the value of MQMD.Feedback when MQMD.MsgType is MQMT_REPORT.

Value of MQSeries MQMD.Feedback	Converted to value of Message Queuing PROP_M_CLASS
MQFB_EXPIRATION	MQMSG_CLASS_NACK_RECEIVE_TIMEOUT
MQFB_COA	MQMSG_CLASS_ACK_REACH_QUEUE
MQFB_COD	MQMSG_CLASS_ACK_RECEIVE
MQFB_APPL_TYPE_ERROR	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_ZERO	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_NEGATIVE	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_TOO_BIG	MQMSG_CLASS_NACK_ERROR
MQFB_BUFFER_OVERFLOW	MQMSG_CLASS_NACK_ERROR
MQFB_LENGTH_OFF_BY_ONE	MQMSG_CLASS_NACK_ERROR
MQFB_NONE	(Not converted)
MQFB_SYSTEM_FIRST	(Not converted)
MQFB_SYSTEM_LAST	(Not converted)
MQFB_APPL_FIRST	(Not converted)
MQFB_APPL_LAST	(Not converted)
MQFB_TM_ERROR	(Not converted)
MQFB_IIH_ERROR	(Not converted)
MQFB_NOT_AUTHORIZED_FOR_IMS	(Not converted)
MQFB_IMS_ERROR	(Not converted)
MQFB_IMS_FIRST	(Not converted)

MQFB_IMS_LAST	(Not converted)
MQFB_QUIT	(Not supported)
MQRC_NOT_AUTHORIZED	MQMSG_CLASS_NACK_ACCESS_DENIED
MQRC_Q_FULL	MQMSG_CLASS_NACK_Q_EXCEED_QUOTA
MQRC_PERSISTENT_NOT_ALLOWED	MQMSG_CLASS_NACK_ERROR
MQRC_MSG_TOO_BIG_FOR_Q_MGR	MQMSG_CLASS_NACK_ERROR
MQRC_MSG_TOO_BIG_FOR_Q	MQMSG_CLASS_NACK_ERROR
MQRC_PUT_INHBITED	(Not converted)

MQMD.ReplyToQ and MQMD.ReplyToQMgr Fields

The MSMQ-MQSeries Bridge converts the MQSeries ReplyToQMgr and ReplyToQ fields to a Message Queuing (also known as MSMQ) format name. The name is assigned both to the response queue property and to the administration queue property of the new Message Queuing message.

The MSMQ-MQSeries Bridge interprets the **ReplyToQMgr** and the **ReplytoQ** fields in the same way as the destination queue name.

If MQMD.ReplyToQMgr is the MSMQ-MQSeries Bridge computer name and MQMD.ReplyToQ begins with PUBLIC_, P_, or DIRECT_OS/, MSMQ-MQSeries Bridge interprets MQMD.ReplyToQ as a Message Queuing format name.

Otherwise, the MSMQ-MQSeries Bridge interprets MQMD.ReplyToQMgr\MQMD.ReplyToQ as a Message Queuing path name and determines the Message Queuing format name.

The following table lists the MQSeries fields and the Message Queuing properties to which they are converted.

MQSeries fields	**Converted to Message Queuing property**
MQOD.ReplyToQMgr and MQOD.ReplyToQ	PROPID_M_RESP_QUEUE
MQOD.ReplyToQMgr and MQOD.ReplyToQ	PROPID_M_ADMIN_QUEUE (same value as PROPID_M_RESP_QUEUE)

Other MQMD Fields

The following table lists the conversions of additional MQMD fields, in addition to the ones described previously, to Message Queuing properties.

Note
To save space in the table, the prefixes MQMD and PROPID_M_ are omitted from the MQSeries field names and the Message Queuing property names, respectively. For example, the first row of data means that MQMD.ApplIdentityData is converted to **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN**.

MQSeries field		**Converted to Messa ge Queuing**	
MQMD.	**Value**	**PROPID_M_**	**Value**
ApplIdenti tyData	Value (MQCHAR32)	LABEL	Value
CorrelId	Value (MQBYTE24)	CORRELATIONID	Last 20 bytes of value
Expiry	MQEI_UNLIMITED Value > 0 (t enths of seconds)	TIME_TO_BE_RECEIVE D	INFINITE Value/10 (seconds)
Format	MQFMT_STRING Any other va lue	BODY_TYPE	VT_BSTR Not converted
Persistenc e	MQPER_ PERSISTENT NOT_PE RSISTENT	DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS
Priority	0, 1 2, 3 4 5 6 7 8 9	PRIORITY	0 1 2 3 4 5 6 7
UserIdenti fier	Value	SENDERID	SID value (if the user is registered in Windows 2000 Not conv erted (if the user is not registered)

Unconverted MQSeries MQMD Fields

The following MQSeries fields have no equivalents in Message Queuing (also known as MSMQ). The MSMQ-MQSeries Bridge ignores these fields and does not transmit them to Message Queuing.

Like all MQMD fields, MSMQ-MQSeries Bridge stores the fields in the Message Queuing message extension property:

- MQMD.AccountingToken
- MQMD.ApplOriginData
- MQMD.BackoutCount
- MQMD.Encoding
- MQMD.MsgId
- MQMD.PutApplName
- MQMD.PutApplType
- MQMD.PutDate
- MQMD.PutTime
- MQMD.StrucId

When the value of MQMD.CodeCharSetID is **MQCCSI_Q_QMG**, the MSMQ-MQSeries Bridge ignores this field and does not transmit it to Message Queuing. When the value of MQMD.CodeCharSetID is **MQCCSI_Q_QMG**, The MSMQ-MQSeries Bridge does not support this value.

When the value of MQMD.Version is **MQPMO_VERSION_1**, the MSMQ-MQSeries Bridge ignores this field and does not transmit it to Message Queuing.

Building a Message Queuing Message

This section explains how the MSMQ-MQSeries Bridge builds a complete Message Queuing (also known as MSMQ) message, including all needed properties, whether or not they have MQSeries equivalents.

Message Body (PROPID_M_BODY)

The Message Queuing (also known as MSMQ) message body is equivalent to the MQPUT or MQGET message buffer of MQSeries. The length of the MQPUT buffer is the Message Queuing message body size.

The following table lists the Message Queuing properties and the MQSeries fields from which they are converted.

Message Queuing property	Converted from MQSeries field
PROPID_M_BODY	Message buffer
PROPID_M_BODY_SIZE	Message buffer length

Queue Format Names (PROPID_M_..._QUEUE)

MSMQ-MQSeries Bridge retrieves the Message Queuing (also known as MSMQ) format names of the destination, response, and administration queues from the MQSeries queue and Queue Manager names.

The following table lists the Message Queuing properties and the MQSeries fields from which they are converted.

Message Queuing properties	Converted from MQSeries fields
PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN	MQOD.ObjectName and MQOD.ObjectQMgrName
PROPID_M_RESP_QUEUE and PROPID_M_RESP_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr
PROPID_M_ADMIN_QUEUE and PROPID_M_ADMIN_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr

Message Class (PROPID_M_CLASS)

The MSMQ-MQSeries Bridge assigns the Message Queuing (also known as MSMQ) message class based on the MQSeries MQMD.MsgType and MQMD.Feedback values. For detailed information, see MQMD.MsgType and MQMD.Feedback Fields.

The following table lists the Message Queuing properties and the MQSeries fields from which they are converted.

Message Queuing properties	Converted from MQSeries fields
PROPID_M_CLASS	MQMD.MsgType and MQMD.Feedback

Message Expiration (PROPID_M_TIME...)

The MSMQ-MQSeries Bridge converts the MQSeries MQMD.Expiry value (in tenths of seconds) to the Message Queuing (also known as MSMQ) **PROPID_M_TIME_TO_BE_RECEIVED** (in seconds). If MQMD.Expiry is set to **MQEI_UNLIMITED**, the value of Message Queuing **PROPID_M_TIME_TO_BE_RECEIVED** is set to INFINITE. For other values of MQMD.Expiry greater than zero, the value of Message Queuing **PROPID_M_TIME_TO_BE_RECEIVED** is converted by dividing MQMD.Expiry by 10. The MSMQ-MQSeries Bridge does not set **PROPID_M_TIME_TO_REACH_QUEUE**.

Value of Message Queuing properties	Converted from MQSeries fields
PROPID_M_TIME_TO_BE_RECEIVED	MQMD.Expiry

Message Acknowledgment and Journaling (PROPID_M_ACKNOWLEDGE, PROPID_M_JOURNAL)

The Message Queuing (also known as MSMQ) message acknowledgment and journaling are converted from values of MQMD.Report.

Message Queuing property	Converted from MQSeries
PROPID_M_ACKNOWLEDGE PROPID_M_JOURNAL	MQMD.Report

Other Message Queuing Properties (PROPID_M_...)

Some Message Queuing (also known as MSMQ) properties have no equivalent in MQSeries. The MSMQ-MQSeries Bridge

assigns values to these properties as listed in the following table.

Message Queuing property	Value assigned by MSMQ-MQSeries Bridge
PROPID_M_APPSPECIFIC	None
PROPID_M_AUTH_LEVEL	Default
PROPID_M_CONNECTOR_TYPE	None
PROPID_M_DEST_QUEUE	Default
PROPID_M_DEST_QUEUE_LEN	Default
PROPID_M_DEST_SYMM_KEY	None
PROPID_M_ENCRYPTION_ALG	None
PROPID_M_HASH_ALG	None
PROPID_M_MSGID	Assigned by Message Queuing
PROPID_M_PRIV_LEVEL	Default
PROPID_M_PROV_NAME	None
PROPID_M_PROV_TYPE	None
PROPID_M_SECURITY_CONTEXT	Default
PROPID_M_SENDER_CERT	Default
PROPID_M_SENTTIME	Time when MSMQ-MQSeries Bridge transmits the message to Message Queuing
PROPID_M_SIGNATURE	None
PROPID_M_SRC_MACHINE_ID	GUID of the MSMQ-MQSeries Bridge machine
PROPID_M_TRACE	Default
PROPID_M_VERSION	0x0010

Equivalent Message Queuing Properties

The following Message Queuing (also known as MSMQ) properties have MQSeries equivalents. The MSMQ-MQSeries Bridge converts the values of each property as listed in the table.

Note

To save space in the table, the prefixes PROPID_M_ and MQMD. are omitted from the Message Queuing property names and the MQSeries field names, respectively. For example, the first row of data means that PROPID_M_BODY_TYPE is converted fr om MQMD.Format.

Message Que uing property		Converted fr om MQSerie s	
PROPID_M_	**Value**	**MQMD.**	**Value**

BODY_TYPE	VT_BSTR Not converted (default)	Format	MQFMT_STRING Any other value
CORRELATION ID	Last 20 bytes of value	MsgId	Value (MQBYTE24)
DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS	Persistence	MQPER_ PERSISTENT NOT_PERSISTENT
LABEL LABEL_L EN	Value	ApplIdentityD ata	Value (MQCHAR32)
PRIORITY	0 1 2 3 4 5 6 7	Priority	0, 1 2, 3 4 5 6 7 8 9
SENDERID SE NDERID_TYPE	SID value MQMSG_SENDERID_TYPE_ SID Not converted MQMSG_SENDERID_TYPE_ NONE	UserIdentifier	Value, if the user is registered in Windows 2000 If the user is not registered in Windows 2000

MSMQ-MQSeries Bridge Extensions Mechanism

Besides the automatic conversion of Microsoft® Message Queuing (also known as MSMQ) and IBM MQSeries messages, the MSMQ-MQSeries Bridge provides a mechanism for sending and receiving explicit MQSeries field values. The MSMQ-MQSeries Bridge Extension Property API supports the message extension property (**PROPID_M_EXTENSION**) of the Message Queuing server. The message extension property provides a way for applications to attach any type of data—in essence, custom properties—to a Message Queuing message.

Similar to the Message Queuing message body property (**PROPID_M_BODY**), the message extension can have any length. However, the message extension has a defined structure that lets an application label its data with a globally unique identifier (GUID) code. Applications can attach multiple extension fields, each labeled with its own GUID and all included in a single message extension property. This is done using the Message Queuing message extension property (**PROPID_M_EXTENSION**).

In This Section

Data Structure of a Message Extension

A message extension is a Message Queuing (also known as MSMQ) message property of arbitrary length. The property symbol of a message extension is **PROPID_M_EXTENSION** and its type indicator is VT_UI1|VT_VECTOR. A message extension is a sequential buffer containing any number of Message Queuing extension fields.

Each extension field comprises three subfields, as listed in the following table.

Subfield	Length of subfield (bytes)	Description
GUID	16	A GUID identifier, typically of the application that created the extension field.
Length	4	The length of the data subfield in bytes.
Data	Value of the length subfield	Any data that is part of the message extension.

For use with the MSMQ-MQSeries Bridge, the GUID identifier is set to the MSMQ-MQSeries Bridge GUID value.

The Message Queuing message extension length property, **PROPID_M_EXTENSION_LEN**, is of type indicator VT_UI4 and represents the overall size in bytes of all message extensions attached to a message. Message Queuing sets the message extension length automatically when you send a message. When you receive or peek at a message, you can look into the message extension length to detect whether the message contains any message extension fields and to determine the necessary receive buffer size.

The MSMQ-MQSeries Bridge Extension API functions work with an alternative data representation for a message extension, called an **EP** object. An **EP** object contains the same fields and subfields as a message extension, but in a format adapted for programming.

How MSMQ-MQSeries Bridge Creates a Message Extension

When the MSMQ-MQSeries Bridge processes a message from MQSeries, it creates a **PROPID_M_EXTENSION** property, which it includes in the message that it transmits to Message Queuing (also known as MSMQ).

In This Section

MQMD Extension Field

Ordinarily, the message extension contains a single extension field with the following structure:

- The MSMQ-MQSeries Bridge globally unique identifier (GUID) code is stored in the GUID subfield of the extension.
- The size of MQMD is stored in the length subfield of the extension.
- The MQMD is copied byte-for-byte into the data buffer of the extension.

The MSMQ-MQSeries Bridge GUID is the value of the sg_MSMQExtMQMD constant which is defined in the Mqsrext.h include file found in the SDK\Include subdirectory.

The MQMD extension has the following GUID for MQMD version 2.

```
static const GUID sg_MSMQExtMQMDE =
{ 0x18ae68f5, 0x989b, 0x11d3,
    { 0x8d, 0xf9, 0x0, 0x0, 0xf8, 0x1a,  0xea, 0x1f }
};
```

Error Extension Field

If the MSMQ-MQSeries Bridge encounters an MQSeries error when it transmits a message from Message Queuing (also known as MSMQ), it records the error in the extension property and places the message on the dead letter queue.

To do this, the MSMQ-MQSeries Bridge adds an extension property to the Message Queuing message, if it does not already exist. Within the extension property, MSMQ-MQSeries Bridge creates an extension field containing the following data:

- The globally unique identifier (GUID) subfield contains a MSMQ-MQSeries Bridge error GUID (different from the GUID used for MQMD).
- The length subfield contains the value 4.
- The data subfield contains a reason code, identical to the codes returned by the MQSeries function MQPUT.

The MSMQ-MQSeries Bridge error GUID is the value of the sg_MSMQExtReasonCode constant, which is defined in the Mqsrext.h include file found in the SDK\Include subdirectory.

If wanted, a Message Queuing application can read messages from the dead letter queue and interpret the reason codes.

Other Extension Fields

If you send an MQSeries message having certain values of MQMD.Report, the MSMQ-MQSeries Bridge adds a second extension field to the new Message Queuing (also known as MSMQ) message. This field is for internal use only, not for use in your applications. The MSMQ-MQSeries Bridge distinguishes the Report extension field from the MQMD and error extension fields by labeling them with different globally unique identifiers (GUIDs).

For more information about other extension fields, see Converting Messages Sent from MQSeries to Message Queuing.

How MSMQ-MQSeries Bridge Converts a Message Extension

If you send a Message Queuing (also known as MSMQ) message including a message extension to MQSeries, the MSMQ-MQSeries Bridge converts the extension in the following way:

- The MSMQ-MQSeries Bridge looks for an extension field identified by the MSMQ-MQSeries Bridge GUID. If it finds one, it reads the MQMD structure from the extension field.
- MSMQ-MQSeries Bridge ignores any other extension fields that may be present in the message extension.
- MSMQ-MQSeries Bridge includes the MQMD structure that it reads from the extension field in the new MQSeries message.

The MQMD structure in the message extension overrides the default MQMD conversions, which are described in Converting Messages Sent from Message Queuing to MQSeries.

A few exceptions to these rules are described in the following sections.

In This Section

- Sender and User Identifiers
- Version Identifiers

Sender and User Identifiers

MSMQ-MQSeries Bridge reads the value of **MQMD.UserIdentifier** stored in the message extension and assigns the value to the **MQMD.UserIdentifier** field in the new MQSeries message.

Version Identifiers

MQSeries uses the following fields for version identification:

- **MQMD.StrucId**
- **MQMD.Version**

When the MSMQ-MQSeries Bridge converts a message extension, it confirms that the values of these fields are for a version of MQSeries that the Bridge supports. If they are not, MSMQ-MQSeries Bridge places the message on the dead letter queue and does not transmit it to MQSeries.

For more information about the supported versions of MQSeries, see Platforms Supported by MSMQ-MQSeries Bridge Extensions. For more information about the permitted values of the version identification fields, see Converting Messages Sent from Message Queuing to MQSeries.

Using Message Extensions

This section suggests a few ways that you can use the message extension property in your messaging applications.

In This Section

- Sending an MQSeries Message to Message Queuing
- Sending a Message Queuing Message to MQSeries

Sending an MQSeries Message to Message Queuing

MSMQ-MQSeries Bridge stores the complete MQMD structure of an MQSeries message in a Message Queuing (also known as MSMQ) message extension. A Message Queuing application can read the extension and retrieve the original MQMD structure.

In this way, a Message Queuing application can retrieve the original values of every MQMD field, regardless of the MSMQ-MQSeries Bridge conversions.

Sending a Message Queuing Message to MQSeries

When you send a Message Queuing (also known as MSMQ) message to MQSeries, you can include a message extension. This can be an extension that you originally received from MQSeries, or one that you created yourself. MSMQ-MQSeries Bridge reads the message extension and uses it to set the MQMD fields of the converted message that it sends to MQSeries.

You can use this feature for two purposes:

- To override the default conversions described in the section
  Converting Messages Sent from Message Queuing to MQSeries

- To supplement the default conversions by assigning MQMD fields that have no Message Queuing equivalent.

The following are some examples of fields that have no equivalents or only partial equivalents (different permitted values or length) among the Message Queuing message properties:

- **MQMD.AccountingToken**
- **MQMD.ApplOriginData**
- **MQMD.CorrelId**
- **MQMD.MsgId**
- **MQMD.MsgType**
- **MQMD.PutApplName**
- **MQMD.PutApplType**
- **MQMD.ReplyToQ**
- **MQMD.ReplyToQMgr**
- **MQMD.Report**

Suppose you want to send a message to an MQSeries application including an MQMD.MsgType value of MQMD_REPLY. The default message conversions provide no way to set this particular value. You can send the value by storing an MQMD data structure in a message extension.

Programming a Message Extension

In a Message Queuing (also known as MSMQ) application, you can program a message extension containing an arbitrary number of extension fields. For use with MSMQ-MQSeries Bridge, build the extension according to the following specifications.

It is recommended that you use MSMQ-MQSeries Bridge Extension Property API to construct the extension with the required syntax. Create a **PROPID_M_EXTENSION** property containing at least one extension field.

Store the MSMQ-MQSeries Bridge globally unique identifier (GUID) code in the GUID subfield of exactly one extension field. The GUID is the value of the sg_MSMQExtMQMD constant, which is defined in the Mqsrext.h include file of the Extension Property API. Store the size of MQMD in the length subfield. Copy a complete MQMD structure byte-for-byte into the data buffer subfield.

When you send the message to MQSeries, the MSMQ-MQSeries Bridge converts the extension field identified by the MSMQ-MQSeries Bridge GUID. Any other extension fields are ignored.

MSMQ-MQSeries Bridge Extension Property API

The MSMQ-MQSeries Bridge Extension Property API is recommended for programming and working with message extensions. The API provides a library of functions that help you create and interpret message extensions. The MSMQ-MQSeries Bridge Extension Property API is supplied as part of the Host Integration Server SDK.

Your Message Queuing (also known as MSMQ) applications can use the API to do the following:

- Read message extensions that you receive from MQSeries
- Create or modify message extensions that you send to MQSeries
- Read or create message extensions for any other Message Queuing messaging purpose

The MSMQ-MQSeries Bridge Extension Property API enables you to create and work with the Message Queuing message extension property. This section provides a few guidelines for using the API functions.

The MSMQ-MQSeries Bridge Extension Property API operates directly on the EP representation of a message extension. In particular, the API functions support the following programming approach:

- Creating or deleting an **EP** object.
- Creating, finding, reading, writing, or deleting extension fields in an **EP** object.
- Converting an **EP** object to a message extension. (**PROPID_M_EXTENSION**) that you can send in a Message Queuing message.
- Converting a message extension that you received in a Message Queuing message to an **EP** object.

You cannot send an **EP** object directly in a Message Queuing message. You must first convert it to a message extension (**PROPID_M_EXTENSION**).

To use the message extension API, include the MSMQext.h header file in your applications. This header files contains constants and function prototypes for the Extension Property API functions. This header file is located in the SDK\Include directory on the Host Integration Server CD and is installed when the SDK package is selected.

If you are using the API in conjunction with MSMQ-MQSeries Bridge, also include the Mqsrext.h header file located in the SDK\Include directory. This file defines the GUID that labels the extension fields.

The Extension Property API functions are handle-based. The following is a summary of the MSMQ-MQSeries Bridge Extension Property API functions. For complete details, see the individual function descriptions in MSMQ-MQSeries Bridge Extensions Reference.

Function	Description
EPAdd	Adds a new extension field to an **EP** object.
EPClose	Frees the extension handle and associated memory of an **EP** object.
EPDelete	Deletes an extension field from an **EP** object.
EPDeleteAll	Deletes all extension fields or all extensions fields matching a specific GUID from an **EP** object.
EPGet	Positions to and optionally retrieves a requested extension field from an **EP** object, storing the GUID, length, and d ata subfields in separate variables. **EPGet** can also be used to locate extension fields containing a specified GUID.
EPGetBuffer	Converts an **EP** object to a message extension and packs the message extension into the supplied buffer.
EPOpen	Creates an **EP** object and optionally unpacks the supplied message extension buffer into it.
EPUpdate	Writes new data to an existing extension field of an **EP** object.

Programming Considerations When Using MSMQ-MQSeries Bridge Extensions

The limitations of specific API functions result from the fact that MSMQ-MQSeries Bridge transmits messages, not API calls, between queuing systems. The MSMQ-MQSeries Bridge transmits messages across the MSMQ-MQSeries interface. The MSMQ-MQSeries Bridge does not transmit API calls across the interface. Thus, Microsoft® Message Queuing (also known as MSMQ) API calls operate only within the Message Queuing environment, and MQSeries API calls operate only within the MQSeries environment. This principle limits the ways in which you can create and access queues.

All Message Queuing API functions operate only within the Message Queuing environment, up to and including foreign computers and queues. For example, you can use the following functions:

- **MQLocateBegin**, **MQLocateNext**, and **MQLocateEnd** to search for foreign queues
- **MQGetMachineProperties**, **MQGetPrivateComputerInformation**, **MQGetQueueProperties**, and **MQGetQueueSecurity** functions to retrieve the properties of foreign queues
- **MQOpenQueue** to open a foreign queue
- **MQSetQueueProperties** and **MQSetQueueSecurity** to set the properties of foreign queues
- **MQCloseQueue** to close a foreign queue

When creating a queue, you can call the Message Queuing function **MQCreateQueue** to create a foreign queue representing an MQSeries queue, but you cannot create the actual MQSeries queue itself. Similarly, you cannot create a Message Queuing queue by calling the MQSeries function **MQOPEN**.

To communicate across the MSMQ-MQSeries interface, your Message Queuing and MQSeries applications should each create their own queues. Alternatively, you can use administration tools such as the Message Queuing Manager or the MQSeries command interface to create the queues.

For proper message delivery, you must ensure that the destination queue for each message actually exists.

You can use the Message Queuing **MQPathNameToFormatName** function to determine a Message Queuing format name for an MQSeries queue. The format name actually refers to the Message Queuing foreign queue. The MSMQ-MQSeries Bridge processes the format name that it finds in a message and directs the message to the MQSeries queue.

When opening a queue, a call to the Message Queuing function **MQOpenQueue** opens the foreign queue, not the MQSeries queue itself. The MSMQ-MQSeries Bridge opens the MQSeries queue as necessary when it transmits a message. If you are sending messages to more that one MQSeries queue, you must open each one separately using its own Message Queuing format name.

In the opposite direction, the MQSeries function **MQOPEN** opens the transmission queue for the Message Queuing computer. The MSMQ-MQSeries Bridge opens the Message Queuing queue when it transmits a message.

When sending a Message Queuing message to a foreign queue with MQSendMessage, Message Queuing delivers the message to the connector queue in the MSMQ-MQSeries Bridge computer. The MSMQ-MQSeries Bridge converts and transmits the message to MQSeries queue. MQSeries delivers a message sent by **MQPUT** to a transmission queue. The MSMQ-MQSeries Bridge reads the message from the MQSeries transmission queue. After converting the message from MQSeries to Message Queuing message properties, MSMQ-MQSeries Bridge transmits the message to the destination Message Queuing queue.

When receiving a message, the MSMQ-MQSeries Bridge does not transmit receive requests across the MSMQ-MQSeries interface. A Message Queuing application can receive a message only from a native Message Queuing queue (the **MQReceiveMessage** function). An MQSeries application can receive only from a native MQSeries queue (the **MQGET** function).

When sending a message from MQSeries to Message Queuing, if you want the MQSeries message to have a value for MQMD.ApplIdentityData, you need the set both of the following:

- Set the **Open** option with **MQOO_SET_IDENTITY_CONTEXT**

- Set the **Put** option with **MQPMO_SET_IDENTITY_CONTEXT**

When a message is retrieved from Message Queuing, the MSMQ-MQSeries Bridge will have converted the Message Queuing **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN** properties from the MQSeries MQMD.ApplIdentityData field value.

The MQMDE extension has the following GUID for MQMD version 2.

```
static const GUID sg_MSMQExtMQMDE =
{ 0x18ae68f5, 0x989b, 0x11d3,
    { 0x8d, 0xf9, 0x0, 0x0, 0xf8, 0x1a,  0xea, 0x1f }
};
```

In This Section

- Transaction Support Using MSMQ-MQSeries Bridge
- Security Using MSMQ-MQSeries Bridge
- Troubleshooting MSMQ-MQSeries Bridge Extensions

Transaction Support Using MSMQ-MQSeries Bridge

The MSMQ-MQSeries Bridge supports both Message Queuing (also known as MSMQ) and MQSeries transactions. The procedure for sending a group of transacted messages is similar in either direction, from Message Queuing to MQSeries or from MQSeries to Message Queuing. Your application should follow these three basic procedures:

- Open a transaction
- Send the messages
- Commit the transaction

At this point, the group of messages reaches the Message Queuing connector queue or the MQSeries transmission queue. Only then does the MSMQ-MQSeries Bridge transmit the messages to the other messaging system. If your application stops the transaction instead of committing, MSMQ-MQSeries Bridge does not handle the messages at all.

Even after you commit a transaction, it is still possible that MSMQ-MQSeries Bridge cannot transmit all the messages. This may occur, for example, if some of the messages are addressed to queues that do not exist in the recipient messaging system. MSMQ-MQSeries Bridge places any undeliverable messages on its dead letter queue.

In the Message Queuing-to-MQSeries direction, the MSMQ-MQSeries Bridge sends transacted messages by a transactional message pipe and untransacted messages by regular message pipe. In the MQSeries-to-Message Queuing direction, MQS->Message Queuing message pipe, and MQS->Message Queuing transactional message pipe do not depend on transaction status.

Security Using MSMQ-MQSeries Bridge

Message authentication and message body encryption are supported from the Message Queuing (also known as MSMQ) sending application up to MSMQ-MQSeries Bridge. Authentication and message body encryption from MSMQ-MQSeries Bridge to MQSeries, or from MQSeries to Message Queuing, are not currently supported.

Troubleshooting MSMQ-MQSeries Bridge Extensions

The MSMQ-MQSeries Bridge generally ignores warnings that it receives from Message Queuing (also known as MSMQ) or MQSeries, but errors are not ignored. Where possible, the MSMQ-MQSeries Bridge transmits messages despite any warnings.

If the MSMQ-MQSeries Bridge is unable to transmit a message to Message Queuing or MQSeries, it places the message on one of its dead letter queues. This can happen, for example, if a message contains an unsupported Message Queuing or MQSeries version identifier or if MSMQ-MQSeries Bridge encounters an error in the recipient messaging system.

The dead letter queues are Message Queuing queues located on the MSMQ-MQSeries Bridge computer. There are two dead letter queues used for this purpose with the following names.

Dead letter queue names	**Comments**
MQBridge dead letter	Used for untransacted messages when errors occur.
MQBridge xact dead letter	Used for transacted messages when errors occur.

Note that these are different from the Message Queuing and MQSeries dead letter queues, where the messaging systems place expired or incorrectly addressed messages.

You can determine whether there are messages on the dead letter queues using the MSMQ-MQSeries Bridge Manager.

If the MSMQ-MQSeries Bridge cannot deliver a message to MQSeries, it records the error in the extension property **PROPID_M_EXTENSION** of the original Message Queuing message and places the message on the dead letter queue. This extension property can be examined to determine the nature of the error encountered.

Registry Settings Used By MSMQ-MQSeries Bridge Extensions

The MSMQ-MQSeries Bridge Extensions uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup** key. These registry settings include the subkeys listed in the following table.

Subkey	Comment
Root Dir	Stores the path to the root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the MSMQ-MQSeries Bridge Extensions dynamic link library (DLL) and other support DLLs are installed.

Creating a Single Sign-On Application

This section provides information about Enterprise Single Sign-On (SSO) technology.

In This Section

- Programming Single Sign-On Overview
- Programming with Enterprise Single Sign-On

Programming Single Sign-On Overview

A business process that relies on several different applications is likely to face the challenge of dealing with several different security domains. Accessing an application on a Microsoft Windows operating system might require one set of security credentials, whereas accessing an application on an IBM mainframe might require different credentials. Dealing with this profusion of credentials is hard for users, and it can pose an even greater challenge for automating processes. To address this problem, BizTalk Server includes Enterprise Single Sign-On (SSO). SSO lets you map a Windows user ID to non-Windows user credentials. This service can simplify business processes that use applications on diverse systems.

To use SSO, an administrator defines affiliated applications, each of which represents a non-Windows system or application. An affiliated application might be a Customer Information Control System (CICS) application that is running on an IBM mainframe, an SAP ERP system that is running on UNIX, or any other kind of software. Each of these applications has its own mechanism for authentication, and so each requires its own unique credentials.

SSO stores an encrypted mapping between the Windows user ID of a user and the associated credentials for one or more affiliated applications. These linked pairs are stored in an SSO database. SSO uses the SSO database in two ways. The first way, called *Windows-initiated Single Sign-On*, uses the user ID to determine to which affiliated applications the user has access. For example, a Windows user account might be linked with credentials that grant access to a DB2 database running on a remote AS/400 server. The second way, called *host-initiated Single Sign-On*, acts in reverse: determining what remote applications have access to a specified user ID, and the privileges that go with that account. For example, a remote application might be linked with credentials that grant access to a user account that has administration privileges on a Windows network.

Note that SSO also includes administration tools to perform various operations. All operations performed on the SSO database are audited; for example, tools are provided that enable an administrator to monitor these operations and set various audit levels. Other tools enable an administrator to disable a particular affiliated application, turn on and off an individual mapping for a user, and perform other functions. There is also a client program that enables end users to configure their own credentials and mappings.

One of the administrative requirements for Single Sign-On is that your local system must know about the credentials that are required to log on to a remote system. Similarly, the remote system must know about the credentials on your local system. Therefore, when you update your credentials, such as when you update your password on your local computer, you must also inform the remote systems that you have done so. The component you design that synchronizes passwords across an enterprise is called a *password sync adapter*.

In This Section

Single Sign-On Interface

The following table describes the COM and .NET Framework interfaces that make up the Single Sign-On interface.

.NET	COM	Description
Microsoft.EnterpriseSingleSignOn.Interop.ISSOAdmin	ISSOAdmin Interface (COM)	Creates, updates, and deletes an SSO application. Also performs other administration functions.
Microsoft.EnterpriseSingleSignOn.Interop.ISSOConfigStore	ISSOConfigStore Interface (COM)	Gets and sets information in the SSO configuration store.
Microsoft.EnterpriseSingleSignOn.Interop.ISSOLookup1	ISSOLookup1 Interface (COM)	Enables you to look up the external credentials on a specified application for the current user.
Microsoft.EnterpriseSingleSignOn.Interop.ISSOLookup2	ISSOLookup2 Interface (COM)	As above, but also enables you to look up the Windows credentials for a specified external user.
Microsoft.EnterpriseSingleSignOn.Interop.ISSOMapper	ISSOMapper Interface (COM)	Enables you to set the external credentials for the current user for a specified application.
Microsoft.EnterpriseSingleSignOn.Interop.ISSOMapping	ISSOMapping Interface (COM)	Creates and maintains the mapping between users and affiliated applications.
Microsoft.EnterpriseSingleSignOn.Interop.ISSOTicket	ISSOTicket Interface (COM)	Creates the ticket that contains the appropriate security information. This ticket is then sent on with the appropriate message from your application.

In addition, Host Integration Server supports the Password Sync Helper (PS Helper) component. You can use PS Helper when you design password synchronization components. The following table describes the COM and .NET Framework interfaces exposed by PS Helper.

.NET	COM	Description
Microsoft.EnterpriseSingleSignOn.Interop.ISSOPSWrapper	ISSONotification Interface (COM)	Handles password changes to and from non-Windows operating systems.
	SExternalAccount Structure (COM)	Describes an external account.
	SPasswordChange Structure (COM)	Describes a password change.
	SPasswordChangeComplete Structure (COM)	Describes the completion of a password change.
	SStatus Structure (COM)	Describes an error or event.
	SAdapterInGroup Structure (COM)	Describes the adapters in a given group.
	SAdapter Structure (COM)	Describes a specific adapter.

Single Sign-On Applications

From a programming perspective, you can write two different kinds of applications using Single Sign-On: a traditional Single Sign-On application that uses the Single Sign-On interface to interact with remote applications, and a password sync adapter that uses the Password Sync (PS) Helper interface to synchronize passwords across your enterprise.

In This Section

Traditional Single Sign-On Applications

The Single Sign-On (SSO) programming architecture contains a mapping component to map between applications and users, a lookup component to look up credentials for a specified use, and an administration component to perform administrative tasks. In addition, SSO also contains a ticketing interface so that your application can issue and redeem tickets.

Mapping

Mapping is the process of linking a specified user with a specified application. You can map between affiliate applications and users who are using **ISSOMapping**, **ISSOMapper**, and **ISSOMapper2**. With **ISSOMapping**, you can create, delete, enable, and disable mappings. With **ISSOMapper**, and **ISSOMapper2**, you can get and set mapping data for the current user.

Lookup

The core of the Single Sign-On programming interface is the ability to look up credentials for specified users. You can look up credentials using **ISSOLookup1**, and **ISSOLookup2**. **ISSOLookup1**, enables the user to retrieve their own external credentials. In contrast, **ISSOLookup2** also enables you to look up the credentials of a remote user for a local affiliate application. The former is necessary for a traditional Single Sign-On application, whereas the latter is useful when you are writing a host-initiated Single Sign-On application.

Administration

You can perform many of the administrative capabilities programmatically through **ISSOAdmin**, **ISSOAdmin2**, and **ISSOConfigStore**. Such tasks include configuring Single Sign-On and creating and describing an application to Single Sign-On. You also can create and modify SSO databases using **ISSOConfigDB**, **ISSOConfigOM**, and ISSOConfigSS. Finally, you can administer the password sync features using **ISSOPSAdmin**.

Communication and Ticketing

Your application will most likely issue messages so that your user can communicate with a remote application. To communicate with a remote application more securely, you must issue and redeem a Single Sign-On ticket. You can also issue and redeem tickets programmatically.

Single Sign-On Applications

Password Sync Adapters

A *password sync adapter* is a component that propagates password changes to and from a non-Windows system. Although password sync adapters are similar to traditional Single Sign-On applications, they have several differences:

- They are administered using a specialized interface.
- They are described using a specialized XML format in the configuration store.
- Host Integration Server uses a specialized feature to organize adapters in the configuration store.

In This Section

Password Sync Programming Architecture

A password sync adapter uses a pull model for interacting with the rest of the Enterprise Single Sign-On system: that is, the adapter actively receives password changes from the Enterprise Single Sign-On (ENTSSO) service and also from the non-Windows system. Similarly, the adapter pushes password changes received from one system to the other. With this model, your adapter interacts with three architectural components: the ENTSSO architecture, the Password Sync (PS) Helper component, and a specified non-Windows system.

Enterprise Single Sign-On Architecture

ENTSSO is the service that implements the Enterprise Single Sign-On technology, and runs as a local service on the same system as your adapter. Therefore, communication between the adapter and ENTSSO is always local. However, a password sync adapter runs in a separate process from the ENTSSO service.

ENTSSO uses the configuration store to store configuration information for an adapter. The Application Users account of a configuration store application corresponds to the access account. When an adapter calls into ENTSSO, ENTSSO checks that the adapter is within the configured access account for that adapter. The access account must be a (local or domain) group account.

Because ENTSSO stores information about an adapter, the adapter can identify itself to ENTSSO by its adapter name. The adapter name corresponds to the configuration store application name and the configuration store identifier used to store the adapter properties. Therefore, adapters must know only their adapter name to access configuration information and to correctly identify themselves to the ENTSSO system at run time.

Password Sync Helper

Password Sync (PS) Helper is a COM component provided by ENTSSO. PS Helper runs in-process with the password sync adapter, and exposes ISSOPSWrapper. Your adapter can call either interface to communicate with the ENTSSO service. The PS Helper passes communications to and from ENTSSO using encrypted (packet privacy) lightweight remote procedure call (LRPC). Although the communications are mainly for password updates, you can also use the interfaces to pass other types of notifications between the adapter and ENTSSO. Because PS Helper runs as a singleton value per process, it is possible for multiple adapters to call the same PS Helper object from within the same adapter process. For more information about using PS Helper programmatically, see Synchronizing Passwords.

Non-Windows System

The non-Windows system is the remote computer your adapter interacts with. How you interact with the non-Windows system is up to you.

See Also

Other Resources

Password Sync Adapters

Adapter Programming Administration

An adapter is a special type of configuration store application: that is, an adapter is a component that shares a namespace with other Single Sign-On and configuration store applications. Therefore, you can access information about an adapter using ISSOConfigStore. But unlike a configuration store application, you do not perform administrative functions on an adapter with the ISSOAdmin interface. Instead, you administer an adapter through ISSOPSAdmin. The reason for a specialized adapter administration interface is so that the system can coordinate other activities with the configuration store.

Concepts

Adapter Programming Configuration

Adapter Groups and Group Adapters

Other Resources

Password Sync Adapters

Adapter Programming Configuration

Every type of password sync adapter has different configuration requirements, depending on what non-Windows system you design the adapter for. Like affiliate applications, you can use the Enterprise Single Sign-On configuration store to store configuration properties centrally and more securely.

As with other configuration store applications, an administrator can use the Enterprise Single Sign-On management user interface to locate and read an XML file that describes the configuration properties for your adapter. The management tools use the XML file to render a property page to gather the required property values, for the specified adapter. You can also use ISSOConfigStore to load and read XML name/value combinations to and from the configuration store, or you can use the SSOPS tool.

You can also use the Enterprise Single Sign-On administration tools to enable and disable an adapter. On initial creation, an adapter is disabled.

Adapter Groups and Group Adapters

An *adapter group* is an administration mechanism that you can use to collect and organize a set of adapters. In contrast, a *group adapter* is a component that services all adapters in an adapter group. For example, you might write a set of adapters that all use the same COM component to transmit password synchronizations over TCP/IP. Your set of adapters is called the adapter group, whereas the component that services them all is called a group adapter. Adapter groups are described in the configuration store. You can retrieve information and updates on an adapter group by using **ISSOPSAdapter.ReceiveNotification**.

A group adapter has the same name as the adapter group. Other than the naming restriction, a group adapter is otherwise identical to a normal adapter. For example, a group adapter can have independent access groups and configuration properties, as described by its configuration file. A group adapter is most likely on the same computer as any adapters in the adapter group. However, this is not currently enforced. Likewise, all adapters in the same adapter group can be expected to be on the same computer.

By using **ISSOPSAdapter.InitializeAdapter**, you can access and initialize a group adapter during startup. When you initialize a group adapter, the system informs the group adapter of all adapters in the adapter group on the current system. In addition, the system sends notifications to the group adapter any time an adapter is added, deleted, enabled, or disabled in the adapter group. However, the group adapter does not receive any password change notifications.

Adapter groups and group adapters are optional using the Administration tool.

What You Should Know Before Programming Single Sign-On

To use this documentation effectively, you should be familiar with the following:

- Microsoft Windows XP, Windows 2000 Server, Windows Server 2003, or Windows Server 2008 operating systems. You should be especially familiar with Windows Security features.
- Administrative features of Enterprise Single Sign-On, especially how to perform administrative actions using the user interface.

Depending on the API and development that you are using, you should also be familiar with the following interfaces:

- COM
- The .NET Framework and the common language runtime
- Windows Networking, and specifically how to send and receive tickets

Programming Single Sign-On Overview

Programming with Enterprise Single Sign-On

Enterprise Single Sign-On (SSO) is a technology implemented in the Enterprise Single Sign-On service (ENTSSO) that enables users to access multiple remote services without having to work their way through additional sign-on screens.

In This Section

How to Determine Current Single Sign-On Access

One of the first tasks you might need to perform for a user is to determine what affiliated applications have already been set up for the current user. You can perform this query with a call to ISSOMapper.GetApplications.

To query the Single Sign-On database for the applications available to the current user

1. Create a new instance of **ISSOMapper**.

   In general, **ISSOMapper** is an interface designed to retrieve information from Single Sign-On (SSO). You will most likely use **ISSOMapper** in many similar queries.

2. Retrieve all applications that are affiliated with the current user by calling GetApplications.

   GetApplications automatically returns only the affiliated applications of the current user.

The following code example demonstrates how to query the Single Sign-On database.

```
private static string[] Applications=null;
. . .
public static string[] GetCurrentUserApplications()
{
   if(Applications==null)
   {
      string[] descs;
      string[] contacts;
      ISSOMapper mapper=new ISSOMapper();
      mapper.GetApplications(out Applications, out descs, out contacts);
   }
   return Applications;
}
```

How to Configure Single Sign-On

Before accessing Enterprise Single Sign-On, you should make sure that Enterprise Single Sign-On is set correctly for the current user. For most configurations, you use one of two interfaces. **ISSOAdmin** is the general administration interface that enables you to create new affiliation applications. However, by using ISSOAdmin.GetGlobalInfo and ISSOAdmin.UpdateGlobalInfo, you can set a variety of flags and administration values. One possible task, as described in the following procedure, is to ensure that SSO ticketing has been enabled.

To enable ticketing

1. Create a new instance of **ISSOAdmin**.
2. Retrieve the current settings through **ISSOAdmin.GetGlobalInfo**.

   If necessary, you may want to confirm that the flags are set to the correct values at this point.
3. Change any relevant flags using **ISSOAdmin.UpdateGlobalInfo**.

   In this particular case, all the flags are being set to validate and enable tickets.

The following example shows how to enable ticketing using Single Sign-On.

```
