Host Integration Server 2009

Microsoft Host Integration Server

This version of Host Integration Server Help provides documentation and in-depth information about Host Integration Server 2009.

 Getting Started Information about new features, prerequisites, and topics for users who are new to Host Integration Server.

Programmer's Guide Information about how to develop Host Integration Server solutions for your environment.

 Samples Information about samples that are available for Host Integration Server.

 Community Resources Host Integration Server community resources such as blogs and forums.

Getting Started

This section contains information about new features, prerequisites, and topics for users who are new to Host Integration Server.

What's New for 2009

The following is an overview of the new features and enhancements in this release of Microsoft Host Integration Server and the BizTalk Adapters for Host Systems.

Expanded Microsoft platform support

- Windows Vista SP1, Windows Server 2008, Hyper-V
- Visual Studio 2008 SP1 and .NET Framework 3.5 SP1
- SQL Server 2008 and BizTalk Server 2009

Extended deployment options and management tools

- IPv6 networking for selected features
- Backup and recovery using VSS Writer
- New common Trace Viewer

Enhanced connectivity to host applications

- Generation of WCF Services based on Transaction Integrator objects
- Improved performance of Transaction Integrator and BizTalk adapter runtimes
- Dynamic Remote Environments for TI and BizTalk adapter
- New migration and deployment tools
- Design tool improvements, including COBOL/400 import/export
- Support for CICS v3.2 and IMS Connect v9

New WCF channel for WebSphere MQ

- With synchronous message correlation
- Built on system service model in .NET Framework 3.5
- Visual Studio project type to support optional data conversion
- Supports WebSphere MQ v7

Expanded connectivity to DB2

- Entity Designer and Entity Provider for DB2
- Improved performance when fetching data from DB2
- Support for DB2 for Linux and HP-UX platforms
- Compatibility with DB2 for z/OS v9 and DB2 UDB V9.5

Improved connectivity to host files

- Off-line data reader for host files ADO.NET provider and BizTalk adapter
- Visual Studio design tools for host files

BizTalk Adapters

This release of Microsoft Host Integration Server 2009 includes the following adapters:

The **Microsoft BizTalk Adapter for Host Applications** is designed for BizTalk Server. It is based on technology in Microsoft Transaction Integrator (TI) for Windows-Initiated Processing, which enables efficient client access to existing IBM mainframe zSeries (CICS and IMS) or midrange iSeries (RPG) server programs. The TI design tools are integrated with Visual Studio and BizTalk Server solutions, enabling IT developers to be highly productive when defining the client proxy and creating the XSD schema. For BizTalk Server administrators, the existing TI Manager, Microsoft Management Console (MMC) snap-in, has been enhanced to improve supportability and support the required remote BizTalk Server solution deployment scenarios.

The **Microsoft BizTalk Adapter for Host Files** is an advanced data adapter that enables IT organizations to access and integrate information stored in host file systems, including mainframe zSeries VSAM datasets and midrange iSeries physical files. The Visual Studio design tool is used within a BizTalk Server solution to define a metadata map of the host program-described files, which is then exported as XSD for use with the BizTalk adapter. The configuration wizards are integrated into the BizTalk Server administration tools, allowing IT pros to define dynamic send ports and static and solicit response receive ports, based on a simplified set of SQL commands (SELECT, INSERT, UPDATE, DELETE). This BizTalk adapter is based on a new Microsoft .NET Framework Data Provider for Host Files that maps SQL to non-relational host datasets and members, This makes it simple for non-programmers to read/write host file data sources.

The **Microsoft BizTalk Adapter for DB2** is a relational database adapter that allows IT professionals to access vital data stored in IBM DB2 database servers on remote host computing platforms, IBM mainframe zSeries and midrange iSeries (DB2/400), and also IBM DB2 Universal Database (UDB) on open platforms. Using standard SQL commands and a configuration wizard built into BizTalk Server administration tools, IT pros can create solutions that read and write to DB2 without any need for database programming. The new DB2 adapter, which is based an updated Microsoft .NET Framework Data Provider for DB2, supports a broad range of functions, including dynamic send ports, and static and solicit response receive ports.

The **Microsoft BizTalk Adapter for WebSphere MQ (Client-Based)** uses IBM WebSphere MQ Client (Base-Client) and IBM WebSphere MQ Extended Transactional Client (Extended-Client) APIs to communicate with remote MQSeries Queue Managers. The adapter enables BizTalk Server to communicate directly with MQSeries Queue Managers deployed on non-Windows operating systems, without needing to deploy and manage WebSphere MQ Server for Windows, to efficiently exchange messages with line-of-business applications across the enterprise. When used with the Base-Client, the adapter provides non-transactional message processing, guaranteeing only the delivery of messages. It is the responsibility of the application on the receiving end to handle any duplicate messages. When used with the Extended-Client, the adapter provides transactional message processing to guarantee once-and-only-once delivery of messages.

Transaction Integrator

Transaction Integrator (TI) is the synchronous COM+ or .NET Framework application integration solution in Host Integration Server. TI enables you to integrate mainframe-based transaction programs (TP) and AS/400 transactions with component-based Windows Server System applications when the following conditions are true:

- A synchronous or transactional solution is needed.
- Both the client and server systems are running at the time the call is made.

If you need an application integration solution that does not require the client and server systems to be running at the time the call is made, use an asynchronous messaging solution such as the MSMQ-MQSeries Bridge instead of TI. In an asynchronous solution, the middle-tier queuing system is running at the time the client issues a request message, the server retrieves the message and sends back the reply, and then the client receives the reply back from the middle tier.

With TI, you can integrate existing mainframe-based TPs with Windows-based COM, distributed COM (DCOM), or applications built on the .NET Framework. You might not even have to modify your TP if you have separated the business logic from the presentation logic. The wizards in TI guide you through the modification process, step by step.

With TI, you can preserve existing CICS and IMS TPs as you move to a three-tier client/server or Web-to-host computing environment. By using TI to invoke mainframe transactions, you can program in the visual object-oriented environments and programming languages that you know while you maintain access to host transactions.

TI supports both SNA connectivity and TCP/IP connectivity without requiring a host footprint or costly host transaction rewrites. You can choose SNA connectivity if you need two-phase commit (2PC), or choose TCP/IP connectivity if you need direct throughput. IBM has not implemented 2PC for the TCP/IP protocol, but for those cases where 2PC is not necessary, TCP/IP can give you direct connectivity.

True integration of online transaction processing (OLTP) with COM- or .NET-compliant systems means the integration of CICS and IMS with Windows-based solutions. CICS and IMS are widely used in the mainframe arena to create distributed OLTP solutions such as customer tracking and order entry. TI integrates CICS and IMS with COM by creating COM interfaces or .NET interfaces to the CICS and IMS transactions and then running the CICS and IMS transactions on the mainframe from Windows.

A TI component in a COM+ application works in concert with the TI run-time environment, Microsoft Distributed Transaction Coordinator (MS DTC), and the associated remote environment (RE) to drive a CICS or IMS TP. Together, they accomplish these tasks:

- Activate the host (mainframe) TP.
- Pass the parameters specified by the TI component to the TP.
- Run the TP.
- Return the results to the TI component.

When you deploy a TI component (a type library .tlb file) in a COM+ application, that COM+ application becomes a TI Automation server. When a client application invokes a method in that TI Automation server, Windows automatically starts the TI run-time environment in the associated remote environment to invoke the mainframe transaction that is associated with that TI method. Component Services in Windows 2000 automatically handles any class factory, early or late binding, or other internal operations needed. The invoked mainframe transaction can call other transactions on the mainframe before it returns the result to the COM-based client application through the TI Automation server.

Security Integration

Enterprise Single Sign-On (SSO) provides services to enable single sign-on for end users in enterprise application integration (EAI) solutions.

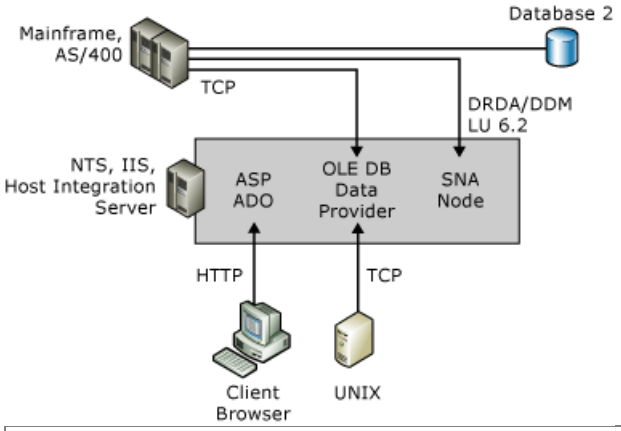
The SSO system maps Microsoft Windows accounts to back-end credentials. SSO simplifies the management of user IDs and passwords, both for users and administrators. It enables users to access back-end systems and applications by logging on only one time to the Windows network. For more information, see Security User's Guide.

Data Integration

Data services included with Host Integration Server 2009 enable you to interact with host data sources, including VSAM and DB2 systems.

The following diagram shows an overview of the Data Integration Services.

Data Integration Services



Note

If you are using TCP/IP to connect to the mainframe or AS/400, you do not have to install or configure the Network Integrati on Services. You can use the Application and Data Integration Services over TCP/IP.

The following services are available.

- OLE DB Provider for AS/400 and VSAM
- OLE DB Provider for DB2
- ODBC Driver for DB2

OLE DB Provider for AS/400
The Data Access Tool simplifies configuration and access to AS/400 systems.

The following diagram shows an overview of the OLE DB Provider for AS/400.

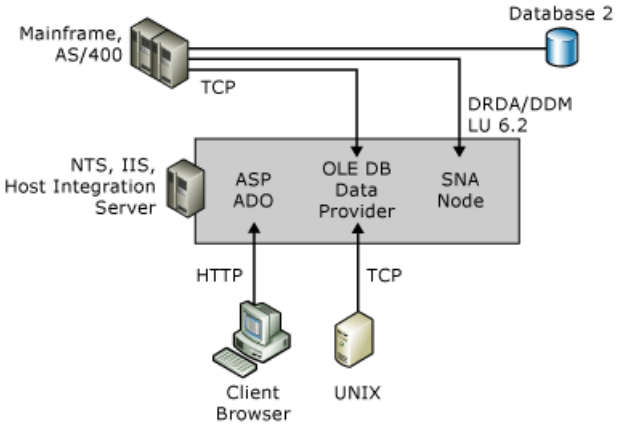
The following diagram shows an overview of the OLE DB Provider for VSAM.

OLE DB Provider for VSAM

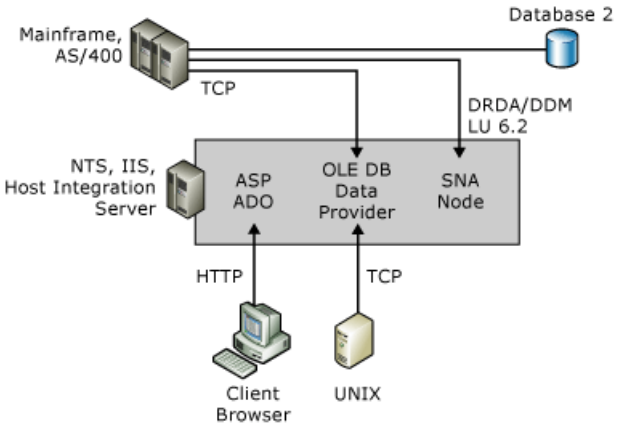


OLE DB Provider for DB2

The Data Access Tool simplifies configuration and access to DB2 systems.

The following diagram shows an overview of the OLE DB Provider for DB2.

OLE DB Provider for DB2



ODBC Provider for DB2

The Microsoft ODBC Driver for DB2 enables access over SNA LU 6.2 and TCP/IP networks to remote DB2 databases. This driver is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester that can connect to most DRDA-compliant DB2 systems, including MVS, VSE, VM, OS/400, AIX RS/6000, Sun Solaris, HP-UX, Digital/Compaq UNIX, OS/2, and Microsoft Windows 2000.

The driver can be used interactively or from an application program to issue SQL statements and execute DB2 stored procedures. Microsoft Office Excel users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. Microsoft Office Access users can import from and export to DB2. By using Microsoft Internet Information Server (IIS) on Windows 2000, developers can publish DB2-stored information to users through a Web browser interface.

The following diagram shows an overview of the ODBC Driver for DB2.

Network Integration

The IP-DLC link service is a Host Integration Server feature that provides SNA connectivity for applications that use dependent and independent sessions over a native IP network. It implements the HPR/IP protocol, which is also known as HPR over IP or Enterprise Extender. Each SNA packet is transmitted natively across the IP network as a UDP datagram.

This version of Host Integration Server supports the following physical connection methods to your host system:

- DLC 802.2 (for supported OSA adapters)
- SDLC
- Channel (ESCON and Bus & Tag)

Physical connections to a host system are provided with link services that support a variety of third-party adapters. A list of supported third-party adapters can be found in the online Help.

This version of Host Integration Server supports the following standard SNA protocols for communications:

- LU 1 and LU 3 (for host printing)
- LU 2 (for 3270 displays)
- LU 6.2 (for APPC)
- LU 0
- LUA

Note
If you are using TCP/IP to connect to the mainframe or AS/400, you do not have to install or configure the Network Integrati on Services. You can use the Application and Data Integration Services over TCP/IP.

Host Services
This version of Host Integration Server provides a range of services that extend mainframe services to LAN users. These include the TN3270 Service for mainframe environments, the TN5250 Service for AS/400 environments, and Host Print Service for both mainframe and AS/400 environments.

Administrative Services
This version of Host Integration Server gives network administrators tools and services to monitor and manage host resources in your enterprise. These services are available for both the hierarchical and peer environments.

Messaging

MSMQ-MQSeries Bridge enables your applications to exchange messages between IBM MQSeries and Microsoft Message Queue Server easily and efficiently. MSMQ-MQSeries Bridge provides connectionless, store-and-forward messaging across messaging systems and computing platforms throughout your network. To learn more about MSMQ-MQSeries Bridge, see Messaging User's Guide

Software Development Kit

This version of Host Integration Server includes a software development kit (SDK). This allows you to create custom applications, run samples, and use tutorials to learn more about Host Integration Server.

For more information, see Development.

Planning for Transaction Integrator

Planning Your Hardware

Because Host Integration Server can be used in a wide variety of situations, there is no simple formula for the amount of processing power a specific computer needs. The information provided in this topic can help you evaluate your hardware requirements, including:

- A list of elements that reduce or increase demands on hardware. This helps you estimate the general level of your processing requirements. For example, a Host Integration Server computer can serve as many as 1500 to 2500 users. This indicates a need for large amounts of processing power, perhaps a Pentium processor with 64 or 128 megabytes (MB) of RAM. However, if your servers each support 500 users and most of those users connect briefly and at random times during the day, less processing power is needed.

- Ways to evaluate the current demand on an existing Host Integration Server computer, and the ability of the existing hardware to support that demand. This gives you a valuable baseline from which to work.

In This Section

Variables Affecting Hardware

Many factors affect the amount of memory and processing power required by a particular Host Integration Server computer. The major variables are:

- Number of clients served.

  This is the most important variable affecting hardware requirements. If you support large numbers of client computers, you need not only servers that have ample memory and processing capacity, but also fast, powerful LAN adapters. Such LAN adapters include their own processor and memory, and can use direct memory access (DMA). Without such adapters, the network interface can become the bottleneck when many clients are being supported. Similarly, SNA adapters must be powerful enough to keep pace with the communications load.

- Demand generated by the clients (constant, intermittent, heavy, light).

- Number of Host Integration Server computers configured to work together within a particular subdomain.

  This is affected by the configuration of the Host Integration Server installation: centralized, branch, or distributed. Host Integration Server computers in a centralized or a distributed configuration can provide load balancing; they can each take a share of the connection load. Server computers in a branch configuration are separated by wide area network (WAN) links, and cannot readily provide load balancing because of the communication delays involved.

- Use of data encryption between clients and servers.

  Data encryption is not dependent on the number of clients being served but on the number of messages that are encrypted. As the number of transactions per second increases, the load on the CPU increases. Using 128-bit encryption instead of 40-bit encryption also increases the load on the CPU.

- Additional network services (file sharing, database access, mail service, and so on) provided by each server computer.

  It is difficult to predict exactly how much processing power is required to run multiple server applications. In many cases, your own requirements to meet a certain level of response time or transaction rate will indicate the specific hardware requirements for your environment.

Estimating Hardware Demands
Best Practices

Estimating Hardware Demands

Use the information in the following table to estimate the amount of processing power required for your Host Integration Server computers.

Installation category	Hardware guidelines
Approximately 1500–5000 users for each server, with up to 15,000 sessions for each server	A multiprocessor system with at least 128 megabytes (MB) of RAM. Connections (such as DLC 802.2 or channel) that are fast enough to avoid bottlenecks (recommended). Multiple SNA adapters, except for channel. Multiple LAN adapters to avoid LAN bottlenecks. Optionally, dedicated Host Integration Server computers that do not provide file sharing or other LAN services (this depends on the load created by other LAN services).
Up to 600 users for each server (heavy use) or up to 1500 users for each server (light or intermittent use)	A Pentium computer, with at least 128 MB of RAM. Connections (such as DLC 802.2 or channel) that are fast enough to avoid bottlenecks (recommended). Multiple SNA adapters may be needed, except for channel connections. Multiple LAN adapters may be needed to avoid LAN bottlenecks. A more powerful CPU and more RAM may be needed if Host Integration Server computers must support significant additional loads, such as file sharing.
Up to 200 users for each server (heavy use) or up to 500 users for each server (light or intermittent use)	A Pentium computer, with at least 128 MB of RAM. A more powerful CPU and more RAM may be needed if Host Integration Server computers must support significant additional loads, such as file sharing.
Up to 25 users for each server	A Pentium computer, with at least 128 MB of RAM. A more powerful CPU and more RAM may be needed if Host Integration Server computers must support significant additional loads, such as file sharing.

Concepts

Variables Affecting Hardware

Best Practices

Best Practices

Several rules of thumb can be applied when selecting your Host Integration Server hardware:

- Try to avoid memory paging.

  It is useful to increase the amount of physical memory in a Host Integration Server computer to avoid paging. This guideline is true for any Windows Server that performs communications-related functions.

- Increase memory when using Host Print service.

  When using Print service, you may need more memory on the Host Integration Server computer if large files or many print jobs are submitted. You also need adequate disk space to temporarily store the spooled print jobs.

- Use TCP/IP instead of Microsoft Networking.

  The Windows Sockets (Winsock) and TCP/IP combination uses less memory on the Host Integration Server computer than Microsoft Networking or other named socket solutions. TCP/IP also provides better performance than Microsoft Networking because of its lower network overhead.

Planning 3270 Connectivity

In the hierarchical SNA network model most frequently associated with a mainframe computer, you access centralized applications from remote terminals across a network.

This network model uses the information display protocol for IBM mainframe computers known as 3270. This protocol facilitates conversations between the mainframe and devices such as terminals, printers, and controllers. Through the definition and assignment of 3270 logical units (LUs), Host Integration Server provides access to these mainframe resources.

Once you establish the physical connection from the Host Integration Server computer to the mainframe, you need to determine the type of 3270 connectivity your users need. The topics in this section detail the networking services Host Integration Server can provide to your users and offers information on ways to set up these services.

In This Section

3270 Access

Host Integration Server provides 3270 connectivity through 3270 logical units (LUs). A 3270 LU is known as a dependent LU because it requires a mainframe to function. Each 3270 LU defined within Host Integration Server is configured to use an existing connection to the mainframe system. Each 3270 LU corresponds to a matching LU resource allocated on the host computer, usually specified within VTAM. The 3270 LU definition in Host Integration Server is identified by a number that matches the number of the corresponding LU resource on the mainframe, and by a user-specified name.

The 3270 LU is further classified by the type of service provided over the connection. Like physical units (PUs) physical units, LU types are designated by numbers. For example, 3270 display data streams are known as LU 2 streams. Within Host Integration Server, a 3270 LU can be configured as one of the following types:

- Display (LU 2)
- Printer (LU 1 or LU 3)
- Application (LUA)
- Downstream

Once configured, these LUs are accessed from an end-user applications using Host Integration Server client software that is installed on the client workstation. The client software manages communications between a 3270 application (like a terminal emulator) and the Host Integration Server computer. Applications designed for the Host Integration Server client API use the LUs defined within Host Integration Server to establish a communications link from the client personal computer to the mainframe via Host Integration Server.

The link between the LU definition in Host Integration Server and the host LU resource is called a *session*. Sessions can be permanent and automatically started during initialization, or established on an as-needed basis. Concurrent sessions can share the same physical devices and communications links.

Using LU Pools
Assigning LUs to Workstations
Providing Hot Backup and Load Balancing

Deployment Strategies

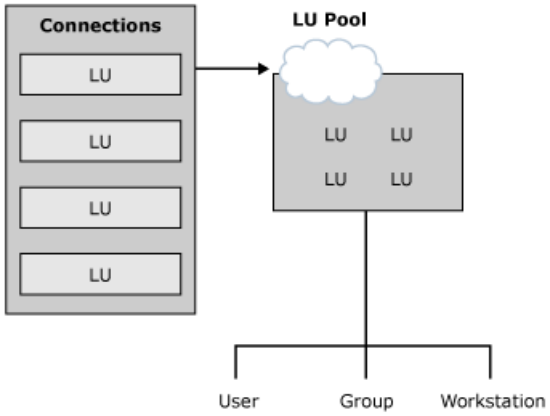
This section describes deployment strategies that can be applied if you are providing 3270 connectivity services including:

- Using LU Pools
- Assigning LUs to Workstations
- Providing Hot Backup and Load Balancing

Using LU Pools

Although you can create individual LUs and assign them to users and groups, using LU pools to manage and deploy a large number of LUs is a more efficient method of administering these resources. LU pools are groupings of LUs that allow you to maximize access to these LUs. As shown in the following illustration, a user, an application, or a downstream system can access the LUs as long as any LU assigned to the pool is free. If any one of the pooled LUs ceases to function, another free LU in the pool is automatically used.

Diagram of creating and assigning LU pools



Creating and assigning LU pools

LU pools also allow groups of intermittent users to use a limited number of host resources more efficiently. Dedicating LUs to specific users who occasionally require host access wastes host resources. Using a pool, you can assign a smaller number of LUs to a group of users who require sporadic access. For example, if a group of 100 users require host access 25 percent of the time, assigning a pool of 25 LUs to the group may fulfill their needs.

See Also

Concepts

Assigning LUs to Workstations

Providing Hot Backup and Load Balancing

Assigning LUs to Workstations

LUs and LU pools can also be assigned to workstations rather than users, effectively locking LUs to a specific machine. Assigning LUs to a workstation makes it easier for users to find and access different resources. For example, 200 hospital employees can share 50 workstations, each of which has a printer attached. Employees may want to access any of the 50 workstations and 50 printers. Instead of assigning 50 printer LUs to a pool and making the pool available to each user, each of the workstations can be added to Host Integration Server and a printer LU can be assigned to each workstation. Now, when a user logs onto any of the 50 workstations, the printer that is attached to the workstation will be available in the list of LUs.

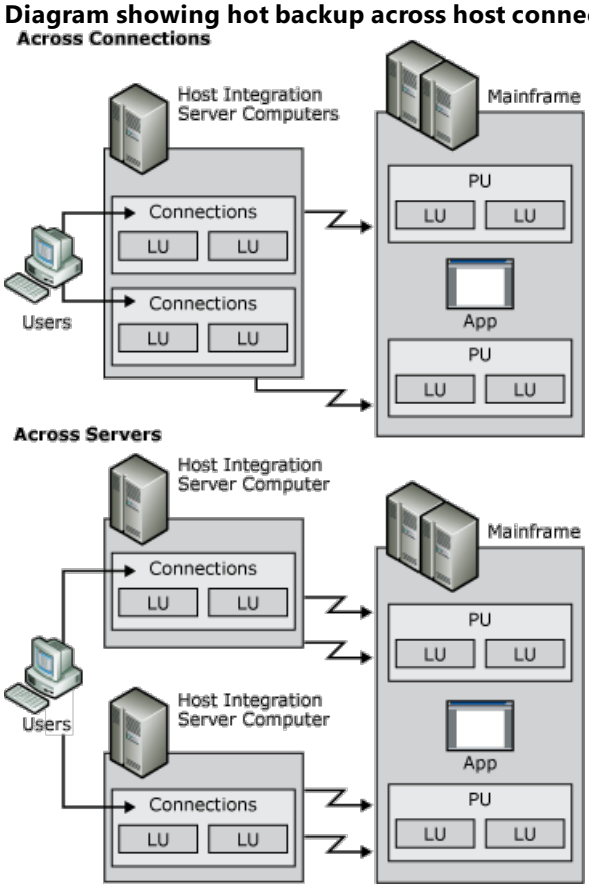
Concepts
Using LU Pools
Providing Hot Backup and Load Balancing

Providing Hot Backup and Load Balancing

The following diagram shows hot backup across host connections on the same server and across servers.

Diagram showing hot backup across host connections on the same server and across servers



To recover from situations where a particular host connection has failed, the Host Integration Server hot backup feature can be configured to allow for similarly configured resources to automatically fill in and support functions dependent on the failed connection. When a failure occurs, a user can simply reconnect to a given resource using an alternate connection or server without reconfiguring client software. Hot backup can be implemented across host connections on the same server, or across several servers in a domain using LU pools as shown in the preceding figure. Implementing fault-tolerant connections is a recommended strategy for enterprises of any size, and helps to provide reliable host access to your users.

Related to hot backup is a feature called load balancing. Load balancing evenly distributes sessions across multiple host connections and multiple servers using 3270 LU pooling. Instead of explicitly requesting specific LUs, users request the first available LU in a pool and Host Integration Server randomly assigns the user a free LU in the pool. Because each LU can be configured using different connections or servers, the server load can be spread out across all configured resources. Load balancing is implemented automatically when a pool is configured with LUs from multiple servers or connections.

Concepts

Using LU Pools

Assigning LUs to Workstations

TN3270 Access

TN3270 is a type of Telnet service that allows access to mainframe computers over a TCP/IP network. Users can connect to mainframes using a TN3270 client and the TN3270 service provided with Host Integration Server.

The TN3270 service supports these protocols:

- TN3270, for display sessions
- TN3287, for printer sessions
- TN3270E, for extended display and print sessions

The TN3270 service uses Host Integration Server features to provide mainframe access and to address issues such as security and redundancy when the data communications path between the client and server contains one or more nonsecured segments.

TN3270 Service

The TN3270 service communicates with Host Integration Server using the LUA (Logical Unit for Applications) API. Because of this, LUA-type connections and LUs must be configured on the server. Once configured, LUA LUs and LU pools can be assigned to the TN3270 service and made available for use by TN3270 clients requesting mainframe access.

Concepts

Setting Port Numbers
Deploying Hot Backup and Load Balancing
Assigning LUs to an IP Address

Deployment Strategies

This section describes deployment strategies that can be applied if you are providing TN3270 connectivity services including:

- Setting Port Numbers
- Deploying Hot Backup and Load Balancing
- Assigning LUs to an IP Address

Setting Port Numbers

As with all TCP/IP services, TN3270 requires a free TCP port in which clients can locate the TN3270 service. By default, the TN3270 service defaults to port 23, the same port as standard Telnet services. Because no two services can share the same TCP port, it is recommended that you change the TN3270 service to use TCP port 24 or some other unused TCP port. When attempting to connect to the TN3270 service from a client application, you must also specify the new TCP port within the application connection settings.

See Also

Concepts

Deploying Hot Backup and Load Balancing

Assigning LUs to an IP Address

Deploying Hot Backup and Load Balancing

A Windows domain can contain one or more Host Integration Server subdomains. Like 3270 LUs, LUA LUs from multiple servers in different subdomains can be assigned to the TN3270 service. This lets you distribute client sessions among the participating servers in the subdomain, thereby balancing the load.

Creating redundant connections to the mainframe and assigning them to a TN3270 service increases service availability. If one server goes down, a client can still access LUA LUs on a different server. Similarly, a single server can be configured with redundant host links to increase hot backup and bandwidth if no other Host Integration Server computers are available.

See Also

Concepts

Setting Port Numbers

Assigning LUs to an IP Address

Assigning LUs to an IP Address

In the same way that you assign 3270 LUs to a user or workstation, you can restrict access to LUA LUs or pools by specifying an IP address or subnet mask for clients that must access the resource. If a workstation has a name that can be resolved using name resolution services like DHCP or WINS, the name can be associated with the resource instead.

Restricting access to clients with specific IP addresses or workstation names increases the security of the LUA resources.

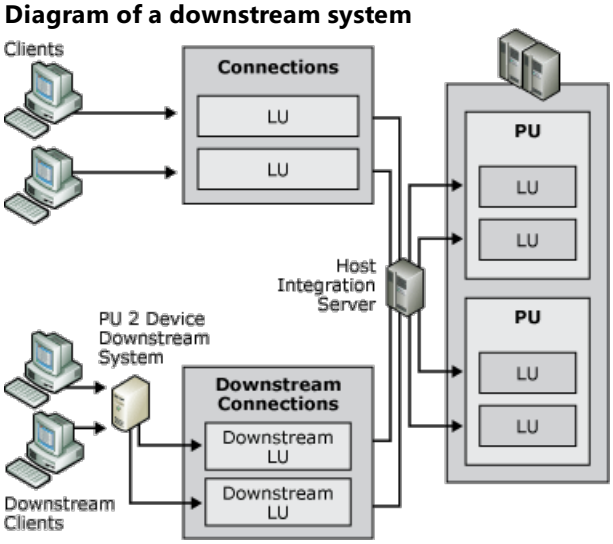
Setting Port Numbers

Deploying Hot Backup and Load Balancing

Downstream Connections

In a hierarchical SNA environment, you configure 3270 communications between SNA nodes using SNA protocols. Usually those nodes are Host Integration Server computers and mainframes. A downstream system, however, is an SNA node that uses Host Integration Server as a physical unit (PU) gateway. To the downstream system, the Host Integration Server computer appears to be the actual mainframe providing the PUs and 3270 LUs. The following figure illustrates a downstream system.

Diagram of a downstream system



A downstream system in this type of environment must be a PU 2 device, for instance, a cluster controller like an IBM 3745, or a client personal computer running a terminal emulator that emulates a PU 2 and acquires LU sessions from the Host Integration Server computer.

On the Host Integration Server computer, two connections are required to support downstream systems:

- A host connection between the server and the mainframe. This can be any standard physical connection method supported by the mainframe.

- A downstream connection between the server and the downstream system. This physical connection can be a DLC 802.2, SDLC, or X.25 connection.

Once configured, Host Integration Server can manage the downstream LUs in a manner similar to other LUs, including assigning them to LU pools.

See Also

Concepts

Deployment Strategies

Deployment Strategies

This type of configuration is useful in environments in which the downstream system may be unable to communicate directly with the mainframe because of hardware or network incompatibilities that the intermediate Host Integration Server computer can resolve.

Using Host Integration Server as a PU concentrator can also help reduce host configuration requirements. LUs from one or more physical units (PUs) can be shared with multiple downstream devices, alleviating the need to configure each downstream device in VTAM on the mainframe system. The result is more efficient use of host resources.

Concepts

Downstream Connections

Planning APPC Connectivity

A peer-oriented SNA network, using the Advanced Program-to-Program Communications (APPC) protocol, relies on each device in the network to communicate directly with the others. Each computer depends primarily on its own intelligence and does not require constant access to a centrally located host computer.

APPC supports display and other application services across an SNA network. Although peer-oriented SNA networks are usually associated with an AS/400 host system, mainframe systems can also support peer-to-peer networking.

Once you establish the physical connection from Host Integration Server to the AS/400, you need to determine the types of APPC services required by your users. This section discusses the APPC services that Host Integration Server can provide to your users and tells how to set up these services.

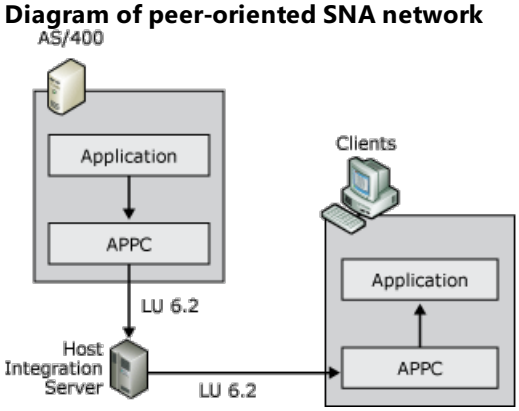
In This Section

Understanding Peer-to-Peer Networking

Devices in peer-oriented SNA networks participate in Advanced-Peer-to-Peer Networking (APPN). Each device, known as a type 2.1 physical unit (PU 2.1), handles all network routing functions, as well as normal computing activities and applications.

LU 6.2 logical units are associated with PU 2.1 devices. Devices in an APPN network appear as LU 6.2 (also called APPC LU) entities. Programs that are executed on these devices are called transaction programs(TPs).

Diagram of peer-oriented SNA network



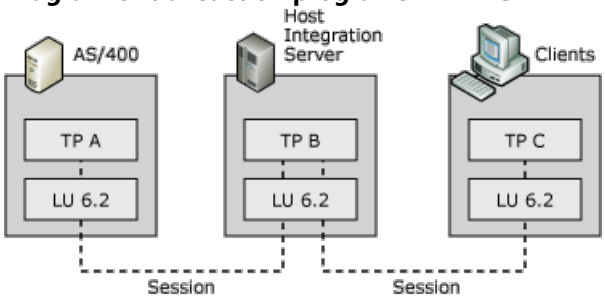
APPC enables TPs on different APPN systems to communicate directly with each other across an APPN network. In APPN networks, Host Integration Server provides support for the APPC protocol and emulates a PU 2.1 low-entry networking (LEN) node.

In the AS/400 environment, APPC is used for a variety of applications, including:

- 5250 access
- TN5250 access
- File transfer

TPs use LU 6.2 names to access other systems and other transaction programs as shown inthe following figure. With Host Integration Server, a transaction program, such as a 5250 terminal emulator, can also use an APPC LU alias to access another TP. In this case, the LU alias maps to an LU name that is actually used to access the other system's TP.

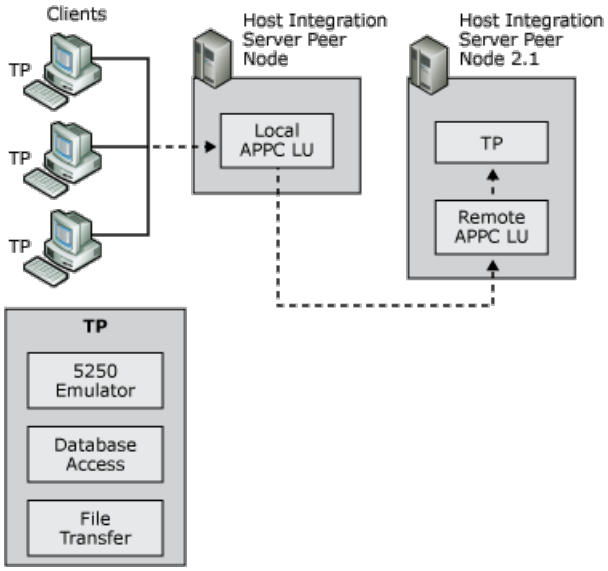
Diagram of transaction programs in APPC



APPC uses pairs of LUs to facilitate simultaneous, bi-directional communication between transaction programs. To achieve this, a local LU and a remote LU are defined on each device in the APPN network.

The perception of local and remote LUs is dependent on the system that you are configuring. When configuring Host Integration Server, the local APPC LU corresponds to the Host Integration Server computer and the remote LU corresponds to the AS/400. Local LUs on one system communicate with remote LUs on another system. If you view the configuration from the AS/400 perspective, the Host Integration Server computer is the remote system and the AS/400 is the local system.

Diagram of conversation components in APPC



When a client/server network TP, such as a 5250 terminal emulator, requests a conversation with a TP on the AS/400 (remote system), the server (local system) acts on behalf of the client request and negotiates an LU 6.2 - LU 6.2 session to the AS/400. The data sent or received from the AS/400 TP is handled by the server and sent to the client TP over the selected client/server protocol. This is illustrated in the preceding figure.

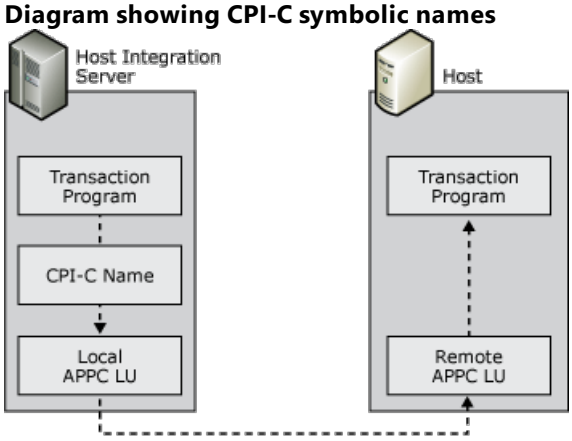
Understanding CPI-C

Understanding CPI-C

Common Programming Interface for Communications (CPI-C) is an application programming interface (API) that uses the LU 6.2 communications architecture. CPI-C comprises a set of C programming language routines that allow applications on computers to communicate with one another to accomplish a processing task, such as copying a file or accessing a remote database.

CPI-C programming provides a mechanism called client-side information that associates a set of parameters with a specified CPI-C symbolic destination name. The CPI-C program uses the symbolic destination name to initialize a conversation using APPC LUs that are associated with the CPI-C symbolic name.

Diagram showing CPI-C symbolic names



Host Integration Server supports the CPI-C API and provides for configuration of CPI-C parameters. These parameters allow applications on the Host Integration Server systems to communicate with applications on any platform that supports APPC communications and CPI-C including mainframes, AS/400s, Windows systems, and UNIX systems.

APPC Applications

Advanced Program-to-Program Communications (APPC) can be used to support a wide range of applications. This section describes how Host Integration Server is used to support the following services:

- 5250 terminal access
- TN5250 terminal access
- APPC file transfers

Concepts
5250 Access
TN5250 Access

5250 Access

If your enterprise contains AS/400 systems, display sessions are provided through APPC using the 5250 data stream. Host Integration Server computers provide APPC access to an AS/400 using 5250 emulation clients. Clients can only communicate with AS/400s using APPC.

For 5250 services, the local APPC LU acts as an identifier for local Host Integration Server clients; the remote APPC LU identifies the AS/400 system. The following figure shows the local and remote LUs used for this configuration.

Diagram showing 5250 access configuration

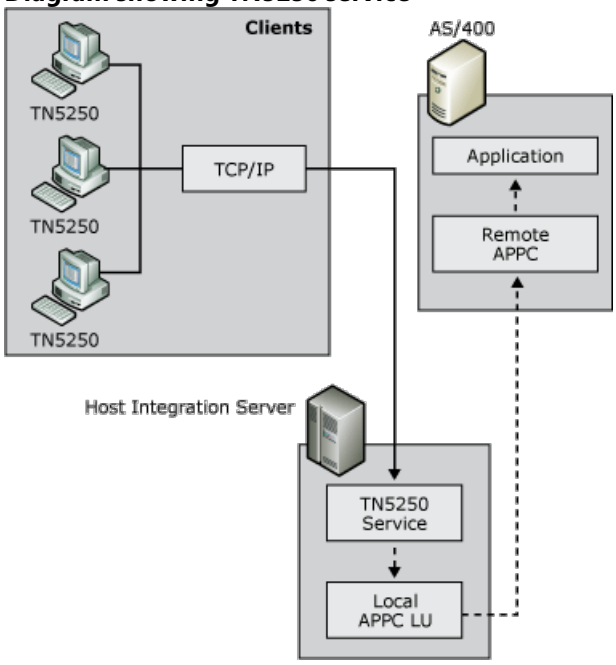
APPC Applications

TN5250 Access

TN5250 is a protocol that allows users to access AS/400 systems over a TCP/IP network using an appropriate TN5250 client terminal emulator. The TN5250 service provided with Host Integration Server enables any TN5250 client to connect to the AS/400 by means of Host Integration Server without installing or configuring TCP/IP on the AS/400. Full 5250 terminal emulation functions are supported by the service, as well as hot backup and security features similar to those provided with the TN3270 service.

Diagram showing TN5250 service



To provide TN5250 access, you need to define local and remote APPC LUs, a mode, an AS/400 user name and password, a terminal type, and, optionally, an IP address and subnet mask.

Planning APPC Connectivity

Using Independent APPC LUs

An independent LU can communicate directly with a peer system and does not need the support of a host computer. Independent APPC LUs, as used in AS/400 APPN networks, provide the ability to run multiple, concurrent, parallel sessions between a local and remote LU pair.

When configuring independent APPC LUs, you should note that when Host Integration Server is used to communicate with a transaction program (TP) on a mainframe over an independent APPC LU, the host system must be running VTAM version 3, release 2 (V3R2) or later. The version of Network Control Program (NCP) required on the mainframe depends on the type of front-end processor (FEP) used. For 3725 systems, NCP V4R3 or later is required. For 3745 systems, NCP V5R2 or later is required.

See Also

Other Resources

APPC Deployment Strategies

Using Dependent APPC LUs

A dependent local APPC LU requires the support of a mainframe in order to communicate with a remote TP. Dependent APPC LUs cannot be used to communicate with AS/400s. Unlike independent APPC LUs, dependent APPC LUs only allow a single session per LU.

Dependent APPC LUs are helpful when configuring Host Integration Server to communicate with a mainframe using a version of VTAM earlier than V3R2. Independent LUs are not supported in earlier VTAM versions. Support for dependent APPC LUs is provided with Host Integration Server for compatibility with older VTAM versions. If possible, use independent LUs.

When configuring APPC dependent LUs, you should specify the network name and LU name. Even though they are not required, they are used by software running on the Host Integration Server computer, such as the Windows Event Log. For example, if a remote APPC LU will be partnered with a dependent local APPC LU, naming the remote APPC LU helps to identify any events associated with the LU in the Windows Event Log.

Other Resources

APPC Deployment Strategies

Choosing Modes

When choosing modes, each LU-LU pair has a mode associated with it that determines session properties for that pair. For independent APPC LU sessions, the Parallel Session Limit parameter is of particular importance because this limit determines the number of simultaneous conversations that a session can support. If you plan to use a remote APPC LU that supports parallel sessions, it can only be used with a mode whose parallel session limit has a value greater than 1.

The following table lists the modes supplied with Host Integration Server and describes the scenarios in which each mode can be used.

Mode Name	Suitability
#BATCH	Batch-oriented sessions
#BATCHSC	Batch-oriented sessions that employ a minimal level of routing security
BLANK	Sessions using a default node name, encoded as eight blank EBCDIC spaces in a BIND APPC command
#INTER	Interactive sessions
#INTERSC	Interactive sessions that employ a minimal level of routing security
QPCSUPP	All sessions with an AS/400 computer
QSERVER	Database connectivity with an ODBC driver

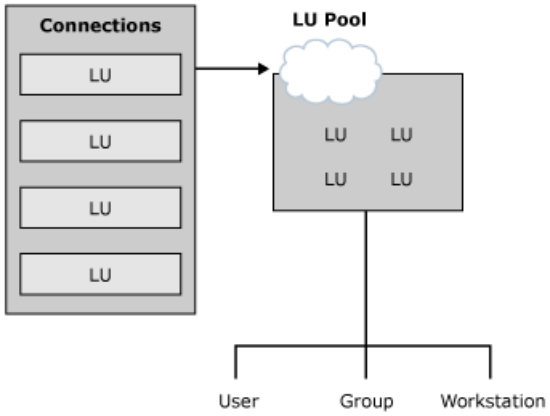
APPC Deployment Strategies

Using LU Pools

Although you can create individual LUs and assign them to users and groups, using LU pools to manage and deploy a large number of LUs lets you administer these resources more efficiently. An LU pool is a grouping of LUs that allows you to maximize access to these LUs as shown in the following figure. A user, an application, or a downstream system can access the LUs as long as any LU assigned to the pool is free. If any one of the pooled LUs ceases to function, another available LU in the LU pool is automatically used.

Diagram showing LU pools



LU pools also allow groups of intermittent users to use a limited number of host resources more efficiently. Dedicating LUs to specific users who occasionally require host access wastes host resources. Using a pool, you can assign a smaller number of LUs to a group of users who require sporadic access. For example, if a group of 100 users require host access 25 percent of the time, assigning a pool of 25 LUs to the group may fulfill their needs.

Other Resources

APPC Deployment Strategies

Configuring LUs

When a user configures a 5250 emulator to access an AS/400, the emulator is configured with the local and remote APPC LU alias names. The LU alias names are mapped to LU names that are used for the conversation with the AS/400.

Host Integration Server allows you to define a default local and remote APPC LU for each user group accessing the AS/400. Setting default values relieves the user from having to remember APPC LU names; these values should be specified, if possible.

When creating local APPC LUs, it is recommended that you use the name of a user or group as the local LU alias. When the session from a particular user or group is active, the LU alias name is displayed in SNA Manager. Matching local LU alias names with user names allows you to tell which 5250 users are connected to the AS/400. This also makes it easy to keep track of which local LU a particular user should use.

To use this method, create a separate local APPC LU with an LU alias that matches the user name of each person or group being added to the SNA subdomain. After the LU is created, assign the LU to the user as the default local APPC LU along with a default remote APPC LU.

In Host Integration Server, you can also specify an implicit incoming remote LUthat defines the properties to use when Host Integration Server receives a request to start a session with a local LU, and the remote LU named in the request is not recognized by Host Integration Server. You can also specify an implicit incoming mode that defines the session characteristics when a mode is not recognized by Host Integration Server.

If you want to accept an incoming request that can arrive by many different remote LUs without explicitly defining each remote LU, you can specify implicit incoming remote LU pairs, along with their mode. When the implicit incoming remote LU and mode are specified, the remote LU does not need to be recognized by the server. As long as the local LU specified in the session request is recognized, the connection can be initiated.

APPC Deployment Strategies

Providing Hot Backup

In the AS/400 environment, Host Integration Server uses a combination of LU names and LU aliases over one or more servers to achieve transparent connections with hot backup to an AS/400.

Hot backup connections to an AS/400

A single Host Integration Server computer can use multiple connections to provide hot backup. To use this method, two or more APPC connections to the same AS/400 are configured and appropriate LUs are grouped into a pool. If one of the connections fails, the clients can reconnect to the AS/400 without reconfiguration.

Host Integration Server can also use multiple Host Integration Server computers as backups to one another. If one of the servers fails, the clients are shifted from the failed server to a working server. Use a combination of connections and servers with hot backup to maintain a high level of host availability in your enterprise.

See Also

Other Resources

APPC Deployment Strategies

Choosing IP Settings

IP settings assigned to the TN5250 definitions allow TN5250 clients to connect to the AS/400. By default, the TN5250 definition is not assigned an IP address or a subnet mask. This allows any TN5250 client to connect to the AS/400.

You can restrict access to the TN5250 service by specifying the IP address or subnet mask of the client workstation(s). When these values are specified, only clients whose IP and/or subnet mask match those specified in the TN5250 configuration are allowed access to the AS/400 through the TN5250 service. You can also specify the workstation name in place of the IP, and use a WINS, DHCP, or other name-resolution service to resolve a friendly name to an IP address.

Host Integration Server (SNA) Remote Access Service

Deployment Strategies

Host Integration Server (SNA) Remote Access Service

SNA Remote Access Service integrates the LU 6.2 transport of Host Integration Server with Windows Remote Access Service, allowing administrators to create virtual LAN connections between Windows systems across an existing SNA network. Using SNA Remote Access Service, the SNA network acts as a network backbone, passing network traffic between the Windows systems that are bridged with the host system.

The functions available with SNA Remote Access Service are the same as those for Remote Access Service over ISDN or X.25, except for the dial-back connection feature, which is not supported by SNA Remote Access Service. The SNA Remote Access Service supports the either the Windows Remote Access Service Server or Windows Remote Access Service client, depending on whether the machine to which SNA Remote Access Service is installed is a Host Integration Server client or server. In addition, a Windows Workstation computer running Host Integration Server client software and SNA Remote Access Service can dial out through the Host Integration Server computer that is also running SNA Remote Access Service.

SNA Remote Access Services is configured using local and remote APPC LUs that are assigned to clients using SNA Remote Access Service to connect to mainframe and AS/400 computers. After SNA Remote Access Service is installed, a SNA Remote Access Service port must be specified for each client or server connection that the computer will support. For example, to support one client and four server connections, a total of five ports must be specified. Each port must be added and configured before it can be used by SNA Remote Access Service.

See Also
Concepts
Choosing IP Settings

Deployment Strategies

Since legacy SNA networks may include smaller-bandwidth links like SDLC, and LAN traffic typically generates more network traffic that can be effectively handled by slower connections, care should be taken to resolve bandwidth needs before deploying SNA Remote Access Service in your enterprise.

Before Windows Remote Access Service clients can connect through SNA Remote Access Service, Host Integration Server must be configured to provide the following items for each client system:

- A peer incoming connection
- A remote APPC LU for each client

Each Host Integration Server computer must also be configured with at least one local APPC LU that can be used by SNA Remote Access Service when communicating with the client system. One local LU is required for each SNA Remote Access Service port that is used. For each connection that you set up for use by SNA Remote Access Service, a corresponding remote APPC LU must be configured. This remote LU defines the local LU on the Remote Access Service client that will be used to connect to the server via SNA Remote Access Service. Once the LUs are configured, each remote user must be given permission to dial in to the server.

If you create a SNA Remote Access Service connection between a client and a server that are also connected by a LAN, you must disable the bindings between the Remote Access Server Service and the network adapter to prevent Windows Remote Access Service from attempting to insert the Remote Access Service client into the LAN. This scenario usually occurs when testing a Remote Access Service connection over a network.

After the APPC LUs are configured, the final step is to create a phone book entry for each connection. If you have configured more than one port for use by SNA Remote Access Service, you can create an additional set of phone book entries by associating the same connection with the additional Remote Access Service ports.

A common use of SNA Remote Access Service is to enable an administrator to manage Host Integration Server computers remotely via the SNA network itself. An administrator working at a Windows Workstation running SNA client software and SNA Remote Access Service can use the service to connect to and administer servers at branch locations connected to SNA network.

Choosing IP Settings

Planning for Transaction Integrator

Before installing and using Transaction Integrator (TI), determine whether your mainframe-based transaction programs (TPs) can be used with TI and whether any of them need modification. Answer the following three questions to find out whether TI can invoke your TP:

- Is the TP irretrievably terminal-oriented, or can you expose a request-response interface?
- What programming model does the TP need?
- Does the TP use data types that TI supports?

To use TI to invoke a mainframe-based transaction program (TP), you must separate the business logic from the presentation logic in the TP. TI uses the request-response model; it does not support conversational or pseudo-conversational transactions. The TP must support the so-called ping-pong request-reply mode.

Although TI does not support screen scraping, it does support eight other communication models. Some CICS and most IMS transactions that expose terminal interface can also be invoked using one of the eight supported models. For example, a CICS transaction might be terminal-oriented but still have the business logic partitioned in a separate link model transaction for load balancing or maintainability.

Host and Automation Data

Communication Models

Transaction Integrator (TI) supports the following communication protocols for interacting with the host computer. These protocols are limited to singlerequest/single response. However, the request and response can consist of multiple data segments in the case of unbounded recordsets.

- **CICS TCP Transaction Request Message Link**

  The host transaction must be IBM DPL-enabled. In other words, the mainframe transaction must be designed to be invoked by EXEC CICS LINK.

- **CICS TCP Transaction Request Message User Data**

  The host transaction must use explicit TCP SEND/RECEIVE.

- **CICS LU 6.2 Link**

  The host transaction must be IBM DPL-enabled (Distributed Program Link), that is, the mainframe transaction must be designed to be invoked by EXEC CICS LINK.

- **CICS LU 6.2 User Data**

  The host transaction must use explicit APPC SEND/RECEIVE.

- **IMS Connect**

  Enables you to use TCP/IP with your IMS-based TP without recompiling it. By using IMS Connect or OTMA, you can connect to existing IMS transactions without linking listeners to the TPs.

- **IMS Implicit**

  The IMS program must use implicit message queue and IMS library CBLADLI (rather than CBLTDLI).

- **IMS Explicit**

  The host transaction must use explicit TCP SEND/RECEIVE.

- **IMS LU 6.2 User Data**

  The IMS program must use an implicit message queue (the common design model).

- **OS/400 Distributed Program Calls**

Planning for Transaction Integrator

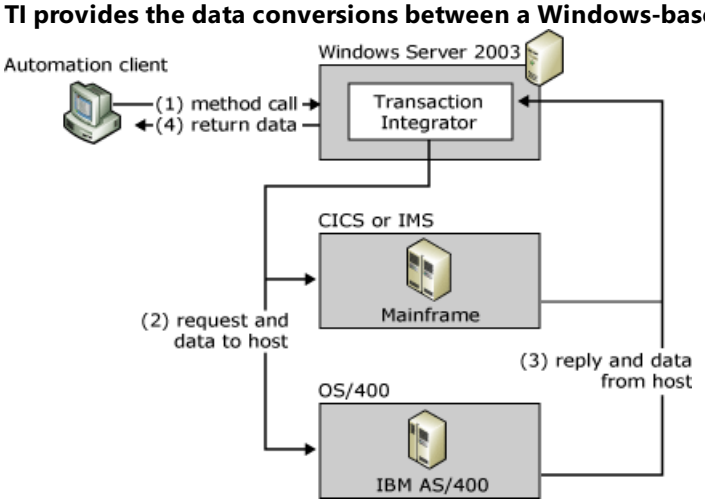
Transaction Integrator Architecture

Transaction Integrator (TI) integrates the IBM Customer Information Control System (CICS), Information Management System (IMS) transaction programs (TP), and OS/400 applications with the Component Object Model (COM) and the .NET Framework by doing the following:

- Creating interfaces to the CICS, IMS, and OS/400 transaction programs.
- Invoking those transactions on the mainframe or midrange computer (also called the host computer) from a Microsoft Windows–based application.

The primary function of TI is to manage the process and data conversions necessary to allow input data to be provided to the host TPs from a COM or .NET Framework application and to send any output data generated from the TP to the Windows-based application. TI provides data type conversion, tabular data definition, and code page translation. The following figure shows an overview of the role that TI plays in the communications between the application and the host.

TI provides the data conversions between a Windows-based application and a host



An example of this type of distributed application is reading a DB2 database on the mainframe to update data in a SQL Server database on Microsoft Windows 2000 Server.

Because all TI processing is done on the Windows 2000 Server or Windows Server 2003 platform, no TI-related executable code (or footprint) is required on the mainframe or midrange computer. TI uses SNA (APPC/LU 6.2) and TCP/IP standard communication protocols for all communications between Windows and the host computer. You can use TI Designer to build TI components, and you can use TI Manager to deploy, configure, and manage those TI components and the TI run-time environment.

In This Section

Online Transaction Processing

Most mainframe and midrange mission-critical applications run as online transaction processing (OLTP) applications underthe direction of a transaction-processing monitor, such as customer information control system (CICS) and information management system (IMS). CICS and IMS are widely used in mainframe environments to create distributed OLTP solutions, such as customer-tracking and order-entry solutions. TI integrates CICS and IMS with COM by creating COM and .NET interfaces to the CICS and IMS transactions and by calling for the services of, or invoking, those transactions on the host from a Windows-based application.

A two-phase commit (2PC) protocol is used when a transaction involves multiple programs running on multiple computers. Use the 2PC protocol to verify that eachl computer has completed its part of the transaction.

Transaction Integrator Architecture

CICS Components

Customer Information Control System (CICS) is a mainframe application system that provides components such as a transaction-processing monitor and a transaction-processing manager for a mainframe computer to run online transaction processing (OLTP) applications. You can install CICS on all three mainframe operating systems: Multiple Virtual Storage (MVS), Virtual Storage Extended (VSE), and Virtual Machine (VM). Due to the popularity of MVS, CICS is commonly installed on MVS mainframe computers. CICS extends the capabilities of a batch-only environment by providing the application system components that allow the mainframe computer to run OLTP applications.

CICS can run online applications on the mainframe computer because CICS acts almost like a separate operating system: it manages its own memory address space, runs its own file management functions, and manages the concurrent execution of multiple transaction applications.

To use Transaction Integrator (TI) successfully, you must understand the following CICS components and terminology:

CICS region

Each instance of CICS running on a mainframe computer is defined in Virtual Telecommunications Access Method (VTAM) by using a VTAM application statement. Each CICS instance defined in an application statement is called a CICS region. It is useful to define multiple CICS regions on a single mainframe computer because it allows you to logically group TPs in separate CICS regions and to use at least one CICS region for test purposes.

TP

The transaction program (TP) is the application software that executes under the supervision of CICS and contains the actual programming code necessary to process the business logic. Other terms that refer to a TP are transaction, host transaction program, application program, and program.

Transaction ID

All TPs that run under CICS are invoked by using a unique, four-character transaction identification (TRANID). This may sometimes be confusing because the transaction ID typically is different than the TP name. For example, the TP that handles CICS resource definitions is called Resource Definition Online (RDO), whereas the transaction ID that starts RDO is CEDA.

Program control table (PCT)

The program control table (PCT) is a CICS table that contains a mapping between TRANIDs and their associated TP names. After the TRANID is invoked, CICS starts the TP associated in the PCT with that TRANID.

File control table (FCT)

The file control table (FCT) is a CICS table that monitors which VSAM files are available to TPs. The FCT lists the name and type of VSAM files and valid operations that users can perform on each file. Although CICS can access other types of data stores, such as DB2, it accesses VSAM most frequently.

RDO

The RDO is a CICS TP that allows a CICS systems programmer to define the resources contained in the internal control tables.

Task

A task executes the functions of the TP; every CICS TP performs its functions by using a task. A CICS TP can use a single task or multiple tasks to perform its functions. Each time a TP is invoked, CICS starts the tasks required to perform its functions. CICS is a multitasking environment, which means that more than one task can, and often is, running at the same time.

Other Resources

Transaction Integrator Architecture

IMS Components

The information management system (IMS) provides a transaction program (TP) Monitor with an integrated TP Manager and hierarchical database. Both the TP Monitor and the database can coordinate transactions with non-IMS TP Monitors and databases.

To use Transaction Integrator (TI) successfully, you must understand the following IMS components and terminology:

IMS region

IMS uses defined regions to perform its functions. The following regions are typically defined in VTAM when using IMS:

- Control region - The main IMS region. It owns all of the databases that IMS transactions access and is responsible for all communications with the databases. It runs continuously and oversees the operation of other dependent regions.
- Message processing region (MPR) - A dependent region used for processing messages. The control region schedules TPs to run in the MPR. You can have multiple MPRs defined on a single mainframe computer.
- Batch message processing (BMP) region - A dependent region used for processing batch operations.

IMS message queue

The IMS message queue is used by TPs to access the MPP region for processing. Each MPP region has an IMS message queue associated with it. Placing application data in the IMS message queue allows the IMS server TP to use standard Get Unique (GU), Get Next (GN), and Insert (ISRT) calls to exchange data with a client application.

Data Language (DL)/I

Data language (DL)/I is the programming language used in traditional IMS environments to access IMS databases. IMS TPs and CICS TPs can be written in many different programming languages, such as COBOL, PL/I, C, VS Pascal, Ada, REXX, or assembler language. However, when any of these TPs needs to access IMS databases, they must use the proper DL/I calls from their application code. Some of the standard DL/I calls are:

- GU. This call retrieves input data to be processed.
- GN. This call retrieves sequential records.
- ISRT. This call inserts data into a database or returns data to an invoking client.

Transaction Integrator Architecture

Two-Phase Commit

A given business logic operation can involve multiple programs running on multiple computers. In this design, the transaction is not considered complete unless all of the programs involved complete their executions successfully. For these programs to verify that all other programs that are part of the transaction have completed their transactions, they must employ the two-phase commit (2PC) protocol.

The term transaction (or any of its derivatives, such as transactional), might be misleading. In many cases, the term transaction describes a single program executing on a mainframe computer that does not use the 2PC protocol. In other cases, however, it is used to denote an operation that is carried out by multiple programs on multiple computers that are using the 2PC protocol.

The 2PC protocol is so named because it employs the following two phases prior to committing the operation performed:

- Phase 1—Prepare. In this phase, each of the programs involved in the transaction sends a message to the TP Manager, such as Microsoft Distributed Transaction Coordinator (MS DTC), informing the TP Manager that it is ready to and capable of performing its part of the operation. This phase is also known as prepare because the programs are prepared either to commit the changes or rollback the changes. If the TP Manager receives confirmation from each of the programs involved, it proceeds to phase 2.

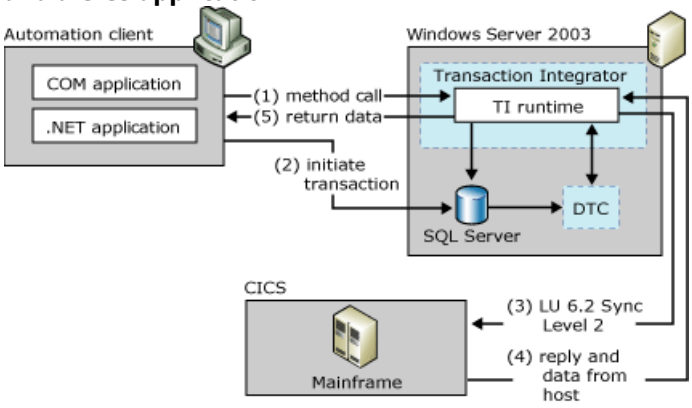
- Phase 2—Commit or Rollback. In this phase, the TP Manager instructs each of the programs to commit or rollback all of the changes that were requested as part of the transaction. A properly executed rollback should return the system to its original state.

Note

The state between phase 1 and phase 2 is known as the in-doubt state. Developers using COM+ or .NET in their applications can decide which parts of the application require access to a TP and which parts do not. TI extends this choice to the mainfra me, as well, by handling calls that require transactions and calls that do not. For applications that require full integration betw een Windows-based two-phase commit and mainframe-based Sync Level 2 transactions, TI provides all the necessary functi onality. TI does this without requiring you to change the client application, without placing executable code on the mainframe , and with little or no change to the mainframe TPs. The client application does not need to distinguish between the TI compo nent (type library) and any other COM+ component reference.

The following figure shows how a Windows-based client application implicitly uses the Microsoft Distributed Transaction Coordinator (DTC) to coordinate the two-phase commit of a distributed transaction involving SQL Server and a CICS TP. DTC coordinates 2PC transactions.

Client application using Transaction Integrator and DTC to coordinate a two-phase commit between SQL Server and a CICS application



Client application using TI and DTC

Two-phase commit (2PC) transactions involve a number of components. To use Transaction Integrator (TI) successfully, you must understand the following 2PC components and terminology:

Sync Point Level 2

TPs can interact with one another by using the LU6.2 protocol at one of three levels of synchronization: Sync Level 0, Sync Level 1, or Sync Level 2. Only one of these three sync levels, Sync Level 2, uses the 2PC protocol. Sync Level 0 has no message integrity, whereas Sync Level 1 supports limited data integrity.

TP Manager

The transaction program (TP) Manager is a system service that is responsible for coordinating the outcome of transactions to be able to achieve atomicity. The TP Managers ensure that the resource managers reach a consistent decision on whether the transaction should commit or abort. The Windows 2000 TP Manager is MS DTC.

Resync service

The LU6.2 Resync Service is a component of Host Integration Server that works with MS DTC to perform automatic recovery to a consistent state as a result of failures at any point in a 2PC transaction. The LU6.2 Resync Service is installed by default when installing Host Integration Server.

Resource Manager

The resource manager is a system service that manages durable data. Server applications use resource managers to maintain the durable state of the application, such as a record of available inventory, pending orders, and accounts receivable. The resource managers work in cooperation with the transaction manager to provide the application with a guarantee of atomicity and isolation (by using the 2PC protocol). Microsoft SQL Server™ and TI are examples of resource managers.

Windows Transactions vs. Mainframe Transactions
Other Resources
Online Transaction Processing

Windows Transactions vs. Mainframe Transactions

In the Host Integration Server Help, a transaction in the Microsoft Windows, COM, COM+, or .NET Framework environments does not mean the same thing as a transaction in the mainframe environment.

- A transaction in the Windows environment is a set of actions coordinated by the Microsoft Distributed Transaction Coordinator (DTC) as an atomic unit of work that meets the ACID test; in other words, a transaction is atomic, consistent, isolated, and durable. Either all the actions in the transaction are completed, or none of them are completed.

- A transaction in the mainframe host (CICS or IMS) environment is a section of code in a structured transaction program (TP), and a TP is a single COBOL program file that contains one or more mainframe transactions. Therefore, a mainframe transaction may or may not meet the ACID test.

A TI Automation server is a TI component deployed in a COM+ or .NET Framework application. A single method in a TI Automation server invokes a single mainframe-based TP. Any TI method in the TI Automation server can invoke any transaction in the TP, but it is the TP that determines which of its transactions to run. The mainframe TP makes this decision based on the information sent to it from the TI Automation server. A CICS or IMS TP can provide any type of service, such as terminal interaction, data transfer, database query, and database updates. A TP can also contain one or more transactions.

A mainframe TP also has a specialized meaning in the IBM CICS environment. Any program that uses Advanced Program-to-Program Communications (APPC) with another program is referred to as a transaction program (TP). APPC is a set of protocols developed by IBM specifically for peer-to-peer networking among mainframes, AS/400s, 3174 cluster controllers, and other intelligent devices. For a TP to communicate directly with another TP using APPC, the two programs must first establish an LU 6.2 session and conversation with each other.

LU 6.2 is the de facto standard protocol for distributed transaction processing in the mainframe environment. It is used by both CICS and IMS subsystems. One program can interact with another program at one of three levels of synchronization:

- Sync Level 0 has no message integrity beyond sequence numbers to detect lost or duplicate messages.

- Sync Level 1 supports the CONFIRM-CONFIRMED verbs that allow end-to-end acknowledgment for client and server.

- Sync Level 2 supports the SYNCPT verb that provides ACID (atomicity, consistency, isolation, durability) properties across distributed transactions by way of two-phase commit (2PC).

Of the three sync levels, only Sync Level 2 provides the same guarantees provided by a Windows, COM, COM+, or .NET Framework transaction.

Note
The TCP/IP protocol is not designed for distributed transaction processing, so TCP/IP does not provide the ACID guarantee th at 2PC in LU 6.2 Sync Level 2 provides. Therefore, it is the network protocol (LU 6.2 or TCP/IP) that determines whether it is p ossible to guarantee that a transaction in a TP operates as an atomic, consistent, isolated, and durable unit.

Thus, in the CICS and IMS environment, the term transaction program (TP) may or may not imply the use of 2PC. The term transaction program refers to the program itself. It is only when the term transaction is qualified by adding the term Sync Level 2 that the Windows developer and the mainframe developer can be sure they are referring to the same thing.

TI supports both Sync Level 0 and Sync Level 2 conversations over LU 6.2 in SNA networks. If a method invocation is part of a DTC-coordinated transaction, TI uses Sync Level 2 to communicate with CICS or IMS version 6.0 with Resource Recovery Services (RRS). If a method invocation is not part of a DTC-coordinated transaction, then TI uses Sync Level 0.

Support for Transactions and Two-Phase Commit

Transaction Integrator Basic Functions

In current Internet-driven, graphical user interface (GUI) computing environments, users usually prefer to access mainframe online transaction processing (OLTP) applications using the same interfaces that they use to access the Internet or their organizations intranet, instead of by using traditional green screen, dumb terminal access methods. Transaction Integrator (TI) provides any application that is compatible with Microsoft Windows 2000 Server or Microsoft Windows Server 2003 access to transactions and data in CICS, IMS, OS/400 applications. By providing this access, TI reduces the time and effort involved in programming specialized interfaces for mainframe computers.

As a generic proxy for a mainframe or midrange computer, TI intercepts object method calls and redirects those calls to the appropriate host application. TI also handles the return of all output parameters and values from the host computer. When TI intercepts the method call, it converts and formats the parameters from the representation understood by the Microsoft Windows platform into the representation that is understandable by the host transaction program (TP).

Transaction Integrator Architecture

Managing Data Input/Output

Most mainframe and midrange transaction programs (TP) rely on a set of input parameters that carry input data, typically provided by a user at a dumb terminal, to the TP. TPs then perform some function with the input data and return output data through their defined output parameters. The primary function of Transaction Integrator (TI) is to manage the process and data conversions necessary to allow input data to be provided to the mainframe TP from a COM or .NET Framework application and to send any output data generated from the TP to a COM or .NET Framework application. To accomplish this, TI provides data type conversion, tabular data definition, and code page translation.

Transaction Integrator Basic Functions

Data Type Conversion

One of the primary features of Transaction Integrator (TI) is converting and formatting a method's data from the data types understood by the Windows platform into the data types understood by a mainframe transaction program (TP). The conversion is defined at design time and implemented at runtime. At design time, the developer uses the TI Designer to associate a COM or .NET data type with a COBOL or RPG data type. TI provides default mappings between standard COM or .NET data types and COBOL or RPG data types, and the developer can either accept the default mappings or override the default with other mappings supported by TI. The TI Designer records the mappings in the TI component library, and the generated COBOL or RPG data declarations reflect them.

Transaction Integrator Basic Functions

Tabular Data Definition

In many cases, the input or output data that Transaction Integrator (TI) handles might be in tabular or array format. TI allows you to define this type of data as one of the following formats:

- Recordset. A recordset provides a means of presenting and manipulating tabular data in a Microsoft ActiveX® Data Objects (ADO) environment. A recordset contains all of the ADO information to make it manageable by any ADO application. A recordset is the primary object used for retrieving and modifying tabular data by using ADO. A recordset object represents a set of records in a table. Recordsets allow TI to support what is effectively an array of a structure (or table in COBOL terminology); it even can support the special case of a structure that is a recordset containing only one row. Each column in the row can contain only a single data element. Recordsets cannot be nested or contain arrays.

- User-defined type (UDT). Unlike recordsets, which must contain all of the formatting necessary to expose them to ADO applications, a UDT is just raw data and can therefore be faster than recordsets. A UDT can contain an ordinary (fixed-size) array. It can also contain a dynamic array. You can combine variables of several different types to create UDTs. UDTs are useful when you want to create a single variable that records several related pieces of information.

- Array. In the COM/COM+ and .NET environments, arrays are SAFEARRAYs that contain information about their bounds and contain the data for the array elements. SAFEARRAYs are mapped to fixed-size arrays on the host computer. SAFEARRAYs have a variable size and require custom information to be marshaled to and from fixed-size arrays on the host computer.

Arrays are created on the mainframe computer during the import process when a simple data type has one or more OCCURS clauses. The OCCURS clause can represent a fixed or variable-length table. Although it is possible in COBOL to have nested OCCURS DEPENDING clauses, only the OCCURS DEPENDING length specifier for the outermost table dimension is supported by TI. The TI Designer ignores nested length specifiers.

Note
A UDT and recordset that have the same fields look the same in COBOL.

Transaction Integrator Basic Functions

Code Page Translation

The choice of language or code page in TI Manager for a remote environment (RE) determines which code page is used to convert from Unicode on the automation side to Extended Binary Coded Decimal Interchange Code (EBCDIC) on the mainframe side. You can either select the language and accept the subsequent default code page for that language, or you can select the specific code page itself.

Transaction Integrator Components

Transaction Integrator (TI) consists of three major components: two graphical user interfaces, TI Designer and TI Manager, and the TI run-time environment that automatically handles the actual transaction integration.

In This Section

TI Designer

TI Manager

TI Runtime

TI Designer

TI Designer is a design-time development tool that is hosted inside, and uses the graphical user interface, of Microsoft Visual Studio. You use TI Designer to set the rules for mapping and resolving data types between a Windows resource (such as COM+, the .NET Framework, BizTalk Server) and an IBM batch or online transaction program.

TI Designer creates TI components stored as type libraries (.tlb files) or .NET Framework assemblies (.dll) describing the methods and data for a mainframe TP. Each TI component includes TI run-time environment settings that associates the component with a specific type of remote environment (RE) class, for example CICS LU 6.2 Link, for the mainframe or midrange host computer. In addition to the description of the methods and Automation parameters, the TI component type library contains custom data describing how data types are mapped between a method in TI Automation server and a mainframe transaction in a COBOL transaction program (TP) or a OS/400 transaction in a RPG transaction program. It also establishes other parameters that affect data conversion at runtime.

TI components are not true COM or .NET Framework components because they are type libraries. However, when you place a TI component in a COM+ or .NET Framework application, the TI component becomes encapsulated in a true COM component or .NET Framework assembly, and the COM+ or .NET Framework application becomes a TI Automation server that can be used by any COM-based or .NET Framework application.

Note
When you create a class in Visual Basic, the component type library is embedded in the .dll file that also contains the logic for the methods. In other words, unlike TI, the type library is not in a separate .tlb file. In the case of TI, the .dll file is a generic .dll file that holds the TI run-time environment. Together, the .tlb file created by TI Designer and the generic .dll file installed by TI are equivalent to the .dll file created for a Visual Basic class.

You can also use TI Designer to import or export the data definition section of the COBOL or RPG code making up mainframe transaction programs (TPs). TI Designer can automatically generate a TI component (type library) from imported COBOL code, or it can export generated COBOL code that you can use in your mainframe TP.

Transaction Integrator Components

TI Manager

TI Manager a design-time administrative tool that is hosted inside, and uses the graphical user interface, of the Microsoft Management Console. You use TI Manager to configure end-points, associate resources with requests, and define security and access rules. The rules and mapping of the data transformations are created in the Transaction Integrator (TI) Designer. TI Manager configures, administers, and manages TI components and the TI run-time environment settings they contain.

TI Manager gives you direct access to Windows Component Services (COM+). By using the Component Services folder in TI Manager, you can configure and administer COM components and COM+ applications, configure your system, deploy components, and configure and monitor services. For example, you can use COM+ to:

- Create new COM+ applications.
- Deploy TI components in COM+ applications.
- Administer application security.
- Administer distributed transactions by using Microsoft Distributed Transaction Coordinator (MS DTC).
- View transaction statistics.
- Resolve transaction states.
- Configure routine component and application behavior, such as participation in transactions.

For more information about application development with Component Services, see COM+ (Component Services) under "Component Services" in the Microsoft Platform SDK.

Transaction Integrator Manager Help

TI Runtime

The TI run-time environment is a specialized run-time environment started by Windows or a requesting IBM application program when the application contains a TI component. For each TI component you create, the TI run-time environment provides the Automation server interface and communicates with the mainframe programs. The TI run-time environment does not have a visible user interface.

As a generic proxy for the mainframe or AS/400 computer, the TI run-time environment intercepts object method calls and redirects those calls to the appropriate mainframe program. It also handles the return of all output parameters and return values from the mainframe. When TI intercepts the method call, it converts and formats the method's parameters from the representation understandable by the Windows 2000 Server or Windows Server 2003 platform into the representation understandable by host transaction programs (TPs).

The TI Automation Server is a COM object that exposes the functionality of a mainframe TP as an Automation interface method. It can expose all of the TP's functionality, a subset, or a superset. A TI Automation server that supports two-phase commit contains the transaction logic that determines when work will be committed or rolled back. A TI Automation server is a TI component that you have deployed in a COM+ application. A client application calls the TI Automation server to invoke the mainframe TP, pass parameters, and return results.

At run time, the TI run-time environment intercepts method invocations from a client application for a TI component library and provides the actual parameter conversion and formatting.

The client application can be any COM-based or .NET Framework application that calls a TI Automation server to invoke a mainframe TP. The client application provides the presentation layer for the application or data. It can be anything capable of calling a COM+ or .NET Framework object, including an Active Server Page (ASP), a Visual Basic application, or even a Microsoft Office application. The client application that uses a TI Automation server (a TI component embedded in a COM+ application) can be running on computer that is running Windows 2000, Windows XP, any later version of Windows, or any other operating system that supports the distributed Component Object Model (DCOM). DCOM is language-independent, so developers can build their client application by using the languages and tools with which they are most familiar, including Microsoft Visual Basic®, Visual Basic for Applications, Microsoft C#®, Microsoft Visual C++®, Microsoft Visual J++™, Delphi, Powerbuilder, and Microfocus Object COBOL. The client application can then easily make calls to the TI Automation server (or any other Automation object) registered on Windows 2000 Server or Windows Server 2003.

Then the TI run-time environment sends and receives the method calls to and from (in and out of) the appropriate mainframe TP. TI uses the TI component library created in TI Designer at design time to transform the parameter data that is passed between the TI Automation server and the mainframe TP. TI also integrates with Component Services and with Microsoft Distributed Transaction Coordinator (DTC) to provide two-phase commit (2PC) transaction support in SNA networks.

The TI run-time environment uses the information in the TI component (type library) and the associated RE to:

- Activate the TP on the mainframe in the RE.
- Pass the parameters specified by the TI component to the TP on the mainframe by way of the associated RE.
- Run the TP.
- Return the results of the TP to the COM+ application (the TI Automation server, which in turn returns the results to the client application that called it.

This The TI runtime environment provides the proxy that the Automation server uses to invoke the mainframe TP. The TI run-time environment provides these functions:

- Translates between Automation and COBOL data types.
- Translates messages to and from the mainframe.
- Provides a generic object for COM+, the behavior of which is described by a TI component (type library) for a specific instance.

Programming Models

Programming Models

A programming model defines the method(s) used to access and integrate server applications with host applications. A programming model is a combination of:

- The communication protocol that is used to exchange data with the remote application program.
- The target host environment used to host the server application program.
- The interaction semantics defined by the application to control connect, data exchange, and disconnect sequences.

Transaction Integrator supports a set of predefined programming models for Windows-initiated processing and for host-initiated processing. The following table summarizes the 11 available WIP programming models depending on the protocol and the target environment.

Protocol	Target/Host Environment	Host Integration Server Programming Model	Host Integration Server COMTI name
TCP/IP	CICS	TCP Transaction Request Message (TRM) Link	MS Link
TCP/IP	CICS	TCP Enhanced Listener Message (ELM) Link	n/a
TCP/IP	CICS	TCP Transaction Request Message (TRM) User Data	Concurrent Server
TCP/IP	CICS	TCP Enhanced Listener Message (ELM) User Data	n/a
TCP/IP	IMS	IMS Connect	IMS Open Transaction Management Architecture (OTMA) Connect
TCP/IP	IMS	IMS Implicit	Implicit
TCP/IP	IMS	IMS Explicit	Explicit
TCP/IP	OS/400	OS/400 Distributed Program Calls (DPC)	n/a
LU6.2	CICS	CICS LU6.2 User Data	CICS using LU6.2
LU6.2	CICS	CICS LU6.2 Link	CICS using Link
LU6.2	IMS	IMS LU6.2 User Data	IMS using LU6.2

The following table summarizes the five available HIP programming models depending on the protocol and the target environment.

Protocol	Target/Host Environment	Host Integration Server Programming Model	Host Integration Server COMTI name
TCP/IP	CICS	TCP Transaction Request Message (TRM) Link	n/a
TCP/IP	CICS	TCP Enhanced Listener Message (ELM) Link	n/a
TCP/IP	CICS	TCP User Data	n/a

TCP/IP	OS/400	OS/400 Distributed Program Calls (DPC)	n/a

Transaction Integrator Architecture

TCP Transaction Request Message Link

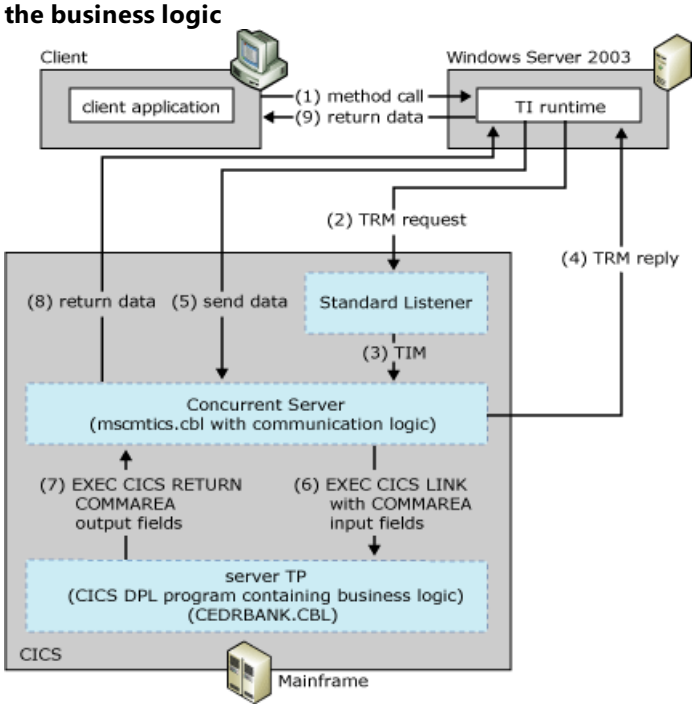
The TCP transaction request message (TRM) Link model allows data and parameters to be passed between TI and the server TP through the COMMAREA. The model also allows a Concurrent Server to Link to a CICS DPL program. The standard Listener for TCP/IP uses two network exchanges to execute a single transaction program and requires the client to:

- Send a Transaction Request Message (TRM) to the standard Listener.
- Receive a TRM reply from the application program.
- Send the application request data stream to the server transaction program.
- Receive the application reply data from the server transaction program.

The TCP TRM Link model is based on the CICS Concurrent Server model. The TCP TRM Link model is a Microsoft variant that supports execution of DPL server application programs within the CICS environment and maintains compatibility with the CICS LU6.2 Link programming model.

The following figure summarizes the workflow occurring between the client, the standard CICS Listener, the Concurrent Server, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Process by which the client starts the default Listener, which passes the call to the concurrent server, which then sends and receives data from the client, which the server then passes to the CICS DPL program for processing by the business logic



Summary Workflow for the TCP TRM Link Programming Model

The TCP TRM Link programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

If the application is a .NET Framework assembly, the TI Automation proxy:

a. Reads in the assembly and meta data created previously by the TI Designer.

b. Maps the .NET Framework data types to COBOL data types.

The TI Automation proxy then:

a. Calls the conversion routines to convert the application data to mainframe COBOL types.

b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

c. passes the data stream to the TCP transport component.

4. The TI TCP transport sends a connect request to the standard Listener using the Internet Protocol (IP) address of the mainframe computer and the port address of the Listener.

5. The standard Listener accepts the connection request and tells TI runtime to send the TRM. The standard Listener then waits for the TRM.

   The TRM is a formatted data record that identifies the server TP to be invoked by using its TRANID. The Listener TP is a special mainframe TP, whose main function is to receive server TP invocations sent by client applications running TCP/IP.

   The TRANID of the IBM-provided, standard Listener TP is CSKL. The TP name of the Listener TP, as it appears in the CICS program control table (PCT) is EZACIC02.

6. TI runtime formats either a standard or custom TRM and sends it to the standard Listener. TI runtime then waits for the TRM reply.

7. The standard Listener receives the TRM, sends TI runtime a receive confirmation, and then reads the contents of the TRM. The Listener interprets the information in the TRM and extracts the transaction ID of the Concurrent Server program that is to service the request.

8. The standard Listener starts the concurrent server TP program (Mscmtics.cbl sample application) that is identified by the TRANID in the TRM using EXEC CICS Start.

   Mscmtics.cbl is the Microsoft sample TP file that is used to pass data between TI and the server TP using the COMMAREA. The Mscmtics.cbl sample TP is developed by Microsoft and provided as part of the Host Integration Server software. It is located in the $\Microsoft Host Integration Server\SDK\Samples\Comti\ProgrammingSpecifics\Tcp. The code must be compiled, linked, and installed on the mainframe computer prior to using this model.

Note
If the standard Listener is unable to start the Concurrent Server, the Listener formats an error message and sends it bac k to the COMTI TCP Transport. Reasons the Listener might be unable to start include: Rejected connection due to limited CICS resources (for example, exceeds the maximum number of CICS tasks or concur rent server tasks) Invalid or disabled TRANID for the concurrent server Invalid, disabled or unavailable Concurrent Server program associated with the transaction ID

Note

The error message from the CICS listener is character based and always begins with the letters EZY. The length of the error message is variable, and the end of the message is determined by the socket closed by the CICS Listener. The standard Listener calls the socket application protocol interface (API) in the host environment. The standard Listener cannot send the TRM Reply. The TRM Reply represents a synchronization process that allows time for the transaction program to be started prior to the application request data being sent by the client. This synchronization process is necessary due to internal CICS architectural consideration (there is no guarantee as to when a transaction program is started after the request is made).

After the standard CICS Listener has issued the start command for the concurrent server transaction, the standard Listener is no longer needed for application processing and is free to listen for another incoming request.

9. After the concurrent server is running, it reads the transaction initial message (TIM) sent by the standard Listener.

   The TIM describes the TCP/IP environment in which the server is running and contains the TCP/IP socket information the concurrent server uses to communicate with the COMTI TCP Transport and the client message header the concurrent server uses to customize its execution behavior. The header contains the name of the server program to be linked to.

10. The Concurrent Server:

    a. Formats the standard or custom TRM reply.

    b. Sends a TRM reply to the TI TCP Transport to inform it that it can now send the application request data.

    c. Issues a receive and waits for the application request data.

    Sending of the TRM reply completes the 1st part of the standard Listener exchange sequence.

11. TI runtime evaluates the TRM and passes the data to the Concurrent Server program through the CICS COMMAREA by using a standard EXEC CICS Link call. TI runtime also sends a socket (that is, 2 byte) shutdown and then waits for the reply data.

12. After the Concurrent Server receives the application request data it links to the serving application program that was specified in the TRMs client message header. The CICS EXEC CICS LINK command is used to start the real server application. The Link command passes the application data received from the COMTI TCP Transport to the common area of memory (COMMAREA) and performs the business logic on the data. All business logic is defined in the server TP.

13. After the server application program has finished processing the request and formulating the reply, it issues an EXEC CICS RETURN command to give control back to the Concurrent Server (mscmtics.cbl) program. The server TP prepares the reply data along with a standard or custom TRM, accepts the data from the COMMAREA, and then sends the application reply data back to the TI TCP Transport through the COMMAREA. Completing the processing of the application data signals the end of the 2nd exchange sequence.

14. The concurrent server closes the socket.

15. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. Receives the message from the TCP transport component.

    b. Reads the message buffer.

    If the application is a COM+ component, the TI Automation proxy:

    a. Maps the COBOL data types to the automation data.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

If the application is a .NET Framework assembly, the TI Automation proxy:

a. Maps the COBOL data types to the .NET Framework data types.

b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

16. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

To implement this model, you must provide TI with an IP address, a port number, and a CICS program name to execute the application passed by the concurrent server program (Mscmtics.cbl). The model requires the installation, within CICS, of the IBM-supplied default Listener (EZACIC02). The CICS IBM default Listener uses IBM-provided default settings.

Host Integration Server includes sample code showing how to implement the TCP TRM Link programming model. The sample code is located at *****installation directory***\SDK\Samples\AppInt**. Start Microsoft Visual Studio, open the tutorial of your choice, and follow the instructions in the **Readme**.

For information about configuring the mainframe and writing server applications for TCP/IP, see TCP/IP V3R2 for MVS: CICS TCP/IP Socket Interface Guide (IBM Document #SC31-7131).

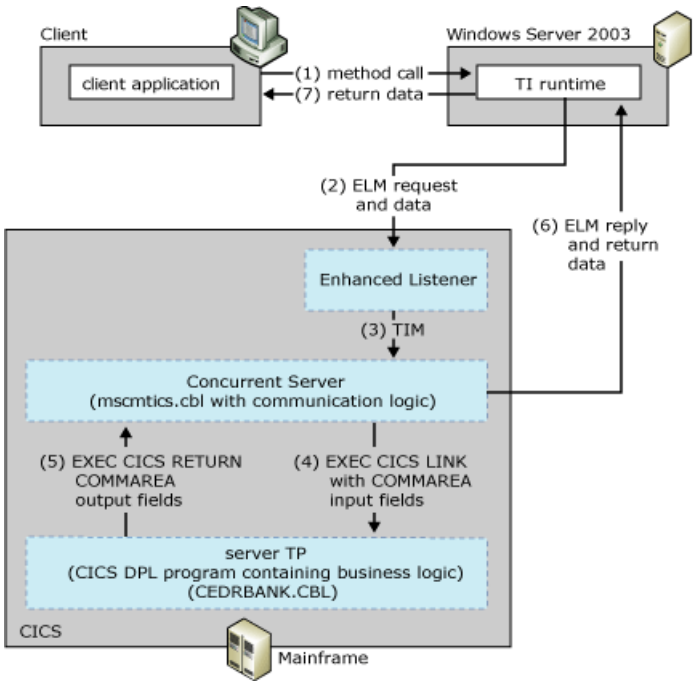
TCP Enhanced Listener Message Link

The TCP enhanced listener message (ELM) Link model allows data and parameters to be passed between TI and the server TP using the COMMAREA. The model also allows a Concurrent Server to link to a CICS DPL program. The enhanced Listener was introduced in CICS Transaction Server version 1.4, and its architecture increases the efficiency of the CICS TCP/IP environment by eliminating the TRM and TRM Reply sequence sequence. The enhanced Listener accepts a header and request data from the client in the initial stream and eliminates the need for the server application to deliver a separate response before the application data is made available. The enhanced Listener requires the client to:

- Construct and send a single data stream composed of a request header followed by the application request data to the server application program
- Receive a single data stream that consists of a reply header and application data from the server application program

The following figure summarizes the workflow occurring between the client, the enhanced CICS Listener, the Concurrent Server, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.



Summary workflow diagram for the TCP ELM Link programming model

The TCP ELM Link programming model works as follows:

1. An application invokes a method in a TI component configured in Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. reads in the type library created previously by the TI Designer
    b. maps the automation data types to COBOL data types

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. reads in the assembly and meta data created previously by the TI Designer
    b. maps the .NET Framework data types to COBOL data types

The TI Automation proxy then:

a. calls the conversion routines to convert the application data to mainframe COBOL types

b. builds the flattened data stream buffer that represents the COBOL declaration or copybook.

c. passes the message to the TCP transport component.

4. The TI TCP transport sends a connect request to the enhanced Listener using the Internet Protocol (IP) address of the mainframe computer and the port address of the Listener.

5. The enhanced Listener accepts the connection request and tells TI runtime to send the ELM. The enhanced Listener then waits for the ELM.

   The ELM is a formatted data record that identifies the server TP to be invoked by using its TRANID. The Listener TP is a special mainframe TP, whose main function is to receive server TP invocations sent by client applications running TCP/IP. The TRANID of the IBM-provided enhanced Listener TP is defined by the user.

6. TI run-time formats the ELM and sends it to the enhanced Listener. TI then bypasses the transport logic that waits for a ELM reply and immediately sends the application request data after the request header. TI then waits for the ELM reply.

7. The enhanced Listener receives the 35 byte ELM, and then reads the contents of the ELM header. The enhanced Listener places the 35 bytes in the transaction initial message (TIM) but does not operate on its content.

   The TIM describes the TCP/IP environment in which the server is running and contains the TCP/IP socket information the concurrent server uses to communicate with the COMTI TCP Transport and the client message header the concurrent server uses to customize its execution behavior. The header contains the name of the server program to be linked to.

8. The enhanced Listener starts the concurrent server TP program (Mscmtics.cbl sample application) that is defined in the Listener Definition.

   Mscmtics.cbl is the Microsoft sample TP file that is used to pass data between TI and the server TP using the COMMAREA. The Mscmtics.cbl sample TP is developed by Microsoft and provided as part of the Host Integration Server software. It is located in the $\Microsoft Host Integration Server\SDK\Samples\Comti\ProgrammingSpecifics\Tcp. It must be compiled, linked, and installed on the mainframe computer prior to using this model.

Note
If the enhanced Listener is unable to start the Concurrent Server, the Listener formats an error message and sends it back to the COMTI TCP Transport. Reasons the Listener might be unable to start include:

- rejected connection due to limited CICS resources (for example, exceeds the maximum number of CICS tasks or concurrent server tasks)
- invalid or disabled TRANID for the concurrent server
- invalid, disabled or unavailable Concurrent Server program associated with the transaction ID

Note
The error message from the CICS listener is character based and always begins with the letters EZY. The length of the error message is variable, and the end of the message is determined by the socket closed by the CICS Listener.

9. The enhanced Listener calls the socket application protocol interface (API) in the host environment. After the enhanced Listener has issued the start command for the concurrent server transaction, the enhanced Listener is out of the application processing loop and is free to listen for another incoming request.

10. The concurrent server retrieves the TIM, connects the socket, and reads the contents of the ELM.

11. TI passes the application data through the CICS COMMAREA to the server application program that contains the business logic using a standard EXEC CICS Link call. TI runtime also issues a shutdown for the sending 1/2 socket and then waits for the reply data.

12. The server TP receives the application data, processes the request, and performs the business logic on the data. All business logic is defined in the server TP.

13. The concurrent server sends the ELM reply header to TI through the COMMAREA.

14. The server TP prepares the reply data and then sends the response to the client through the COMMAREA.

15. The application reply data stream consists of two parts. The first is an ELM reply that informs the transport as to the success or failure of the request. The TCP Transport will consume the ELM reply from the stream and then, if the ELM reply indicates the call was successful, receive the application reply data until the socket is closed by the Concurrent Server.

16. The concurrent server closes the sockets

17. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. Receives the message from the TCP transport component.

    b. Reads the message buffer.

    If the application is a COM+ component, the TI Automation proxy:

    a. Maps the COBOL data types to the automation data.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

    If the application is a .NET assembly, the TI Automation proxy:

    a. Maps the COBOL data types to the .NET Framework data types.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

18. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

To implement this model, you must provide TI with an IP address, a port number, and a CICS program name to execute the application passed by the concurrent server program (Mscmtics.cbl).

Host Integration Server includes sample code showing how to implement the TCP ELM Link programming model. The sample code is located at \installation directory\SDK\Samples\AppInt. Start Microsoft Visual Studio, open the tutorial of your choice and follow the instructions in the Readme.

For information about configuring the mainframe and writing server applications for TCP/IP, see TCP/IP V3R2 for MVS: CICS TCP/IP Socket Interface Guide (IBM Document #SC31-7131).

TCP Transaction Request Message User Data

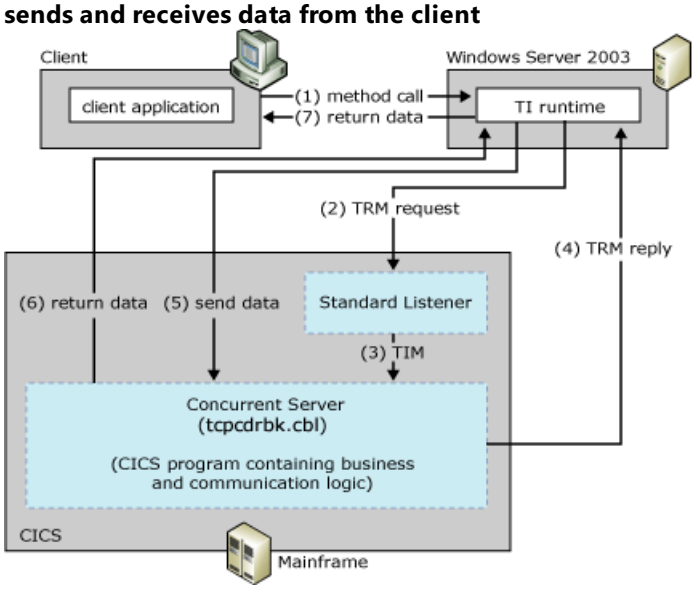
The TCP transaction request message (TRM) User Data programming model allows data and parameters to be exchanged directly between TI and the host TP. The TCP TRM User Data model is based on the CICS Concurrent Server model. The standard Listener uses two network exchanges to execute a single transaction program and requires the client to:

- Send a Transaction Request Message (TRM) to the standard Listener
- Receive a TRM reply from the application program
- Send the application request data stream to the server transaction program

Receive the application reply data from the server transaction program

The following figure summarizes the workflow occurring between the client, the standard CICS Listener, and the Concurrent Server. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Process by which the client starts the default Listener, which passes the call to the concurrent server, which then sends and receives data from the client



Summary Workflow Diagram for the TCP TRM User Data Programming Model

The TCP TRM User Data programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

    If the application is a .NET Framework assembly, the TI Automation proxy:

    b. Maps the .NET Framework data types to COBOL data types.

    The TI Automation proxy then:

a. Calls the conversion routines to convert the application data to mainframe COBOL types.

b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

c. Passes the message to the TCP transport component.

4. The TI TCP transport sends a connect request to the standard Listener using the Internet Protocol (IP) address of the mainframe computer and the port address of the Listener.

5. The standard Listener accepts the connection request and tells TI runtime to send the TRM. The standard Listener then waits for the TRM.

   The TRM is a formatted data record that identifies the server TP to be invoked by using its TRANID. The CICS Listener TP is a special mainframe TP, whose main function is to receive server TP invocations sent by client applications running TCP/IP.

   The TRANID of the IBM-provided, standard Listener TP is CSKL. The TP name of the Listener TP as it appears in the program control table (PCT) is EZACIC02.

6. TI runtime formats the TRM and sends it to the standard Listener. TI waits for the TRM reply.

7. The standard Listener receives the TRM, sends TI runtime a receive confirmation, and then reads the contents of the TRM. The Listener interprets the information in the TRM and extracts the transaction ID of the Concurrent Server program that is to service the request.

8. The standard Listener starts the concurrent server TP program that is identified by the TRANID in the TRM (Mscmtics.cbl sample application) using EXEC CICS Start.

   Mscmtics.cbl is the Microsoft sample TP file that is used to pass data between COMTI and the server TP using the COMMAREA. The Mscmtics.cbl sample TP is developed by Microsoft and provided as part of the Host Integration Server software. It is located in the $\Microsoft Host Integration Server\SDK\Samples\Comti\ProgrammingSpecifics\Tcp. It must be compiled, linked, and installed on the mainframe computer prior to using this model.

Note

If the standard Listener is unable to start the Concurrent Server, the Listener formats an error message and sends it back to t he COMTI TCP Transport. Reasons the Listener might be unable to start include:

- rejected connection due to limited CICS resources (for example, exceeds the maximum number of CICS tasks or concurrent server tasks)
- invalid or disabled TRANID for the concurrent server
- invalid, disabled or unavailable Concurrent Server program associated with the transaction ID

Note

The error message from the CICS listener is character based and always begins with the letters EZY. The length of the error m essage is variable, and the end of the message is determined by the socket closed by the CICS Listener.

1. The standard Listener calls the socket application protocol interface (API) in the host environment. The standard Listener cannot send the TRM Reply. The TRM Reply represents a synchronization process that allows time for the transaction program to be started prior to the application request data being sent by the client. This synchronization process is necessary due to internal CICS architectural consideration (there is no guarantee as to when a transaction program is started after the request is made).

After the standard CICS Listener has issued the start command for the concurrent server transaction, the standard Listener is out of the application processing loop and is free to listen for another incoming request.

2. After the concurrent server is running, it reads the transaction initial message (TIM) sent by the standard Listener.

   The TIM describes the TCP/IP environment in which the server is running and contains the TCP/IP socket information the concurrent server uses to communicate with the COMTI TCP Transport and the client message header the concurrent server uses to customize its execution behavior.

3. The Concurrent Server:

   a. Formats the TRM reply.

   b. Sends a TRM Reply to the TI TCP Transport to inform it that it can now send the application request data.

   c. Issues a receive and waits for the application request data.

   Sending of the TRM Reply completes the 1st part of the Standard Listener exchange sequence.

4. TI evaluates the TRM and passes the data to the Concurrent Server. TI also sends socket shutdown, and then TI waits for the reply data.

5. After the Concurrent Server receives the application request data, the server performs the business logic on the data.

6. After the server has finished processing the request and formulating the reply, prepares the reply data and then sends the response directly to the client. Completing the processing of the application data signals the end of the 2nd exchange sequence.

7. The concurrent server closes the socket.

8. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

   a. Receives the message from the TCP transport component.

   b. Reads the message buffer.

   If the application is a COM+ component, the TI Automation proxy:

   a. Maps the COBOL data types to the automation data.

   b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

   If the application is a .NET Framework assembly, the TI Automation proxy:

   a. Maps the COBOL data types to the .NET Framework data types.

   b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

9. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

To implement this model, you must provide TI with an IP address, a port number, and a CICS program name to execute the application passed by the concurrent server program (Mscmtics.cbl). The model requires the installation, within CICS, of the IBM-supplied default Listener (EZACIC02). The CICS IBM default Listener uses IBM-provided default settings.

Host Integration Server includes sample code showing how to implement the TCP TRM Link programming model. The sample

code is located at *****installation directory***\SDK\Samples\AppInt**. Start Visual Studio, open either the tutorial you want to use, and follow the instructions in the **Readme**.

For information about configuring the mainframe and writing server applications for TCP/IP, see TCP/IP V3R2 for MVS: CICS TCP/IP Socket Interface Guide (IBM Document #SC31-7131).

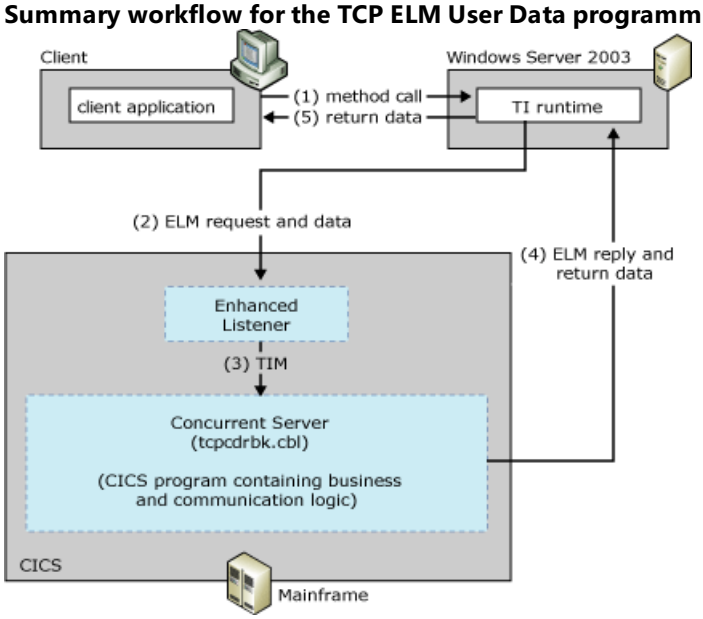
TCP Enhanced Listener Message User Data

The TCP enhanced listener message (ELM) User Data model allows data and parameters to be passed directly between TI and the server TP.

The following figure summarizes the workflow occurring between the client, the enhanced CICS Listener, the Concurrent Server, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Summary workflow for the TCP ELM User Data programming model



TCP ELM User Data Programming Model

The TCP ELM User Data programming model works as follows:

1. An application invokes a method in a TI component configured in Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. Reads in the assembly and meta data created previously by the TI Designer.
    b. Maps the .NET Framework data types to COBOL data types.

    The TI Automation proxy then:
    a. Calls the conversion routines to convert the application data to mainframe COBOL types.
    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.
    c. Passes the message to the TCP transport component.
4. The TI TCP transport sends a connect request to the enhanced Listener using the Internet Protocol (IP) address of the mainframe computer and the port address of the Listener.

5. The enhanced Listener accepts the connection request and tells TI run-time to send the ELM. The enhanced Listener then waits for the ELM.

   The ELM is a formatted data record that identifies the server TP to be invoked by using its TRANID. The Listener TP is a special mainframe TP, whose main function is to receive server TP invocations sent by client applications running TCP/IP.

6. TI run-time formats the ELM and sends it to the enhanced Listener. TI then bypasses the transport logic that waits for a ELM reply and immediately sends the application request data after the request header. TI then waits for the ELM reply.

7. The enhanced Listener receives the 35 byte ELM, and then reads the contents of the ELM header. The enhanced Listener places the 35 bytes in the transaction initial message (TIM) but does not operate on its content.

   The TIM describes the TCP/IP environment in which the server is running and contains the TCP/IP socket information the concurrent server uses to communicate with the COMTI TCP Transport and the client message header the concurrent server uses to customize its execution behavior. The header contains the name of the server program to be linked to.

8. The enhanced Listener starts the concurrent server TP program (Mscmtics.cbl sample application) that is identified by the TRANID in the ELM using EXEC CICS Start.

   Mscmtics.cbl is the Microsoft sample TP file that is used to pass data between TI and the server TP using the COMMAREA. The Mscmtics.cbl sample TP is developed by Microsoft and provided as part of the Host Integration Server software. It is located in the $\Microsoft Host Integration Server\SDK\Samples\Comti\ProgrammingSpecifics\Tcp. It must be compiled, linked, and installed on the mainframe computer prior to using this model.

Note

If the standard Listener is unable to start the Concurrent Server, the Listener formats an error message and sends it back to t he COMTI TCP Transport. Reasons the Listener might be unable to start include:

- rejected connection due to limited CICS resources (for example, exceeds the maximum number of CICS tasks or concurrent server tasks)
- invalid or disabled TRANID for the concurrent server
- invalid, disabled or unavailable Concurrent Server program associated with the transaction ID

Note

The error message from the CICS listener is character based and always begins with the letters EZY. The length of the error m essage is variable, and the end of the message is determined by the socket closed by the CICS Listener. The enhanced Listene r calls the socket application protocol interface (API) in the host environment. After the enhanced Listener has issued the start command for the concurrent server transaction, the enhanced Listener is out of the application processing loop and is free to listen for another incoming request.

1. After the concurrent server is running, it reads the transaction initial message (TIM) sent by the standard Listener.

   The TIM describes the TCP/IP environment in which the server is running and contains the TCP/IP socket information the concurrent server uses to communicate with the COMTI TCP Transport and the client message header the concurrent server uses to customize its execution behavior.

2. The concurrent server sends the TRM to TI and waits for the application request data.

3. TI evaluates the TRM and passes the data directly to the concurrent server program (Mscmtics.cbl). TI also sends socket shutdown, and then TI waits for the reply data.

4. After the data is received, the server TP performs the business logic on the data. All business logic is defined in the server

TP.

5. The server TP prepares the reply data and then sends the response directly to the client.
6. The concurrent server closes the socket
7. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:
    a. receives the message from the TCP transport component.
    b. reads the message buffer

    If the application is a COM+ component, the TI Automation proxy:
    a. maps the COBOL data types to the automation data
    b. calls the conversion routines to convert the mainframe COBOL types to the application data

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. maps the COBOL data types to the .NET Framework data types
    b. calls the conversion routines to convert the mainframe COBOL types to the application data
8. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

Host Integration Server includes sample code showing how to implement the TCP ELM User Data programming model. The sample code is located at \installation directory\SDK\Samples\AppInt. Start Microsoft Visual Studio, open the tutorial you want to use, and follow the instructions in the Readme.

For information about configuring the mainframe and writing server applications for TCP/IP, see TCP/IP V3R2 for MVS: CICS TCP/IP Socket Interface Guide (IBM Document #SC31-7131).

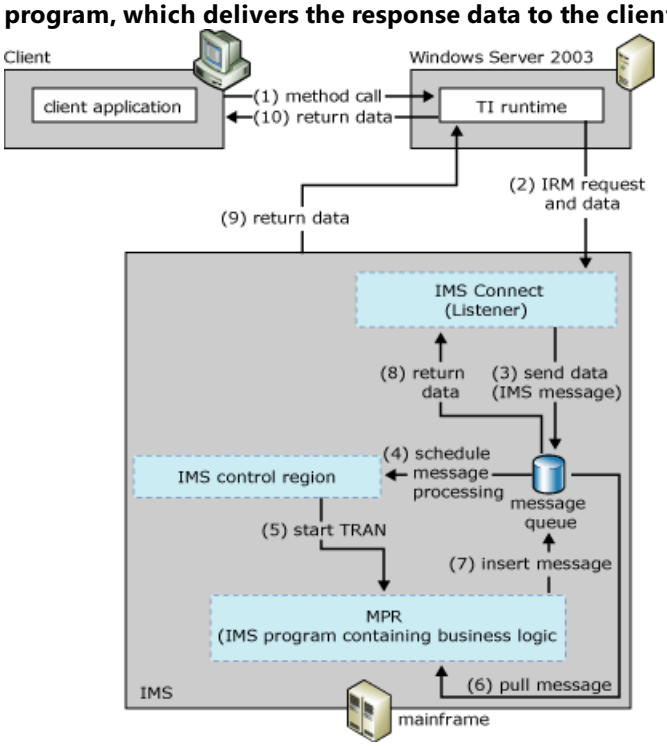
IMS Connect

The IMS Connect programming model provides access to information management systems (IMS) transactions using TCP/IP. This model uses the IMS message queue for processing data.

The following figure summarizes the workflow occurring between the client, the default IMS Listener, the Concurrent Server, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Process by which the client passes input data to the ITOC listener and the HWSIMSO0 provides access to the IMS program, which delivers the response data to the client



Summary Workflow Diagram for the IMS Connect Programming Model

The IMS Connect programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. Rreads in the assembly and meta data created previously by the TI Designer.
    b. Maps the .NET data types to COBOL data types.

    The TI Automation proxy then:
    a. Calls the conversion routines to convert the application data to mainframe COBOL types.
    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.
    c. Passes the message to the TCP transport component.

4. The TI runtime sends an initial request message (IRM) to the IMS Connect, either HWSIMSO0 or HWSIMSO1, using the Internet Protocol (IP) address of the mainframe computer and the port address of the IMS Connect as stored in the TCP/IP profile data set (hlq.PROFILE.TCPIP) supplied by IBM.

   HWSIMSO0 and HWSIMSO1 are IBM-supplied host web server (HWS) exit routines that define the request and reply protocols between the TI Automation server (a TI component in a COM or .NET Framework application) and ITOC. The HWS runs in an MVS address space that is separate from the IMS regions and performs the listener services for the IMS connection.

5. The IMS Connect exit routine takes control of the IMS application (referred to as the IMS TCP/IP Open Transaction Management Architecture (OTMA) Connection (ITOC)).

6. The TI run-time environment sends an ITOC request header to ITOC and HWSIMSO0.

7. The HWSIMSO0 exit routine:

   - Validates the ITOC request header
   - Receives all request data from the TI run-time environment
   - Interfaces with security routines
   - Drives the OTMA process to connect to an IMS data store
   - Places and retrieves message segments into and from the IMS message queue through OTMA
   - Sends all reply data segments to the TI run-time environment
   - Controls recovery operations within IMS

8. ITOC reads the ITOC header information, locates the correct IMS region, and schedules the execution of an IMS transaction in that IMS region. The ITOC header must contain this information:

   - ITOC HWS exit routine identifier (default '*IRMREQ*')
   - IMS data store identifier
   - Transaction identifier
   - Flow control information
   - IBM's Resource Access Control Facility (RACF) security credentials
   - Protocol control flags

9. HWSIMSO0 schedules the correct IMS message queue

10. The TI run-time sends the request data segments to ITOC

11. The TI run-time sends EOM

12. IMS Control region sends to message processing region (MPR)

13. After all request data is placed on the IMS message queue, the transaction is scheduled for execution

14. The IMS server application program uses the standard CBLTDLI Get Unique (GU), Get Next (GN), and Insert (INSRT) call interface commands to retrieve the request data and to place reply data on the IMS message queue.

15. MPR returns data to TI. ITOC sends EOM-CSMOKY ITOC returns the following information to the TI run-time environment:

    - Request mod message
    - Reply data segments
    - End-of-message segment
    - CSMOKY segment

16. ITOC and the ITOC exit routine then remove the reply data from the message queue and deliver it back to the TI run-time environment.

17. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. receives the message from the TCP transport component.

    b. reads the message buffer

    If the application is a COM+ component, the TI Automation proxy:

    a. maps the COBOL data types to the automation data

    b. calls the conversion routines to convert the COBOL data types to the application data

    If the application is a .NET Framework assembly, the TI Automation proxy:

    a. maps the COBOL data types to the .NET Framework data types

    b. calls the conversion routines to convert the COBOL data types to the application data

18. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

For information about configuring the mainframe and writing server applications for TCP/IP, see TCP/IP V3R2 for MVS: IMS TCP/IP Application Developers Guide (IBM Document #SC31-7186) and IMS Connect Guide and Reference V1R2 (IBM Document #SC27-0946).

Host Integration Server includes sample code showing how to implement the IMS Connect programming model. The sample code is located at *****installation directory***\SDK\Samples\AppInt**. Start Visual Studio, open the tutorial you want to use, and follow the instructions in the **Readme**.

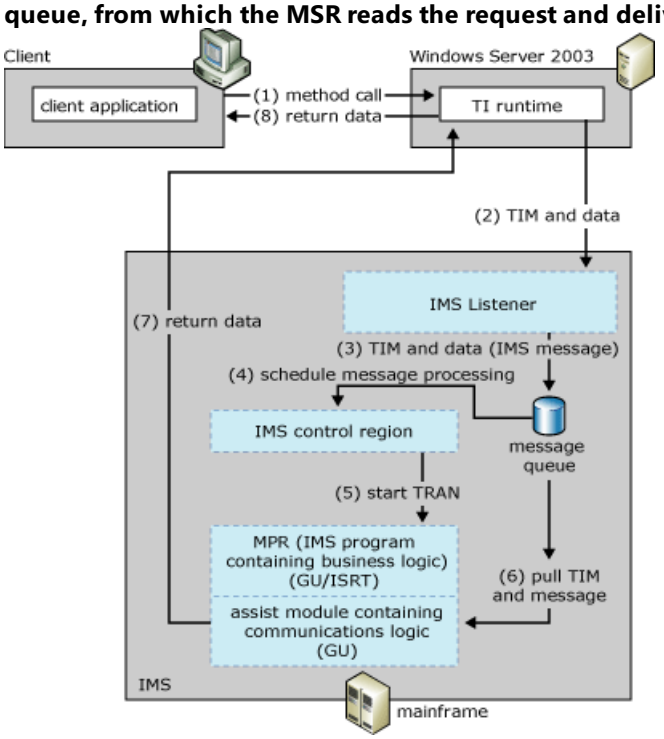
IMS Implicit

The IMS Implicit programming model provides access to information management systems (IMS) transactions using TCP/IP. This model uses the IMS message queue for processing data. This model is known as an implicit mode of communication because each IMS application implicitly issues all socket calls.

The following figure summarizes the workflow occurring between the client, the default IMS Listener, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Process by which the client passes input data to the BMP Listener, which in turn puts the data into the message queue, from which the MSR reads the request and delivers the response data to the client



Summary workflow diagram for the IMS Implicit programming model

The IMS Implicit programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. Reads in the assembly and meta data created previously by the TI Designer.
    b. Maps the .NET Framework data types to COBOL data types.

    The TI Automation proxy then:
    a. Calls the conversion routines to convert the application data to mainframe COBOL types.
    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

c. Passes the message to the TCP transport component.

4. The TI Automation proxy sends a TRM and the application data to the default IMS Listener using the proper Internet Protocol (IP) address of the mainframe computer and the port address of the default Listener.

   The TRM is a formatted data record that identifies the IMS server TP to be invoked by using its TRANID. EZAIMSLN is the default Listener TP supplied by IBM, whose main function is to receive server TP invocations sent by client applications running TCP/IP.

5. The Listener receives the TRM and data and then creates a transaction initiation message (TIM)

6. The Listener inserts the TRANID along with the client data into the IMS message queue that is associated with the MPP region in which the server TP is running. The server TP runs concurrently with the Listener.

7. After the connection is established, the Listener releases control and continues to listen for more client TCP/IP calls. The Listener is able to maintain multiple concurrent connections.

8. The IMS control region schedules the transaction in a message processing region (MPR) and passes the socket to the IMS server TP.

9. The server TP is coded to use the IBM-supplied Assist Module (CBLADLI, instead of the standard COBOL DL/I module, CBLTDLI) to intercedes between the server TP and the TI run-time environment, thereby allowing the server TP to exchange data with TI by using DL/I calls (GU, GN, and ISRT).

   The Assist Module translates IMS programming calls to TCP/IP socket API calls that are understood by TCP/IP client applications such as TI. When developing IMS TPs, you do not need to learn the TCP/IP sockets interface because the Assist Module performs all of the necessary translations.

10. The server TP calls the Assist Module and reads the request from the queue using GU and GN commands. All business logic is defined in the concurrent server TP.

11. After processing of the data is complete, the server TP uses the DL/I ISRT call to return data to the TI runtime by way of TCP/IP.

12. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. Receives the message from the TCP transport component.

    b. Reads the message buffer.

    If the application is a COM+ component, the TI Automation proxy:

    a. Maps the COBOL data types to the automation data

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data

    If the application is a .NET Framework assembly, the TI Automation proxy:

    a. Maps the COBOL data types to the .NET Framework data types.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

13. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

Host applications are written using standard IMS commands. However, the commands use the CBLADLI application programming interface (API), rather than the standard CBLTDLI API.

In addition, the proper IMS control regions must be defined in an APPL statement in VTAM.

For information about configuring the mainframe and writing server applications for TCP/IP, see TCP/IP V3R2 for MVS: IMS TCP/IP Application Developers Guide (IBM Document #SC31-7186).

Host Integration Server includes sample code showing how to implement the IMS Connect programming model. The sample code is located at \installation directory\SDK\Samples\AppInt. Start Visual Studio, open the tutorial you want to use, and follow the instructions in the Readme.

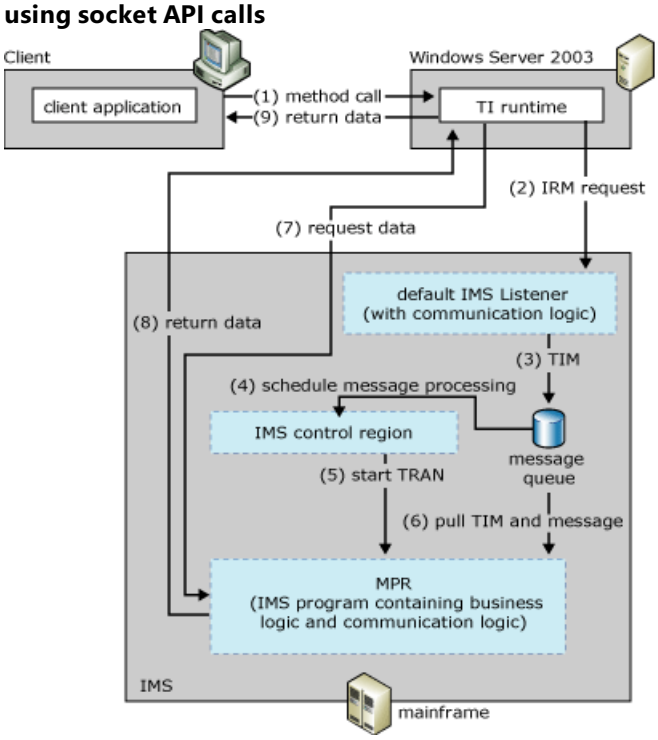
IMS Explicit

The IMS Explicit programming model provides access to IMS transactions by using TCP/IP. This model does not use the IMS message queue for processing data. This model is known as an explicit mode of communication because each IMS application must specify all socket calls explicitly.

The following figure summarizes the workflow occurring between the client, the default IMS Listener, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Process by which the client passes input data to the BMP listener, which in turn puts the data into the message queue, from which the IMS region schedules execution in the MPR and delivers the response data to the client using socket API calls



Summary Workflow Diagram for the IMS Explicit Programming Model

The IMS Explicit programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. Reads in the assembly and meta data created previously by the TI Designer.
    b. Maps the .NET Framework data types to COBOL data types.

    The TI Automation proxy then:
    a. Calls the conversion routines to convert the application data to mainframe COBOL types.
    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

c. Passes the message to the TCP transport component.

4. The TI Automation proxy sends a TRM and the application data to the default IMS Listener using the proper Internet Protocol (IP) address of the mainframe computer and the port address of the default Listener.

   The TRM is a formatted data record that identifies the IMS server TP to be invoked by using its TRANID. EZAIMSLN is the IBM-supplied default Listener TP, whose main function is to receive server TP invocations sent by client applications running TCP/IP.

5. The Listener receives the TRM and creates a transaction initiation message (TIM).

6. The Listener inserts the TRANID along with the client data into the IMS message queue that is associated with the message processing region (MPR) in which the server TP is running. The server TP runs concurrently with the Listener.

Note
All IMS host server programs must be administered to IMS as NonResponse transactions.

7. After the connection is established, the Listener releases control and continues to listen for more client TCP/IP calls. The Listener is able to maintain multiple concurrent connections.

8. The IMS control region schedules the transaction in the MPR and passes the socket to the IMS server TP.

9. The server TP uses the standard COBOL DL/I module, CBLTDLI, to initiate the transfer of data from the TI run-time environment by way of APPC/MVS.

   The server TP uses a series of socket API calls to send and receive data directly with the TI runtime. You will need to learn the TCP/IP sockets interfaces and make those calls explicitly in your program.

10. After processing of the data is complete, the server TP uses the DL/I ISRT call to return data to the TI runtime by way of APPC/MVS.

11. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. Receives the message from the TCP transport component.

    b. Reads the message buffer.

    If the application is a COM+ component, the TI Automation proxy:

    a. Maps the COBOL data types to the automation data.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

    If the application is a .NET assembly, the TI Automation proxy:

    a. Maps the COBOL data types to the .NET Framework data types.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

12. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

In addition, the proper IMS control regions must be defined in an APPL statement in VTAM.

Host Integration Server includes sample code showing how to implement the IMS Connect programming model. The sample

code is located at *****installation directory***\SDK\Samples\AppInt**. Start Microsoft Visual Studio, open the tutorial you want to use, and follow the instructions in the **Readme**.

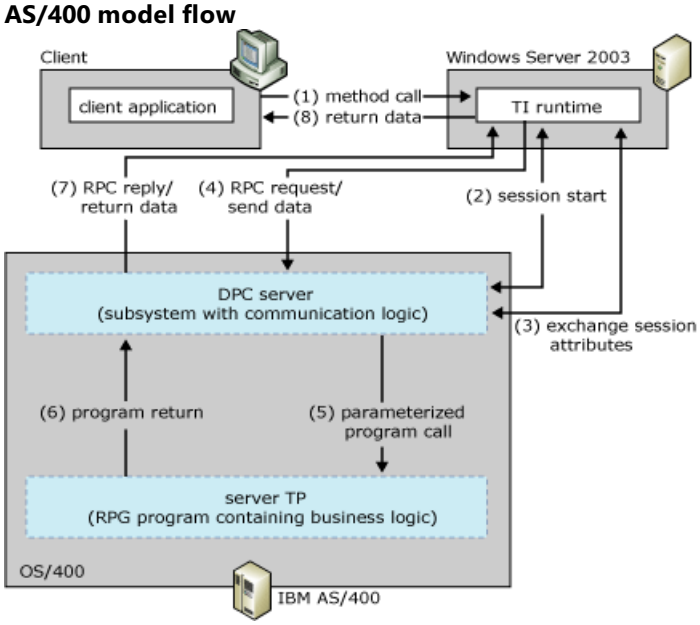
OS/400 Distributed Program Calls

The OS/400 Remote Command and Distributed Program Calls (DPC) programming model allows most AS/400 applications to interact with TI in request-reply fashion (client-initiated only) with minimum modifications. DPC is a documented protocol that supports program to program integration on an AS/400, which can be accessed easily from PC based applications using the TCP/IP networking protocol.

Note
This interface does not support host-initiated processing (HIP); AS/400 integration is for client-initiated calls only.

The following figure summarizes the workflow occurring between the client, the default DPC Server, and the AS/400 transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

AS/400 model flow



Summary Workflow Diagram for the OS/400 DPC Programming Model

The OS/400 DPC programming model works as follows:

1. An application invokes a method in a TI component configured in Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is COM+ component, the TI Automation proxy:
    a. Reads in the type libraries previously created by the TI Designer.
    b. Maps the automation data types to AS/400 RPG data types.

    If the application is a .NET Framework assembly, the TI Automation proxy:
    a. Reads in the assembly and metadata previously created by the TI Designer.
    b. Maps the .NET Framework data types to AS/400 RPG data types.

    The TI Automation proxy then:
    a. Calls the conversion routines to convert the application data to AS/400 RPG types.
    b. Builds the parameterized message buffer that represents the RPG PLIST.

c. Passes the message to the AS/400 DPC transport component.

4. The TI TCP transport sends a connection request to the DPC Server system using the Internet Protocol (IP) address of the AS/400 computer and the port address of the server. The TI TCP transport then waits for a reply.

5. The DPC Server on the AS/400 accepts the session request and issues a receive. The DPC Server then waits for the start server request.

6. The TI automation proxy sends the DPC Server a start server request and issues a receive. The TI TCP transport then waits for a start server reply.

7. The DPC server processes the start server request, sends a start server reply, and then issues a receive. The DPC Server then waits for an exchange attributes request.

8. The TI runtime processes the start server reply, sends the attributes request, and issues a receive. The TI runtime then waits for an exchange attributes reply.

9. The DPC server processes the exchange attributes request, sends a exchange attributes reply, and then issues a receive. The DPC then waits for a remote program call request.

10. TI runtime processes the exchange attributes reply and then sends remote program call request followed immediately by remote program call reply and the converted data.

11. The DPC server processes the request, sends remote program call reply followed by remote program call parameters and data.

12. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. Receives the message from the TCP transport component.

    b. Reads the message buffer.

    If the application is a COM+ component, the TI Automation proxy:

    a. Maps the OS/400 data types to the automation data.

    b. Calls the conversion routines to convert the OS/400 RPG types to the application data.

    If the application is a .NET assembly, the TI Automation proxy:

    a. Maps the AS/400 data types to the .NET Framework data types.

    b. Calls the conversion routines to convert the OS/400 RPG types to the application data.

13. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

Note
The maximum size of a message is 32,767 bytes, including field headers and data.

Note
The RMTPGMCALL can pass maximum 35 parameters as IN or OUT, or as IN/OUT in any combination.

Host Integration Server includes sample code showing how to implement the IMS Connect programming model. The sample

code is located at *****installation directory***\SDK\Samples\AppInt**. Start Microsoft Visual Studio, open the tutorial you want to use, and follow the instructions in the **Readme**.

For information about configuring the mainframe and writing server applications for IBM AS/400e, see the ILE RPG/400 Programmers Guide Version 4 (IBM Document #SC09-2507-02) and the ILE RPG/400 Reference Version 3 (IBM Document #SC09-2077-01).

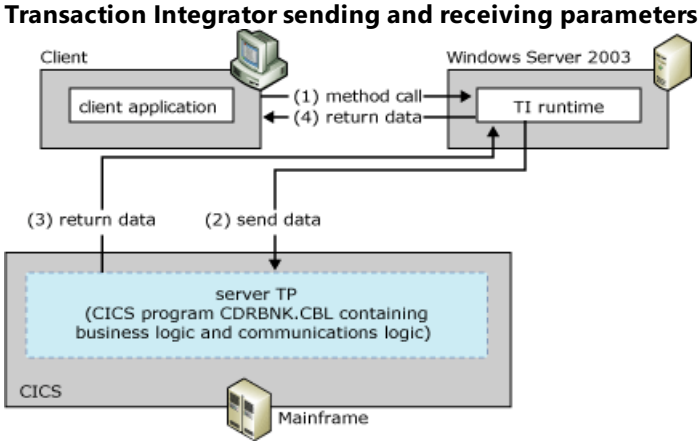
CICS LU6.2 Link

The CICS LU6.2 Link programming model is one of the simplest models that you can use to implement TI functionality.

The following figure summarizes the workflow occurring between the client, the default CICS Mirror Transaction, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Transaction Integrator sending and receiving parameters with DPL information from a CICS Mirror Transaction



Summary workflow diagram for the CICS LU6.2 Link programming model

The CICS LU6.2 Link programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.

2. The TI runtime calls the TI Automation proxy.

3. If the application is a COM+ component, the TI Automation proxy does the following:

    a. Reads in the type library created previously by the TI Designer.

    b. Maps the automation data types to COBOL data types.

    If the application is a .NET assembly, the TI Automation proxy does the following:

    a. Reads in the assembly and metadata created previously by the TI Designer.

    b. Maps the .NET Framework data types to COBOL data types.

    The TI Automation proxy then:

    a. Calls the conversion routines to convert the application data to mainframe COBOL types.

    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

    c. Passes the message to the SNA transport component.

4. TI sends the TP Name CSMI request specified by the TI component method to the CICS Mirror Transaction using DPL information and the LU6.2 protocol. (IBM provides CSMI with CICS on the TI prerequisite systems.)

    The CICS Mirror Transaction is a special CICS TP that acts as a gateway between TPs running in different CICS regions, thereby allowing them to exchange data through the COMMAREA. TI takes advantage of this standard method of communication between CICS TPs to access mainframe TPs. CSMI handles all APPC and transactional properties required on the communication. The TRANID for this TP is CSMI.

    The Distributed Program Link (DPL) is the protocol used when communicating with CSMI. TI uses DPL to communicate

with CSMI.

5. CSMI (the CICS Mirror Transaction) takes control and issues an EXEC CICS Link command to the requested server TP in CICS. (The name of this program can be associated the remote environment (RE) and with the method name in TI Designer.)

6. The CICS Mirror transaction passes the COMMAREA that contains the input fields to the server TP.

   The COMMAREA is a communication area of up to 32 KB containing all of the data that is passed to and from the mainframe program. Many CICS TPs, written in COBOL, use this area of the mainframe transaction code to exchange data. When using the CICS Link using LU6.2 programming model, TI appears to the mainframe TP as just another CICS TP exchanging data through the COMMAREA.

   The Server TP is the TP that TI invokes on behalf of the client application. It contains the business logic being executed and is identified by its TRANID in the method call of the client application.

Note
The term server TP is used to identify the TP that TI is accessing. This clarification is necessary because access to mainframe applications may and typically does involve a number of TPs.

7. When the server TP is finished processing, it issues an EXEC CICS RETURN command, which returns the data in the COMMAREA to the CICS Mirror transaction with all output fields updated.

8. The CICS Mirror transaction returns the output data, if any is required, to TI.

9. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

   a. receives the message from the SNA transport component.

   b. reads the message buffer

   If the application is a COM+ component, the TI Automation proxy:

   a. maps the COBOL data types to the automation data

   b. calls the conversion routines to convert the mainframe COBOL types to the application data

   If the application is a .NET assembly, the TI Automation proxy:

   a. maps the COBOL data types to the .NET Framework data types

   b. calls the conversion routines to convert the mainframe COBOL types to the application data

10. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

Only the flow model is supported with CICS Link, so unbounded recordsets are not supported for this class of TP. Fixed-sized recordsets (that is, bounded recordsets) are supported.

CSMI also handles any Sync Level 2 interactions with TI, and thus transparently provides the 2PC capability for programs in this class.

Existing CICS programs may already be structured this way. Instead of TI issuing the LU 6.2 request, another CICS TP might already issue an EXEC CICS Link to run the CICS program shown in the previous illustration. In that case, both the existing CICS TP and the TI component can coexist and run the same CICS program.

Note

CSMI is the default mirror transaction name, but you can specify a different name.

Host Integration Server includes sample code showing how to implement the CICS LU6.2 Link programming model. The sample code is located at \installation directory\SDK\Samples\AppInt. Start Microsoft Visual Studio, open the tutorial you want to use, and follow the instructions in the Readme.

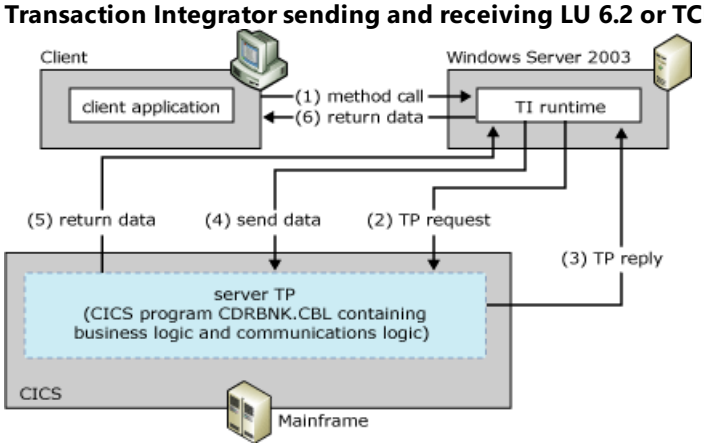
Transaction Integrator Components

CICS LU6.2 User Data

The CICS LU6.2 User Data programming model provides direct invocations and data exchanges between TI and the server TP. No other communication components are required with this model.

The following figure summarizes the workflow occurring between the client, the default CICS Mirror Transaction, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Transaction Integrator sending and receiving LU 6.2 or TCP/IP from the mainframe transaction program



Summary workflow diagram for the CICS LU6.2 User Data programming model

The CICS LU6.2 User Data programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.

2. The TI runtime calls the TI Automation proxy.

3. If the application is a COM+ component, the TI Automation proxy:

    a. Reads in the type library created previously by the TI Designer.

    b. Maps the automation data types to COBOL data types.

    If the application is a .NET assembly, the TI Automation proxy:

    a. Reads in the assembly and metadata created previously by the TI Designer.

    b. Maps the .NET Framework data types to COBOL data types.

    The TI Automation proxy then:

    a. Calls the conversion routines to convert the application data to mainframe COBOL types.

    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

    c. Passes the message to the SNA transport component.

4. The TI proxy sends the TP invocation request specified by the TI component method to the server TP by using the LU6.2 protocol. In this message, TI sends the TRANID of the server TP that the method is invoking.

5. TI and the server TP communicate directly by issuing APPC or Common Programming Interface for Communications (CPI-C) verbs to receive and send the input and output fields, respectively.

6. If necessary, the server TP issues the appropriate verbs to implement Sync Level 2 properties and 2 phase commit.

7. The mainframe TP closes the socket.

8. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

    a. Receives the message from the SNA transport component.

    b. Reads the message buffer

    If the application is a COM+ component, the TI Automation proxy:

    a. Maps the COBOL data types to the automation data.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

    If the application is a .NET assembly, the TI Automation proxy:

    a. Maps the COBOL data types to the .NET Framework data types.

    b. Calls the conversion routines to convert the mainframe COBOL types to the application data.

9. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

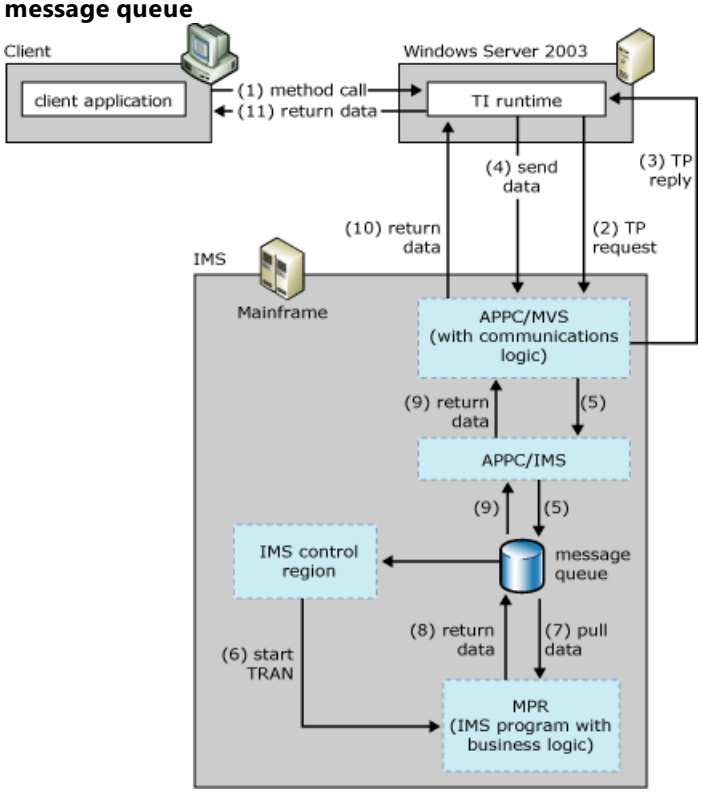
IMS LU6.2 User Data

The IMS LU6.2 programming model provides access to IMS transactions using LU6.2.

The following figure summarizes the workflow occurring between the client, the default IMS Listener, and the mainframe transaction program. The numbers in parentheses indicate the approximate order in which events occur. A more detailed description of the events follows the figure.

Transaction Integrator sending and receiving LU 6.2 from MVS/APPC, which then sends and receives from the IMS message queue



Summary workflow diagram for the IMS LU6.2 User Data programming model

The IMS LU6.2 programming model works as follows:

1. An application invokes a method in a TI component configured in either Component Services or the .NET Framework.
2. The TI runtime calls the TI Automation proxy.
3. If the application is a COM+ component, the TI Automation proxy:
    a. Reads in the type library created previously by the TI Designer.
    b. Maps the automation data types to COBOL data types.

    If the application is a .NET assembly, the TI Automation proxy:
    a. Reads in the assembly and meta data created previously by the TI Designer.
    b. Maps the .NET Framework data types to COBOL data types.
4. The TI Automation proxy then:
    a. Calls the conversion routines to convert the application data to mainframe COBOL types.
    b. Builds the flattened data stream buffer that represents the COBOL declaration or copybook.

c. Passes the message to the SNA transport component.

5. The TI Automation proxy sends the transaction execution request (TER) and the user data to MVS APPC through the IBM-supplied multiple virtual storage/advanced program-to-program communications (APPC/MVS) application.

6. APPC/MVS application instructs IMS to place the transaction execution request and user data on the IMS message queue.

7. IMS schedules the server TP into a message processing region (MPR).

8. After execution begins, the TP issues a DL/I Get Unique (GU) command to get the input parameters that were sent by the TI runtime. If there is an input unbounded record set, the TP also makes one or more Get Next (GN) calls to get each row of the record set that was sent.

9. After the TP processes the inputs and makes any database calls, it makes one or more Insert (ISRT) calls to place the output parameters and possibly an output or return-value unbounded recordset into the IMS message queue to be packaged and returned to the TI runtime through the APPC/MVS application.

10. The TI Automation proxy receives the reply data and processes the reply. The TI Automation proxy:

11. receives the message from the SNA transport component.

12. reads the message buffer

    If the application is a COM+ component, the TI Automation proxy:

13. maps the COBOL data types to the automation data types

14. calls the conversion routines to convert the mainframe COBOL types to the application data

    If the application is a .NET assembly, the TI Automation proxy:

15. maps the COBOL data types to the .NET Framework data types

16. calls the conversion routines to convert the mainframe COBOL types to the application data

17. The TI runtime sends the converted data back to the COM or .NET Framework application that invoked the method.

Host Integration Server includes sample code showing how to implement the IMS LU6.2 User Data programming model. The sample code is located at *****installation directory***\SDK\Samples\AppInt**. Choosing the Appropriate Programming Model

A TI programming model determines the method used to access and integrate host applications and TI configuration requirements depending on the specific TI programming model being used. Implementing TI may require modification to the existing mainframe TPs to be able to fit the programming models that it supports. Specifically, this may be necessary when:

- A TP does not expect a simple request-reply response.
- A CICS TP has terminal processing logic embedded in the same TP with the business logic. This type of TP must be restructured as two separate TPs. Accesses business logic that already exists on the mainframe computer as TPs. You can use this function, or you can create the methods on the COM side and then create the necessary server TPs on the mainframe computer. This is still a viable option because TI may be better for accessing some types of data, such as those stored in VSAM data sets, than standard data access methods.

You must carefully analyze the business requirements of your organization so that you can implement transaction access by using one of the programming models provided in TI.

TI supports the programming models listed in the table below. Some of the factors you should consider when choosing the appropriate programming model for your organization are:

- the network procotol
- the maximum size of the message or data that can be sent to the host
- whether you need to use two-phase commit transactions in host applications
- whether you have to write your own communications protocol to support a Link program
- whether you want the server to have the ability to maintain the client to server context, also referred to as a persistent connection
- other requirements specific to a particular model.

The following table summarizes the similarities and differences among the programming models.

Programming Model	Network Protocol	Maximum Message or Data Size	Supports Two-phase Commit?	Write Own Communi-cations Protocol?	Supports Persistent Connect-ions?	Other Requirements
TCP Transaction Request Message Link	TCP/IP	32 KB	No	No (see sample code)	Yes	• See mscmtics.cbl sample application. • 1:many relationship between server application and port.
TCP Enhanced Listener Message Link	TCP/IP	32 KB	No	No (see sample code)	Yes	• See mscmtics.cbl sample application. • 1:1 relationship between server application and port.

TCP Transaction Request Message User Data	TCP/IP	unlimited	No	Yes (Server TPs are coded to handle all socket calls over TCP/IP)	Yes	• 1:many relationship between server application and port.
TCP Enhanced Listener Message User Data	TCP/IP	unlimited	No	Yes (Server TPs are coded to handle all socket calls over TCP/IP)	Yes	• 1:1 relationship between server application and port.
IMS Connect	TCP/IP	10MB	No	No	No	• No inbound (from TI to the host) unbounded recordsets are allowed. TI cannot send unbounded recordsets to the host; only those recordsets coming back from the host to TI are supported. • Dependent on the IBM supplied HWSIMSO0 and HWSIMSO0 exit routines.
IMS Implicit	TCP/IP	unlimited inbound 32KB outbound	No	No	No	
IMS Explicit	TCP/IP	unlimited	No	Yes (IMS TPs are coded to handle all socket calls over TCP/IP)	No	
OS/400 Distributed Program Calls	TCP/IP	32KB	No	No	Yes	

CICS LU6.2 Link	LU 6.2	32KB	Yes	No	No	• Server TPs are already coded to use the COMMAREA. Note CICS Link does not support multiple send-and-receive commands. Therefore, variable length record sets are not supported, but fixed-sized recordsets are supported. • CICS TPs do not contain the necessary logic to handle issuing APPC verbs directly, but instead must rely on the CICS Mirror transaction. • The TP is coded for a simple send-and-receive sequence.
CICS LU6.2 User Data	LU 6.2	unlimited	Yes	Yes (Server TPs are coded to handle all APPC and Sync Level 2 communica-tions.)	Yes	• Existing TPs contain the proper code necessary to manage their own APPC and Sync Level 2 communications. • Can use multiple send-and-receive commands.
IMS LU6.2 User Data	LU 6.2	unlimited	Yes	No	No	• Each server TP must have the embedded code necessary to handle all data communications using the LU6.2 protocol.

Implementing a specific programming model requires that you install and configure the appropriate software on your mainframe or AS/400 computer. When choosing the appropriate programming model for your organization, you might want assess how closely your current host configuration match the minimum requirements. The following table summarizes the minimum software and configuration requirements for each programming model.

Programming Model	**To use this model, you must install and configure**
TCP Transaction Request Message Link	• IBM MVS operating system 4.3 or later. • IBM CICS 4.0 or later. • The Listener TP, which is included in CICS TCP/IP, configured and started. • TCP/IP for MVS version 3.2 or later. • At least one CICS region defined in an APPL statement in VTAM with TPs configured.

TCP Enhanced Listener Message Link	• IBM MVS operating system 4.3 or later. • IBM CICS Transaction Server 1.3 or 2.0. • The Listener TP, which is included in CICS TCP/IP, configured and started. • TCP/IP for MVS version 3.2 or later. • At least one CICS region defined in an APPL statement in VTAM with TPs configured.
TCP Transaction Request Message User Data	• IBM MVS operating system 4.3 or later. • IBM CICS 4.0 or later. • The Listener TP, which is included in CICS TCP/IP, configured and started. • TCP/IP for MVS version 3.2 or later. • At least one CICS region defined in an APPL statement in VTAM with TPs configured.
TCP Enhanced Listener Message User Data	• IBM MVS operating system 4.3 or later. • IBM CICS Transaction Server 1.3 or 2.0. • The Listener TP, which is included in CICS TCP/IP, configured and started. • TCP/IP for MVS version 3.2 or later. • At least one CICS region defined in an APPL statement in VTAM with TPs configured.
IMS Connect	• IBM MVS operating system 4.3 or later. • IBM IMS 4.1 or later. • The Listener TP included in IMS TCP/IP. • TCP/IP for MVS version 3.2 or later. • IMS TCP/IP.

IMS Implicit	• IBM MVS operating system 4.3 or later. • IBM IMS 4.1 or later. • The Listener TP included in IMS TCP/IP. • TCP/IP for MVS version 3.2 or later. • IMS TCP/IP.
IMS Explicit	• IBM MVS operating system 4.3 or later. • IBM IMS version 4.1 or later. • The Listener TP included in IMS TCP/IP. • TCP/IP for MVS version 3.2 or later. • IMS TCP/IP.
OS/400 Distributed Program Calls	• IBM OS/400 release 4 version 1 or later.
CICS LU6.2 Link	• IBM MVS operating system version 4.3 or later. • IBM CICS version 3.3 or later. • The CICS Mirror transaction, which is included in CICS version 3.3 or later. • VTAM. • At least one CICS region defined in an Application (APPL) statement in VTAM with TPs configured. • The proper VTAM PU, LU, and Mode definitions necessary to establish Systems Network Architecture (SNA) connectivity
CICS LU6.2 User Data	• IBM MVS operating system 4.3 or later, including OS/390. • IBM CICS 3.3 or later. • VTAM. • At least one CICS region defined in an APPL statement in VTAM with TPs configured. • The proper VTAM PU, LU, and Mode definitions necessary to establish SNA connectivity.

IMS LU6.2 User Data	• IBM MVS operating system 4.3 or later. • MVS/APPC must be installed on the mainframe computer. MVS/APPC is included with the operating system. • IBM IMS 4.0 or later. • IBM IMS 6.0 or later if using 2PC protocols (Sync Point level 2). • IBM Recovery Resource Services (RRS) if using 2PC protocols (Sync Point level 2). In addition, the proper IMS control regions must be defined in an APPL statement in VTAM.

Programming Models

Supported Data Flow Models

Transaction Integrator (TI) supports the following four data flows:

- Non-transactional Data Flows That Support Bounded Recordsets
- Non-transactional Data Flows That Support Unbounded Recordsets
- Transactional Data Flows That Support Bounded Recordsets
- Transactional Data Flows That Support Unbounded Recordsets

The following table shows the mainframe-based programming models and the data flows that TI supports.

Mainframe Programming Models	Non-transactional bounded recordsets	Non-transactional unbounded recordsets	Transactional bounded recordsets	Transactional unbounded recordsets
TCP Transaction Request Message (TRM) Link	X			
TCP Enhanced Listener Message (ELM) Link	X			
TCP Transaction Request Message (TRM) User Data	X	X		
TCP Enhanced Listener Message (ELM) User Data	X	X		
IMS Connect	X			
IMS Implicit	X			
IMS Explicit	X	X		
OS/400 Distributed Program Calls	X			
CICS LU6.2 Link	X		X	
CICS LU6.2 User Data	X	X	X	X
IMS LU6.2	X	X	X	X

Programming Models

Non-transactional Data Flows That Support Bounded Recordsets

For each method invocation, TI converts and sends the input parameters to the transaction program (TP). The mainframe TP executes, processes the input data (for instance, accessing or updating the database), and sends its response back to TI. Then TI receives the output parameters from the TP and converts them to return to the invoker.

This data flow model does not support unbounded recordsets. (An unbounded recordset has no set number of rows.)

The following server models support this data flow model:

- CICS LU6.2 Link
- CICS LU6.2 User Data
- IMS LU6.2
- TCP Transaction Request Message (TRM) Link
- TCP Transaction Request Message (TRM) User Data
- IMS Explicit
- IMS Implicit
- IMS Connect
- OS/400 Distributed Program Calls

See Also

Other Resources

Supported Data Flow Models

Non-transactional Data Flows That Support Unbounded Recordsets

This model supports one or more consecutive sends followed by one or more consecutive receives. Therefore, the last input parameter of the method invocation can be an unbounded recordset (that is, a recordset with no set number of rows).

The input parameters are converted and sent, and then each row of the recordset is converted and sent to the mainframe transaction program (TP). The mainframe TP executes, receives the input data and each row of the recordset, processes the data (perhaps doing database accesses and/or updates), and then sends its response back to TI. TI receives any output parameters from the TP and converts them to return to the invoker. Then each row of an unbounded recordset is received, if appropriate. The mainframe TP has no notion of a recordset; it is just receiving or sending tabular data. TI handles all conversion to and from the recordset.

The following server models support this data flow model:

- CICS LU6.2 User Data
- IMS LU6.2
- TCP Transaction Request Message (TRM) User Data
- IMS Explicit

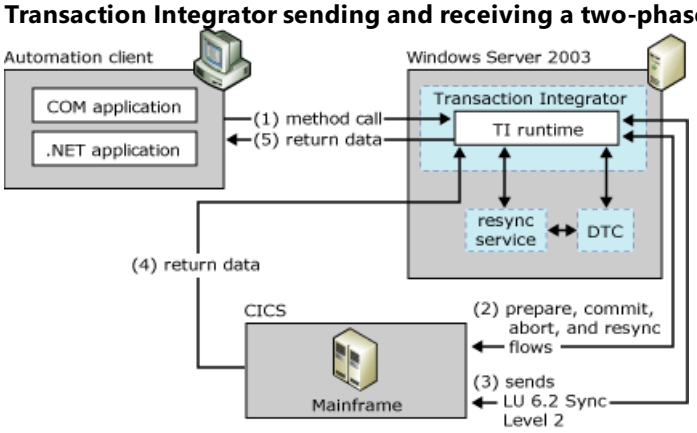
Supported Data Flow Models

Transactional Data Flows That Support Bounded Recordsets

This data flow model does not support unbounded recordsets. (An unbounded recordset has no set number of rows.)

The following figure shows what happens when a TI component participates in a COM+ transaction (a DTC-coordinated two-phase commit [2PC] exchange). TI uses LU 6.2 Sync Level 2 to manage the transaction. This capability applies to CICS and to IMS version 6.0 with Resource Recovery Services (RRS).

Transaction Integrator sending and receiving a two-phase commit exchange from a mainframe via LU 6.2



TI sending and receiving a two-phase commit

This transactional model does not support unbounded recordsets. (An unbounded recordset has no set maximum number of rows.) The transactional model is supported only by the LU 6.2 protocol, not the TCP/IP protocol. Therefore this model supports the following server models only:

- CICS LU6.2 Link
- CICS LU6.2 User Data
- IMS LU6.2

Microsoft Distributed Transaction Coordinator (DTC) works with the TI run-time environment and with the SNA LU 6.2 Resync TP service to provide the necessary 2PC flows as well as transaction log synchronization and recovery services. TI Automation clients can remain completely uninvolved in transaction commit or rollback decisions, or they can participate as shown in the following Visual Basic code. TI Automation clients are never aware of, nor involved in, transaction recovery. The following code sample is for a Visual Basic client that is involved in transaction control.

```
'Get object context reference
Set ctxObject = GetObjectContext()
'Create object instance for an example ProgID
Set obj = ctxObject.CreateInstance ("A.B.1")
'Invoke a method on the object with some parameters
ret = obj.YourMethod(c,d,e)
Do any other work that is part of this transaction
'If application finds all is well, then commit, otherwise roll back
If<something is not OK> Then
   ctxObject.SetAbort
Else
   ctxObject.SetComplete
End if
```

If a client remains uninvolved in transaction control, the TI run-time environment automatically commits transactions that have no run-time environment failures and automatically rolls back those transactions that have failures. The TI run-time environment, however, cannot detect or react to application-specific conditions that require a transaction to initiate a rollback. These must be handled by the client application. For example, an "out of cash" situation in an automated teller machine must be handled by the client application.

Supported Data Flow Models

Transactional Data Flows That Support Unbounded Recordsets

This model supports one or more consecutive sends followed by one or more consecutive receives. Therefore, the last input parameter and/or the return value of the method invocation can be an unbounded recordset (that is, a recordset with no set number of rows).

The CICS Link programming model cannot be used, so this data flow model supports only these two server models:

- CICS LU6.2 User Data
- IMS LU6.2

Supported Data Flow Models

Iterative vs. Concurrent TCP/IP Models

IBM defines two models for accessing server applications in CICS and IMS. In both models, there is a TCP/IP connection Listener and a Server aspect to the total application. The manner in which the Listener and Server portions of the application are implemented determines whether the model is Iterative or Concurrent.

- Iterative model. In the Iterative model, the Listener and Server portions of the application coexist in the same CICS or IMS TP and run as part of the same CICS task. The server application, therefore, holds the socket until all application processing has completed. This means that after a client TP starts a server TP, another client TP cannot access the Listener or the server TP until the first client is finished.

- Concurrent model. In the Concurrent model, the Listener and Server portions of the application run under the control of different tasks. The Listeners purpose is to accept the connection and invoke the Server task. The Server portion of the application deals with all sending and receiving of application data and performing application-dependent processing. This model allows a higher degree of transaction concurrency because the listening socket is not held by a single client and can instead listen concurrently to multiple clients. Even though the CICS MS Link using TCP/IP programming model is not called concurrent, the server TP does work concurrently instead of iteratively.

In the four TI-supported TCP/IP models other than IMS Connect, there is both a TCP/IP connection Listener aspect and a Server aspect. The manner in which the Listener and Server portions of the application are implemented determines whether the Iterative or the Concurrent access model is used. The Concurrent access model requires the use of a Transaction Request Message (TRM); the Iterative model does not. The TRM is a formatted data record that identifies the IMS or CICS transaction program (TP) to be invoked and its characteristics.

In This Section

Iterative Model

Concurrent Model

Other Resources
Programming Models

Iterative Model

In the Iterative model, the Listener and Server portions of the application coexist in the same CICS or IMS TP, so the TP holds the socket until all application processing has been completed. The Iterative model uses this sequence:

1. Create a socket
2. Bind it to a local address
3. Listen (make TCP/IP aware that the socket is available)
4. Select (wait for a connection request)
5. Accept the connection request
6. Read or write the data
7. Close

The advantages of the Iterative model are:

- Simplicity
- Reduced network overhead and delay because a TRM exchange sequence is not required
- Less CPU intensive
- Higher single-threaded transaction throughput

The disadvantages of the Iterative model are:

- Severely limits concurrent access to TPs that run for a long time
- Server application contains all of the SEAPI calls (Create to Close)
- Each TP has its own Listener, which means duplicate code
- Select with timeout causes a CICS region to sleep

See Also

Other Resources

Iterative vs. Concurrent TCP/IP Models

Concurrent Model

In the Concurrent model, the Listener and Server portions of the TP run under the control of different tasks. The Listener's sole purpose is to accept the connection and spawn the Server task. The Server portion of the application sends and receives data and performs TP-dependent processing. This model allows a higher degree of concurrency because the listening socket is not held for an extended period of time.

The Listener must receive a TRM as the first data from the TI run-time environment. The TRM tells the Listener which TP to invoke and the characteristics of that program. After sending the TRM, the TI run-time environment must wait for a response before sending data. The Listener of the Concurrent model follows this sequence:

1. Create a Listening socket
2. Bind it to a local address
3. Listen (make TCP/IP aware that the socket is available)
4. Select (wait for a connection request)
5. Accept the connection
6. Read the TRM
7. Check the validity of the requested transaction ID (TRANID)
8. Give a socket (prepare TCP/IP for the transfer of the socket)
9. Start the task
10. Synchronize on the worker task acceptance of the socket
11. Select (wait for connection request)

The Worker task of the Concurrent model follows this procedure:

1. Take a socket (accept the socket request from the Listener).
2. Write a response to the TRM.
3. Read or write application data.
4. Close.

The advantages of the Concurrent model are:

- Easy to implement concurrent access to TPs that run for a long time.
- One Listener is shared by many TPs.
- Server TCP/IP logic is simple.

The disadvantages of the Concurrent model are:

- Increased network overhead and delays due to the requirement of the TRM exchange.

- More CPU and resource intensive than is the Iterative model.

Iterative vs. Concurrent TCP/IP Models

Host-Initiated Processing

Host-initiated processing (HIP) enables a host application to call a method of a COM or .NET object, pass parameters to the method, and receive parameters back from the method. As data travels first from the host to the client and then from the client to the host, the data is transformed from a format understandable by the host to the format appropriate for the client

Host-initiated processing is implemented in the following steps:

1. The HIP service process, called an application, begins listening for incoming connections on a list of endpoints specified by a local environment definition.

2. The client application, running on the host, initiates a TCP connection to a HIP system using one of the endpoints

3. The HIP service process checks if there is an established association between the endpoint and the clients host name or IP address. If no association is found, the connection is aborted.

4. The association uniquely identifies the work plan that is a sequence of workflows to be performed to complete the clients request. There are three types of work plans:

    a. Endpoint

    b. Transaction Request Message

    c. Data.

Endpoint

The endpoint work plan consists of a single final workflow. The association is directly mapped to a method of a COM object that is to be invoked for the clients request processing. The endpoint workflow performs the following:

1. Receives client data

2. Unpacks data and populates parameters for the method

3. Creates the object and calls the method

4. Packs returned parameters into the client data

5. Sends client data

6. Closes connection.

Transaction Request Message

The Transaction Request Message (TRM) work plan consists of two workflows: TRM and Final workflow. TRM workflow handles initial part of the conversation when client sends the TRM and the workflow replies with the TRM Reply. Depending on the type of TRM, the TRM workflow can use one of three TRM Handlers: Microsoft Concurrent Server, Microsoft Link, IBM Concurrent Server. The TRM workflow performs the following:

1. Receives and unpacks the TRM using the assigned input format

2. Passes the TRM to the assigned handler

3. The handler returns the resolution information and the positive TRM Reply

4. The resolution information, which is expected to be character data, is converted to Unicode using the code page associated with the host environment

5. Workflow queries the database if there is a mapping to a method of an object defined for the resolution information
6. In case the match is not found, the handler is called to get the negative TRM Reply
7. The TRM Reply is packed using the assigned output format and sent. In the negative case, the connection is aborted
8. Workflow passes control to Final workflow along with the method identity found

Data

The Data determinant work plan consists of two workflows: Data Determinant and Final workflow. Data Determinant workflow preprocesses the client data trying to find a match to one of the determinants defined for the association. Determinant includes a string of characters and the position of the string in the client data. Each determinant is mapped to a method of an object. At startup the determinants are pre-converted to all code pages of hosts associated with determinants. The rules are enforced that determinants for an end point – host association are not duplicated or one determinant is not a part of the other. The workflow follows these steps:

1. The list of determinants for the given End Point – Host combination is obtained and sorted by the sum of the length and position in ascending order
2. The first determinant is taken from the list
3. A part of client data is received
4. The data is checked if it matches the determinant
5. In case of no match the next determinant is taken from the list, more client data received if needed, data compared to determinant
6. When no available determinant matches the data the connection is aborted
7. If a determinant is found the control is passed to Final workflow along with the method identity and the client data already read. There could be a situation when the determinant data is located within or even after the client data mapped to the methods parameters.

Note

A HIP MVS client must perform a socket shutdown immediately after a socket send and before a socket receive. Failure to perform an immediate socket shutdown causes the TI runtime to refuse the data, break the connection, and log an 808 event message (**A Transaction Integrator HIP application received more data than expected.**) to the server application event log. In addition, the packet containing the data being sent to the workstation might appear misleading: the Microsoft Network Monitor shows the data within the packet and data length not being excessive.

Windows-Initiated Processing

Windows-Initiated Processing

Windows-initiated processing (WIP) enables Windows-based client applications to invoke mainframe based transaction programs (TPs). Transaction Integrator (TI) along with the Windows operating system includes everything you need to build, deploy, and manage TI components that enable mainframe transaction programs (TPs) to interoperate with Windows-based COM and .NET applications.

The following programming models support Windows-initiated processing:

- TCP Transaction Request Message Link
- TCP Enhanced Listener Message Link
- TCP Transaction Request Message User Data
- TCP Enhanced Listener Message User Data
- IMS Connect
- IMS Implicit
- IMS Explicit
- OS/400 Distributed Program Calls
- CICS LU6.2 User Data
- CICS LU6.2 Link
- IMS LU6.2 User Data

Transaction Integrator Architecture

What WIP Does

Windows-initiated processing (WIP) enables Windows-based client applications to invoke mainframe based transaction programs (TPs). Transaction Integrator (TI) provides a COM or .NET object interface (an Automation interface), maps data types to convert from the Intel-based architecture to the OS/390-based or OS/400-based architecture, and interacts with the host TPs.

Windows-Initiated Processing

How TI Associates a Method with a TP

TI generally establishes some type of association between a method call in the Windows environment and the corresponding TP on the mainframe.

In the CICS TRM and ELM Link programming models, you can specify three names:

- Mainframe transaction program (TP) name
- TI component's method name
- Source TP Name

The name of the mainframe TP is constant for a given remote environment (RE). CSMI (the Mirror transaction) is an example of a mainframe TP Name. Each method name can be associated with a different mainframe TP Name. In addition, a third name, called the Source TP Name, can be specified for each method. The Source TP Name can be used with DB2 to associate a specific mainframe TP (and TI method) with a region control task (RCT).

In the CICS TRM and ELM User Data programming models, each method in a TI component is associated with a TP Name, and multiple methods can be associated with the same TP Name. If multiple methods are associated with the same TP Name, TI assumes that the TP is able to distinguish between the requests generated by each method. The TI run-time environment should optionally provide Meta data to assist the TP with this process. When Meta data is included, the method name is sent as a fixed-length character string (32 characters) and is always the first item sent. The method name is left justified in the field and padded with blanks. Developers can specify the method-TP Name mapping on a per-method basis or as a default for the entire component.

When COBOL that is imported to build a TI component library contains REDEFINES clauses, the TP can expect different kinds of requests. The developer should consider creating a method for each REDEFINES group that represents a different message format. All of the methods created from these REDEFINES groups can map to the same TP.

What WIP Does

How TI Enables TPs to Return Exceptions

TI provides a Meta data mechanism for returning exceptions from Automation server applications like TI applications. TI uses this mechanism to provide the mainframe developer with an optional way to return mainframe error information (also known as exception data) back through the normal application.

A transaction program (TP) returns error information as optional Meta data that includes an exception block as part of the reply message. The exception block contains information, in a standard format, that can be used to populate an Automation exception structure.

TI error messages have numbers in the range 0-9999. Meta data error message numbers returned from the mainframe can fall within the same range. To distinguish TI error messages from Meta data messages returned from the mainframe, TI adds 10000 to the number of any Meta data error message returned from the mainframe.

A TP can also use this mechanism to provide information regarding the TP state to the TI run-time environment. Specifically, a TP can indicate whether the TP:

- Is willing to commit the work performed so far (and deallocate the conversation).
- Can perform no more work on the current conversation and expects the client to prepare and commit.
- Has encountered an error that will prevent it from committing the transaction.

While it is always possible for a TP to deallocate the conversation abruptly, TI exceptions allow it to return detailed information about the error to the calling client application.

TI uses the information contained in the exception block to update state information in the TI run-time environment and (if requested) return an exception to the client application.

The following table shows the fields in the EXCEPINFO exception structure.

Field	**Description**
wCode	The error code returned in the exception block.
bstrSource	Generated automatically by TI based on information about the customer's object and the remote TP.
bstrDescription	From the exception block. This error description comes from the remote TP.
bstrHelpFile	Formed by taking the Help path associated with the object's component library (in the Registry) and combining it with an unqualified file name included as custom information in the component library. This allows the developer to identify the file name of the Help file as it was created, while giving the administrator ultimate control over where the Help file is installed during deployment.
dwHelpContext	From the exception.
scode	Same as *wCode*.

It is possible for the TP to return state information without actually raising an exception. To keep the mainframe TP code as straightforward as possible, the exception data is part of the optional Meta data and is returned in all cases, whether an error occurs or not.

What WIP Does

WIP Programming Model

The programming models provide a synchronous bridge between the component object model (COM) or the .NET Framework and the mainframe transaction-programming model. Consequently, Transaction Integrator (TI) has no APIs that a developer must use.

Although TI uses existing mainframe programming models, you may need to make some changes to an existing mainframe transaction program (TP) if any of the following are true:

- The TP uses a conversational or pseudo-conversational mode. TI supports only the nonconversational TP model known as the ping-pong or request-reply conversational sequence in conversations between clients and servers. The TI programming model requires nonconversational method calls; that is, a single input message and a single output message. See "Supported Conversational Model" for more information.

- The TP has terminal processing logic embedded in the same program with the business logic. To get this program to work with TI, you must first restructure it as two separate TPs, one for the terminal processing logic and the other for the business logic. Then you can use TI with the business logic TP.

- A CICS Link transaction program (TP) using LU 6.2 uses explicit EXEC SYNCPOINT commands. There may be a way to work around this issue without rewriting the TP. For more information, see TPs with Explicit SYNCPOINT Commands.

The topics in this section give you the details on the mainframe programming models and how they are addressed in the TI programming model.

Windows-Initiated Processing

Supported Conversational Model

TI supports only the nonconversational (ping-pong) model. A mainframe transaction program (TP) may not expect a request-reply (ping-pong) nonconversational sequence like that required by TI, in which case, you will need to modify the mainframe TP. The mainframe TP may be set up to communicate with other TPs by using the conversational or pseudo conversational models, neither of which are supported by TI.

In a nonconversational transaction, the entire exchange of data between the client and server occurs within a single method call. The exchange of data can be fairly complex (for example, if recordsets are used), but the base application has no opportunity to delay the exchange of data or otherwise cause the conversation to remain idle.

A pseudo-conversational TP attempts to get conversational-type client/server interactions while avoiding the scalability problems associated with true conversations. Pseudo-conversations are implemented by TPs that maintain state for clients over a series of nonconversational requests. An application-specific context handle is used to retrieve the saved state over the course of the pseudo-conversation. TI does not support the pseudo-conversational model.

WIP Programming Model

TPs with Explicit SYNCPOINT Commands

CICS LU 6.2 Link transaction programs (TPs) cannot use explicit EXEC SYNCPOINT commands to control the transaction semantics of COM+ transactions. However, if an existing CICS Link TP does issue explicit EXEC SYNCPOINT commands, you do not need to modify the TP to have it work successfully with TI. You need only meet the following two requirements for TI components that execute within the transaction.

- Set the TI component's transaction property to **Does not support transactions**. You define a component's transaction property when you create the component in TI Designer. Once you deploy the TI component in a COM+ application, you can view or modify its transaction property in TI Manager.

- Configure the remote environment (RE) that describes the region on the mainframe and that hosts the CICS Link TP to allow the use of explicit SYNCPOINT commands for non-transactional components.

To configure the RE to allow the use of explicit SYNCPOINT commands

1. In TI Manager, right-click the RE that you want to configure, click **Properties**, and then click the **CICS Mirror TP** tab.
2. Select the **Allow use of explicit SYNCPOINT commands for nontransactional components** check box.
3. Click OK.

If the two requirements are not met, the transaction will not work on either the Windows or the mainframe side. In which case, TI writes a message to the Windows 2000 Event Log explaining the cause of the failure.

WIP Programming Model

Support for Transactions and Two-Phase Commit

In COM terminology, a transaction is always a unit of work that is atomic, consistent, isolated, and durable (ACID). In mainframe terminology, a transaction may or may not be an ACID transaction; in mainframe terminology, a transaction is a set of operations or commands in a transaction program (TP). This difference in terminology can be confusing. The word transaction as it is used in TI Manager and TI Designer always refers to an ACID transaction.

Two-phase commit (2PC) is a protocol that allows a set of application (or cross-application) operations or commands to be either all rolled back or all committed as a single transactional unit.

Note
If you invoke a TI Automation server over the TCP/IP protocol, there is no support for two-phase commit transactions. Two-phase commit works only over the SNA APPC/LU 6.2 protocol.

A TI component has four possible transactional properties:

- Requires transaction
- Requires new transaction
- Supports transactions
- Does not support transactions

The first two choices require the mainframe TP to be transactional (that is, meet the ACID properties) and to support Sync Level 2. This is transparent to the mainframe TP if it is a CICS Link or IMS version 6.0 or later program. The third choice requires the mainframe TP to support Sync Level 2 requests and handle the transaction semantics appropriately. The fourth choice is required for IMS TPs prior to IMS version 6.0 and for any CICS TPs that support only Sync Level 0 or Sync Level 1.

If a TI component is invoked within the scope of a COM+ transaction, TI will establish a Sync Level 2 conversation with CICS (otherwise, Sync Level 0 is used). This is transparent to the client of the TI component. If the mainframe TP is a CICS Link program, the transactional nature of the conversation is transparent to the TP as well, since IBM's mirror transaction in CICS (CSMI) handles the Sync Level 2 protocol, and the TP to which it is linked is unaware whether Sync Level 0 or Sync Level 2 is being used.

TI complies with the COM+ programming model by calling SetComplete or SetAbort when it completes the operation of each method call from the client. If no errors were detected, TI calls SetComplete; otherwise it calls SetAbort. TI also calls SetAbort if the mainframe TP indicates that the transaction should not commit by setting the DisableCommit flag in the meta data error block returned. TI Automation client applications can also choose to call SetAbort if they determine that there are application-level problems that should prohibit the transaction from committing.

When the client's method call returns, the TP on the mainframe has performed some unit of work, but any changes to protected resources in CICS are not yet committed. TI uses new DTC interfaces to enlist the Sync Level 2 conversation on the DTC transaction. When DTC is ready to commit or abort the transaction, it communicates with TI to drive the appropriate two-phase commit flows on the LU 6.2 conversation. Again, all of the 2PC work is performed transparently by TI on the client's behalf.

Although the TI object can be deactivated when the method completes, the conversation must be maintained until the transaction commits or aborts. Users can adversely affect performance and tie up system resources if their application code makes one or more transactional method calls but does not commit the transaction for a long period of time. Conversations can be quickly consumed by poorly structured user code.

When a conversation is waiting to commit, it will be divorced from the object with which it was associated. TI manages a pool of these "waiting" conversations and performs the required sync-level operations when the appropriate notifications are received from DTC. When possible, TI reuses these conversations to minimize overhead.

TI also provides a resynchronization service (SNA LU 6.2 Resync TP). This Windows 2000 service is configured to be the auto-started invokable service for the SNA-defined Resync TP (0x06f2). The Resync service implements the "Exchange Log Names" and "Compare States" functions of an SNA transaction manager. It allows both DTC (Distributed Transaction Coordinator) and CICS to initiate the recovery process as required during system startup or following a system or communication failure.

For information about IBM's SNA SyncPoint or 2PC flows, *SNA SyncPoint Services Architecture Reference (IBM SC31-8134-00)*. All TI 2PC flows are implemented in conformance with this architecture.

Note
For information on how to use CICS Link TPs that use explicit SYNCPOINT commands, see TPs with Explicit SYNCPOINT Commands.

In summary, to use two-phase commit, you must meet all of the following requirements:

- The local and remote LUs must each have SyncPoint support enabled in the Host Integration Server node.
- The local and remote LUs should each point to the computer that is running Resync services.
- The remote environment (RE) must have Sync Level 2 support enabled. To check this, right-click the RE in TI Manager, click Properties, and then click the LU 6.2 tab.
- The TI component must have Transaction Support set to Supported, Required, or Requires New. To check this setting, right-click the TI component in TI Manager, click Properties, and then click the Transactions tab.
- The remote host computer must be configured for Sync Level 2 support.

Providing a Fail-Safe Environment for ACID Transactions

ACID (atomic, consistent, isolated, and durable) transaction processing using two-phase commit (2PC) generally requires a fail-safe environment, which is an environment that ensures continuation in spite of hardware failures. This is often called 2PC failover or hot backup.

Host Integration Server includes enhancements to the **SNA LU 6.2 Resync TP** commonly called the Resync service along with enhancements to the configuration and APPC DLL to make 2PC failover work through two or more redundantly configured Host Integration Server SNA servers (computers). In the event of a failure of one of the servers (computers), a separate Host Integration Server computer running either TI or the DB2 Provider can continue to initiate transactions through an alternate server (computer).

To configure 2PC failover to work with Host Integration Server, complete these tasks:

- Configure two Host Integration Server servers to support the same SyncPoint-enabled local APPC LU alias but with different LU names. Have these local APPC LUs point to the same computer name where Microsoft Distributed Transaction Coordinator (DTC) service and the Resync service are running (that is, a separate Host Integration Server computer that supports TI or an application that uses the DB2 Provider). Also, have both servers support the same remote APPC LU alias and name.

- In the applicable TI remote environment (RE), configure the local and remote LU aliases, and choose transactional support. If the application is using the DB2 Provider, configure the Universal Data Link with the local and remote APPC LU aliases, and set the **Units of Work** property to DUW.

When the Resync service starts, it searches all SyncPoint-enabled local APPC LUs that specify the computername where the Resync service is running. Resync then initiates an Exchange Log Names request over every found local APPC LU with all SyncPoint-enabled remote APPC LUs.

When a TI Automation server (application) or the DB2 Provider invokes a transaction program (TP) on the mainframe and initiates a conversation, the APPC DLL locates any available Host Integration Server server (computer) that supports the LU/LU pair.

In this way, a TI Automation server (application) or the DB2 Provider gains fault tolerance by getting a conversation through any Host Integration Server server (computer) that supports the LU/LU pair. The Resync service then coordinates the DTC transaction log reconciliation when a Host Integration Server SNA server (computer) comes back online, if a server (computer) failure occurs during a transaction. Note that this configuration does not provide fault tolerance for the Host Integration Server server (computer) that is running only TI or the DB2 Provider, not the SNA service.

Note
Clustering the servers (computers) that are running the SNA service is not recommended. Instead of using Windows Clustering, use the configuration recommendations described in this topic.

Note
2PC works only when you are using the SNA (APPC/LU 6.2) protocol to communicate with the host system. Neither TI nor the DB2 Provider support 2PC over the TCP/IP transport, so there is no 2PC failover solution for TCP/IP-based systems.

Windows-Initiated Processing

Using TI in a Non-DPL Environment

A non-linked environment (that is, a non-DPL environment) is one that does not use IBM Distributed Program Link (DPL). You can use TI to invoke a mainframe transaction program (TP) that uses the **EXEC CICS RECEIVE INTO** and **EXEC CICS SEND FROM** COBOL commands. These two COBOL commands are useful when you want a CICS TP to take on SNA (APPC/LU 6.2) conversation responsibilities and therefore bypass the Mirror TP. In other words, the **EXEC CICS RECEIVE INTO** and **EXEC CICS SEND FROM** COBOL commands are most often used in a non-linked environment to transfer data to and from an LU of type 6.2 (APPC).

TI supports the LU 6.2 model for both linked and nonlinked environments. You can create the following remote environment (RE) types to support each model:

- **CICS Link using LU 6.2**

  Use this in an IBM DPL environment that uses the Mirror TP.

- **CICS using LU 6.2**

  Use this in a non-DPL environment that bypasses the Mirror TP.

Many customers use TI in a non-DPL environment. The only concern is whether terminal logic is embedded with the business logic. When a COBOL TP supports IBM DPL, the presentation logic has already been separated from the business logic, so you probably will not need to modify the COBOL. However, if the TP was written to communicate with a terminal, it is likely that you will need to modify the COBOL code to separate the business logic from the presentation logic.

For example, the following sample COBOL code shows how to handle unbound recordsets by using the **EXEC CICS RECEIVE INTO** and **EXEC CICS SEND FROM** COBOL commands:

```

In This Section

Security Overview

As corporate networks become increasingly integrated with the Internet and other external networks, the threat of unauthorized access to your corporate resources grows significantly. When you plan your networking environment, you must strike a balance between protecting your resources and allowing users unobstructed access to data.

The following list includes some of the questions that must be answered as you prepare to secure your Host Integration Server environment:

- How can I authenticate users who require host resources?
- How can I control access to host resources?
- How can I control sensitive data flowing between workstations and host applications?
- How can I maintain security while connecting my host network to external sources like the Internet?
- How can I make host resources easier to access for authenticated users, yet maintain a more secure and easy-to-administer host environment?

This section helps answer these questions and describes how to implement the security features to create a more secure LAN-to-host environment.

Other Resources

Understanding Windows Security

File System Choices and Security

One of the keys to controlling security on Host Integration Server computers is the configuration file. To maintain good security with this file, be sure to install the Host Integration Server server software on an NTFS (NT File System) partition. With NTFS, you can assign permissions on a file-by-file basis. With the FAT (File Allocation Table) file system or HPFS (High Performance File System), this is not possible. Installing Host Integration Server software on an NTFS partition is especially important for the primary server because this computer contains the master copy of the configuration file used by all Host Integration Server computers in the subdomain.

If you must install Host Integration Server on a non-NTFS partition, you can limit a users ability to view or change a Host Integration Server configuration file through the Host Integration Server SNA Manager, but you will not be able to set file permissions on the configuration file itself.

In addition, if you choose to install the software for one or more servers on a FAT or HPFS partition, you can set appropriate Read and Change permissions on the share, which gives servers access to the configuration file. (This is unnecessary for Host Integration Server software installed on an NTFS partition, because file permissions established through the Host Integration Server SNA Manager place tighter control on the configuration file than can be established by controlling the share.)

Securing Host Integration Server 2009 Files and Directories

If you install Host Integration Server onto an NTFS volume, you can control which SNA subdomain users can modify the Host Integration Server configuration file. A Host Integration Server administrator can control access to the configuration using the Host Integration Server SNA Manager. By specifying access permissions for users, you can control who has the ability to administer, change, or view a configuration.

When you install Host Integration Server, you create a single directory tree that contains the files needed to configure and use Host Integration Server. To control access to the configuration files in these shares, use the following guidelines:

- Create domain user accounts to run the SnaBase and SnaServer services. A domain user account is one that is allowed to log on to the network.
- Disable the Windows domain guest account.

At least one domain user or group must have Full Control permissions over all the shares, preferably a trusted group such as Administrators. If no user or group has Full Control permissions, the only person who can change the share permissions is the owner of the share. If necessary, this individual can change his or her permissions to Full Control as needed.

Understanding Windows Security

Authentication

When Host Integration Server receives a request to access a host resource, such as an LU for a terminal session, the server must have some way to verify the request.

User validation is a fundamental security issue that you can address using one of two methods: Domain Authentication and Workstation Authentication. The method you choose depends upon the type of service being requested.

Domain Authentication

A *domain*, as it pertains to Windows, is a group of computers that share a network resource database and have a common security policy. A Windows domain contains a *primary domain controller* (PDC) computer that acts as the resource and user manager for the entire domain. One or more computers in the domain can be configured to act as a *backup domain controller* (BDC). The BDC can take over for the PDC should any problems arise. The remaining computers in the domain are user workstations or servers that provide resources to domain users.

Within a Windows domain, Host Integration Server computers are logically grouped into an entity called a *subdomain*. Each SNA subdomain can contain up to 15 Host Integration Server computers, and a Windows domain can contain an unlimited number of subdomains. It is common to have multiple domains that manage user accounts independently of one another.

The domain model provides two key advantages over peer-to-peer networks with regards to security:

- You can manage user accounts from a central location.
- You can set up one unified security system for all user accounts in the domain.

Host Integration Server relies on the PDC or BDC to provide authentication services to users requesting access to host resources. Only users who have been validated by the PDC or BDC can gain access to resources provided by servers in the subdomain.

You can use domain authentication to verify users who request resources provided by these services:

- 3270 or 5250 terminal access from workstations using Host Integration Server client software
- APPC, CPI-C, or LUA applications built using Host Integration Server APIs

See Also
Concepts
Authentication
Workstation Authentication

Workstation Authentication

When you receive a request from a source that is external to the corporate network containing the SNA subdomain, or if you are not using a domain-type network, domain authentication is usually difficult to implement.

In this case, Host Integration Server performs workstation authentication on the following services:

- TN3270 terminal access
- TN5250 terminal access
- 3270 access from terminal emulators connecting through Host Integration Server client software

For these services, you can specify a list of allowed client workstation IP addresses for defined resources. When Host Integration Server receives a session request, it determines whether the requesting IP (or workstation name for TN3270E connections) matches that specified for the requested resource. Once verified, Host Integration Server allows the request to proceed.

Note
This type of authentication is not as secure as domain security because workstation names and the IP address are transmitted in clear text over the network.

Domain Authentication

Client Logon

The logon process conducted by a user on a client system performs the essential task of identifying the user to the Windows domain and to Host Integration Server computers in the domain. The way that Host Integration Server handles the logon process depends on the network software on the client system.

For any type of client computer, once the clients logon process for one Host Integration Server computer has been completed, additional servers can provide services without another interactive user logon. Servers can repeat the logon verification without the user being involved.

If you maintain tight security with the logon to a mainframe, it may make sense to keep access open-ended on the Host Integration Server computer.

Understanding Windows Security

Denying Access to Host Integration Server

You can use one of two methods to deny a user or group the ability to use Host Integration Server. Either remove the user or group from the list of those who have permissions, or assign No Access to the user or group.

When removing a user or group from the list of those who have been granted permissions, be sure to consider all groups to which a particular user belongs. To deny access to that user, either remove the applicable groups from the list of those with permissions, or remove the user account from these groups. Otherwise, the user can receive access through one of the groups (unless the second method, assigning No Access, is used).

You can deny all access to a user or group by assigning No Access, which overrides any other permissions that may apply to a user. For example, if a user belongs to a group that has Read permission, but the user has No Access, the user is not permitted administrative access. Likewise, if a user belongs to Group1 and Group2, and Group1 has Read permission while Group2 has No Access, the user is not permitted administrative access.

The following table provides recommendations for using the two methods of denying access.

Method of denying access	**Recommended situations for use**
Remove from list of those granted permissions	Use when you want to deny access to a medium or large group. If you then want to grant access to specific users in that group, add those users to the list of those with permissions. In contrast, if you assign No Access to a large group, none of the members of the group will be allowed access, even if explicit access is assigned to them through other accounts.
Assign No Access	Use when you want to deny access to an individual user or a small group. If you then want to grant access to other groups to which the affected users belong, you can do so. The No Access permission overrides the other permissions for the affected users. In contrast, if you attempt to deny an individual user access by removing the user from the list of those granted permissions, a group to which the user belongs might be left in the list. The permissions assigned to that group would be given to the user.

Understanding Windows Security

Security Audit

When you set up security auditing, you specify events for which the system will create event log entries.

You can monitor system events using the Host Integration Server SNA Manager. When you configure the properties, you can view a detailed problem analysis, significant system events or general information messages, or you can disable audit logging.

You can cause the system to create an entry every time a member of the Administrators group changes the configuration file. The entry would include the time, the user and process IDs, and other information.

When you set up auditing with Host Integration Server, you are able to record not only access to the configuration file, but the running of Host Integration Server processes. However, using a file system other than NTFS limits the possibilities for auditing, just as it limits the possibilities for setting permissions. When Host Integration Server is not installed on NTFS, the only event that will actually result in log entries is the starting of the Host Integration Server SNA Manager. However, auditing information for this event is useful, if limited.

Auditing is an important way of collecting security-related information. However, there is a small performance overhead for each audit check the system performs. In addition, if you record a wide variety of events, the event log can grow very quickly. For these reasons, you may want to be selective when specifying events to be audited. You may want to focus on such events as Read Domain (Success), Write Domain (Success), and Manage Domain (Success). This list of events is a suggestion only. All the events offered for auditing through Host Integration Server can be useful, depending on the situation.

Among the events recorded when you enable auditing are the actions of Host Integration Server itself. For more information about event logs, the Event Viewer, and strategies for auditing, see your Windows documentation.

See Also

Other Resources

Understanding Windows Security

Viewing and Interpreting Audited Events

Events audited by Host Integration Server are recorded on the server in which they occur. They are not stored centrally, in contrast with other records generated through Host Integration Server.

The records generated through auditing are stored in the security section of the event log. In contrast, other Host Integration Server events are recorded in the application section of the log.

Note
When you view log entries for audited events related to Host Integration Server, you will see a record of actions carried out by Host Integration Server itself, as well as actions carried out by users. The source of the actions carried out by Host Integration Server is the account under which the service is running.

The event details for some events will list an item called **Accesses** in the **Description** box. Unusual information may be shown here for events related to Host Integration Server.

Use the following table for interpreting this information.

Information shown for Accesses (under Description)	**Meaning**
Unknown specific access (bit 0)	Read Domain access. This access applies when someone starts or attempts to start the Host Integration Server SNA Manager. (Host Integration Server must read the configuration file in order to function.)
Unknown specific access (bit 1)	Write Domain access. This access applies when someone starts the Host Integration Server SNA Manager in write mode — that is, when someone starts Host Integration Server and the primary Host Integration Server computer is available.
Unknown specific access (bit 2)	Manage Domain access. This access applies when someone starts or attempts to start the Host Integration Server SNA Manager.

Understanding Windows Security

Firewall Support Overview

Host Integration Server client computers and servers can interoperate with screening routers, where the client computer knows the address of the Host Integration Server computer. Host Integration Server client computers and servers can also interoperate with full-blown Internet firewalls, where the end user is not allowed to know the IP address of the Host Integration Server computers.

A firewall is a network security device that restricts access to network resources by allowing traffic only through specified port numbers. These port numbers are commonly defined in software components to allow Internet firewalls to filter packets based on port number, thereby denying or accepting their propagation to the private network. In many instances, the services of a firewall are provided in conjunction with a network router that bridges two network segments together.

Host Integration Server can be configured to use specific software port numbers, allowing administrators of Internet firewalls to filter packets based on port number. By assigning specific destination port numbers to Host Integration Server components, Host Integration Server can interoperate with screening routers and full-blown firewalls.

If the Host Integration Server address is known, the client workstation configures the appropriate port and destination IP of the Host Integration Server computer in the client software, for example, 1477 and 128.124.1.2. Alternatively, the Host Integration Server computer's service port numbers can be changed to the port number requested by the client.

You can configure destination port numbers in Host Integration Server for end-user and Administrator clients using TCP/IP, IPX/SPX.

Each network transport has the following three components for which you can assign destination ports.

DatagramPort

This port is used for datagram (mostly broadcast or multicast) traffic. Use the **Server Broadcasts** dialog box in the Host Integration Server SNA Manager to control which transport is used for server-to-server communication.

SnaBasePort

This is the port to which the server SnaBase listens for new client sponsor connections. Sponsor connections are used by the Host Integration Server client to learn about the SNA subdomain in which it participates.

SnaServerPort

This is the port where the SNASERVR.EXE waits for new application session requests.

If the Host Integration Server address is not known, the Host Integration Server IP transport replaces the real destination IP address with the address of a firewall. The firewall then maps the connection request to the actual Host Integration Server computer. This takes place when the transport opens a connection to a Host Integration Server-based computer for application sessions or a sponsor connection.

Host Integration Server supports firewalls primarily on TCP/IP networks. It may also be possible to implement firewalls on IPX/SPX. For more information on configuring a firewall, consult your network documentation.

Note
The clients obtain the Host Integration Server ports through the sponsor connection. On IPX/SPX, the clients get the SnaBase ports from the NetWare bindery and VINES StreetTalk, respectively. There is no need to configure any port numbers on these two client network types.

It is also possible to create IP mappings which, by overriding service table entries, replace a specified IP address with a firewall address. To create a mapping, add an IPMapping key under the SnaTcp key, and then add a REG_SZ value for each mapping. An example is shown below:

```
IPMapping
xxx.xxx.x.xxx = yyy.yy.yy.yyy
```

With this mapping, any attempts at establishing a connection with *xxx.xxx.x.xxx* will instead connect to *yyy.yy.yy.yyy*.

For additional information on firewall support, including client-side registry settings and the use of DLS with firewalls, see the following Knowledge Base articles: Q139508, Q164590, Q224303, and Q215838.

Understanding Windows Security

Data Encryption

Data Encryption helps secure traffic between the client computer and Host Integration Server on a per-user basis. There is a client component and a server component. The data encryption is implemented transparently to any application that is written to the Host Integration Server APIs (application program interfaces). Any software, such as a third-party emulator, that is written to use the Host Integration Server client APIs will automatically benefit from the encryption.

Host Integration Server lets you encrypt data for client-to-server and server-to-server communications.

Client-to-server encryption prevents information from being sent in clear text between Host Integration Server client workstations and Host Integration Server computers. Data encryption enhances network security on the client-to-server communications path for all applications using Host Integration Server client connections, including 3270/5250 emulators and APPC logon IDs and passwords. Data encryption is enabled by default.

Server-to-server encryption can be used to help provide more secure communications across your network, the Internet, or any other wide area network. If a user enables data encryption, information transferred through Distributed Link Service (DLS) is automatically more secure.

Data encryption is also supported in the distributed deployment of SNA Open Gateway Architecture (SOGA), which uses Host Integration Server to help provide more secure server-to-server communications across the Internet, intranets, and other WANs.

Host Integration Server lets you encrypt data for client-to-server and server-to-server communications.

Client-to-server encryption prevents information from being sent in clear text between Host Integration Server client workstations and Host Integration Server computers. Data encryption enhances network security on the client-to-server communications path for all applications using Host Integration Server client connections, including 3270/5250 emulators and APPC logon IDs and passwords. You can enable data encryption on a user-by-user basis using the Host Integration Server SNA Manager.

Server-to-server encryption can be used to provide more secure communications across your network, the Internet, or any other wide area network. If a user enables data encryption, information transferred through the Distributed Link Service (DLS) is automatically secure.

Data encryption is enabled for Distributed Link Service by adding the domain user account under which Host Integration Server services such as SnaBase or SnaServer are running to the SNA subdomain. The actual encryption is implemented in the transport providers layer of the Host Integration Server architecture. You can then enable data encryption settings for the user account, as described above.

Understanding Windows Security

Maximizing Product Security

In addition to the general guidelines elsewhere in this section, the following specific recommendations can help you increase the security of your Host Integration Server deployment. Since all of these actions are performed during deployment or configuration, procedures are located in the appropriate sections of this documentation.

Note
Whereas these recommendations apply across the entire product, the Transaction Integrator Threat Mitigation section also of fers information specifically for TI users.

Single Sign-On

The most effective action you can take is to use integrated security by using the Host Integration Server Single Sign-on (SSO) feature. It is especially important to use SSO because certain data used by the product is impossible or unwise to encrypt, making it potentially vulnerable. The SSO feature reduces or eliminates this issue.

Accessing SQL Server Databases

When you are accessing a SQL Server database:

- Because the Resync service will access this database -- and the database may service multiple, unsecured domains -- you should always use a local SQL Server database and never grant remote access to it.
- Use only Windows NT integrated security, and restrict access to only privileged Windows NT accounts.
- Use only Host Integration Server security groups which were created with the Host Integration Server Configuration Wizard.

When you are connecting via SNA Protocol:

- When connecting to an upstream Host Integration Server computer, use client/server encryption.
- When implementing SNA Open Gateway Architecture (SOGA) Distributed Link Service (DLS) across wide area networks, use server-to-server encryption.
- Locate upstream Host Integration Server computers within the data center using secure Token Ring, Ethernet, Bus and Tag Channel, or ESCON fiber channel attachments.

When you are connecting via TCP/IP protocol:

- Use upstream Windows software router computers or hardware routers to encrypt the TCP/IP traffic.
- Locate the upstream router within the data center using either secure Token Ring or Ethernet connections to the host.
- Because DRDA AR sometimes stores data in plain text:
    - Use direct network connections over a private segment, with static IP or SNA addresses.
    - Use IPSec where supported for IP communications between host and Windows servers.
- When connecting an SNA LU6.2 network to a mainframe or AS/400, with the Host Integration Server computer deployed as the SNA gateway to a downstream Host Integration Server computer, use Host Integration Server server-to-server data encryption.
- For SNA LU6.2 network connections to mainframe, use the IP-DLC Link Service in conjunction with IPSec.
- Use encryption that is part of the Host Integration Server server-to-server and client-to-server connections.

- When connecting to a mainframe DB2 for z/OS, use IPSec on an IP-DLC, and also use NNS on the target system to utilize direct connections to DLUS and APPN Peer resources.

When you are accessing DB2 DUW over the IP Resync Service:

- Increase the level of security access rights to the SQL Server database which stores the UOWID mapping tables.
- Use the (default) separate SQL Server database, as opposed to one shared with other applications.

To protect unencrypted data and credentials in the com.cfg file:

- Implement IPSec.
- Deploy the Host Integration Server computer in an isolated network segment.
- Increase security settings on the host account used for session security.

When using the TN3270 Server:

- Stop and restart the TN3270 Server whenever a new CRL is downloaded. Otherwise, you will be using an out of date CRL, which could permit unwanted access to the host.

Server-to-Host Security

The following actions will increase server-to-host security, especially on an APPN Network or UDP sockets for HPR/IP Protocol Traffic:

- Deploy Host Integration Server in a secure network segment, and use encryption that is part of the Host Integration Server server-to-server and client-to-server connections.
- Use IPSec on the IP-DLC connection.
- Use NNS on the target system to utilize direct connections to DLUS and APPN Peer resources.
- Use a direct IP-DLC Connection to CS/390 (DLUS) and NNS, or a direct IP-DLC Connection to a peer APPN node.

Additional Security Recommendations

Finally, as in the following recommendations, be vigilant about access to every file, connection, or other product component:

- In general, use System or User DSNs rather than file DSNs, as System and User DSNs are more secure.
- When using the OLE DB Provider for AS/400 and VSAM, store your HCD files in a secure local folder or share that can only be accessed by the developer and the runtime application.
- When using Transaction Integrator, place any objects going to CICS or IMS in a remote environment that requires Enterprise Single Sign-On.
- Be vigilant about your access control list (ACL). Although it is possible to install Host Integration Server and inherit a previous ACL, you should remove any existing ACLs and replace them with new ones.
- Store Printer Definition Tables (PDTs) and Printer Definition Files (PDFs) in a secure location to prevent their being replaced with a rogue file.
- Since trace files may contain non-encrypted data, always store them in a secure location, and delete them as soon as trace analysis is complete.

- Minimize unwanted access to the Resync Service by running it on the same computer as the application it services.

- Enable LUA Security for TN3270 access to the host, and then add the service account to the Configured Users folder. Among other things, this provides encryption if the TN3270 service uses LUs on another server.

- Enable LUA Security for TN5250 access to the host. This increases security by requiring explicit assignment of LUs to user records.

- When using the printing feature associated with the TN3270 Server, reconfigure the display and printer to use the same port. This is necessary because, since these two items are configured separately, they are often inadvertently configured to different ports, and subsequently different security settings.

- Always use IPSec when using the TN3270 or TN5250 Servers. Although data might be safe between the client and server without IPSec, that same data may become vulnerable between the server and the host. Using IPSec reduces the attack surface, ensures data encryption, and makes access available only to authorized users.

Understanding Windows Security

Resource Security

This section describes accessing Host Integration Server resources, including Display LUs, Printer LUs, and LU pools.

In This Section

3270 Terminal Access

Users or groups who require access to 3270 sessions from workstations using Host Integration Server client applications must be members of the SNA subdomain. Therefore, they are also members of the Windows domain of which the subdomain is a part.

Once enrolled in the SNA subdomain, you can assign specific 3270 (LU type 2) resources to the appropriate accounts. The users can access only the specific resources you allocate to them.

The preferred method for maintaining security in your environment is by using domain security to authenticate users, and then limiting their access by assigning them only specified resources.

See Also

Other Resources

Resource Security

5250 Terminal Access and APPC Access

Users who want Advanced Program-to-Program Communications (APPC) access need not be defined in the SNA subdomain, but they must be members of a Windows domain.

For 5250 terminal access using a Host Integration Server client computer within the network, the AS/400 supplies the required security for logon to the AS/400.

For APPC access programmed into specific applications, you maintain security through the actual programmatic conversation, if required.

Resource Security

Securing the TN3270 and TN5250 Services

You can help secure TN3270 and TN5250 services by specifying client workstation IP addresses that have permission to use the resources provided. With TN3270E clients, you can specify a workstation name in place of the client IP address.

The method employed for verifying workstations can also be used to allow only specified IPs to request resources allocated to them.

Resource Security

Transaction Integrator Security

Security affects Transaction Integrator (TI) in two ways. First, TI components can be assigned security attributes in the same way as other COM+ components. This requires no TI development. Second, the TI run-time environment needs to deal with the security mechanisms of the remote environment (RE). TI provides two security options with an optional override for each:

- Package-level (also known as application-level)
- 4User-level
- Optional explicit-level override

When configured for user-level credentials, TI makes use of the APPC Privileged Proxy feature for single sign on. This requires that the user context that the APPC application (TI, in this case) is running under be a member of the **HSDomain_Proxy** group. (The **HSDomain_Proxy** group is one of the two groups created when the host security domain is created.) By default, the **HSDomain_Proxy** group contains the **Domain Admins** group. If TI is not running under the context of a user in the **Domain Admins** group, you will need to add the user to the **HSDomain_Proxy** group.

When deploying a TI component, the administrator must choose either package-level security or user-level security as the default. The optional explicit-level security override is a separate option that the administrator can enable or disable; the override applies regardless of which security option (package-level or user-level) is in place. If the explicit-level override is disabled, base applications will not be permitted to use the callback to provide user credentials. The administrator can also turn on the optional Already Verified settings.

In This Section

Application-Level Security

When using application-level (or package-level) security, the Transaction Integrator (TI) run-time environment uses the Single Sign-On support in Host Integration Server to authenticate itself to the host by using the Windows 2000 security identity of the COM+ application. The COM+ application containing the TI component must be configured in COM+ to run under a Windows account that maps to valid mainframe credentials.

When a TI component is deployed in a COM+ Application which itself is configured as a Library application or package (instead of a Server application or package) on the **Activation** tab of its property page, the choice of security level (Package-level or User-level) for a TI remote environment (RE) is ignored. A Library application (or package) runs in the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user ID.

Although the TI security level is ignored in Library COM+ applications, both of the following security options on the RE property page are accepted by both Library and Server COM+ applications:

- Allow application to override selected authentication
- Use Already Verified or Persistent Verification authentication

The Library application deployment model is supported by COM+. It offers better performance than the Server application deployment model in certain situations. TI supports both models. For example, Internet Information Services (IIS) documentation recommends that COM+ Automation servers that will be invoked from an active server page (ASP) be deployed in a COM+ Library application rather than a COM+ Server application. This way, IIS can control the level of multitasking on a system and kick off new Windows processes to support very high hit rates. By deploying in a Library Application, each IIS process gets its own set of TI components. Also, as a developer debugging a new application, you might prefer to debug a Library COM+ application instead of a Server COM+ application because the Library application simplifies debugging. All the breakpoints come up in one Windows process, and you can more easily see the flow of control.

To set the security level

1. Start TI Manager, and double-click **COM Transaction Integrator** for the computer.
2. Double-click **Remote Environments**.
3. Right-click the specific remote environment (RE) that you want to set, and then click the **Security** tab.
4. Select the **Set security on** check box.
5. Click **Authenticate with package credentials**, or click **Authenticate with User credentials**.

See Also
Other Resources
Transaction Integrator Security

User-Level Security

If user-level security is enabled, the TI run-time environment provides the client identity to the Single Sign-On support of Host Integration Server before allocating the LU 6.2 conversation or connecting to the remote TCP/IP end point. This enables TI to use the client's identity (the identity of the client that invoked the COM+ component that resulted in the invocation of the TI component) to map to a mainframe credential by using the Host Integration Server Single Sign-On capability to authenticate itself with the mainframe.

When a TI component is deployed in a COM+ Application which itself is configured as a Library application or package (instead of a Server application or package) on the **Activation** tab of its property page, the choice of security level (Package-level or User-level) for a TI remote environment (RE) is ignored. A Library application (or package) runs in the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user ID.

Although the TI security level is ignored in Library COM+ applications, both of the following security options on the RE property page are accepted by both Library and Server COM+ applications:

- Allow application to override selected authentication
- Use Already Verified or Persistent Verification authentication

The Library application deployment model is supported by COM+. It offers better performance than the Server application deployment model in certain situations. TI supports both models. For example, Internet Information Services (IIS) documentation recommends that COM+ Automation servers that will be invoked from an active server page (ASP) be deployed in a COM+ Library application rather than a COM+ Server application. This way, IIS can control the level of multitasking on a system and kick off new Windows processes to support very high hit rates. By deploying in a Library Application, each IIS process gets its own set of TI components. Also, as a developer debugging a new application, you might prefer to debug a Library COM+ application instead of a Server COM+ application because the Library application simplifies debugging. All the breakpoints come up in one Windows process, and you can more easily see the flow of control.

Transaction Integrator Security

Single Sign-On in Transaction Integrator

Single Sign-On (SSO) is a mechanism that enables a user to enter a user name and password once to access multiple applications. It gives users simplified logon and maintenance of the many passwords needed to access Windows and back end systems and/or applications. It enables applications to integrate by automating the process of logging on to the host/backend system.

In general, there are three types of single sign-on services:

- **Common authentication single sign-on:** These services enable you to connect to multiple applications within your computer. Your credentials are requested and verified once when you log into the computer, and these credentials are used to determine what actions you can perform based on your permissions. An example of this type of single sign-on is Exchange Server, which uses Windows Integrated Security. Once the user has logged on to Windows, they do not need to provide additional credentials to access their e-mail.

- **Internet single sign-on:** These services enable you to access resources over the Internet by using a single set of user credentials. The user provides a set of credentials to log on to different Web sites that belong to different organizations. An example of this type of single sign-on is Windows Live ID.

- **Intranet single sign-on:** These services enable you to connect to multiple heterogeneous applications and systems within the enterprise environment in your company. An example of this type of single sign-on is Enterprise Single Sign-On, which provides a framework for Windows applications to integrate with non-Windows applications to enable single sign-on.

SSO facilitates the translation of credentials by the Security Policy Wizard. SSO lets you define and manage the relationship between foreign host user ID and password credentials to Windows credentials. The basis for managing these relationships is the SSO Affiliated Application.

An Affiliated Application is a grouping of well defined host user identities under a logical entity that reflects the host administrators view of application processing systems in the non-Windows environments.

When SSO is handed a set of host credentials (user ID and password) along with a valid SSO Affiliated Application, SSO returns a Windows Access Token that represents the Windows credentials. HIP uses this Access Token when setting up the execution thread for methods on server object.

To make this process easier, the Security Policy must know which SSO Affiliated Applications are to be queried in an attempt to gain access to the Windows credentials (access token) needed to execute methods on the server object. The wizard pane lets the user select from a list of valid SSO Affiliated Applications and add them to the Security Policy being defined. The wizard pane also lets the user remove SSO Affiliated Applications previously defined to the Security Policy.

Special Security Settings for TCP/IP

Two special security settings are available for the TCP/IP protocol for CICS and IMS:

- Link and Concurrent Server Mainframe authentication for the TCP/IP CICS MS Link and Concurrent server must have a user exit, EZACIC06, coded on the mainframe to validate the user ID and password supplied by TI. The user ID and password are part of the CICS transaction request message that is formatted by TI and used to initiate the TCP/IP server application in CICS. Refer to the IBM TCP/IP and CICS documentation for further detail.

- For TCP/IP IMS Explicit, IMS Implicit, and IMS Connect or OTMA Mainframe authentication for TCP/IP IMS Explicit, IMS Implicit, and IMS Connect or OTMA must have a user exit, IMSLSECX, coded on the mainframe to validate the user ID and password supplied by TI. The user ID and password are part of the IMS transaction request message that is formatted by TI and used to initiate the TCP/IP server application in IMS. Refer to the IBM TCP/IP and IMS documentation for further detail.

Transaction Integrator Security

Mainframe Authentication for CICS LINK

Resource-level authentication is recommended in the CICS region. Due to a restriction imposed by the IBM Distributed Program Link (DPL) protocol, a user ID and password transmitted from the workstation by TI are ignored and not used for transaction-level authentication. The target CICS region expects, under the circumstances, that authentication has been completed by the application that executes the IBM DPL; for example, a TI application on the PC. (Traditionally, the application that executes an IBM DPL has been another CICS region.) Instead, for transaction-level authentication, the target CICS region associates the default user ID for the region with the transaction ID of the CICS (mirror transaction) task and the user ID from the sender is ignored. Unless this is taken into consideration, attempts to secure the mirror transaction can cause an application malfunction because of the failure to authenticate.

Other Resources

Transaction Integrator Security

AS/400 Security

The support for AS/400 security is the same as for other Windows-initiated operations against the mainframe, with the following adjustments:

- No support for RACF, AFC/2, Kerberos, or Top Secret.
- Integrate with AS/400 native security system only.
- Support Single Sign-On via SSO.

Transaction Integrator Security

Limitations of User Access Level Sign On

When you sign on with only user access permissions, you have restricted capabilities for using Transaction Integrator. For TI Manager, user access:

- Allows you to view COM+ applications
- Does not allow you to open TI Manager
- Does not allow you to export a COM+ application.

For TI Designer, user access:

- Allows you to open TI Designer
- Allows you to create and save new type libraries
- Allows you to open and save existing type libraries.

Transaction Integrator Security

Transaction Integrator Threat Mitigation

Product security is a top priority across Microsoft. Beginning with the Windows Security Push in 2002, Microsoft has invested additional time and resources to developing more secure code and detailed instructions for deploying and securing your computing environment. The Host Integration Server product team conducted a complete threat modeling analysis to identify and mitigate potential areas of concern. A threat model is a security-based analysis that helps you determine the highest-level security risks posed to a product or application and how attacks can manifest themselves.

Although Microsoft has mitigated all possible internal security threats to Host Integration Server, there are steps you should take to mitigate threats from elsewhere in your network environment. Threat modeling helps you evaluate the threats to the applications you are writing or running, and thereby reduce the overall risk to your computer system. For more information about threat model analysis, see Chapter 4 Threat Modeling in Michael Howard and David LeBlanc, *Writing Secure Code 2nd Edition*, Redmond, WA: Microsoft Press. 2003.

Howard and LeBlanc summarize six categories of possible security threats to your computing environment:

- **Spoofing identity**. Spoofing threats allow an attacker to pose as another user or allow a rogue server to pose as a valid server. An example of user identity spoofing is illegally accessing and then using another users authentication information, such as username and password.

- **Tampering with data**. Data tampering involves malicious modification of data. Examples include unauthorized changes made to persistent data, such as that held in a database, and the alteration of data as it flows between two computers over an open network, such as the Internet.

- **Repudiation**. Repudiation threats are associated with users who deny performing an action without other parties having any way to prove otherwise—for example, a user performing an illegal operation in a system that lacks the ability to trace the prohibited operations.

- **Information disclosure**. Information disclosure threats involve the exposure of information to individuals who are not supposed to have access to it—for example, a users ability to read a file that she was not granted access to and an intruders ability to read data in transit between two computers.

- **Denial of service**. Denial of service (DoS) attacks deny service to valid users— for example, by making a Web server temporarily unavailable or unusable. You must protect against certain types of DoS threats simply to improve system availability and reliability.

- **Elevation of privileges**. In this type of threat, an unprivileged user gains privileged access and thereby has sufficient access to compromise or destroy the entire system. Elevation of privilege threats include those situations in which an attacker has effectively penetrated all system defenses and become part of the trusted system itself, a dangerous situation indeed.

Howard and LeBlanc also point out that some threat types can interrelate. For example, it is possible for information disclosure threats to lead to spoofing threats if the users credentials are not secured. Similarly, elevation of privilege threats are by far the worst because if someone can become an administrator or root on the target computer, every other threat category becomes a reality. Conversely, spoofing threats might lead to a situation where escalation is no longer needed for an attacker to achieve his goal.

To mitigate threats that originate outside Transaction Integrator but which can negatively affect TI components and your application, Microsoft recommends that you do the following:

- Protect the MSHIS60_HIP Database and SQL Server Stored Procedures

- Protect the TI DCGen COM+ Application and TCP/IP Listeners

- Protect the COM+ and .NET Servers

- Protect the Raw User Data

- Protect the HIP Listener
- Protect the Local File System, Database, and Registry
- Protect the Client Proxy
- Protect the Remoting Session
- Protect TI from Unauthorized Mainframe or AS/400 Access
- Protect the TI Runtime Environment
- Protect Mainframe Security Credentials from Being Overridden
- Protect the TI Runtime and Host Environments from Data Overflows

Protect the MSHIS60_HIP Database and SQL Server Stored Procedures

To prevent an attacker from spoofing their identity or tampering with the data or stored procedures in the HIP database, you should do the following:

- Run the HIP Service in a valid Windows privileged account and use Windows integrated security to access the HIP SQL Server database.
- Allow only privileged accounts access to the HIP SQL Server database.
- Use a local SQL Server database and do not allow remote access.
- Use only Windows integrated security and restrict access to only privileged Windows accounts.

You can also help mitigate this threat with the following deployment scenarios:

- Service-based Security
- Host-initiated Single Sign-On (SSO).

You can learn more about this threat by reading about:

- How to secure remote access to SQL Server (for example, integrated Windows security).

Protect the TI DCGen COM+ Application and TCP/IP Listeners

To prevent an attacker from spoofing their identity, tampering with the data on the host, elevating their privileges, or denying service, you should:

- Use ASP.NET Admin to set the level of user or role-based security for Application Directory
- Tighten COM+ Application Security on the TI DCGen package
- Use TI Manager to set the security level for a remote environment
- Move the TI Designer-generated .dll to the remoting client computer.

You can also help mitigate this threat with the following deployment scenario:

- ASP.NET web client

You can learn more about this threat by reading about:

- ASP.NET application and IIS security
- Multiple levels of authorized users.

See Also
Reference
New Security Policy Wizard

Protect the COM+ and .NET Servers

To prevent an attacker from spoofing their identity, tampering with the data on the host, elevating their privileges, accessing restricted data, or denying service, you should:

- Use bounded recordsets
- Use static IP addresses on the host
- Run server components in-process with a HIP Service account.

You can also help mitigate this threat with the following deployment scenario:

- Send properly-formatted messages (for example, ELM, TRM, DPL, SNA, IP)
- Service-based security

See Also
Concepts
Bounded Recordsets

Protect the Raw User Data

To prevent an attacker from reading data packets on the network and either tampering with the data or disclosing the data, or to prevent an attacker from denying service, you should:

- Place the computer running Transaction Integrator (TI) and the host in a secure location.
- Use direct network connections over a private segment
- Use IPSec, where supported, for IP communications between host and Windows servers
- For SNA LU6.2 network connections to mainframe or AS/400 computers, use Host Integration Server server-to-server data encryption when deploying upstream an Host Integration Server computer as a SNA gateway to a downstream TI HIP computer
- For SNA LU6.2 network connections to mainframe, use Host Integration Server IP-DLC Link Service in conjunction with IPSec.

See Also

Reference

Configuring an IP-DLC Link Service

Protect the HIP Listener

To prevent an attacker from spoofing their identity, tampering with the data, or denying service, you should run the HIP services in valid Windows privileged account.

To protect the HIP listener

1. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
2. In the details pane, right-click **HIPService**, and then click **Properties**.
3. Click **This account**,and then specify a valid Windows privileged account.
4. Type the password for the user account in **Password** and in **Confirm password**, and then click **OK**. If you select the **Network Service** account, the password must be blank.

You can also help mitigate this threat with the following deployment scenario:

- Service-based security

See Also
Reference
Services Account Screen

Protect the Local File System, Database, and Registry

To prevent an attacker from spoofing their identity, accessing restricted data, or tampering with the data, you should do the following:

- Place the computer that is running Transaction Integrator (TI) in a secure location.
- Confirm that the access permissions to TI programs, TI components, and the registry are set correctly.
- Use host-initiated Single Sign-On (SSO) in conjunction with valid host UID and PWD passed in the initial connection flows. You should not run the COM Server program in context of the default COM+ security context. Using both UID and PWD causes the HIP application to validate both items when calling SSO.
- Not use DCOM to remote calls from HIP Application server to a second Windows Server hosting COM+ server application.
- Use a secure network connection (for example, CICS TRM over IPSec-protected TCP/IP network connection).

You can also help mitigate this threat with the following deployment scenarios:

- Service-based security
- Host-initiated SSO

You can learn more about this threat by reading about the following:

- How to help secure remote access to SQL Server (for example, integrated Windows security)
- How to send a valid host user ID
- How to send a valid host password

Concepts

Single Sign-On in Transaction Integrator

Protect the Client Proxy

To prevent an attacker from tampering with a properly formatted message (for example, a TRM, DPL, SNA, or IP) sent by the client computer to the TI runtime or to prevent an attacker from sending a malformed message to the TI runtime, you should do the following:

- Move the .NET Framework assembly DLL generated by TI Designer to the remote client computer.

You can learn more about this threat by reading about the following:

- .NET remoting
- ASP.NET Web clients

See Also

Other Resources

Transaction Integrator Threat Mitigation

Protect the Remoting Session

To prevent an attacker from tampering with the remote session or denying service, you should do the following:

- Use HTTPS between the remoting client and the server
- Use separate ASP.NET application contexts for various levels of privileged users, thereby preventing lower-privileged users from affecting sessions belonging to higher-privileged users.

You can also help mitigate this threat with the following deployment scenario:

- ASP.NET Web client.

You can learn more about this threat by reading about the following:

- Multiple levels of authorized users
- ASP.NET application and IIS security
- Properly-formatted TRM, DPL, SNA, IP, and other messages
- Valid host user ID and password
- Valid Windows user ID for Single Sign-On (SSO).

Other Resources

Transaction Integrator Threat Mitigation

Protect TI from Unauthorized Mainframe or AS/400 Access

To prevent an attacker from using the mainframe or AS/400 connection to access the server running Transaction Integrator, you should:

- Utilize direct network connections over private segment.
- Use IPSec, where supported, for IP communications between the host and Windows servers.
- For SNA LU6.2 network connections to mainframe or AS/400 computers, use Host Integration Server server-to-server data encryption when deploying upstream Host Integration Server computer as SNA gateway to downstream TI HIP computer.
- For SNA LU6.2 network connections to mainframe, use Host Integration Server IP-DLC Link Service in conjunction with IPSec.

Introduction to the IP-DLC Link Service

Protect the TI Runtime Environment

To prevent an attacker from instantiating multiple Transaction Integrator (TI) components to launch a denial of service attack on the TI runtime environment, you should:

- Store all TI component type libraries and .NET assemblies in a secure directory.
- Confirm that the access permissions on all type libraries and .NET assemblies are set correctly.
- Confirm that the access permissions on the directory where the type libraries and .NET assemblies are stored are set correctly.

See Also

Other Resources

Transaction Integrator Threat Mitigation

Protect Mainframe Security Credentials from Being Overridden

To prevent an attacker from gaining control over security credentials used to access a mainframe host, you should do the following:

- Use host-initiated Single Sign-On (SSO) in conjunction with valid host UID and PWD passed in the initial connection flows.

- Set the ClientContext to not allow security credentials to be overridden when using the **SelectionHint** property.

Remote Environment Selection Using the SelectionHint Property

Protect the TI Runtime and Host Environments from Data Overflows

To prevent an attacker from using inbound, unbounded recordsets to launch a denial of service attack on either the Transaction Integrator (TI) runtime or host environment, you should:

- Store all TI component type libraries and .NET assemblies in a secure directory.
- Confirm that the access permissions on all type libraries and .NET assemblies are set correctly.
- Confirm that the access permissions on the directory where the type libraries and .NET assemblies are stored are set correctly.

Deployment

This section provides instructions for deploying and configuring Host Integration Server. This includes how to test and verify connections with the mainframe or AS/400 computer.

In This Section

Installation Guide

This document contains information about the basic installation process for Microsoft® Host Integration Server 2009.

You can download the latest version of this topic at http://go.microsoft.com/fwlink/?LinkId=141188.

It is important to read the entire document before you start the installation because it contains hardware and software requirements, correct installation procedures, and other information necessary for successful installation.

Note
It is also important to read the Readme.htm file before you start installation. The Readme.htm file is located in your download folder, and contains late-breaking information and known issues that you should understand before installation.

This document contains:

- Hardware and Software Requirements
- Installing the Product

Hardware and Software Requirements

In the following sections, the version numbers listed are minimum requirements. Versions later than those listed here are supported unless otherwise noted.

Hardware Prerequisites

The minimum hardware requirements for a complete installation of Host Integration Server 2009 are as follows:

- 450 megahertz (MHz) or higher Intel Pentium-compatible CPU
- 512 megabytes (MB) of RAM
- 6-gigabyte (GB) hard disk
- CD drive or DVD drive
- Super VGA monitor (800 x 600) or higher-resolution monitor with 256 color
- For HIS Designer only: Display Super VGA (1024x768) or higher-resolution monitor with 256 colors
- Microsoft Mouse or compatible pointing device

Software Prerequisites

Important
Microsoft Host Integration Server 2009 will not install on a computer that already has the Microsoft OLE DB Provider for DB2 installed. If you have the OLE DB provider installed on your computer, you must uninstall it before you install Host Integration Server 2009.

Supported Operating Systems

To install Host Integration Server 2009, you must be running one of the following operating systems:

- Microsoft Windows® XP Professional with Service Pack 2 (x86 or x64)
- Microsoft Windows Server® 2003 Service Pack 2 (x86 or x64)
- Windows Server 2003 R2 Service Pack 2 (x86 or x64)

- Microsoft Windows Vista® Service Pack 1 (x86 & x64)
- Windows Server 2008 (x86 & x64)

Product Prerequisites

Host Integration Server 2009 requires the following prerequisites:

- .NET Framework version 3.5 SP1
- Microsoft XML Core Services (MSXML) 6.0 SP1

Note
Setup will install redistributable prerequisites automatically from the Web or from a pre-downloaded CAB file. Automatically installing from the Web or downloading the CAB file requires Internet access. You can download the CAB file at: http://go.microsoft.com/fwlink/?LinkId=133541.

Feature Prerequisites

If you choose to install only selected features of Host Integration Server 2009, the following tables outline which software prerequisites you will need.

Server Installation

Feature	Requirement
Developer Design Tools	Microsoft Visual Studio® 2005 SP1 or Visual Studio 2008
BizTalk Adapter for Host Applications	Microsoft BizTalk® Server 2006, BizTalk Server 2006 R2, or BizTalk Server 2009
BizTalk Adapter for DB2	BizTalk Server 2006, BizTalk Server 2006 R2, or BizTalk Server 2009
BizTalk Adapter for Host Files	BizTalk Server 2006, BizTalk Server 2006 R2, or BizTalk Server 2009
BizTalk Adapter for WebSphere MQ	BizTalk Server 2006, BizTalk Server 2006 R2, or BizTalk Server 2009
MSMQ-MQSeries Bridge	Message Queuing with routing support

Configuration After Server Setup

You can install the Server software without running the Configuration Tool, and then run the Configuration Tool later (on the **Start** menu). Eventually, however, you must run the Configuration Tool. To do this, you will need the software listed in the following table. It can be installed either on the local Host Integration Server computer or on a remote computer.

Feature	Requirement
DB2 Distributed Transactions	Microsoft SQL Server® 2005 SP2 or SQL Server 2008
Transaction Integrator	SQL Server 2005 SP2 or SQL Server 2008
Enterprise Single Sign-On	SQL Server 2005 SP2 or SQL Server 2008

MQ Connectors

The following are the supported versions of WebSphere MQ:

Software Requirements

You must have the following software installed before you can install the adapter.

- BizTalk Adapter for WebSphere MQ (Client-Based)
    - IBM WebSphere MQ Client 6.0 with Fix Pack 6.0.1.1 or higher

    - IBM WebSphere MQ Client 7.0 (required for 64-bit)
    - IBM WebSphere MQ Extended Transactional Client (for transactional support)
- MSMQ-MQSeries Bridge
    - IBM WebSphere MQ Client 6.0 with Fix Pack 6.0.1.1 or higher
    - IBM WebSphere MQ Client 7.0 (required for 64-bit)
    - IBM WebSphere MQ Extended Transactional Client (for transactional support)
- WCF Channel for WebSphere MQ
    - IBM WebSphere MQ Client 6.0 with Fix Pack 6.0.1.1 or higher
    - IBM WebSphere MQ Client 7.0 (required for 64-bit)
    - IBM WebSphere MQ Extended Transactional Client (for transactional support)

Note
When using Extended-Client, in addition to configuring the adapter receive locations and send port, ensure that you refer to t he “How to Configure the MQSC Adapter for Transactional Messaging” topic in the Host Integration Server 2009 documentat ion for additional information. Also refer to the Known Issues section in the Readme file.

Refer to your IBM documentation for additional information about how to obtain and install WebSphere MQ Extended Transactional Client or WebSphere MQ Client.

Installing the Product

The following sections contain installation information for Host Integration Server 2009.

Important Notes About Installation

If you are upgrading a Host Integration Server 2004 or Host Integration Server 2006 computer, Host Integration Server 2009 Setup will upgrade your configuration automatically.

New to the Product Installation

The product installation now includes both Server and Client components, and also a developer-only and documentation-only installation.

To Install Host Integration Server 2009

1. In Windows Explorer, locate the installation folder in which you extracted the Setup files.
2. Double-click **Setup.exe**. The Host Integration Server 2009 Installation panel appears.
3. Click the product name to start installation.

   The Installation Wizard appears and guides you through the rest of the installation process.
4. Click **Finish** when you are finished.

To Uninstall Host Integration Server 2009 Using Add or Remove Programs

1. Click **Start**, point to **Settings**, and then click **Control Panel**.

2. In **Control Panel**, open **Add or Remove Programs**, select the name of the product, and then click **Change/Remove**.

   The **Add or Remove Application** dialog box appears.

3. Click **Remove**, and then click **Next**.

   The Uninstall Wizard appears and automatically starts the uninstall process.

4. When the wizard has completed the process, click **Finish**.

Note
Uninstalling Host Integration Server 2009 does not uninstall Enterprise Single Sign-On (SSO). To uninstall SSO, see "Uninstalling Enterprise Single Sign-On" later in this document.

Configuring Host Integration Server 2009

Host Integration Server 2009 contains an update to the Configuration Tool that is used during setup to complete the initial installation. On first use of the Configuration Tool, a **Configuration – Start** panel gives the user the option of doing a Basic or Custom configuration.

Basic Configuration

To install by using the default setting, you can use the **Basic configuration** option. When you click **Configure**, the tool proceeds using the default settings, together with the minimum information supplied by the user on the **Configuration - Start** panel.

Custom Configuration

If you choose **Custom configuration** and then click **Configure**, you are presented with a list of configuration panels based on the features selected during installation. Selecting an item in the left pane displays its associated settings in the right pane. After you have entered your configuration settings, you can click **Apply Configuration** in the toolbar to implement those settings. Note that any settings made in the initial **Configuration - Start** panels are populated as defaults in the custom configuration.

Updating the Configuration

You can update the configuration later by running the Configuration Tool on the **Start** menu. Individual settings can be changed on each panel. To update the service account or database settings for all panels, click the **View** menu and then select **Service Accounts** or **Databases**. In these dialog boxes you can multi-select all the rows by using the CTRL key, and bulk edit the settings.

Unconfigure

A feature can be disabled by unconfiguring that feature. Select **Unconfigure Feature** on the menu, select the feature to be unconfigured, click **OK**, and then continue through the wizard. This process removes any settings (for example, services and registry keys) that were created when the configuration was previously applied.

Unattended Configuration

The Configuration Tool can export a configuration file that can be used to perform an unattended installation and configuration. Select **Export Configuration** on the **File** menu. The unattended installation consists of two steps: setup and configuration.

Unattended Installation

Unattended installation is useful for installing Host Integration Server 2009 on a large number of computers to ensure that they are all configured in exactly the same way. It is also useful if you need to change or update the existing configuration of a large number of computers.

You perform an unattended installation by creating a "model" installation on one computer, which you then apply to the other computers.

To perform unattended installations

1. Using the standard Windows-based installation program, perform a full installation on a single computer. Because the installation parameters you choose will be saved as a model, make the selections you want to use on the other installations.

2. When setup is complete, run the Configuration Tool on the same computer. As in step 1, make the selections you want to use on the other installations. Select **Export Configuration** on the **File** menu, and save the configuration XML file.

3. If you need to update the configuration XML file, select **Import Configuration**, open a saved file, and make any necessary changes. This option is available only until you have completed configuration. If you need to make an update after configuration, you will need to configure the system again.

4. On the appropriate server computer, open a command prompt and run the Unattended Installation command (see the following sections). Where the command calls for the configuration file, use the name and location of the HISServerConfig.xml file created in step 1. You can also use the options listed in the "Options" section.

Commands

Use the following commands and options for unattended installation.

```
Setup.exe /InstallPlatform /L c:\HISInstall.log /S c:\HISServerConfig.xml /INSTALLDIR C:\HI
S
```

```
Configuration.exe /L c:\ConfigFramework.Log /S c:\HISServerConfig.xml
```

Options

/InstallPlatform

This flag causes the installation program to install any platform prerequisites.

/L c:\HISInstall.log

This flag determines the log file location that is created during setup.

/S C:\HISServerConfig.xml

This flag specifies the configuration file (list of features) that is used on installation. The file "HISServerConfig.xml" contains information about which features to install and how they should be configured. Sample copies of these files are located in the Support\Unattended_Installs directory of the installation folder. This file can also be created during setup by clicking **Save** in the summary panel of the Configuration Tool.

/INSTALLDIR

This option tells Setup where to install the product.

Unattended Uninstall

Use the following command for unattended uninstall:

```
Setup.exe /l C:\UninstallLog.txt /REMOVE ALL /Product HIS
```

Note that Setup.exe will need to have the install location appended to the beginning to ensure that the correct Setup.exe program is launched.

Uninstalling BizTalk Adapters

Uninstall will not delete the adapter registration from BizTalk Server. This is because there could be other instances of the adapter installed on different BizTalk Server computers in the group. If you want to clean this up, after you have uninstalled the last adapter installation from all the BizTalk Server computers in the group, you can manually delete the adapter from the BizTalk Server Administration console or by using Windows Management Instrumentation (WMI).

Uninstall will not undeploy the schema DLLs (for example, MQSeriesEx.dll or MQSeries.dll) from the BizTalk Management database.

Uninstalling Enterprise Single Sign-On

Uninstall

Uninstalling Host Integration Server does not uninstall Enterprise Single Sign-On. To uninstall this feature, follow these steps:

1. Click **Start**, point to **Settings**, and then click **Control Panel**.

2. Double-click **Add or Remove Programs**.

3. In the **Add or Remove Programs** dialog box, click **Microsoft Enterprise Single Sign-On**, and then click **Remove**.

4. Click **Yes** when you are prompted to confirm removal of Microsoft Enterprise SSO.

Note
If you have BizTalk Server Runtime, Development, or Administration features installed, or Host Integration Server Administration features installed, you cannot uninstall the SSO Runtime or Administration components until all dependencies are removed.

Unattended Uninstall

Note
You will need the original installation media to perform unattended uninstalls of Single Sign-On Server or Client versions.

Use the following commands for unattended uninstall:

Host Integration Server 2009 Server

```
MSIEXEC /X <Drive>\Platform\SSO\SSO.msi\SSO.MSI
```

Host Integration Server 2009 Client

```
MSIEXEC /X <Drive>\Platform\SSO\CLIENT\SSOClient.msi
```

Note
If you have BizTalk Server Runtime, Development, or Administration features installed, or Host Integration Server Administration features installed, you cannot uninstall the SSO Runtime or Administration components until all dependencies are removed.

Special Considerations When Installing Enterprise Single Sign-On

The following sections contain information about installation of the Enterprise Single Sign-On (SSO) feature. Because of this feature's complex relationships to other features and systems, and because of its importance to system security, we recommend that you read these sections carefully before you install Enterprise Single Sign-On.

Installing SSO and Creating the Master Secret Server

Initial installation of Enterprise Single Sign-On must be done on the server that you will use as the Master Secret Server. This is also the only Master Secret Server allowed in the entire SSO system.

To install Enterprise Single Sign-On, run the Host Integration Server 2009 or BizTalk Adapters for Host Systems Setup program and under the **Server** node, select **Enterprise Single Sign-On** and continue installation.

After installation is complete, the Configuration Wizard starts. Select the Custom Configuration mode. Because this is the Master Secret Server, select the option to "Create a new SSO System" when configuring Enterprise SSO. This creates the Master Secret Server and the SSO Credential database.

Processing Servers for Enterprise Single Sign-On

In a multi-computer environment, after the Master Secret Server and Credential database have been created, you can install Enterprise Single Sign-On on subsequent computers. These are typically the computers on which Host Integration Server 2009 is also installed.

The initial installation process is the same as on the first computer. Configuration, however, becomes slightly different. Because the Master Secret Server and the SSO Credential database are already in place, select "Join an existing SSO System" when configuring Enterprise SSO.

EntSSO Administration Installation Only

You can install just the Enterprise Single Sign-On Administration feature. To do this, when you run the installation program, under the **Client** node, select only **Enterprise Single Sign-On Administration** and continue installation.

Only SSO administrative components will be installed. The hardware and software requirements are the same as for a typical EntSSO installation.

Note
While the SSO Administration feature in Host Integration Server 2009 is compatible with the server version of SSO in BizTalk Server 2009, the administrative components of Enterprise SSO in BizTalk Server 2009 are not compatible with the server version of Enterprise SSO in Host Integration Server 2009. Enterprise SSO MMC snap-ins require MMC 3.0. It is not supported on Windows 2000.

Installing the SSO Administration feature installs command-line-based utilities (ssomanage.exe and ssoconfig.exe) and an MMC snap-in that can be accessed by clicking **Start**, pointing to **All Programs**, and then clicking **Microsoft Enterprise Single Sign-on**. To run the SSO administrative command-line utilities after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On. You can use ssomanage.exe to specify the SSO server you want to use for management. To do this, open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On, and then run **ssomanage -serverall <SSO server name>**.

SSO Client Installation

The SSO client utility (ssoclient.exe or SSOClientUI.exe) enables end users to configure their client mappings in the Credential database. You can install the client utility from a self-extracting file (SSOClientInstall.exe), which is installed with the SSO Administration feature. This also installs the UI-based SSO client utility that can be accessed by clicking **Start**, pointing to **All Programs**, and then clicking **Microsoft Enterprise Single Sign-on**.

To install the SSO client utility, you must be running one of the following operating systems on the client computer:

- Windows Server 2003 (x86 or x64), Windows Server 2003 R2 (x86 or x64)
- Windows XP Professional with Service Pack 1
- Windows Vista

Note
The UI-based SSO client utility (SSOClientUI.exe) requires .NET Framework 2.0.

To run the command-line-based SSO client utility (ssoclient.exe) after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On.

Password Synchronization

To install the password synchronization feature, run the installation program under **Server – Enterprise Single Sign-On**; select the **Enterprise Single Sign-On Password Management** sub-feature and continue with installation.

Password Change Notification Service (PCNS) can be obtained from the following location: http://go.microsoft.com/fwlink/?LinkID=68145.

Upgrading from an Earlier Version of SSO

Host Integration Server 2009 and the Microsoft BizTalk Adapters for Host Systems include Microsoft Enterprise Single Sign-On version 4.0. Previous Microsoft products include the following versions of Enterprise Single Sign-On:

- Enterprise SSO v1 is included in Microsoft BizTalk Server 2004
- Enterprise SSO v2 is included in Microsoft Host Integration Server 2004
- Enterprise SSO v3 is included in Microsoft BizTalk Server 2009 and Microsoft Connected Services Framework Server 3.0

Upgrade Procedure

If Enterprise SSO was installed with Host Integration Server 2004, installing the BizTalk Adapters for Host Systems or Host Integration Server 2009 will automatically upgrade SSO. (Note that you must first perform the upgrade on the Master Secret Server.)

If Enterprise SSO was installed with one of the preceding products other than Host Integration Server, follow the procedure below to upgrade to this release of SSO.

To perform these operations, you must be an SSO Administrator and a computer Administrator.

1. Make a secure backup of the SSO Credential database from your SQL Server computer before performing an upgrade.

2. Make sure you have a secure backup of the current secret from the Master Secret Server.

3. Upgrade Enterprise SSO on the Master Secret Server. To do this, follow these steps:

    - Run **setup.exe** for Microsoft BizTalk Adapters for Host Systems or Microsoft Host Integration Server 2009 package.

    - In the custom setup tree, select **Enterprise Single Sign-On**, and clear all other options to only install Enterprise SSO. This will uninstall the earlier version and install the new version.

    - After installation is completed, start the Configuration Wizard to configure Enterprise SSO.

    - In the Configuration Wizard, select **Custom Configuration**. In the left pane, select **Enterprise SSO**, and in the right pane, select **Enable Enterprise Single Sign-On**. All the settings will be unavailable. Select **Apply Configuration**, and then click **Next** to continue with the configuration. This will also upgrade the SSO database if it is required.

    - After configuration is completed, restore the secret from the backup on the Master Secret Server.

4. Upgrade Enterprise SSO on other SSO servers. To do this, follow these steps:

    - Run **setup.exe** for Microsoft BizTalk Adapters for Host Systems or Microsoft Host Integration Server 2009 package.

    - In the custom setup tree, select **Enterprise Single Sign-On**, and clear all other options to only install Enterprise SSO. This will uninstall the earlier version and install the new version.

    - After installation is completed, start the Configuration Wizard to configure Enterprise SSO.

    - In the Configuration Wizard, select **Custom Configuration**. In the left pane, select **Enterprise SSO**, and in the right pane, select **Enable Enterprise Single Sign-On**. All the settings will be unavailable. Select **Apply Configuration**, and then click **Next** to continue with the configuration.

Note
Services dependent on ENTSSO may be stopped after the upgrade. Check your System and Application event log for errors a nd warnings. You might have to restart any services that are dependent on the ENTSSO service on the computer where the u pgrade was performed.

Using Host-Initiated SSO Functionality in Enterprise Single Sign-On

Host-Initiated Single Sign-On uses the protocol transition feature of Windows Server 2003 to perform Single Sign-On for the non-Windows user. This feature requires Windows Server 2003 and must be in a domain that has its Domain Functional Level set to Windows Server 2003.

Supported Host Platforms
SNA connectivity, 3270 terminal emulation, host print service, and SNA programming interfaces

- IBM z/OS, OS/390, MVS, VSE and VM

SNA connectivity, 5250 terminal emulation, host print service, and SNA programming interfaces

- IBM i5/OS V5R4 & V6R1 and later

IP-DLC Link Service

- IBM z/OS 1.8 and later

OLE DB Provider for DB2, ODBC Driver for DB2, Managed Provider for DB2, and BizTalk Adapter for DB2

- IBM DB2 V8 and V9 for z/OS to support an SNA LU6.2 or TCP/IP network connection
- IBM i5/OS V5R4 & V6R1 to support an SNA LU6.2 or TCP/IP network connection
- IBM DB2 for Universal Database V8.2 and later for Windows and AIX operating systems to support a TCP/IP network connection

OLE DB Provider for AS/400 and VSAM, Host File Transfer ActiveX Control, Managed Provider for Host Files, and BizTalk Adapter for Host Files

- IBM Distributed File Manager (DFM) V1R4, V1R5, V1R6, and V1R7 to support an SNA LU6.2 network connection (DFM is a component of IBM Data Facility Storage Management Subsystem (DFSMS) for z/OS)
- IBM i5/OS V5R4 & V6R1 to support an SNA LU6.2 or TCP/IP network connection

AS/400 Data Queues ActiveX Control

- IBM i5/OS V5R4 & V6R1 to support an SNA LU6.2 network connection

Transaction Integrator and BizTalk Adapter for Host Applications

- IBM CICS Transaction Server for VSE/ESA V2R3 to support an SNA LU6.2 network connection
- IBM CICS Transaction Server for z/OS V2.3, V3.1, and V3.2 to support an SNA LU6.2 or TCP/IP network connection
- IBM IMS Version 9.1 & 10.1, with IMS Connect 2.2,to support an SNA LU6.2 or TCP/IP network connection
- IBM i5/OS V5R4 & V6R1 to support a TCP/IP network connection

IP-DLC Link Service

SNA Open Gateway Architecture

Organizations with IBM mainframe or AS/400 computers are now consolidating their SNA-only and non-SNA networks into single TCP/IP-based wide area networks (WANs). In the past, two parallel networking systems have been deployed in most organizations: the traditional SNA network used to connect computers and hardware controllers with IBM mainframes and AS/400 computers, and local area networks (LANs) used primarily to access files and client/server applications running on local server computers.

Many organizations are seeking a single WAN solution that provides access to all desktops, servers, and host systems across a single networking protocol. At the same time, TCP/IP is emerging as the protocol of choice because of its versatility, openness, and ability to support Internet and intranet connections.

Many organizations cannot integrate their networks because of the need to ensure reliable and secure access to their existing IBM host systems—on which most organizations base their mission-critical daily operations.

SNA Open Gateway Architecture (SOGA) satisfies the requirement for reliable and secure host connectivity in the context of an integrated WAN. SOGA is a scalable framework for SNA enterprise connectivity, offering multiple options for integrating branch offices by means of routed inter-networks with IBM mainframe and AS/400 computers. This framework encompasses components from leading channel attachment and inter-networking vendors while deploying Host Integration Server computers in both traditional and innovative ways.

SOGA supports industry standards for SNA host access and presents flexible options for integrating host data across open WANs, such as those composed of Data Link Switching (DLSw), Frame Relay (RFC 1490), and Asynchronous Transfer Mode (ATM). Request for Comment (RFC) 1490 specifies methods of encapsulating TCP/IP and SNA within Frame Relay. The SOGA blueprint consists of three core elements:

- Flexible SNA gateway deployment models
- High-performance SNA gateway configurations
- Efficient wide area network utilization

Deploying Host Integration Server 2009

Deploying Host Integration Server 2009

Whether your enterprise consists of a single office or many branches spread throughout the world, SNA Open Gateway Architecture (SOGA) offers three flexible deployment models to implement Host Integration Server in your environment.

When planning your deployment strategy, ask the following questions:

- With what type of host systems do I need to connect?
- What kind of performance and host availability do my users expect?
- What kind of networking infrastructure is in place?

By answering these questions and using the information provided in this section, you can determine the best deployment strategy for your enterprise.

Connecting Servers

After you have determined a suitable deployment model and subdomain configuration, you must choose how to connect Host Integration Server computers to the host system, to client workstations, and to other Host Integration Server computers.

This section explores how to choose:

- Connections between Host Integration Server computers and the host
- Network protocols for Host Integration Server computers and clients

To understand the connectivity options, you should first examine the different physical connections and network protocols that Host Integration Server supports.

Connection Methods

Host Integration Server supports many different connection methods. However, not all may be available in your environment. When you choose a connection method, you should keep in mind:

- Deployment model you are implementing
- Host networking infrastructure that is in place
- Host systems to which you are connecting
- Expected usage level of host resources
- Level of performance and response expected by your users

IP-DLC Link Service

802.2 Data Link Control (DLC)

Token Ring, Ethernet, and Fiber Distributed Data Interconnect (FDDI) connections use the IEEE DLC 802.2 protocol to connect to the host. In a mainframe environment, Host Integration Server usually connects to a front-end processor (FEP) or a communications controller, such as an IBM 3174. Occasionally, you can establish a connection to an adapter within a mainframe. With an AS/400 system, the connection goes directly to a network adapter in the AS/400 computer.

Token Ring connections are typically limited to 4 or 16 megabits per second (Mbps). Token Ring solutions are still found in some mainframe environments. In many scenarios, a Token Ring connection provides good performance at a reasonable cost in equipment.

Ethernet is a common connection type for local area networks (LANs) with workstations or computers. This connection type is also common in peer-type networks.

FDDI connections use fiber cabling to achieve connections reaching 100 Mbps or greater. The FDDI line communicates through an FEP that is channel-attached to the mainframe. This may limit the overall speed of communications. In many cases, this type of connection can provide a reasonably cost-effective solution if you require higher throughput and a channel solution is not possible.

DLC connections are well suited for the centralized and distributed deployment models, because both strategies implement Host Integration Server computers close to the host. You can also deploy data link control (DLC) in a branch model using routers or bridges that can route traffic between the branch offices and the central host system.

Host Integration Server supports DLC connections over any network adapter supported by Windows using the Windows-based DLC network transport driver.

Concepts

Synchronous Data Link Control (SDLC)

Channel

Other Resources

Connection Methods

Synchronous Data Link Control (SDLC)

SDLC connections use a standard phone line (leased, public, point-to-point, or multidrop). An SDLC adapter within the Host Integration Server computer connects to a modem that uses the phone line to establish a connection with the host system. In a mainframe system, the SDLC connection uses a front end processor (FEP), a communications controller, or an integrated SDLC adapter. In an AS/400 system, the connection goes directly into the AS/400 computer.

SDLC throughput is limited by the medium used for the connection and the capabilities of the SDLC adapter in the Host Integration Server computer. The cost to implement SDLC grows significantly as faster line types are used. In general, SDLC connections are much slower than 802.2 connections. The following table lists the common line types and their speeds:

Line type	**Typical speed**
Analog (conventional phone line)	9600 to 19200 bits per second (BPS)
Digital Data System (DDS)	56 to 64 kilobits per second (Kbps)
Integrated Services Digital Network (ISDN)	56 to 128 Kbps
T1 carrier system	1.544 megabits per second (Mbps)
T3 carrier system	2.048 Mbps

SDLC connections are useful for wide-area connections between geographically disparate locations or when bandwidth and usage requirements are low. Because of these factors, SDLC is ideally suited for branch-type deployment strategies.

Host Integration Server supports SDLC connections using the link support included with Host Integration Server or through an SDLC link service available through various third-party vendors. Not all supported SDLC adapters support all link speeds listed in the previous table.

Channel

Other Resources

Connection Methods

Channel

Channel connections provide direct channel attachment to a mainframe. There are two types of channel connections: older Bus & Tagchannel connections, which can reach speeds of up to 4.5 megabytes per second (MBps), and newer ESCON connections, which can reach speeds approaching 17 MBps. Support for channel connections is limited to adapters supported natively through Host Integration Server.

Enterprise System Connection (ESCON) channel attachments use standard fiber cable and increase throughput significantly.

ESCON is an ideal connection method in centralized or distributed deployments where high performance and responsiveness are required.

The following table summarizes all common connection methods that can be used with Host Integration Server.

Method	Throughput	Characteristics
Token Ring	4 or 16 MBps	Midrange performance using data link control (DLC) protocol Supports multiple host connections using a single adapter Uncomplicated and inexpensive to implement Suitable for a wide range of purposes
Ethernet	10 GBps	Midrange performance using DLC protocol Supports multiple host connections using a single adapter Uncomplicated and inexpensive to implement Suitable for light to medium network traffic conditions
FDDI	100 MBps	High performance using DLC protocol Supports multiple host connections using a single adapter Relatively expensive to implement Suitable for higher-performance connections
SDLC	9600–19200 bits per second (BPS)	Low performance using SDLC protocol Supports 256 sessions over a single host connection Uncomplicated and inexpensive to implement Suitable for low-traffic WAN connections
Channel: Bus & Tag	4.5 MBps	High performance Supports a high number of host connections. More expensive Suitable for high-performance connections
Channel: ESCON	17 MBps	Highest performance Supports a high number of host connections More expensive Suitable for conditions where maximum throughput is required

Choosing Server-to-Host Connections

In Host Integration Server terms, a host connection is the data communications path between Host Integration Server and a host system. For a mainframe, the connection corresponds to a physical unit (PU) definition in Virtual Telecommunications Access Method (VTAM). On the AS/400 computer, the connection corresponds to an Advanced Program-to-Program Communications (APPC) controller definition.

For each physical adapter or connection, you install and configure an appropriate link service within Host Integration Server. A link service is a Windows-based service or device driver that is used to control server-to-host communication adapters supported by Host Integration Server. Once configured, the link service is available for use not only on the configured Host Integration Server computer, but also on any server in the subdomain using the Distributed Link Service (DLC) feature. See Distributed Link Service for more information.

After you configure the link services, you can configure the connections. Using a host connection, a client computer on a LAN can communicate with the mainframe system. For some link services, it is possible to define multiple connections over a single host link.

In SNA terms, a physical unit (PU) is the combination of a physical connection and the link service it uses. In an SNA network, Host Integration Server provides PU 2 or PU 2.1 functionality similar to that of an IBM cluster controller.

Several factors should be taken into account when determining a physical connection method to your mainframe:

- Performance requirements
- Expected server loads
- Existing network infrastructure
- Chosen Host Integration Server deployment model
- Cost

You should plan for enough future capacity to support additional connections to your host system. Ethernet connections are the best choice for an all-purpose connection to a host.

For some link services, multiple host connections are possible using a single adapter, most notably the IP-DLC link service. Host Integration Server supports up to 250 host connections per server. Up to four instances of Host Integration Server are supported on a single computer.

Mainframe Connection Summary

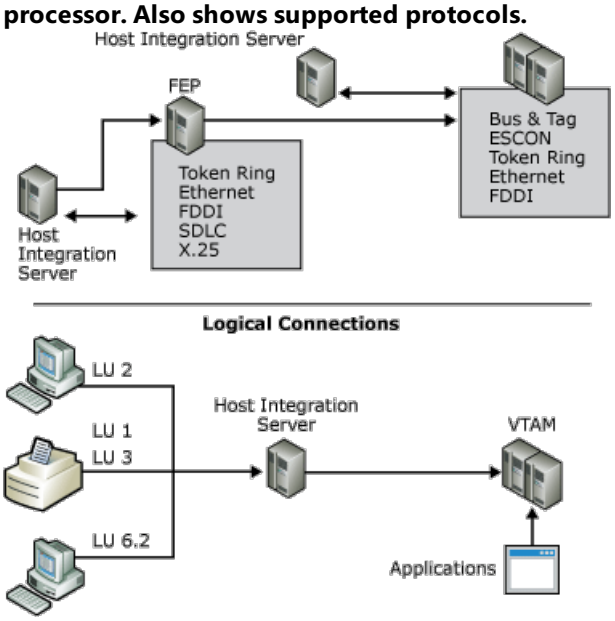
AS/400 Connection Summary

Mainframe Connection Summary

The hierarchical SNA network model provides access to a centralized processing resource from elements on the network. This model is most frequently associated with mainframe environments in which centralized applications are accessed from remote terminals across a network.

Devices in a hierarchical SNA network, such as terminals or cluster controllers, are called physical units (PUs). A number designates each class of device. For example, the mainframe is known as a PU 5 device.

Diagram of network model showing Host Integration Server connecting to a mainframe and to a front-end processor. Also shows supported protocols.



Host Integration Server can directly connect to the mainframe if a high-performance connection is required. These physical connection methods are available:

- Open Systems Adapter, supporting Token Ring, Ethernet, and Fiber Distributed Data Interconnect (FDDI) connections
- Bus & Tag channel connection
- Enterprise System Connection (ESCON) channel connection

Connections to a front-end processor (FEP), which is a PU 4 device, are also supported. These types of connections may be easier to implement depending on your existing infrastructure and the physical proximity of the Host Integration Server to the mainframe. For an FEP, you can use one of the following connection methods:

- Token Ring
- Ethernet
- FDDI
- SDLC

In a hierarchical SNA network, Host Integration Server emulates a cluster controller and supports all standard protocols:

- LU 2, for 3270 terminal sessions
- LU 1 or 3, for SCS or 3270 printer sessions
- LU 6.2, for Advanced Program-to-Program Communications (APPC) and Common Programming Interface for Communications (CPI-C) applications

- LU 0, 1, 2, or 3, for logical unit application (LUA) RUI/RI general-purpose, customized applications

Any combination of these protocols can be used over a given physical connection.

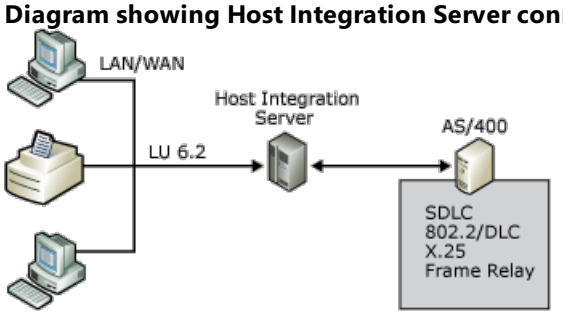
Choosing Server-to-Host Connections

AS/400 Connection Summary

In the peer-oriented SNA network model, all computers on the network can communicate directly with each other. Advanced Peer-to-Peer Networking (APPN) is the architecture developed by IBM that enables distributed data processing. APPN defines how components communicate with each other, and the level of network-related services, like routing sessions, that are supplied by each computer in the network.

Diagram showing Host Integration Server connecting to an AS/400 with several connection methods



In an APPN network, Host Integration Server emulates a type 2.1 physical unit device (PU 2.1). Host Integration Server computers can connect to an AS/400 computer using several connection methods:

- Token Ring
- Ethernet
- FDDI
- SDLC

Frame relay or bridging solutions can also be implemented to transport SNA traffic over wide area network (WAN) connections in branch-based deployment models. Host Integration Server operates as an APPN low-entry networking (LEN) node and communicates with other APPN nodes using the Advanced Program-to-Program Communications (APPC) or LU 6.2 protocol.

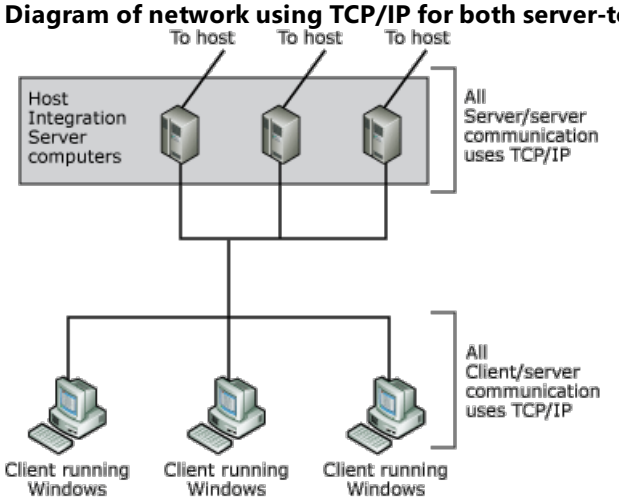
Choosing Server-to-Host Connections

Choosing Network Protocols for Host Integration Server

After you determine the server-to-host connection, you must choose the protocols to use for two additional Host Integration Server communication paths: client/server communication and server/server communication. You can use one protocol for both, or you can use a combination of different protocols, if all servers share at least one client/server protocol and use it for server/server communication.

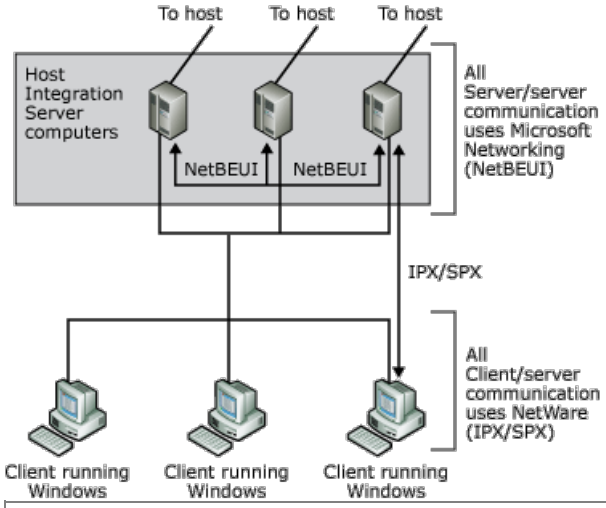
Deploying a single protocol across your wide area network (WAN) is the easiest way to manage your communications. The following figure shows a network in which TCP/IP is used for all types of communication involving Host Integration Server computers and clients.

Diagram of network using TCP/IP for both server-to-server and server-to-client communication



You may decide to gradually implement Host Integration Server throughout your enterprise, in which case you may need to use existing protocols for certain connections. The following figure shows a local area network (LAN) in which two protocols are used. For server/server communication, Microsoft Networking (Named Pipes) is used.

Diagram of network using NetBEUI for server-to-server communication and IPX/SPX for server-to-client communication



Note
IPX\SPX is no longer supported in this version of Host Integration Server.

Similarly, other combinations of protocols can be used, if all the Host Integration Server computers share one protocol and use that protocol for server/server and client/server communication.

In This Section

Choosing Client/Server Network Protocols

Choosing Server/Server Network Protocols

See Also

Other Resources

Choosing Client/Server Network Protocols

Host Integration Server client computers can communicate through a number of different local area APIs or network transports: Microsoft Networking (Named Pipes), or TCP/IP (sockets). The network software and the Host Integration Server software must be installed correctly on both clients and servers for them to handle different protocols correctly. Correct installation ensures two essential aspects of communication:

- Host Integration Server computers and client computers are visible to each other on the LAN. This results when the network software is installed correctly on all affected computers.

- Host Integration Server computers communicate with clients over the correct LAN protocol. Clients direct their communication to the correct subdomain name or (for some clients using Microsoft Networking (Named Pipes) or TCP/IP) to one or more correct server names.

TCP/IP is the standard network protocol for client/server applications. Its high performance and routing ability make it suitable for many wide area network (WAN) environments. In many cases, TCP/IP will be the best protocol choice for your network, especially if TCP/IP is already deployed to some degree in the LAN segment on which the Host Integration Server computers and clients reside.

Choosing Network Protocols for Host Integration Server

Choosing Server/Server Network Protocols

Host Integration Server computers communicate with each other using mailslot messages or directed datagrams over a network. Host Integration Server enables you to make choices concerning these broadcasts.

You can select among the following protocols for server broadcasts: Microsoft Networking (Named Pipes), and TCP/IP.

Important
You must make sure that at least one protocol is available on all Host Integration Server computers in the subdomain, and th at this protocol is used for server/server communication and client/server communication.

Note
For example, if all Host Integration Server computers in a subdomain use TCP/IP, the protocol used for server/server commu nication must be TCP/IP, and all servers must use TCP/IP for client/server communication as well.

Using multiple server/server transport protocols can add significantly to network overhead. This is because every server broadcast must be sent out through all protocols selected in the Host Integration Server management console.

For highest efficiency, select only one protocol for broadcasts between Host Integration Server computers. Remember that the protocol must be available on all Host Integration Server computers in the subdomain. Where multiple choices are available (multiple protocols are bound to the network adapters on all Host Integration Server computers), select a protocol other than Microsoft Networking (Named Pipes). This is recommended because of design requirements for mailslot broadcasts. When these broadcasts are sent over Microsoft Networking (Named Pipes), there is the local system cannot determine which protocol the receiving system will be using, so the broadcast is sent over all protocols bound to the local adapter. This causes multiple mailslot broadcasts by means of Microsoft Networking (Named Pipes) for adapters to which several protocols are bound. The multiple broadcasts cause an increase in network traffic.

In subdomains in which all Host Integration Server adapters can use multiple protocols, TCP/IP protocol is recommended. You may be able to select extra protocols that do not exist in your network. However, selecting these has no effect.

The Host Integration Server management console also allows you to specify a parameter called Mean Time Between Server Broadcasts. For optimum efficiency, you should specify a value greater than or equal to 60 seconds (the default). The smaller this value, the less the efficiency, but the more likely the broadcasts will compensate for lost messages. It is recommended that you choose a value of 120 seconds or greater initially. If you encounter an increased number of lost messages, this value should be reduced until a low number of messages are lost.

Concepts

Choosing Client/Server Network Protocols

Installing Host Integration Server 2009 Clients

Other Resources

Choosing Network Protocols for Host Integration Server

Installing Host Integration Server 2009 Clients

Host Integration Server client software allows client workstations to communicate with Host Integration Server computers to access host resources. Client software is installed on each workstation using applications that communicate using any Host Integration Server programmatic interfaces. Client software is available for the following platforms:

- Microsoft Windows Server 2008
- Microsoft Windows Server 2003
- Windows 2000 Server

The fastest Host Integration Server client/server network interface is TCP/IP, although you can use other local area network (LAN) protocols such as Microsoft Networking (Named Pipes) if your LAN supports them. If you select TCP/IP or Microsoft Network, the remote installation option is recommended. Selecting "local" requires the client workstation to be on the same TCP/IP subnet as the Host Integration Server computer, which is uncommon in routed IP networks.

Note
Host Integration Server client software is not required to use services such as TN3270 and TN5250. Applications, such a TN3270 emulator, communicate directly with these services using TCP/IP and do not use the Host Integration Server client/server interface.

Host Integration Server 3270 Connectivity

In the hierarchical SNA network model most frequently associated with a mainframe computer, you access centralized applications from remote terminals across a network. This network model uses the information display protocol for IBM mainframe computers known as 3270. This protocol facilitates conversations between the mainframe and devices such as terminals, printers, and controllers. Through the definition and assignment of 3270 logical units (LUs), Host Integration Server provides access to mainframe resources.

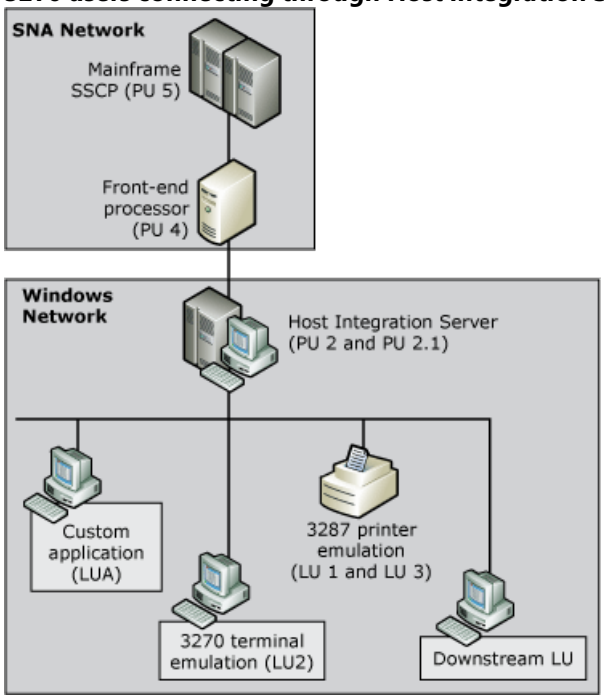
A 3270 LU is known as a dependent LU because it requires a mainframe to function. Each 3270 LU defined within Host Integration Server is configured to use an existing connection to the mainframe system. Each 3270 LU corresponds to a matching LU resource allocated on the host computer, usually specified within Virtual Telecommunications Access Method (VTAM). The 3270 LU definition in Host Integration Server is identified by a number that matches the number of the corresponding LU resource on the mainframe, and by a user specified name.

The 3270 LU is further classified by the type of service provided over the connection. Like physical units (PUs), numbers designate LU types. For example, 3270 display data streams are known as LU 2 streams. Within Host Integration Server, a 3270 LU can be configured as one of the following types:

- Display (LU 2)
- Printer (LU 1 or LU 3)
- Application (LUA)
- Downstream

After the LUs are configured, they are accessed from client computers and applications using Host Integration Server client software that is installed on the client workstation. The client software manages communications between a 3270 application (like a terminal emulator) and the Host Integration Server computer. Applications designed for the Host Integration Server client API use the LUs defined within Host Integration Server to establish a communications link from the client workstation to the mainframe by means of Host Integration Server.

3270 users connecting through Host Integration Server to a mainframe



The link between the LU definition in Host Integration Server and the host LU resource is called a session. Sessions can be permanent and automatically started during initialization, or established on an as-needed basis. Concurrent sessions can share the same physical devices and communications links.

A 3270 user communicating with a host uses a 3270 LU. The 3270 LU has a specific name (recognized by the host), is associated with a specific connection, and supports a specific use (either printing, or terminal emulation of a particular size). A collection of 3270 LUs that will be used by a group of users can be placed in an LU pool, so that whenever a user needs an LU,

the next one in the pool will be made available. The connection, the 3270 LU, the 3270 LU pool, and the list of users (or groups) are the basic elements to configure when supporting 3270 users in a Host Integration Server installation.

Concepts

LUA Access

Precedence of Accounts in Determining LU Access

Downstream Connections

LUA Access

Logical unit application (LUA) is an application programming interface (API) that allows you to write customized applications to communicate with the host. LUA LUs enable programmable control over the SNA messages that are sent between the communications software and the host. LUA LUs can be used to communicate with LU types 0, 1, 2, or 3 at the host as long as the application sends the appropriate SNA messages required by the host.

An LUA application uses a local LU, which uses Host Integration Server to communicate with the host system. When Host Integration Server connects to the host, there are three progressive sessions:

1. The PU-SSCP between the Host Integration Server physical unit (PU) and the system services control point (SSCP) on the host.

2. The SSCP-LU session between the LUA LU at the computer running the application and the SSCP.

3. The LU-LU session between the LUA LU at the computer running the application and the host LU.

The LU session's normal flow carries most of the data. The other flows are used only for control purposes.

The Host Integration Server configuration file contains information that is required for LUA applications to communicate. An LUA LU is configured to use a connection to the host by the link service that is installed. It is then given the LU number that matches that of an LU on the host.

The configuration may include LUA LU pools. A pool is a group of LUs with similar characteristics, and it allows an application to use any free LU from the pool. This feature can be used for allocating LUs on a first-come, first-served basis when there are more applications than LUs available, or for providing a choice of LUs on different connections, as well as providing hot backup and load balancing.

The communications components to be configured include:

- A link service for communicating with the host.

- A connection to the host that uses the link service.

- A Host Integration Server service which owns the connection. This component is configured automatically.

- An LUA LU on a Host Integration Server service, configured to use the connections, with an LU number that matches an LU on the host.

You can perform the following actions with LUA LUs:

- Assign an LUA LU, or a range of LUA LUs, to a connection. A range of LUA LUs will allow multiple applications to use LUAs simultaneously. Configure the numbering for a new range of LUA LUs by specifying the lowest LU number and the number of LUs in the range.

  After creating a range of LUs, you can change the numbering of individual LUs in the range.

- Configure properties for a new LUA LU or a new range of LUA LUs. This includes specifying the LU name and LU number for the LUs.

- Group LUA LUs into one or more LUA LU pools. An LUA LU pool contains a number of LUs that are made available as a group to LUA applications. A given application can get LU access as long as one of the pooled LUs is available.

- View or modify an existing LUA LU, regardless of whether it was created as part of a range.

- Copy properties from one LU to another.

- Move an LU from one connection to another.

- Delete an LU.
- Move an LUA LU from one connection to another.

Check with the host administrator to determine the appropriate names and numbers for LUA LUs on your system. The LU Number for LUs on 802.2 or Synchronous Data Link Control (SDLC) connections should match the LOCADDR= parameter of the LU definition in VTAM or in the NCP Gen.

If the number you specify has already been assigned to an LU or an APPC LU-LU pair on the current connection, you must use a different number. The range for LU numbers is from 1 through 254.

The LU Name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

If the High Priority LU is assigned to a pool, the priority setting of the pool overwrites the setting of the LU.

On an 802.2 or SDLC connection, you can configure multiple LUs at one time by configuring them as a consecutively numbered range. Multiple LUA LUs will allow multiple applications to access the host simultaneously. After configuring the range of LUs, you can modify the numbering and properties of individual LUs in the range.

Concepts

Precedence of Accounts in Determining LU Access

Downstream Connections

Precedence of Accounts in Determining LU Access

When user and group account memberships overlap, the highest-priority account that contains a 3270 LU or pool determines the access the user gets. Accounts are prioritized as follows:

1. User accounts (highest priority)
2. Subdomain groups
3. Local groups
4. Well-known groups such as Everyone (lowest priority)

For example, if a 3270 LU called LU 1 is assigned to a user account (a high-priority account) called JOHND, and at the same time an LU called LU 2 is assigned to a local group (a low-priority account) of which JOHND is a member, JOHND will be given access to LU 1, not LU 2.

LUA Access
Downstream Connections

Downstream Connections

A downstream connection enables a remote computer without a direct connection to the host computer to pass information back and forth using Host Integration Server as the gateway. To the downstream system, there appears to be a direct connection to the host. Host Integration Server accomplishes this by passing information back and forth between the downstream system and the host.

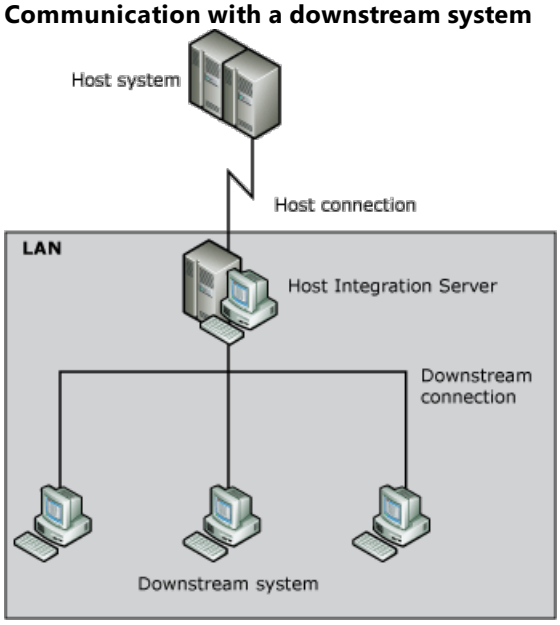
Downstream connections and LUs enable Host Integration Server to support communication between 3270 nodes using SNA protocols. A downstream system is an SNA node (a Host Integration Server computer or mainframe) that uses Host Integration Server as a physical unit (PU) gateway. To the downstream system, the Host Integration Server computer appears to be the 3270 host providing the PUs and LUs. The downstream system may be unable to communicate directly with the 3270 host because of hardware or network incompatibilities that are supported by the intermediate Host Integration Server computer.

One method of reducing host configuration requirements is to concentrate PUs on the SNA gateway computer and pass the LUs to attached downstream physical units (DSPUs). LUs from one or more PUs can be shared with one or more downstream devices. This allows for more economical use of configured resources and alleviates the need to configure each downstream device in host Virtual Storage Access Method (VSAM).

Communication by means of a downstream connection and downstream LU in Host Integration Server is always dependent (controlled by a host). Independent communication, including APPC, is not available by means of downstream LUs on Host Integration Server.

The following figure illustrates downstream connections.

Communication with a downstream system



The information that Host Integration Server passes from the downstream system to the host includes LU information. Therefore, Host Integration Server does not store detailed LU configuration information for downstream LUs. However, Host Integration Server does require all the usual connection information for the host and downstream connections.

Two connections are needed for a downstream system: a downstream connection (from the downstream system to Host Integration Server) and an upstream connection, which is an ordinary host connection from Host Integration Server to the host.

You can configure the upstream connection as you would any other connection to the host. After that, you can configure the downstream connections. These must be 802.2 or SDLC.

LUA Access

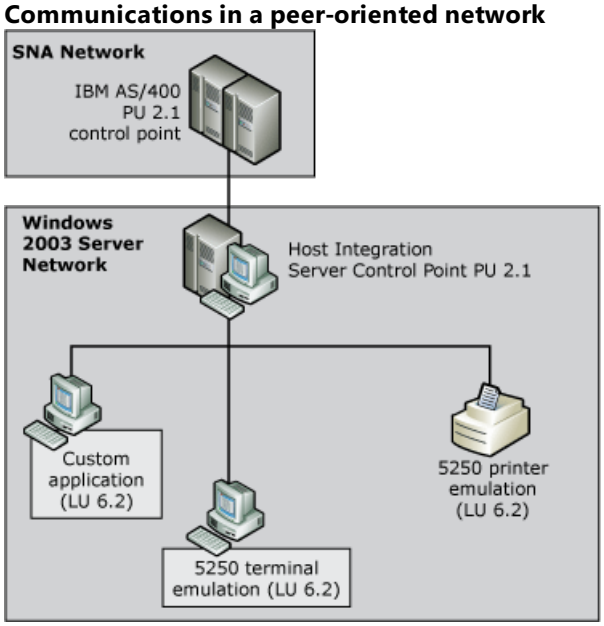
Precedence of Accounts in Determining LU Access

Host Integration Server 5250 (AS/400) Connectivity

In the peer-oriented SNA network model, all computers on the network can communicate directly with each other. Advanced Peer-to-Peer Networking (APPN) enables distributed data processing, defines how components communicate with each other, and determines the level of network-related services that are supplied by each computer in the network. Although peer-oriented SNA networks are usually associated with an AS/400 host system, mainframe systems can also support peer-to-peer networking.

IBM AS/400 computers use the 52xx series of devices. In particular, 5250 describes the terminal display data stream. The Advanced Program-to-Program Communications (APPC) protocol is used to support 5250 terminals and other APPN network computers, devices, and programs to communicate with each other. Each device in an APPN network is known as a type 2.1 physical unit (PU 2.1). In addition, the APPC protocol defines associated logical units as APPC LUs (also called LU 6.2).

Communications in a peer-oriented network



In an APPN network, Host Integration Server computers emulate PU 2.1 devices and can connect to an AS/400 using several connection methods:

- Token Ring
- Ethernet
- Fast Ethernet
- FDDI
- SDLC

Frame relay or bridging solutions can also be implemented to transport SNA traffic over wide area network (WAN) connections in branch-based deployment models.

APPC

Connecting to an AS/400 Using 5250 Terminals

APPC

Advanced Program-to-Program Communications (APPC), or LU 6.2, provides a transport vehicle for programs on peer systems to communicate with each other over the SNA network. APPC is software that enables high-speed communications between programs on different computers.

APPC is a change from the terminal-to-host connections used in many 3270 systems. APPC moves to a distributed transaction programming environment by providing a common set of SNA protocols that brings compatibility at a program communications level.

APPC serves as translator between application programs and the network. When applications on one computer pass information to the APPC software, APPC translates the information and passes it to a network interface. APPC translates the information back into its original format and passes it to the corresponding partner application. APPC can be used across any of the standard types of connections supported by SNA and is not tied to any particular physical connection.

APPC generally uses a local APPC LU (LU 6.2) and one or more remote APPC LUs. A local APPC LU can be independent or dependent. In full peer-oriented APPN networks, typically implemented in an AS/400 environment or under the most modern evolution of mainframe technology, the independent APPC model applies. Dependent APPC is used in older mainframe networks, and its functions are reduced.

Local and remote APPC LUs work together in pairs. The local APPC LU is assigned to a server (unlike other LU types, which are assigned to connections). The remote APPC LU is assigned to the connection. Host Integration Server uses dynamic partnering to create any possible LU partnership on demand when local and remote LUs and modes recognize each other.

With dynamic APPC partnering, an administrator configures remote LUs, but does not need to partner them with local LUs. Host Integration Server will automatically partner the LUs when needed.

With dynamic APPC configuration, an administrator does not need to configure remote LUs. If a connection is designated to support dynamic APPC configuration, Host Integration Server will automatically define a remote LU and partner it with a local LU when needed.

Independent APPC provides the ability to run multiple, concurrent, parallel sessions between a single pair of LUs. Dependent APPC allows only a single session between a given pair of LUs.

Programs that use APPC are referred to as transaction programs (TPs). There are two types of TPs: those that can invoke a conversation, and those that can be invoked. A TP can provide any type of service: terminal emulation, data transfer, database query or update, and so on.

The characteristics that govern the interactions between TPs using an LU 6.2-LU 6.2 connection are determined by the mode associated with the connection. The mode can be associated in a fixed manner with a given LU, or it can be supplied by the invoking TP when a session is first initiated.

Host Integration Server 5250 (AS/400) Connectivity
Connecting to an AS/400 Using 5250 Terminals

Connecting to an AS/400 Using 5250 Terminals

Host Integration Server computers provide access to AS/400 computers by emulating 5250 display terminals. A 5250 user communicating with an AS/400 must use a pair of APPC LUs (LU 6.2). This pair contains a local LU and a remote LU (as viewed by the Host Integration Server computer). Together, these two LUs (along with the mode that they use) contain the configuration information needed for establishing a session with the AS/400 computer.

A local APPC LU can be either independent or dependent. An independent local APPC LU can communicate directly with a peer system. A dependent APPC LU requires the support of a mainframe. These are described in more detail in later sections.

The 5250 user can share this pair of LUs with many other users at the same time, or the 5250 user can have exclusive possession of the LUs (depending on the Host Integration Server configuration). In addition, Host Integration Server computers can be configured so that users can start 5250 emulation sessions without knowing the names of LUs to request. This configuration is accomplished with the use of default LUs that are specified for each 5250 user or for groups of users.

APPC

Using Wizards

Using Wizards

You can configure 5250 terminal emulation using the wizard provided with Host Integration Server. Available under the **Tools** menu, the wizard takes you through each step of configuring AS/400 connection properties, creating remote APPC LUs linked to your AS/400 computer, and, if necessary, creating local APPC LUs.

In addition to wizards, several features of Host Integration Server can simplify configuration for APPC:

- Implicit Incoming Remote LU and Implicit Incoming Mode, which allow Host Integration Server to accept requests that arrive by unrecognized remote LUs and modes.

- Default Local APPC LU and the Default Remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.

- Default Outgoing Local APPC LU Pool, which allows LUs to be allocated dynamically to any invoking TP (transaction program) that does not specify a local LU.

- Single-System APPC, which allows two local APPC LUs residing on the same server to communicate with each other using defined parameters.

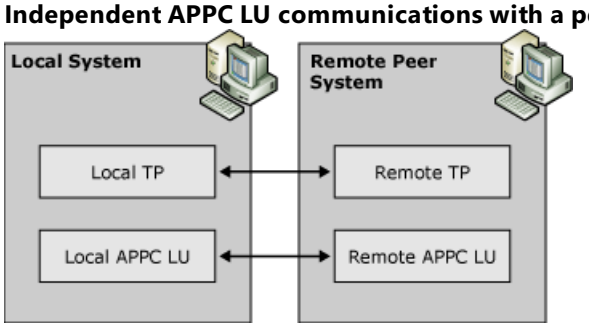
Independent APPC LUs

In APPC, an independent LU can communicate directly with a peer system and does not need the support of a host computer.

Independent APPC LUs provide the ability to run multiple, concurrent, parallel sessions between a single pair of LUs. Programs that use independent APPC LUs are referred to as transaction programs (TPs) and may provide any type of service: terminal emulation, data transfer, database query or update, and so on.

The following figure illustrates how an independent local APPC LU can communicate directly with a peer system.

Independent APPC LU communications with a peer system



Modes determine the interactions between TPs on an APPC-APPC connection. Modes can be assigned to an LU or supplied when the session is first established. For more information about modes, see APPC Mode Definition later in this section.

When configuring independent APPC LUs, note the following:

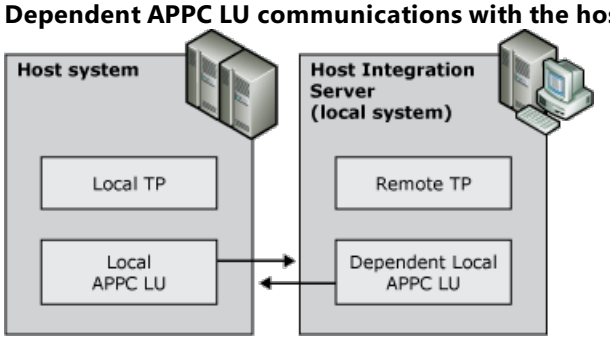
- If the independent local APPC LU communicates with a TP on a mainframe, the host system must be using VTAM version 3, release 2 or later with either NCP version 5, release 2 or later (3745 systems), or NCP version 4, release 3 or later (3725 systems).
- For independent LUs that communicate with a host, the LOCADDR parameter should be set to 0 in VTAM or in the NCP Gen.
- On connections used for independent APPC, the exchange identification (XID) type must be Format 3.
- The Network Name parameter is required. The default is the network name of Host Integration Server.
- An LU Name parameter is required to identify local and remote APPC LUs to other components on the network. In contrast to 3270 LUs, independent APPC LUs do not need an LU number.
- If the remote APPC LU supports parallel sessions, it can only be used with a mode whose parallel session limit has a value greater than 1.

Dependent APPC LUs

A dependent local APPC LU requires the support of a mainframe to communicate with a remote TP. Dependent APPC LUs cannot be used to communicate with an AS/400 computer.

The next figure illustrates how a dependent APPC LU can communicate with the host.

Dependent APPC LU communications with the host



Dependent local LUs have the following characteristics:

- Allow only a single session per LU.
- Use a connection configured with a Remote End of Host, not Peer.
- Only type of APPC LUs that Host Integration Server supports when communicating with a mainframe using a version of VTAM earlier than version 3, release 2.
- Require the mainframe VTAM to use a value of 1 or greater in the LOCADDR parameter in the NCP Gen.

The Network Name and LU Name are recommended but not required, because they are used only by local software such as the Microsoft® Windows® event log software. The default is the network name specified for the Host Integration Server computer. If a network name is not specified for the server, the default is APPN.

For a remote APPC LU that will be partnered with a dependent local APPC LU, the LU Name is recommended but not required. It identifies the LU to local software, such as the Windows event log software.

A number identifying the LU on its connection is required and should match the LOCADDR=parameter for the LU definition in VTAM or in the NCP Gen. Check the numbering for any non-APPC LUs on the connection that the remote APPC LU will use because this number must be unique.

The usual range for LU numbers is from 2 through 254.

A dependent APPC LU requires the support of a mainframe. During LU configuration, you need to select a host type of the connection to which the LU will be assigned. Also, the remote LU needs the same name as defined on the remote system services control point (SSCP). This name is required when using dependent APPC.

Configuring Dependent LUs

Configuring Dependent LUs

When you configure a dependent LU, make sure you do the following:

- Set up a single session for each dependent LU. (Only one session is allowed for each dependent LU.)
- Specify the remote end, using **Host**.
- Use VTAM 3.2 or later for host-to-APPC LU communication.

Set the host VTAM to a value of 1 or greater in the *LOCADDR*= parameter of the LU definition.

Dependent APPC LUs

APPC Mode Definition

A mode is associated with an LU-LU pair, and determines the session properties for that pair. One of the key mode properties is the Parallel Session Limit. This limit determines whether an LU-LU pair can perform only one interaction at a time or multiple concurrent interactions.

Parallel sessions are used only with independent APPC. If parallel sessions are to be allowed with an LU-LU pair, the local LU must be independent, and the remote LU in the pair must support parallel sessions.

If the LU-LU pair can have multiple parallel sessions, other mode properties, such as Minimum Contention-Winner Limit, determine to what extent each LU can initiate interactions.

The following table lists the modes provided with Host Integration Server.

Mode name	To be used for
#BATCH	Batch-oriented sessions
#BATCHC	Batch-oriented sessions using compression
#BATCHSC	Batch-oriented sessions that employ a minimal level of routing security
BLANK	Sessions using a default mode name, encoded as eight blank EBCDIC spaces in BIND
#INTER	Interactive sessions
#INTERC	Interactive sessions using compression
#INTERSC	Interactive sessions that employ a minimal level of routing security
QPCSUPP	All sessions with an AS/400 computer
QSERVER	The ODBC drivers

The configuration parameters of the modes provided with Host Integration Server are shown in the following table.

Configuration parameter	#BATCH #BATCHSC and BLANK	#INTER and #INTERSC	QPCSUPP	QSERVER
Parallel Session Limit	8	8	64	8
Minimum Contention Winner Limit	4	4	32	4
Partner Contention Winner Limit	0	0	0	0
Automatic Activation Limit	0	0	0	0
High Priority Mode	No	Yes	Yes	Yes
Pacing Send Count	3	7	7	7
Pacing Receive Count	3	7	7	7
Max Send RU Size	1024	1024	1024	1024
Max Receive RU Size	1024	1024	1024	1024

The mode name and configuration parameters are used for both dependent and independent APPC LUs.

The Parallel Session Limit defines the number of sessions that can be activated. If the local APPC LU is dependent, specify 1 for the parallel session limit. Dependent local APPC LUs cannot have parallel sessions. Independent local APPC LUs can have from 1 through 1024 parallel sessions. The default is 1.

The Minimum Contention Winner Limit is the guaranteed number of sessions the local machine can initiate. The Partner Contention Winner Limit is the guaranteed number of sessions the remote machine can initiate. Each session can be established without permission from the partner LU. The sum of both must be less than or equal to the Parallel Session Limit. The range for each is from 0 through the Parallel Session Limit; the default is 0.

The Automatic Activation Limit specifies the number of Contention Winner sessions to be activated for the local LU whenever the connection for this mode is started. In a Contention Winner session, the LU can initiate conversations without permission from the partner LU. For a single-system APPC (communication between two local LUs), this field is meaningless. The range is from 0 through the Minimum Contention Winner limit.

High Priority Mode defines the priority of the data sent. This is beneficial for segregating batch data from interactive data. Batch data typically has a lower priority than interactive data.

Pacing Send Count and Pacing Receive Count allow you to specify the maximum number of frames without an SNA pacing response from either the local or remote APPC LU. For example, if you specify 0, the local APPC LU can send an unlimited number of frames without receiving a response. In this case, the remote APPC LU can negotiate and set a limit on the count. The range is from 0 through 63; the default is 4.

The request/response unit (RU) sets the size of the data message that can be sent or received. If an application needs to send a file that is larger than the specified size, it needs to break it up before sending the file. The minimum RU size on Host Integration Server is 256. The range for Max Send RU Size and Max Receive RU Size is from 256 through 16384; the default is 1024.

To add an APPC mode definition

1. In the SNA Manager tree, click **APPC Modes**.
2. On the **Action** menu, point to **New**, and click **Mode Definition**.
3. On each tab, configure the mode properties.
4. On the **Action** menu, click **Save configuration**.

Concepts
Implicit Incoming Remote LU and Implicit Incoming Mode
Default Local APPC LU and the Default Remote APPC LU
Default Outgoing Local APPC LU Pool

Implicit Incoming Remote LU and Implicit Incoming Mode

An implicit incoming remote LU is a remote APPC LU that defines the properties to use when Host Integration Server receives a request to start a session with a local LU and when the remote LU named in the request is not recognized by Host Integration Server.

An implicit incoming mode is a mode that defines the properties to use when Host Integration Server receives a request to start a session and the mode named in the request is not recognized by Host Integration Server.

An implicit incoming remote LU requires an implicit incoming mode. An implicit incoming mode must be configured for any remote LU that will be used as an implicit incoming remote LU. An implicit incoming mode can be (but does not have to be) configured for remote LUs that will only be used explicitly.

You may want to accept incoming requests that arrive by many different remote LUs without having to explicitly define each remote LU on a Host Integration Server computer. The Implicit Incoming Remote LU and Implicit Incoming Mode allow for flexible acceptance of requests. When these two items have been configured, and an incoming request is received by Host Integration Server, the remote LU need not be recognized, as long as the local LU specified in the request is recognized. In such a situation, Host Integration Server uses the properties of the Implicit Incoming Remote LU and Implicit Incoming Mode for that LU-LU session.

For a session to be established, the incoming local LU name must be recognized by Host Integration Server. Then the incoming remote LU must either be recognized explicitly or handled implicitly (if an implicit incoming remote LU has been configured). If the remote LU is recognized explicitly, but the mode is not recognized (as part of an LU-LU pair), Host Integration Server internally creates a new mode definition with the correct name using the properties of the implicit incoming mode. Alternatively, if the remote LU is handled implicitly, Host Integration Server also handles the mode implicitly, by internally creating a mode, as described.

To use an implicit incoming remote LU

1. In the SNA Manager tree, expand an SNA subdomain, expand the server you want to work with, expand **SNA service**, and then expand **Local APPC LUs**.
2. Right-click the first local LU that you want to configure, and click **Properties**.
3. Click the **Advanced** tab, and specify the **Implicit Incoming Remote LU** for incoming conversations, and then click **OK** to exit.
4. Using steps 2–4, configure each local LU that the remote system will call.
5. Expand **Remote APPC LUs**, right-click the remote LU that you want to configure, and then click **Properties**.
6. Click the **Options** tab, and select the **Implicit Incoming Mode**.
7. On the **Action** menu, click **Save configuration**.

Note
All incoming requests must specify a local LU name that is recognized by Host Integration Server, even when using an implici t incoming remote LU and implicit incoming mode.

APPC Mode Definition

Default Local APPC LU and the Default Remote APPC LU

Default Outgoing Local APPC LU Pool

Default Local APPC LU and the Default Remote APPC LU

If a user or group uses transaction programs, 5250 emulators, or APPC applications, you can assign a default local APPC LU and a default remote APPC LU. These default LUs are accessed when the user or group member starts an APPC program (a TP, 5250 emulator, or APPC application) and the program does not specify LU aliases.

With Host Integration Server, you can assign a default local APPC LU and a default remote APPC LU to each user or group. A user or group member can then start APPC programs (TPs, 5250 emulators, or APPC applications) that do not specify LU aliases. Host Integration Server will use the default local APPC LU and the default remote APPC LU assigned to that user or group.

There are two steps before assigning default APPC LUs to a user or group:

1. The user or group must have an account on the local area network.

2. The user or group must be added to the list used by Host Integration Server.

If a user is assigned LUs through one or more accounts, such as group accounts and the user's individual account, one account determines the access for that user. The account that determines this access is the account found first when searching is performed in this order:

- User accounts (highest priority)
- Domain groups
- Local groups
- Well-known groups such as Everyone (lowest priority)

For example, suppose a user account (a high-priority account) called JOHND contains LOCLU1 as the default local APPC LU, but no default remote APPC LU. At the same time, suppose a local group (a low-priority account) of which JOHND is a member contains LOCLU2 as the default local APPC LU, and REMLU2 as the default remote APPC LU. For JOHND, the high-priority assignment, the default local APPC LU of LOCLU1 will be combined with the only other available assignment, the default remote APPC LU of REMLU2.

APPC Mode Definition

Implicit Incoming Remote LU and Implicit Incoming Mode

Default Outgoing Local APPC LU Pool

Default Outgoing Local APPC LU Pool

With Host Integration Server, you can set up a pool of local APPC LUs that will be allocated dynamically for any invoking transaction program that does not specify a local LU. This feature is designed to coexist with the default local and remote LUs for users and groups, and does not override these settings.

Both of the default APPC LU features (the default outgoing local APPC LU pool and the default local and remote LUs for users and groups) allow client computers to start a session without specifying an LU name. This helps to simplify administration by eliminating APPC configuration for client computers.

If an application begins the invoking process but does not specify a local APPC LU, Host Integration Server first tries to determine the default local APPC LU of the associated user or group (the user or group logged on at the system where the application is running). If no such LU can be substituted, Host Integration Server attempts to assign an LU from the default pool of outgoing local APPC LUs. If no LUs are available from the default pool, the attempt to begin the invoking process is rejected.

The default outgoing local APPC LU pool differs from, and should not be confused with, 3270, LUA, and downstream pools.

Concepts

APPC Mode Definition

Implicit Incoming Remote LU and Implicit Incoming Mode

Default Local APPC LU and the Default Remote APPC LU

Single-System APPC

Single-system APPC has two local APPC LUs residing on the same server. The LUs communicate with each other using defined parameters. You do not need to define a connection because the LUs are communicating with each other on the same system.

For a single-system APPC, you will need to assign two local APPC LUs to a server, not to a connection. Configuration of the local APPC LUs includes specifying the LU Alias, Network Name, and LU Name. Each of these labels identifies an LU to a particular set of software components.

If Common Programming Interface for Communications (CPI-C) is used, configure one or more CPI-C symbolic destination names. For more information, see CPI-C Access in the next section.

Single-system APPC is generally used for testing transaction programs. The basic steps for configuring single-system APPC are as follows.

To configure single-system APPC

1. Assign two local APPC LUs to a server.
2. Configure the local APPC LUs by specifying the LU Alias, Network Name, and LU Name.
3. If an appropriate mode has not already been configured, configure it.

Note
For single-system APPC, the Automatic Activation Limit specified in the mode is meaningless. Use one of the local LUs for the originator conversation and the other local LU for the destination conversation.

Concepts

APPC Mode Definition
Implicit Incoming Remote LU and Implicit Incoming Mode
Default Local APPC LU and the Default Remote APPC LU
Default Outgoing Local APPC LU Pool

CPI-C Access

Common Programming Interface for Communications (CPI-C) provides a consistent application programming interface for network applications. CPI-C is a set of C-language routines that applications distributed across an SNA network can use to communicate as peers and exchange data to accomplish a processing task.

CPI-C programming provides a mechanism, called side information, that associates a set of parameters with a specified symbolic destination name. The CPI-C program then uses the symbolic destination name to initialize a conversation.

If you are using applications based on CPI-C, you configure one or more CPI-C symbolic destination names. A CPI-C symbolic destination name is a name assigned to a set of properties for a CPI-C conversation.

LU partners will need to recognize each other. This is accomplished using fully qualified names and LU aliases. The fully qualified name is a two-part name that identifies the remote LU. The first part of the fully qualified name is the network name and the second part is the remote LU name.

You will also need a mode name. For more information about modes, see the section APPC Mode Definition earlier in this section.

Conversation-level security requires a match between the user ID and password supplied by the invoking TP, and the user ID and password stored on the server where the remote TP resides. If the ID and password do not match, the session is not activated.

Transaction Programs

The part of an application that initiates or responds to APPC communications is called a transaction program (TP). TPs use APPC to exchange data with other TPs on a peer-to-peer basis.

Similar to a conversation when people talk with each other, the communication between two transaction programs is called a conversation. An application running on your computer can have many conversations active at one time, either with one other transaction program or with different transaction programs.

There are two types of TPs: TPs that can invoke (initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

If your Host Integration Server installation contains multiple systems (client computers or Host Integration Server computers), you can place invokable TPs on more than one system. When an invoking request is received in such an installation, there will (potentially) be a choice of systems on which to run the invokable TP. You can maintain specific control over this choice, or you can allow the choice to be made randomly by Host Integration Server (to distribute the load).

You can maintain specific control over this choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique LU alias. With this arrangement, the information provided by the invoking TP (in the ALLOCATE verb) can specify the particular system on which the TP should run.

You can avoid controlling this choice of system, and allow the choice to be made randomly by Host Integration Server, by setting the **DloadMatchLocalFirst** registry entry to **NO**, as described in the *Host Integration Server Administrators Reference*. Then use invokable TPs that leave the local LU alias unspecified. When an incoming request is received, it is routed randomly, rather than preferentially, to the local Host Integration Server computer. In addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. Host Integration Server will start the TP, choosing randomly among the available systems.

Following are three of the possible ways that TPs can be arranged to run.

In This Section

TP Name Unique for Each TP

If you want to specify the system on which the invokable transaction program (TP) will run, you can use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the invokable TP (and system) by naming the TP. This makes it unnecessary for an invokable TP to specify any LU alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unspecified
Invoking Transaction Programs
Invoking TPs and Host Integration Server Configuration
Invokable Transaction Programs
Invokable TPs and the Host Integration Server Configuration

Other Resources

Transaction Programs

TP Name Not Unique; Local LU Alias Unique

Instead of using a unique transaction program (TP) name to specify the system on which the invokable TP will run, you can give the same name to multiple invokable TPs, but associate each TP with a unique local LU alias. Configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

Concepts

TP Name Unique for Each TP
TP Name Not Unique; Local LU Alias Unspecified
Invoking Transaction Programs
Invoking TPs and Host Integration Server Configuration
Invokable Transaction Programs
Invokable TPs and the Host Integration Server Configuration

Other Resources

Transaction Programs

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable TP runs, use the same name for multiple invokable TPs, but do not specify an LU alias in the registry or environment variables for the TPs. In such a situation, there are no associated aliases in the list of available invokable TP names on a Host Integration Server computer. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

If you set the **DloadMatchLocalFirst** registry entry to **NO**, as described in the *Microsoft Host Integration Server Reference*, the server randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems, and provides hot backup (so that you can take systems online and offline without disrupting service).

Invoking Transaction Programs

An invoking TP initiates a conversation with other TPs. An invoking TP can be located on any system on the SNA network.

An invoking TP identifies itself by issuing a TP_STARTED verb. TP_STARTED specifies the name of the invoking TP, and may specify the LU alias that the TP uses (or may leave the LU alias blank).

Next, the invoking TP initiates the invoking process by issuing an ALLOCATE verb. In ALLOCATE, the invoking TP specifies the name of the invokable TP, and may also specify the partner LU alias (the LU alias to be used by the invokable TP).

Invoking TPs and Host Integration Server Configuration

For Host Integration Server to support the beginning of the invoking process (to accept the TP_STARTED and ALLOCATE verbs issued by an invoking TP), the following parameters must be configured correctly:

- If the invoking TP specifies the LU alias that it uses (in TP_STARTED), that LU alias must match a local APPC LU alias on the supporting Host Integration Server computer.

- If the invoking TP leaves the LU alias blank in TP_STARTED, one of two methods for designating a default LU must be used on the supporting Host Integration Server:

    - Assign a default local APPC LU to the user or group that starts the invoking TP (the user or group logged on at the system from which TP_STARTED is issued).

      – or –

    - Designate one or more LUs as members of the default outgoing local APPC LU pool.

  If the invoking TP leaves the LU alias blank in TP_STARTED, Host Integration Server first attempts to determine the default local APPC LU of the associated user or group, and then attempts to assign an available LU from the default outgoing local APPC LU pool. If these attempts fail, Host Integration Server rejects the TP_STARTED request.

- In most situations, the supporting Host Integration Server must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, Host Integration Server contains two local LUs paired together (for invoking and invokable TPs that are in the same domain). In this situation, a connection to a host or peer is not necessary.

- If the invoking TP specifies the partner LU alias (in ALLOCATE), that LU alias must match a remote LU alias. In addition, that remote LU alias must be paired with the local LU alias specified in TP_STARTED. If the LU alias is left blank in ALLOCATE, a default remote APPC LU must be assigned to the user who started the invoking TP. If the default remote APPC LU is used, it must be paired with the local LU that will be used. Otherwise, the ALLOCATE verb fails.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured on another Host Integration Server computer, as described in the next section.

Invokable TPs and the Host Integration Server Configuration
Other Resources
Transaction Programs

Invokable Transaction Programs

An invokable TP is a TP that can be invoked by another TP. Invokable TPs are written or configured to supply their names to Host Integration Server as a notification that they are available for incoming requests. Host Integration Server invokable TPs can be run on any Host Integration Server computer or on a Windows Server™ 2003 or Windows 2000 client.

There are two types of invokable TPs:

- **Operator-started invokable TPs**

  An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies Host Integration Server of its availability by issuing a RECEIVE_ALLOCATE verb. RECEIVE_ALLOCATE provides the name of the invokable TP.

- **Autostarted invokable TPs**

  An autostarted invokable TP can be started by Host Integration Server when needed. The TP must be registered on its local system, so that it can be identified to Host Integration Server. (For details about how the TP is registered, see *Microsoft Host Integration Server APPC Applications* or *Microsoft Host Integration Server CPI-C Applications*.) The registered information defines the TP as autostarted, and must specify the TP name. The registered information may also specify the local LU alias that the invokable TP will use.

  If no local LU alias is registered with autostarted TPs, the resulting Host Integration Server configuration can be more flexible in responding to invoking requests.

  After an autostarted invokable TP is started by Host Integration Server, the TP issues RECEIVE_ALLOCATE (just as an operator-started TP does). RECEIVE_ALLOCATE must provide the same TP name as was registered for the TP.

Each Host Integration Server maintains a list of invokable TP names and any LU aliases associated with the TP names. When a request comes in from an invoking TP, Host Integration Server compares the requested invokable TP name and the associated LU alias to the list of available invokable TPs (which may include associated LU aliases). For details about how this comparison is carried out, see *Microsoft Host Integration Server APPC Applications* or *Microsoft Host Integration Server CPI-C Applications*.

If a match is found, Host Integration Server signals the system containing the requested TP to connect to that Host Integration Server computer.

If no match is found, Host Integration Server rejects the incoming request.

Invokable TPs and the Host Integration Server Configuration

For Host Integration Server to receive requests from an invoking TP on another system, and then route those requests to an invokable TP, certain parameters must be configured correctly:

- Host Integration Server must have a connection to the system from which the invoking TP's request is sent.

- Host Integration Server must have a remote LU capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly. When configured explicitly, there is an explicit match between a remote LU alias on Host Integration Server and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an Implicit Incoming Remote LU (with its Implicit Incoming Mode) is used. Several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the server receiving the request. Second, the local LU on the server must have an Implicit Incoming Remote LU assigned to it. The properties of the Implicit Incoming Remote LU will be used for that LU-LU session. For more details about how an Implicit Incoming Remote LU works, see Implicit Incoming Remote LU and Implicit Incoming Mode, earlier in this section.

- Appropriate local LUs must be defined in the Host Integration Server configuration file.

APPC Security

Owners of APPC transaction programs may want to allow only a limited set of users to start the program. APPC provides a mechanism, called APPC conversation security, by which the client transaction program identifies its user to the server system.

There are three levels of security for client programs: None, Same, and Program:

- If the level of security is None, the client system sends no security information (user ID or password).
- If the level of security is set to Same, APPC tries to determine a user ID for the client program. If the server system requires a password and the client system permits APPC to retrieve one for the user ID, APPC will also send the password to the server system. If no user ID is available, or if the server requires a password but the client system does not allow APPC to retrieve the password, no security information is sent to the server. This is sometimes referred to as downgraded to security NONE.
- If the security level is set to Program, the client transaction program will override any security information that the local system may provide. The client program must supply both a user ID and a password. CPI-C programs may get the user ID and password by either prompting the user to enter the information or by checking the CPI-C side information. Not all systems allow this option.

If the client program uses SECURITY=SAME or SECURITY=PROGRAM, APPC on the server must check the user ID and password regardless of the server transaction's security requirements. This requirement can cause unexpected problems and is not recommended.

To configure session security for remote LUs

1. In the SNA Manager tree, expand an SNA subdomain, expand the server you want to work with, expand **SNA service**, and then expand **Remote APPC LUs**.
2. Right-click the LU that you want to configure, and click **Properties**.
3. Click the **Options** tab. Under **Session-Level Security**, select an option.
4. Click **OK**.
5. On the **Action** menu, click **Save configuration**.
6. To put the changes into effect, you must restart the server.

Note
Setting the security for remote LU sessions is optional.

Optimizing Communications

Servers used primarily for communications need to provide fast throughput, but they do not need to provide fast file access (as a file server would). Faster throughput will result if portions of memory are set aside for communications programs (such as Host Integration Server or Microsoft® SQL Server™).

Such dedicated memory includes nonpaged memory, or portions of memory that are never swapped to disk, but remain available for immediate use at all times. If more memory is dedicated to Host Integration Server or similar programs, less memory is available for file sharing.

Windows Server 2003 or Windows 2000 Server allow you to view or change network throughput options. However, Host Integration Server installation automatically sets the option to maximize throughput for network applications.

Servers used primarily for communications run many important background processes (processes not related to user actions in the current window). These servers generally do not need to run foreground processes at maximum speed. Host Integration Server throughput can be increased by making the operating system more responsive to background processes and less responsive to foreground processes.

A server that is less responsive to foreground processes will run local applications such as word-processing software, spreadsheets, or SNA Manager more slowly. Tasking is most appropriate for servers used primarily to support client systems, and not for servers used locally as desktop computers.

To optimize background processing for a computer running Windows Server 2003 or Windows 2000 Server

1. Click **Start**, point to **Settings**,click **Control Panel**, and then double-click **System**.
2. Select the **Advanced** tab.
3. In the **Performance** box, click **Performance Options**.
4. In the **Application response** box, **select Applications or Background services**.
5. Click **OK**, and then click **OK** again.

Transaction Programs

APPC Mode

A mode is associated with an LU-LU pair, and determines the session properties for that pair. One of the key mode properties is the Parallel Session Limit. This limit determines whether an LU-LU pair can perform only one interaction at a time or multiple concurrent interactions.

Parallel sessions are used only with independent APPC. If parallel sessions are to be allowed with an LU-LU pair, the local LU must be independent, and the remote LU in the pair must support parallel sessions.

If the LU-LU pair can have multiple parallel sessions, other mode properties, such as Minimum Contention-Winner Limit, determine to what extent each LU can initiate interactions.

The following table lists the modes provided with Host Integration Server.

Mode name	To be used for
#BATCH	Batch-oriented sessions
#BATCHC	Batch-oriented sessions using compression
#BATCHSC	Batch-oriented sessions that employ a minimal level of routing security
BLANK	Sessions using a default mode name, encoded as eight blank EBCDIC spaces in BIND
#INTER	Interactive sessions
#INTERC	Interactive sessions using compression
#INTERSC	Interactive sessions that employ a minimal level of routing security
QPCSUPP	All sessions with an AS/400 computer
QSERVER	ODBC drivers

APPC Mode Definition

Notes Section

This section contains notes about AS/400 computers, local and remote names, time-outs for 802.2 connections, and adapter and adapter addresses.

Note About AS/400 Computers

To connect to an AS/400 computer, supply both local node and remote node parameters for the Network Name and the Control Point Name. These properties are configured in separate dialog boxes:

- **Local node (server) properties.** In the **Server Properties** dialog box of the computer running Host Integration Server, type the **Control Point Name** and the **Network Name**. The server Network Name must correspond to the RMTNETID parameter in the AS/400 APPC controller description. (The default for the AS/400 computer network ID is typically APPN.) If this value is set to ***SAME**, refer to the Local Network ID parameter in the AS/400 Network Attributes screen (using the **dspneta** command). The server Control Point Name must match the RMTCPNAME parameter in the AS/400 APPC controller description. For 802.2 connections, the AS/400 computer can be configured to automatically create the APPC controller description when the computer running Host Integration Server first connects to the AS/400 computer, by setting the AUTOCRTCTL parameter to ***YES** in the AS/400 Token-Ring or Ethernet line description. However, for SDLC connections, the APPC controller description must be manually created.

  If you specify a CPNAME in **Connection Properties**, it overrides the CPNAME in the **Server Properties** dialog box. The CPNAME in **Server Properties** is the default and will be used unless it is changed in **Connections Properties**.

- **Remote node (connection) properties.** In the **Properties** dialog box for an 802.2 or SDLC connection, type the **Network Name** and **Control Point Name (CP name)** of the AS/400 computer into the **Network Name (Remote Node)** and **Control Point Name (Remote Node)** fields. The AS/400 Network Name and Local Control Point Name can be found on the AS/400 Network Attributes screen using the DSPNETA. For more information about these fields, click Help on the **Properties** dialog box for the connection.

  On an AS/400 computer, the Network Name is specified in the Local network ID parameter in the Network Attributes screen and in the RMTNETID parameter on the APPC controller description. For more information, see your APPN documentation.

Using Remote Node Identifiers

You can use several types of parameters to specify the remote node with which a connection should connect:

Remote address (802.2 connections only)

This parameter is required for 802.2 connections. For outgoing calls, it is used to specify the remote host, peer, or downstream system being called. This parameter is the **Remote Network Address**.

Network Name (Remote Node) and Control Point Name (Remote Node)

As a general guideline, use these parameters if the administrator of the remote host, peer, or downstream system uses them.

These two parameters work together; if either parameter is supplied, the other should also be supplied. These parameters are used only for Format 3 exchange identifications (XIDs), one of two types of exchange identification. Format 3 XIDs are generally used for APPC. If a connection does not use Format 3 XIDs, there is no need to specify these parameters.

Remote Node ID

As a general guideline, use this parameter if the administrator of the remote host, peer, or downstream system uses it. This parameter can be used in Format 0 XIDs or Format 3 XIDs, the two types of identification exchange. **Format 0 XID**s are generally used for 3270 communication and for LUA; **Format 3 XID**s are generally used for APPC.

Note About Local and Remote Names

The **Network Name** and **Control Point Name** for the remote node are different from the **Network Name** and **Control Point Name** for the local node. The remote **Network Name** and **Control Point Name** are specified in the **Connection Properties** dialog box. The local **Network Name** and **Control Point Name** are specified in the **Server Properties** dialog box.

Configuring Multidrop Connections

In a multidrop connection, one primary computer communicates simultaneously with multiple secondary computers. Host

Integration Server supports multidrop connections used for downstream systems on leased SDLC lines.

You can configure up to four multidrop connections on each line, with a computer running Host Integration Server as the primary server on each.

Configure each connection to be used in the multidrop configuration according to the instructions that follow.

To configure multidrop connections

1. Configure a link service for an SDLC line with the **Constant RTS** option not selected.
2. Configure each connection to be used in the multidrop configuration as follows:
    - In the **SDLC Properties** dialog box, select the same link service for each connection.
    - In the **SDLC Properties** dialog box, under **Remote End**, select **Downstream**.
    - Make all the parameters identical for each configuration, except for **Poll Address**, and possibly the **Local Node ID** and **Remote Node ID**. For these parameters, obtain values from the downstream system administrators. Make the **Poll Address** unique for each station.
3. For the primary connection in the multidrop configuration, on the SDLC page of the **SDLC Properties** dialog box, select the **Multidrop Primary** box.

For information about using the configuration dialog boxes, click **Help** in the **SDLC Properties** dialog box.

Note About Time-outs for 802.2

The time-outs for 802.2 (**t1**, **t2**, and **ti**) are derived from basic timer values that are set in the Windows registry. Host Integration Server is designed with the assumption that these registry values will not be changed after they have been set by the DLC (802.2) driver. If these registry values are changed, the choices displayed in the **Response Timeout**, **Receive ACK Timeout**, or **Inactivity Timeout** fields may no longer reflect the actual amounts of time that Host Integration Server waits.

Simplified Facility Data Example

The following simplified example shows how identifiers allow each facility request to be distinguished from the ones that follow:

40AAAA20BB

The example contains two requests. The first request begins with a 4, indicating that after the two-character identifier there are four characters (in this case, four occurrences of the A character). The second request follows, beginning with a 2, indicating that after the two-character identifier there are two characters (two occurrences of the B character).

Standard Facility Data Example

The facility data string in this example initiates a connection using 256-byte packets, a sending window of 7, a receive window of 4, and charges reversed. The facility requests that do this are as follows:

- 42 08 08 for Packet Size
- 43 04 07 for Window Size
- 01 01 for reverse charging

When these requests are concatenated, the following facility data string is created:

4208084304070101

Common Identifier Table

The following table shows commonly used identifiers for facility requests.

Facility	Identifier	Parameters	Meaning

Reverse charging	01	00 01	Reverse charging NOT requested Reverse charging requested
Packet Size	42	0r0s	r = Receive Packet Size s = Send Packet Size
			r and s can have the following values:
			6 for 64-byte packets 7 for 128-byte packets 8 for 256-byte packets 9 for 512-byte packets A for 1024-byte packets
Window Size	43	0r0s	r = Receive Window Size s = Send Window Size r and s can be from 1 through 7. They are usually set equal, making the send and receive windows the same size.

In this table, send and receive operate from the view of the initiator of the connection.

Note About Local Adapter Address

When communicating with the administrator of a remote host, peer, or downstream system, you may need to tell that administrator the address of your local adapter.

To determine the local address of an 802.2 adapter, at the command prompt, type:

net config server

In the resulting display, the address of the local adapter appears in the line labeled **Server is Active On**.

Primary Configuration Server

The primary configuration server is the Host Integration Server computer designated to contain the domain-wide configuration file. The configuration file reflects the Host Integration Server resources for the SNA subdomain, including all Host Integration Server computers, link services, LUs, 3270 users, and so on. There can be only one primary server in the subdomain.

Backup Configuration Server

The backup configuration server is a Host Integration Server computer on which the configuration file is replicated by Host Integration Server. There can be more than one backup server in an SNA subdomain. Host Integration Server will load the copy of the configuration file located on a backup Host Integration Server computer if the primary Host Integration Server computer goes down. In this case, servers and connections can be started and stopped, but the configuration cannot be changed or saved.

Identifiers in Incoming XIDs

When deciding which type of remote node identifier to specify for a connection that accepts incoming calls, it may be helpful to understand how Host Integration Server uses exchange identifications (XIDs) from incoming calls.

When Host Integration Server receives an XID from an incoming call, it looks at the XID for some type of identifier of the remote system that made the call. It compares this identifier, in the order shown in the following list, against identifiers stored in the Host Integration Server configuration. If it finds a match, it accepts the call. If it finds that identifiers are left unspecified (in the configuration or the XID), and the connection is an SDLC connection, Host Integration Server accepts the call, pending further exchange of information. In other cases—when every comparison yields a mismatch, or when identifiers are left unspecified but the connection is 802.2—Host Integration Server rejects the incoming call.

Identifiers are compared in the following order:

1. If the incoming XID is Format 3, Host Integration Server examines the XID for a remote node Network Name and Control Point Name. If these parameters are present in both the Incoming XID and in the Host Integration Server configuration, and they match, the call is accepted. If the parameters are present and do not match, the call is rejected.

2. If the parameters were not available for the preceding step, Remote Node IDs are examined next. (Remote Node IDs may be used in either Format 0 or Format 3 XIDs.) If a Remote Node ID is present in both the Incoming XID and in the Host Integration Server configuration, and they match, the call is accepted. If the parameters are present and do not match, the call is rejected.

3. If the parameters were not available for the preceding steps, for 802.2 connections, remote addresses are examined:

   For 802.2 connections, the Remote Network Address in the Host Integration Server configuration is compared to the address from which the XID was received. If the addresses match, the call is accepted; if not, the call is rejected.

4. For 802.2 connections, if no match is found in any of the preceding steps, the incoming call is rejected.

   For SDLC connections, if no match is found in the preceding steps, but identifiers were left unspecified in the configuration or the XID, the call is accepted, pending further exchange of identifiers. However, if identifiers were not left unspecified and no identifiers match, the call is rejected.

Guidelines for Identifiers for 802.2 Connections

The following table lists guidelines for identifiers for 802.2 connections.

Conn. type	**Allowed call directions**	**Guidelines for identifiers for remote node**
802.2	Outgoing	Use Remote Network Address
802.2	Incoming	Match the identifiers used on the remote system: Remote node Network Name and Control Point Name or Remote Node ID or Remote Network Address
802.2	Both	Use a combination of outgoing plus incoming identifiers

Guidelines for Identifiers for SDLC Connections

The following table lists guidelines for identifiers for SDLC connections.

Conn. type	**Allowed call directions**	**Guidelines for identifiers for remote node**
SDLC	Outgoing	If Host Integration Server supplies the phone number to the modem, specify Dial Data (phone number of remote system)
SDLC	Incoming	Match the identifiers used on the remote system: Remote node Network Name and Control Point Name or Remote Node ID
SDLC	Both	Use a combination of outgoing plus incoming identifiers

Making and Testing a Connection

This section provides the procedures used to make successful connections. Several steps are required to connect your host system to Host Integration Server.

One way to remember the four steps required to make a successful connection is with the acronym **LCLUA** that stands for **L**-Link Service, **C**-Connection, **LU**-LUs and **A**-Adding and Assigning Users.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

For information about configuring Host Integration Server for your enterprise environment, see Configuring Your Enterprise.

Making a Connection

Complete the following steps to give users and groups access to the mainframe environment, install connections, and verify the installation.

(For information on the new IP-DLC Link Service, see IP-DLC Link Service.)

Install Host Integration Server

- Verify Host connection information.
- Verify Microsoft Windows Server 2003 or Windows 2000 Server configuration information.
- Verify Host Integration Server SNA service configuration information
- Install Host Integration Server.
- Install appropriate link services.

Configure Host Integration Server

- Step 1 (L) Creating and Configuring Link Services
- Step 2 (C) Creating and Configuring Connections
- Step 3 (LU) Creating and Configuring 3270 LUs
- Step 4 (A) Adding and Assigning Users

Test Host Integration Server

- Testing Connections with the 3270 Client
- Testing Connections with the 5250 Client

Items to Consider for a Successful Connection

For a connection to be established successfully, a number of software settings and hardware characteristics must work together.

The following table outlines items to consider when configuring a connection with Host Integration Server.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

Element	Considerations
Host configuration settings must match the connectionandserversettings on the Host Integration Server computer.	**Mainframe node ID settings**: For most mainframes, IDBLK and IDNUM in the physical unit (PU) definition must match the two parts of the Remote Node ID on the Host Integration Server connection. **AS/400 name settings**: For the AS/400 computer, local and remote control point names (CP names) and network names must be matched with corresponding Host Integration Server settings **Addresses**: For 802.2, X.25, or channel connections, you must match the host settings with equivalent settings on the Host Integration Server connection. **BTU length**: For the mainframe, the BTU length is set through MAXDATA in the PU definition. For the AS/400 computer, this is set through MAXFRAME. These should equal the Max BTU Length on the Host Integration Server connection. **Other settings**: With SDLC, the NRZ/NRZI settings on the host must match those on the Host Integration Server connection.
For SDLC and X.25 **Communications hardware**: line, modem (if applicable), and adapter characteristics must match thelink serviceandconnectionsettings on the Host Integration Server computer.	**Speed and duplexing**: For SDLC and X.25, note the speed and duplexing capabilities of the line, modem (or DCE), and adapter, to be sure that they will not be exceeded by the settings in the Host Integration Server link service and connection. Settings for fast transmission or for full duplexing cause greater demands on hardware. The hardware element with the smallest capacity limits the capacity of the entire system.

IP-DLC Link Service

Using SNA Manager

SNA Manager provides an interface for configuration and operation of Host Integration Server components. SNA Manager allows flexibility in viewing and managing SNA server subdomains, computers, link services, connections, logical units (LUs), sessions, and users. It integrates the administration of TN3720 service, TN5250 service, Host Print service, Shared Folder Gateway service, and Host Security Integration.

You can view all Host Integration Server computers in an SNA server subdomain and manage multiple subdomains at the same time. This allows for central configuration and administration of all servers in an enterprise. You can remotely configure and manage Host Integration Server computers across all popular protocols, including TCP/IP, IPX/SPX, and Microsoft Networking.

SNA Manager can be installed on any computer running Windows Server 2003 or Windows 2000 Server, enabling management of the entire Host Integration Server network from a single computer. In addition, SNA Manager allows more than one administrator to simultaneously view and manage the same SNA server subdomain.

SNA Manager provides a hierarchical, tree-like view of an SNA server subdomain and all its resources.

In the console tree, the subdomain is presented as a hierarchical collection of resources. At the top of the hierarchy is the subdomain itself, which contains Servers, LU Pools, Configured Users, Workstations APPC Modes, CPI-C Symbolic Names, and Host Security Domains. You can view as much of the subdomain detail as needed by opening and closing folders.

When you click an item in the console tree, the details pane shows resources available to the item. Double-clicking an item that does not contain other objects displays the properties of the item.

Shortcut menus (available by right-clicking an object) allow selection of the appropriate command for a particular object. For example, if you select a server and right-click, a shortcut menu allows you to stop the service, control all other services, insert new resources, and view and configure the properties.

SNA Manager lets you administer more than one SNA subdomain by displaying each domain in a separate window with its own hierarchical arrangement of resources.

SNA Manager also simplifies administrative tasks by providing wizards to step you through many of the more complicated tasks, such as configuring AS/400 connectivity, configuring 3270 display LUs, and creating a range of LUs.

How to Open a Subdomain

Before you can configure Host Integration Server components, you must open a subdomain.

The **Start Subdomain** dialog box can be used to change SNA subdomains including:

- Local SNA Subdomain
- Remote SNA Subdomain
- Offline Configuration

To open a subdomain

1. Start SNA Manager.
2. In SNA Manager, right-click **SNA Manager** (top level), and select **Open Subdomain**. The **Start SNA Manager for** dialog box appears.
3. Select the appropriate settings for your subdomain, and click **Finish**.

How to Configure Server Properties

The **Server Configuration** dialog box can be used to change Host Integration Server properties, including:

- Server Name
- Subdomain Name
- Active Directory OU Name
- Server Role - Primary or Backup
- Restart - MngAgent and SnaBase

To configure server properties

1. Start SNA Manager.
2. In SNA Manager, right-click the server, and select **Properties**.
3. To change the server name, click **Change** near the top of the **Server Configuration** tab. Note that the server must be offline before you can change the name.
4. To set the Group Identity (Subdomain name and Active Directory), Server Role (Primary or Backup), or Network Transports (TCP/IP is default), click **Change** near the bottom of the **Server Configuration** tab.
5. Make the appropriate changes to your configuration, and then click **OK**.
6. You must save your configuration to keep the properties you set. Right-click the server, and click **Save Configuration**.

IP-DLC Link Service

Step 1 (L) Creating and Configuring Link Services

This section details creating and configuring link services. The maximum number of 802.2 link services that one Host Integration Server computer can support is:

- 64 per network adapter (limited by SAP)
- 255 per SNA server (limited by index from 0x01 to 0xFF)

However, SNA Manager allows only 64 link services per Host Integration Server computer, no matter how many adapters are installed on the server. To configure the number higher than this, use the utility Linkcfg.exe.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

In This Section

Creating Link Services

By default, when Host Integration Server is installed, all the software files required by all standard link services are copied to the server, but the link services themselves are not installed or configured.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

The following sections contain procedures detailing how to create link services using SNA Manager.

In This Section

How to Create the DLC 802.2 Link Service

The following procedure details creating a new DLC 802.2 link service.

To create the DLC 802.2. link service

1. Start SNA Manager.
2. In SNA Manager, right-click the server on which to add the link service, point to **New**,and then click **Link Service**.
3. Select the **DLC 802.2 Link Service**, and click **Add**.
4. Configure the following link service information (if required):
   - Title
   - Adapter
   - Local Service Access Point (SAP)
   - Use Fixed SAP option
   - Allow Link Server to be Distributed option
5. Click **OK**.

   The **Insert Link Service** box will continue to be displayed, allowing you to insert additional link services as needed.
6. After you have finished adding the needed link services, click **Finish**.
7. Right-click **Link Services**, and then click **Save configuration**.

Note
When the link services have been inserted, SNA Manager displays them in the **Link Services** folder.

3. Verify the script file is for the **LU3 Print Demo**, and click **OK**.

   The **Insert Link Service** box will continue to be displayed, allowing you to insert additional link services as needed.
4. After you have finished adding the needed link services, click **Finish**.
5. Right-click **Link Services**, and then click **Save configuration**.

Note
When the link services have been inserted, SNA Manager displays them in the **Link Services** folder.

Configuring Link Services

By default, when Host Integration Server is installed, all the software files required by all standard link services are copied to the server. After the link services are installed, they must be configured for your host environment.

The following sections contain procedures detailing how to configure link services.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

In This Section

How to Configure the DLC 802.2 Link Service

Use the following procedure to configure the DLC 802.2 link service.

To configure the DLC 80.2. link service

1. In SNA Manager, expand the server, and then click **Link Service**.
2. Right-click the DLC 802.2 **(SNADLC1)** link service, and click **Properties**.
3. In **Properties**, click **Configure**.
4. Make configuration changes, and click **OK**.
5. Click **OK** to close the **Properties** dialog box.

Step 2 (C) Creating and Configuring Connections

This section details creating and configuring connections.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

In This Section

Creating Connections

Configuring Connections

Creating Connections

With Host Integration Server, you can create connections with wizards or manually. Host Integration Server provides you with three wizards to aid you in installing and configuring connections to your host environment (HE).

These tools step you through configuring connection properties, creating 3270 display LUs and an LU pool, and assigning the LUs to the LU pool.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

How to Create a 3270 Connection Using a Wizard

The following procedure details using a wizard to create a 3270 connection. The 3270 Continuous link service will be used as an example.

To create a 3270 connection using a wizard

1. In SNA Manager, right-click the server on which to add a connection.
2. Point to **All Tasks**, and then select the **3270 Wizard** option.
3. Click **Next** on the **Welcome** screen.
4. Select the computer where SNA service resides, and click **Next**.
5. Enter a **Name** for the connection, **DM3270**, and click **Next**.
6. Select the appropriate link service, **SNADEMO1**, and click **Next**.
7. Accept the default Local Node ID information, and click **Next**.
8. Accept the default PU address information, and click **Next**.
9. Accept the default LU information, and click **Next**.
10. Click **Add** to add a member (user).
11. Select a member, click **Add**, and then click **OK**.
12. Click **Next**.
13. Click **Finish** to complete the wizard.
14. Click **OK** on the final wizard information page.
15. When the wizard completes, right-click **SNA Service**, and click **Save configuration**.
16. Stop and then start SNA service.

How to Create a 3270 Connection Manually

The following procedure details creating a 3270 connection manually.

To create a 3270 connection manually

1. In SNA Manager, expand the server on which to create the connection, and then expand **SNA Service**.
2. Right-click **Connections**, point to **New**, and then click the type of connection (802.2) to be created.
3. Configure the **Connection Properties**. You are required to specify which link service to use for the connection, as well as the name of the connection and additional information. The choices you make depend on the purpose of the connection.

   The following information must be configured correctly to make a connection:

   - General Tab
   - Address Tab
   - System Identification Tab
   - DLC 802.2 Tab

4. Click **OK**.
5. Right-click **SNA Service**, and then click **Save configuration**.
6. Stop and then start SNA service.

To display this dialog box after the connection has been created, double-click the connection in the tree view, or select the connection, and click **Properties** in the **View** menu.

Configuring Connections

If you run a wizard to create your connections, most of the configuration information will be added with the criteria you entered when the wizard runs. The AS/400 Wizard, the Mainframe APPC/LU6.2 Wizard, and the 3270 Wizard step you through configuring connection properties, creating 3270 display LUs and an LU pool, and assigning the LUs to the LU pool.

If you need to configure a connection manually, you may need to verify the host connection information before you can proceed. For more information, see Verifying Host Connection Information.

For information on the new IP-DLC Link Service, see IP-DLC Link Service.

Step 3 (LU) Creating and Configuring 3270 LUs

This section details information regarding creating and configuring LUs.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

In This Section

Creating LUs

After configuring the connection, you can create the 3270 LUs. The LUs can be display (terminal emulation) LUs, printer LUs, application LUs (LUAs), or downstream LUs.

Each 3270 LU is configured based on the type of connection used. If the connection is channel, 802.2, X.25, or SDLC, the LUs need an LU number, which identifies the LU on its connection. This number should match the LOCADDR= parameter of the LU definition in Virtual Telecommunications Access Method (VTAM) or in the Network Control Program (NCP) GEN. Up to 254 LUs can be configured for each connection, and they can be consecutively configured as a range of LUs.

You can create LUs one at a time or in a consecutively numbered range. When creating a range of LUs, all the LUs are given the same properties. You can modify individual LUs after creating them.

In This Section

How to Create a 3270 Display LU

The following procedure details how to create a display LU.

To create a 3270 display LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**, point to **New**, and then click **Display LU**.

   You can define LUs in this **Properties** dialog box. Keep the default for the **LU Number** box as 2. Two is the first available number, because one is reserved for the host.

   The LU number is meaningful to the connection. You can add a user-friendly name in the **LU Name** box.
3. Type the LU Name, **LU 2**. Leave the other boxes as they are.
4. Click the **Display Model** tab and choose **2 (24 X 80)** as the display station model. Because models can change without notification, click **Model can be overridden**.
5. Click the **Associated Printer** tab. When configuring an LU, these boxes are generally left blank.
6. Click **OK**.

How to Create a 3270 Printer LU

The following procedure details how to create a printer LU.

To create a 3270 printer LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**, point to **New**, and then click **Printer LU**.

   You can define LUs in this **Properties** dialog box. Keep the default for the **LU Number** box as 3. Three is the first available number, because two was used in the previous example and one is reserved for the host.

   The LU number is meaningful to the connection. You can add a user-friendly name in the **LU Name** box.
3. Type the LU Name, **LU 4**. (You might have expected LU 3, but LU 3 is reserved for the LU3 demo.) Leave the other boxes as they are.
4. Type a comment (optional).
5. If you are using compression, select the **Use Compression** box.
6. If the workstation is secured, select the **User Workstation Secured** box.
7. Click **OK**.

To configure a 3270 downstream LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Connections**.
2. Right-click the appropriate connection, **DM3270**. You should see the available LUs in the details pane.
3. Click the **Downstream LU**, **LU 5**, and then click **Properties**.
4. Make appropriate configuration changes, and then click **OK**.

How to Configure a Local APPC LU

The following procedure details how to configure a local APPC LU.

To configure a local APPC LU

1. In SNA Manager, expand **Servers**, expand **SNA Service**, and then expand **Local APPC LUs**.
2. Right-click the appropriate **Local APPC LU**, and then click **Properties**.
3. On the **General** tab:
   - Verify LU Alias.
   - Verify Network Name.
   - Verify LU Name.
4. On the **Advanced** tab:
   - Verify you are a member of the local APPC LU pool, and then select the **Member of Default Outgoing Local APPC LU Pool** box.
   - Verify the amount of time in seconds for **Timeout for Staring Invokable TPs**.
   - Verify the **Implicit Incoming Remote LU**.
   - Verify the **LU 6.2 Type**.
   - Verify **SyncPoint Support**.
5. Click **OK**.

Step 4 (A) Adding and Assigning Users

This section describes adding users and assigning LUs to configured users.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

In This Section

How to Add New Users

Although Host Integration Server uses the User accounts of the Windows Server 2003 or Windows 2000 Active Directory directory service, users must be configured to use Host Integration Server resources such as LUs.

To add new users

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Right-click **Configured Users**, point to **New**, and then click **User**.
3. Select a user (or group) from the list, and click **OK**.

See Also

Tasks

How to Assign LUs to Configured Users

How to Assign Remote APPC LUs to Configured Users

Other Resources

IP-DLC Link Service

How to Assign LUs to Configured Users

Although Host Integration Server uses the User accounts of the Windows Server 2003 or Windows 2000 Active Directory directory service, users must be configured to use Host Integration Server resources such as LUs.

To assign LUs to configured users

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Expand **Configured Users**. Select a user, and then right-click **Assign LUs**.
3. Select an LU, and then click **OK**.

The list of LUs that a particular user can access depends on how the user connects to Host Integration Server. If Active Directory is used, a user can access any LUs assigned directly to the user account and can also access any LUs assigned to any of the groups the user is a member of. If not using Active Directory, a user can only access LUs assigned directly to the user, or if no LUs are assigned to the user account, then the user can access LUs assigned to exactly one group. The groups are checked in the following order: global groups, local groups, well known groups. There is no ordering within a group.

Testing Connections

The topics in this section detail testing, including running and configuring, the 3270 and 5250 Client applications.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

In This Section

Testing Connections with the 3270 Client

Testing Connections with the 5250 Client

Testing Connections with the 3270 Client

The 3270 Client can be used to access your mainframe (3270) environment.

In This Section

How to Run the 3270 Client

The following procedure details running the 3270 Client application.

To run the 3270 client

1. Start **SNA Manager**.
2. On the **Tools** menu, click **3270 Client**. This launches the Host Integration Server 3270 Client application.
3. Next, configure the 3270 Client application. For details, see How to Configure the 3270 Client.

How to Configure the 3270 Client

The following procedure details configuring the 3270 Client application.

The 3270 continuous demo will be used for this procedure.

To configure the 3270 client

1. Start SNA Manager.
2. On the **Tools** menu, click **3270 Client**.
3. On the **Session** menu, click **Session Configuration**.
4. Select the correct LU or pool name, **DM3270**, and then click **OK**.
5. Next, run the 3270 demonstration. For details, see Running the 3270 Client Demonstration.

How to Run the 3270 Client Demonstration

The following procedure details running the 3270 continuous demonstration.

To run the 3270 client demonstration

1. Start SNA Manager.
2. On the **Tools** menu, click **3270 Client**.
3. On the **Session** menu, click **Connect**, which connects you to the 3270 demonstration script.
4. Return to SNA Manager. The status of the DM3270 connection should show **Active**.

Testing Connections with the 3270 Client

Testing Connections with the 5250 Client

The 5250 Client can be used to access your AS/400 environment. The following topics detail running and configuring the 5250 Client application.

In This Section

How to Run the 5250 Client

The following procedure details running the 3270 Client application.

To run the 5250 client

1. Start SNA Manager.
2. Right-click **SNA Service**, and click **Start**.
3. On the **Tools** menu, click **5250 Client**. This launches the Host Integration Server 3270 Client application.
4. Next, configure the 5250 Client application. For details, see Configuring the 5250 Client.

How to Configure the 5250 Client

The following procedure details configuring the 5250 Client application.

The 5250 (AS/400) demo will be used for this procedure.

To configure the 5250 client

1. Start SNA Manager.
2. On the **Tools** menu, click **5250 Client**.
3. On the **Session** menu, click **Session Configuration**.
4. Select the correct LU or pool name, **DM5250**, and then click **OK**.
5. Next, run the 5250 demonstration. For details, see Running the 5250 Client Demonstration.

How to Run the 5250 Client Demonstration

The following procedure details running the 5250 demonstration.

To run the 5250 client demonstration

1. Start SNA Manager.
2. On the **Tools** menu, click **5250 Client**.
3. On the **Session** menu, click **Connect**, which connects you to the 5250 (AS/400) demonstration script.
4. Return to SNA Manager. The status of the DM5250 connection should show **Active**.

Configuring Your Enterprise

Making and Testing a Connection provides the basic steps to configure a link service, make a connection, create logical units (LU), and log on to a host computer; this section follows a similar format and provides the concepts and procedures for configuring Host Integration Server in your enterprise.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

In This Section

Creating and Configuring Link Services

By default, when Host Integration Server is installed, all the software files required by all standard link services are copied to the server, but the link services themselves are not installed or configured.

For information about the IP-DLC Link Service, see IP-DLC Link Service.

The following procedures detail how to create link services using SNA Manager:

- How to Create the DLC 802.2 Link Service
- How to Create the 3270 Demonstration
- How to Create the 5250 Demonstration
- How to Create the LU1 Print Demonstration
- How to Create the LU3 Print Demonstration

The following procedures detail how to configure link services using SNA Manager:

- How to Configure the DLC 802.2 Link Service
- How to Configure the 3270 Demonstration
- How to Configure the 5250 Demonstration
- How to Configure the LU1 Print Demonstration
- How to Configure the LU3 Print Demonstration

Creating and Configuring Connections

You can create connections between Host Integration Server and your host computer with wizards or manually. Host Integration Server provides three wizards to help you install and configure connections to your host environment (HE).

The AS/400 Wizard, the Mainframe APPC/LU 6.2 Wizard, and the 3270 Wizard step you through configuring connection properties, creating 3270 display LUs and an LU pool, and assigning the LUs to the LU pool.

For information about the new IP-DLC Link Service, see IP-DLC Link Service.

The following procedures detail how to create connections:

Mainframe (3270) environments:

- Creating a 3270 Connection Using a Wizard
- Creating a 3270 Connection Manually

AS/400 (5250) environments:

- Creating a 5250 Connection Using a Wizard
- Creating a 5250 Connection Manually
- Creating a 5250 Local APPC LU
- Creating a 5250 Remote APPC LU

If you use a wizard to create your connections, most of the configuration information is added along with the criteria you entered when the wizard runs.

If you need to configure a connection manually, you may need to verify some of your connection information. For more information, see Important Connection Information.

Service Connection Point

During installation, a Service Connection Point in Active Directory is created by Host Integration Server 2009 that identifies this instance of the product. The Active Directory Schema defines a **serviceConnectionPoint** (SCP) object class to make it easy for a service to publish service-specific data in the directory. Users can search the Global Catalog for all instances of the product's Service Connection Point. When the Host Integration Server 2009 is uninstalled, the Service Connection Point is removed from Active Directory.

Service Connection Point properties

Property	Value\Description
serviceClassName	HISServer (matching the SPN used for Kerberos)
serviceBindingInformation	Name of the HIS Subdomain (blank if SNA Gateway is not installed)
serviceDNSNameType	'A' (meaning host type)
serviceDNSName	NETBIOS Host name
Keywords	List of words to identify this server.

Keyword list

Keyword	Description
"Host Integration Server 2009"	Product Name
"Microsoft"	Company Name
"8.0"	Product Version
{3CA45AFD-4759-4768-9BA2-FA516043DA34}	SNA Gateway
{39707A81-0933-453f-8D90-6A0CFA851D94}	Data Providers
{7609DE49-9AAC-41f0-A606-9BA2D69012A0}	Transaction Integrator
{80B96EA7-CD92-4067-BC4A-AC59F1B87602}	MSMQ-MQSeries Bridge
{52163C3B-D6D5-4c71-A768-DA581AA5D632}	Session Integrator

Creating and Configuring LUs

After you configure the connection, you can create the 3270 LUs. The LUs can be display LUs (terminal emulation), printer LUs, application LUs (LUAs), or downstream LUs.

Each 3270 LU is configured based on the type of connection used. If the connection is channel, 802.2, X.25, or Synchronous Data Link Control (SDLC), the LUs need an LU number, which identifies the LU on its connection. This number should match the LOCADDR= parameter of the LU definition in Virtual Telecommunications Access Method (VTAM) or in the Network Control Program (NET) Gen. Up to 254 LUs can be configured for each connection, and they can be consecutively configured as a range of LUs.

You can create LUs one at a time or in a consecutively numbered range. When you create a range of LUs, all the LUs are given the same properties. You can modify individual LUs after creating them.

For information about the new IP-DLC Link Service, see IP-DLC Link Service.

For procedures about creating LUs, see the following:

- Creating a 3270 Display LU
- Creating a 3270 Printer LU
- Creating a 3270 Application LU (LUA)
- Creating a 3270 Downstream LU
- Creating a Local APPC LU
- Creating a Remote APPC LU

For procedures about configuring LUs, see the following:

- Configuring a Range of 3270 LUs
- Assigning LUs to Workstations
- Associating 3270 Printer LUs with 3270 Display LUs
- Configuring Downstream Connections
- Configuring APPC LUs for TPs or 5250 Emulation
- Precedence of Accounts in Determining Default LUs

To modify a 3270 LU

1. In SNA Manager, ensure that the appropriate service is inactive by right-clicking **SNA service**, and then click **Stop**.
2. Double-click **Connections**, and then double-click the connection that contains the LU you want to view.
3. Right-click the LU whose properties you want to view, and then click **Properties**. Click the appropriate tab to view or modify the LU properties.
4. Click **Save Configuration** on the **Action** menu if you made changes, and then restart the affected service.

Note
Restarting the server disconnects all users. Try to schedule configuration changes when they least affect users.

How to Configure a Range of 3270 LUs

You can create a consecutively numbered range of logical units (LU). To do so, you must identify the base LU name limited to eight characters on which the numbered range of names will be built.

After identifying the base LU name, you can create the LUs by identifying the number of LUs in the range and the number the range will start with. Host Integration Server will create LUs using the sequential numbering scheme.

To configure a range of 3270 LUs

1. In SNA Manager, ensure that the appropriate service is inactive by right-clicking **SNA service**, and then click **Stop**.
2. Right-click the connection to which you want to assign the LUs. Point to **All Tasks**, and then click the **Range of LUs**.
3. Fill in the LU Creation Wizard, and click **Finish** when done.
4. On the **Action** menu, click **Save Configuration**.
5. On the **Action** menu, click **Refresh**.

Note
When you create a range of LUs, all the LUs are given the same properties. You can modify individual LUs after creating them.

See Also

Tasks

Creating and Configuring LUs

How to Create LU Pools

Although you can create individual LUs and assign them to users and groups, using LU pools to manage and deploy a large number of LUs is a more efficient method of administering these resources.

LU pools are groupings of 3270, LUA, or downstream LUs that allow you to maximize access to LUs. A user, LUA application, or downstream system using the pool can get LU access as long as one of the pooled LUs is available. If some of the pooled LUs are not functioning, the user, LUA application, or downstream system will not be affected, as long as another LU in the pool is available.

LU pools allow groups of intermittent users to use resources efficiently. For example, ten 3270 users who only need intermittent access may find that a pool of five 3270 LUs is adequate for their needs.

If a user needs access to multiple LU sessions, you can assign one LU or LU pool for each session that the user needs. A pool can be assigned multiple times to the same user.

An LU can be removed from an LU pool by simply deleting it from the pool.

The following procedures will help you manage your LU pools:

- To create LU pools
- To assign a 3270 LU to a connection
- To assign LUs and LU pools to users and groups
- To view LUs or pools assigned to users
- To add 3270 LUs to a pool
- To add a workstation and assign LUs
- To remove an LU from a pool

To create LU pools

1. In SNA Manager, right-click the **Pools** folder, point to **New**, and then click **3270 Display LU Pool**.
2. In **Pool Properties**, enter a name for your pool, up to eight characters in length. A comment is optional.
3. Leave the check box cleared, and click **OK**.
4. The new pool appears in the **Pools** folder.

To assign a 3270 LU to a connection

1. In SNA Manager, expand SNA service for the server you are working with, and then expand **Connections**.
2. Right-click the connection where you want to add the LU, point to **New**, and click the type of 3270 LU you want to assign.
3. In the **3270 LU Properties** box, enter the LU Name. The LU number is system-assigned.
4. Click **OK** to exit.
5. On the **Action** menu, click **Save Configuration**.

To assign LUs and LU pools to users and groups

1. In SNA Manager, right-click the LU or LU pool, click **Assign to User**, and then select the users you want to assign.
2. Click **OK**.
3. Verify that the state of the server is active and that the connections are available (either **OnDemand** or **Active**). If the server is not active, right-click the server in SNA Manager, and then click **Start**.

To view LUs or pools assigned to users

1. In SNA Manager, double-click **Configured Users**. Then click the user or group that you want to view. The details pane shows the LUs and pools assigned to that user or group, plus other details, such as status and LU number.
2. To view local or remote APPC LUs assigned to a user or group, right-click the targeted user or group, and click **Properties** under **Configured Users**. Click the **APPC Defaults** tab. When you are done viewing, click **Cancel**.

To add 3270 LUs to a pool

1. In SNA Manager, expand **Servers**, and then expand the server you are working with.
2. Expand **Connections**, and then click the connection that contains the needed 3270 LUs.
3. In the right pane, right-click the 3270 LU that you want to assign and click **Assign Pool**.
4. In the dialog box, click the pool to which you want to assign the LU, and then click **OK**.
5. Repeat steps 2 and 3 for each LU that you want to assign to a pool.
6. On the **Action** menu, click **Save Configuration**.

Note

To verify that the LUs are in the correct pool, make sure the **Pools** node is expanded, double-click the name of the affected p ool, and view its LUs in the details pane.

Note

Both the LUs and the LU pool must be of the same type (3270).

To add a workstation and assign LUs

1. In SNA Manager, right-click **Workstations**, point to **New**, and then click **Workstation**.
2. Fill in the **Workstation Properties** dialog box.
3. Click **OK** to add the new workstation.
4. To assign LUs to the workstation, double-click **Connections**, and then double-click the connection that contains the needed LUs.
5. Right-click the LU that you want to assign, and click **Assign to Workstation**.
6. In the dialog box, click the workstation, and then click **OK**.
7. On the **Action** menu, click **Save Configuration**.

Note

All workstation users must be members of the same SNA subdomain. You can avoid having to add each user to the subdom ain by assigning the **Everyone** group to the subdomain and assigning no LUs to the group.

To remove an LU from a pool

1. In SNA Manager, click **Pools**.
2. Right-click the LU that you want to remove, and then click **Delete**.
3. In the **Confirmation** dialog box, click **Yes** to delete the LU.
4. On the **Action** menu, click **Save Configuration**.
5. On the **Action** menu, click **Refresh**.

Note

An empty pool provides no LU access.

See Also

Tasks

Creating and Configuring LUs

How to Assign LUs to Workstations

You can assign LUs to a workstation rather than a user, which makes it possible to lock LUs to a particular workstation. Assigning an LU to a workstation makes it easier for users to find and access different resources. For example, it makes it easier for a user at a workstation to use a printer located near the workstation, instead of one assigned to the user.

With this feature, you can insert a workstation object and define it by specifying parameters such as IP address, workstation name, and others. You can then assign 3270 display and printer LUs to the workstation. These LUs will be accessible to any users connecting from those workstations. The LUs do not need to be specifically assigned to the user.

For example, 200 hospital users share 50 workstations and 50 printers. Users may want to use any of the 50 workstations and 50 printers. They can log on to any of the 50 workstations and print using the printer attached to that workstation. Instead of assigning all 50 printers to 200 user accounts, the administrator can add the 50 workstations to Host Integration Server and assign a printer LU to each workstation. When a user logs on to any of the 50 workstations, the printer attached to that workstation will be available in the list of LUs.

You can also configure a workstation so that it will only allow the use of those LUs assigned to the workstation, regardless of the user who is logged on. You can assign LUs to workstations in the same manner that LUs are assigned to users.

For example, if the workstation is flagged for restricted access, a user cannot gain unauthorized access to other LUs regardless of the user ID and password that is used. This feature enhances network security.

To assign LUs to workstations

1. In the Host Integration Server console tree, right-click **Workstations**, point to **New**, and then click **Workstation**.
2. Fill in the **Workstation Properties** dialog box.
3. Click **OK** to add the new workstation.
4. To assign LUs to the workstation, click **Connections**, and then click the connection that contains the LUs.
5. Right-click the LU that you want to assign, and click **Assign to Workstation**.
6. Click the workstation, and click **OK**.
7. On the **Action** menu, click **Save Configuration**.

Note
All workstation users must be members of the same SNA subdomain. You can avoid having to add each user to the subdom ain by assigning the **Everyone** group to the subdomain and assigning no LUs to the group.

Tasks

How to Associate 3270 Printer LUs with 3270 Display LUs

How to Associate 3270 Printer LUs with 3270 Display LUs

Users who have host applications with direct relationships between display LUs and printer LUs can associate printers with the LUs.

You can associate a printer LU with a display LU. This feature is designed to support specialized host applications that have hard-coded associations between display LUs and printer LUs. When a 3270 display LU is configured to have an associated printer and then subsequently assigned to a user or group, users will see both the display LU and a special printer LU named ASSOCPRT. When users connect to the display LU, they can then open the ASSOCPRT LU, which Host Integration Server maps to the defined associated printer LU.

You can also add display LUs with associated printer LUs to LU pools. The LU pools can then be assigned to users and groups.

When multiple display LUs are assigned to users, the order in which the resources are opened is important. If all of the display LUs have associated printers, the user should alternate opening displays and ASSOCPRTs. If some of the display LUs do not have associated printers, use a naming convention so the user can determine the display LUs that have associated printers from those that do not.

To associate printer LUs to display LUs

1. In the Host Integration Server console tree, click **Pools**.
2. Right-click the display LU that you want to associate with a printer, and click **Properties**.
3. Click the **Associated Printer** tab.
4. In the **Associated Printer LU** box, select the printer that you want to associate, and then click **OK**.
5. Repeat steps 2 through 4 for each display LU that you want to associate with a printer LU.
6. On the **Action** menu, click **Save Configuration**.

Note
Printer LUs are available to any users or groups that have been assigned the corresponding display LUs.

Note
Associated printer LUs are assigned a generic placeholder name of *ASSOCPRT*.

Tasks

How to Assign LUs to Workstations

How to Configure Downstream Connections

You can configure Host Integration Server to enable downstream LUs to communicate with the host. Following are the general procedures:

1. Gather needed information about the host and downstream systems, including information about identifiers, such as addresses and exchange identification (XID), and information about Max BTU Length.

2. Configure the host connection as you would configure any other host connection. When specifying the remote end for the connection, select **Host System**.

3. Select the host connection and assign and configure one or more new downstream LUs.

4. Optionally, you can put downstream LUs into a pool to maximize their availability.

5. Configure the downstream connection. When specifying the remote end for the connection, select **Downstream**.

   The downstream connection can be an 802.2, SDLC, or X.25 connection. It cannot be a channel connection.

6. Select the downstream connection and associate the downstream LUs (from step 3) and LU pools (from step 4) with that connection.

7. If necessary, reorder the downstream LU numbers; that is, the LU numbers used by the downstream system.

   A downstream LU has two LU numbers: one recognized by the downstream system and one recognized by the host. These numbers need not match.

To put configuration changes into effect, save the configuration file and restart the server (if you have added a link service or connection).

Note
It is recommended that you manually separate the sessions of your downstream pools if you are upgrading from SNA Server 4.0 or later. If this is not done, you may experience incorrect behavior from Host Integration Server when attempting to connect downstream client computers.

After creating the downstream LUs, you must associate them with the downstream connection they will use. Downstream LUs do not stand alone and need to be mapped to the upstream LU. Associating the LUs with the upstream connection maps the correct downstream LUs to the correct upstream LUs.

Downstream LUs have two parameters:

- The LU number, which identifies the LU to the host.

- The downstream LU number, which identifies an LU or LU pool to the downstream system.

The LU number and the downstream LU number need not match, and probably will not match. The downstream LU number should match the LU number on the downstream system.

Check with the host administrator for the correct value of the LU number. It should match the LOCADDR= parameter of the LU definition in VTAM or in the NCP Gen. If the number you specify has already been assigned to an LU or an APPC LU-LU pair on the current connection, you must change the number. The range for LU numbers is 1 through 254.

Host Integration Server assigns a downstream LU number to each LU or LU pool assigned to the downstream connection. Host Integration Server assigns downstream LU numbers starting with 2 and ascending sequentially. Therefore, one way to change downstream LU numbers is to reorder the list of LUs for the downstream connection. Another way to change downstream LU numbers is to use empty LU pools to take up unwanted numbers, leaving the correct (larger) numbers for other LU pools or LUs.

Note

The LU numbers generated for an LU range are sequential. If the numbers assigned by your host administrator are not sequential, you can modify the numbers of individual LUs after they have been created.

You can move one or more downstream LUs to a different host connection, regardless of whether the LUs were created as part of a range. Although downstream LUs can be associated with multiple downstream connections, they can be assigned to only one host connection.

You can configure multiple LUs simultaneously by configuring them as a consecutively numbered range. After configuring the range of LUs, you can modify the numbering of individual LUs in the range.

To configure a downstream connection

1. In the Host Integration Server console tree, expand **Servers**, expand the server you are working with.
2. Right-click **Connections**, point to **New**, and click either **802.2**, **SDLC**, or **X.25**.
3. Fill in the **Connection Properties** dialog box, type a name for the new downstream connection, select a link service, and type a comment.
4. Under **Remote End**, select **Downstream**.
5. Under **Allowed Directions**, select an option. For SDLC downstream connections, select **Outgoing Calls**.
6. If you selected **Outgoing Calls**, under **Activation**, select either **On Server Startup** or **By Administrator**.
7. Click the other tabs to specify other connection parameters between the downstream system and Host Integration Server. Click **OK** to exit.
8. On the **Action** menu, click **Save Configuration**.
9. To put the configuration changes into effect, you must restart the server.

Note

Restarting the server disconnects all users. Try to schedule configuration changes when they least affect users.

Note

Two connections are needed for a downstream system: a downstream connection (from the downstream system to the computer running Host Integration Server) and an ordinary host connection (from the computer running SNA Server to the host).

Note

Activation does not affect incoming calls. A connection that accepts incoming calls begins to listen for these calls when the server node is started.

To assign a downstream LU to a host

1. Before you begin, verify that you have configured the host connection that the downstream LU will use.
2. Ensure that the server is inactive. If necessary, right-click the appropriate server node, and click **Stop**.
3. Double-click **SNA service**, and then double-click **Connections**.
4. Right-click the host connection to which you want to assign a downstream LU, point to **New**, and then click **Downstream LU**.
5. Enter the LU name. Click **OK** to exit.
6. On the **Action** menu, click **Save Configuration**.

Note

After you assign a new downstream LU to a host, you must also associate that LU with a downstream connection.

Note

A downstream LU pool must contain LUs from a single server. Downstream LUs cannot access pooled downstream LUs from multiple servers.

To view or modify a downstream LU

1. Right-click the LU whose properties you want to view, and click **Properties**.
2. In the **Properties** dialog box, do one of the following:
   - View the properties and click **Cancel**.
   - Modify the properties and click **OK**.
3. If you made changes, on the **Action** menu, click **Save Configuration**.
4. Stop and restart **SNA service**.

To assign a downstream LU

1. In the Host Integration Server console tree, expand **Servers**, expand the server you are working with, and then click **Connections**.
2. Right-click the host connection to which you want to assign the downstream LU, point to **New**, and click **Downstream LU**.
3. Fill in the **Connection Properties** dialog box, and click **OK**.
4. On the **Action** menu, click **Save Configuration**.

To associate a downstream LU with a downstream connection

1. Verify that the server is inactive. If necessary, right-click the service node and click **Stop**.
2. In the Host Integration Server console tree, select the downstream LUs from the host connection.

   To select several adjacent items, click the first item you want, hold down SHIFT, and click the last item.

   To select several nonadjacent items, hold down CTRL as you click the items that you want.
3. Drag the LUs from the host connection to the downstream connection.
4. On the **Action** menu, click **Save Configuration**.

Important

If a downstream system needs access to multiple LU sessions, assign one LU or LU pool for each session needed. You can ass ign a pool multiple times to the same downstream connection.

Note

Before you can associate downstream LUs with a downstream connection, you must define the host connection, downstream connection, and the LUs.

Note

Downstream LU pools must contain LUs from a single server. Downstream LUs cannot access pooled downstream LUs from multiple servers.

Tasks

Creating and Configuring LUs

How to Reorder Downstream LUs

An administrator might create a downstream LU called DOWNLU3, and then realize that two additional LUs are needed. After creating the LUs, with the names DOWNLU2 and DOWNLU4, the LUs would be associated with the listed LU numbers.

LU name	Downstream LU number
DOWNLU3	2
DOWNLU2	3
DOWNLU4	4

To change the downstream numbers so that they match the digits in the LU names, DOWNLU2 could be reordered so that it is placed before DOWNLU3.

LU name	Downstream LU number
DOWNLU2	2
DOWNLU3	3
DOWNLU4	4

To reorder the numbering of downstream LUs

1. Verify that the server is inactive. If necessary, right-click the server node, and click **Stop**.
2. In the Host Integration Server console tree, select the downstream connection with which the LUs are associated.
3. Select one or more LUs and pools that you want to move up in the list.

   To select several adjacent items, click the first item you want, hold down SHIFT, and click the last item.

   To select several nonadjacent items, hold down CTRL as you click the items that you want.
4. To move LUs up or down in the list, click the up or down arrow buttons on the Host Integration Server toolbar.
5. To put configuration changes into effect, restart the server.

To create a downstream pool

1. Right-click **Pools**, point to **New**, and then click **Downstream LU Pool**.
2. Type a pool name and, if desired, a comment. This name identifies the pool on SNA Server, not on the host or downstream system.
3. To add LUs to the new downstream pool, double-click **Connections**, and then double-click the connection that has the LUs you want to work with.
4. Verify that the **Pools** node is fully expanded, and drag the first LU into the pool.
5. To add more LUs to the pool, drag each LU from its place in the **Connections** folder to its downstream LU pool.
6. On the **Action** menu, click **Save**.

Note
Downstream LU pools must contain LUs from a single server. Downstream LUs cannot access pooled downstream LUs from multiple servers.

Tasks

Creating and Configuring LUs

How to Configure APPC LUs for TPs or 5250 Emulation

The following is an overview of the procedures to add and configure APPC LUs:

1. Assign the local APPC LU to a server.
2. Configure the local APPC LUs:
    - For an independent LU, specify the LU Alias, Network Name, and LU Name. Depending on system configuration, you may need to specify other information.
    - For a dependent LU, specify LU Alias, LU Number, and LU Name. Depending on system configuration, you may need to specify other information.
3. Create a remote APPC LU on a connection and configure the remote APPC LU:
    - For a remote LU to be used with an independent local LU, specify the LU Alias, Network Name, and LU Name. Depending on system configuration, you may need to specify other information. For communication with an AS/400 computer, make the remote LU name the same as the name of the AS/400 computer.
    - For a remote LU to be used with a dependent local LU, specify the LU Alias, Network Name, LU Name, and Uninterpreted LU Name. Depending on system configuration, you may need to specify other information.
4. Optionally, configure session security for the remote LU.
5. You must configure an appropriate mode if it has not already been done.
6. Optionally, assign a default local APPC LU and a default remote APPC LU to users and groups.
7. If you are using Common Programming Interface for Communications (CPI-C), configure one or more CPI-C symbolic destination names.
8. If you are using the display verb, you may want to change the default connection that Host Integration Server uses for the verb. To ensure that all changes take effect, restart the server.

Note
APPC LUs are used for transaction programs (TPs) or for 5250 emulation. APPC LUs used with TPs are generally for communication between TPs on different systems, not communication between TPs on a single system.

To add local and remote APPC LUs

1. In the Host Integration Server console tree, double-click **SNA service**, and then click **Local APPC LUs**.
2. On the **Action** menu, point to **New**, and click **Local LU**.
3. Configure the properties for the local LU, and then click **OK**.
4. To add the remote LU, click **Remote APPC LUs**.
5. On the **Action** menu, point to **New**, and click **Remote LU**.
6. Configure the properties for the remote LU, and click **OK**.
7. On the **Action** menu, click **Save Configuration**.

Note

APPC uses both local and remote LUs. These LUs need to be properly configured before Host Integration Server can communicate with the AS/400 computer.

Note

The option, **Member of Outgoing Local APPC LU Pool**, differs from other types of LU pools, such as the 3270, LUA, and downstream LU pools.

Note

Configuring session security for remote LUs is optional.

To configure incoming APPC sessions

1. Verify that you have configured a remote LU to represent the incoming host or that you have configured one remote LU for each host.
2. In the Host Integration Server console tree, double-click **Local APPC LUs**, and then click the local LU that you want to configure.
3. On the **Action** menu, click **Properties**.
4. Click the **Advanced** tab, specify the **Implicit Incoming Remote LU**, which is the name of the incoming host, and then click **OK**.
5. Repeat steps 2–4 for each local APPC LU that you want to configure.
6. On the **Action** menu, click **Save Configuration**.

Note

All incoming requests must specify a local LU name that is recognized by Host Integration Server, even when using an Implicit Incoming Remote LU and Implicit Incoming Mode.

To assign default APPC LUs to users or groups

1. In the Host Integration Server console tree, double-click **Configured Users**, and click the user or group that you want to configure.
2. On the **Action** menu, click **Properties**.
3. Click the **APPC Defaults** tab.
4. In the **Local APPC LU** box, select a default local APPC LU.
5. In the **Remote APPC LU** box, select a default remote APPC LU, and then click **OK**.
6. On the **Action** menu, click **Save Configuration**.

See Also

Tasks

Creating and Configuring LUs

Precedence of Accounts in Determining Default LUs

When user and group account memberships overlap, the highest-priority account that contains a default local APPC LU determines that LU for the user, and the highest-priority account that contains a default remote APPC LU determines that LU for the user. Accounts are prioritized as follows:

1. User accounts (highest priority)
2. Subdomain groups
3. Local groups
4. Well-known groups such as Everyone (lowest priority)

For example, suppose a user account (a high-priority account) called JOHND contains LOCLU1 as the default local APPC LU, but no default remote APPC LU. At the same time, suppose a local group (a low-priority account) of which JOHND is a member contains LOCLU2 as the default local APPC LU, and REMLU2 as the default remote APPC LU. For JOHND, the high-priority assignment, a default local APPC LU of LOCLU1, will be combined with the only other available assignment, a default remote APPC LU of REMLU2.

To assign or edit CPI-C information

1. In the Host Integration Server console tree, click **CPI-C Symbolic Names**.
2. On the **Action** menu, point to **New**, and click **CPI-C Symbolic Name**.
3. Fill in the **Properties** dialog box, and click **OK**.
4. On the **Action** menu, click **Save Configuration**.

Note
If you are using applications based on Common Programming Interface for Communications (CPI-C), use this procedure to c onfigure the CPI-C symbolic destination name.

To configure the default display verb

1. In SNA Manager, select the subdomain that you want to configure.
2. On the **Action** menu, click **Properties**.
3. Click the **Display Verb** tab.
4. Select the default connection for the display verb, and click **OK**.
5. On the **Action** menu, click **Save Configuration**.

Note
When the display verb does not specify a connection, Host Integration Server uses the connection that you specify in this pro cedure. If you do not specify a default display verbconnection, Host Integration Server randomly selects a connection for the verb to use.

Configuring hot backup involves setting up a system environment in which one resource can automatically fill in if another fails. In such a configuration, resources are interchangeable.

To configure hot backup for 5250 LUs

1. Configure one connection to the AS/400 computer for each computer that runs Host Integration Server and supports the 5250 protocol.
2. Create a local LU on each server, specifying the following:

- For **LU 6.2 Type**, select **Independent**.
- For **LU Alias**, specify the same string on each server.
- For **LU Name**, specify a unique string on each server. This is required to avoid device name conflicts across servers.

3. Create a remote LU on each server and give all the remote LUs the same LU name and alias, (which must match the Control Point Name of the AS/400 computer).

   Be sure that the **Supports Parallel Sessions** box is selected for these LUs.

4. Make the local and remote LUs available to users and groups, by doing one of the following:
   - For each group or user that uses 5250, select the appropriate default local APPC LU and the appropriate default remote APPC LU.
   - To keep this process simple, use or create a group that includes all 5250 users, and assign the appropriate default LUs to that group.
   - For the 5250 emulator, have users specify the local and remote LUs when configuring a session on the emulator.

Note
To achieve hot backup, Host Integration Server chooses a server to connect with the AS/400 computer based on availability. This distributes the load more evenly.

Note
To configure hot backup for 5250 users, you must configure multiple servers and pairs of LUs that can all handle sessions to the intended AS/400 computer.

Note
For better protection against failure, use multiple servers, and not multiple connections on the same server.

To configure a server with multiple connections to the same AS/400 computer

1. In the Host Integration Server console tree, double-click **Connections**.
2. Click the first connection that you want to configure.
3. On the **Action** menu, click **Properties**.
4. Click the **System Identification** tab, and fill in the properties for the local and remote node.
5. Click **OK** to exit the dialog box.
6. Repeat steps 2 through 5 for each connection to the same AS/400 computer.
7. On the **Action** menu, click **Save Configuration**.
8. After you configure a connection, you must stop and restart the server.

Important
Each connection to the same AS/400 computer must use a separate link service.

Note
This procedure makes the fully qualified network name unique for each connection.

Note

The settings that you specify in this procedure override the fully qualified network name configured in the properties for the server.

To configure a connection for dynamic definition of remote APPC LUs

1. Select the connection that you want to configure.
2. On the **Action** menu, click **Properties**.
3. On the **General** tab in the **Properties** dialog box, select **Supports Dynamic Remote APPC LU Definition**, and click **OK**.
4. On the **Action** menu, click **Save Configuration**.

Tasks

How to Configure APPC LUs for TPs or 5250 Emulation

User Management

Although Host Integration Server uses the User accounts of the Microsoft Windows Server 2003 or Windows 2000 Active Directory directory service, users must be configured to use Host Integration Server resources such as LUs.

To create users

1. In SNA Manager, expand the SNA subdomain where the users reside.
2. Right-click **Configured Users**, point to **New**, and then click **User**.
3. Select a user (or group) from the list, and then click **OK**.

To view active 3270 users

1. In SNA Manager, expand **Servers**, and then expand the server you are working with.
2. Click **Active Users**. The results pane shows the active 3270 users and provides details such as **User Name**, **Client**, and **Server**.

Operations

This section includes individual Users Guides for all feature sets of Host Integration Server. These guides contain the concepts, procedures, and security best practices necessary to operate your deployment of Host Integration Server.

In This Section

BizTalk Adapters

This release of Microsoft Host Integration Server includes the following four adapters:

- The **Microsoft BizTalk Adapter for Host Applications** is designed for BizTalk Server. It is based on technology in Microsoft Transaction Integrator (TI) for Windows-Initiated Processing, which enables efficient client access to existing IBM mainframe zSeries (CICS and IMS) or midrange iSeries (RPG) server programs. The TI design tools are integrated with Visual Studio and BizTalk Server solutions, enabling IT developers to be highly productive when defining the client proxy and creating the XSD schema. For BizTalk Server administrators, the existing TI Manager, Microsoft Management Console (MMC) snap-in, has been enhanced to improve supportability and support the required remote BizTalk Server solution deployment scenarios.

  For more information, see BizTalk Adapter for Host Applications.

- The **Microsoft BizTalk Adapter for Host Files** is an advanced data adapter that enables IT organizations to access and integrate information stored in host file systems, including mainframe zSeries VSAM datasets and midrange iSeries physical files. The Visual Studio 2005 design tool is used within a BizTalk Server solution to define a metadata map of the host program-described files, which is then exported as XSD for use with the BizTalk adapter. The configuration wizards are integrated into the BizTalk Server administration tools, allowing IT professionals to define dynamic send ports and static and solicit response receive ports, based on a simplified set of SQL commands (SELECT, INSERT, UPDATE, DELETE). This BizTalk adapter is based on a new Microsoft .NET Framework Data Provider for Host Files that maps SQL to non-relational host datasets and members. This makes it simple for non-programmers to read and write host file data sources.

  For more information, see BizTalk Adapter for Host Files.

- The **Microsoft BizTalk Adapter for DB2** is a relational database adapter that enables IT professionals to access vital data stored in IBM DB2 database servers on remote host computing platforms, IBM mainframe zSeries and midrange iSeries (DB2/400), and also IBM DB2 Universal Database (UDB) on open platforms. Using standard SQL commands and a configuration wizard built into BizTalk Server administration tools, IT professionals can create solutions that read and write to DB2 without any need for database programming. The new DB2 adapter, which is based on an updated Microsoft .NET Framework Data Provider for DB2, supports a broad range of functions, including dynamic send ports, and static and solicit response receive ports.

  For more information, see BizTalk Adapter for DB2.

- The **Microsoft BizTalk Adapter for WebSphere MQ (Client-Based)** uses IBM WebSphere MQ Client (Base-Client) and IBM WebSphere MQ Extended Transactional Client (Extended-Client) APIs to communicate with remote MQSeries Queue Managers. The adapter enables BizTalk Server to communicate directly with MQSeries Queue Managers deployed on non-Windows operating systems, without needing to deploy and manage WebSphere MQ Server for Windows, to efficiently exchange messages with line-of-business applications across the enterprise. When used with the Base-Client, the adapter provides non-transactional message processing, guaranteeing only the delivery of messages. It is the responsibility of the application on the receiving end to handle any duplicate messages. When used with the Extended-Client, the adapter provides transactional message processing to guarantee once-and-only-once delivery of messages.

  For more information, see BizTalk Adapter for WebSphere MQ.

Operations

BizTalk Adapter for DB2

The BizTalk Adapter for DB2 is a send and receive adapter that enables BizTalk orchestrations to interact with host systems. Specifically, the adapter enables send and receive operations over TCP/IP and APPC connections to DB2 databases running on mainframe, AS/400, and UDB platforms. Based on Host Integration Server technology, the adapter uses the Data Access Library to configure DB2 connections, and the Managed Provider for DB2 to issue SQL commands and stored procedures.

The adapter serves two main functions:

- For **Send** operations (both One Way and Solicit Response), the adapter sends SQL commands and stored procedures to a DB2 instance, with the option of soliciting a response.

- For **Receive** operations (One Way only), the adapter creates an SQL command or stored procedure that polls DB2 objects and creates per-row messages, which are then submitted to the BizTalk message system.

In addition, the BizTalk Adapter for DB2 uses the standard BizTalk Adapter tracing tool as a troubleshooting mechanism.

Installation Components

You can only install BizTalk Adapter for DB2 on a computer that is already running BizTalk Server and its prerequisites.

Required Components

The adapter installation package installs the following on your BizTalk Server computer:

- BizTalk Adapter for DB2
- Managed Provider for DB2
- Data Access Library
- Nodeless Host Integration Server server installation and configuration
- DRDA IP Resync Service (DUW)
- SNA Resync Service

Optional Components

- Distributed Units of Work for DB2
- Host Integration Server configured for APPC connections
- Microsoft Enterprise Single Sign-On

Apart from this installation, and the configuration steps outlined in the other topics in this section, no additional registration is necessary.

How to Create a Send Port for the DB2 Adapter

You create a send port for the BizTalk Adapter for DB2 by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions in the Single Sign-On (SSO) database.

To configure a send port

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click B**izTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a send port.
3. Right-click **Send Ports**, point to **New**, and then click **Static One-way Send Port**.

   The **Send Port Properties** dialog box appears.
4. In the **Transport Type** field, select **DB2**.
5. Click **Configure**.

   The **DB2 Transport Properties** dialog box appears.
6. Configure the following properties:

Use this	To do this
Connection String	The name of a connection string that is used to connect to the DB2 database. To configure a new or existing Connection String, click the ellipsis (**...**). This starts the Data Source Wizard. To access Help, click **Help** on the wizard pages, or open the Host Integration Server Help and look in **Technical Reference - UI Help - Data Integration Help - Data Source Wizard**.
Document Target Namespace	The target namespace that is used in the XML documents that are sent to DB2.
Response Root Element Name	The root element name that is used in the XML documents that are received from DB2. (This property may be empty for a one-way port.)
URI	Uniform resource identifier. A name to identify the send port location. Default is DB2://.

7. Click **OK** to return to the **Send Port Properties** dialog box.
8. In the **Send Handler** field, select the host instance on which the send adapter is running.
9. In the **Send Pipeline** field, select the pipeline that processes messages that are sent through this port. To configure a Send Pipeline, click "**..**".

   For more information, click **Help** on the property pages.
10. You can configure additional properties by clicking the following tabs: **Transport Advanced Options**, **Backup Transport**, **Outbound Maps**, **Filters**, **Certificate**, and **Tracking**.

    For more information click **Help** on these tabs.
11. When you are finished with configuration, click **OK** to close the **Send Port Properties** dialog box and return to the BizTalk Server Administration console tree.
12. In the **Send Ports** window, right-click the send port in the **Name** column and select **Enlist**.
13. Right-click the send port in the **Name** column and select **Start**.

BizTalk Adapter for DB2

How to Create a Receive Port and a Receive Location for the DB2 Adapter

You create a receive port and receive location for the BizTalk Adapter for DB2 by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions in the Single Sign-On (SSO) database.

To configure a receive port and a receive location

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a send port.
3. Right-click **Receive Ports**, point to **New**, and then click **Static One-way Receive Port**.

   The **Receive Port Properties** dialog box appears.
4. Configure the properties and then click **OK**.

   For more information, click **Help**.
5. In the console tree, right-click **Receive Locations**, point to **New**, and then click **One-way Receive Location**.

   The **Select a Receive Port** dialog box appears.
6. Select the receive port you created in step 3, and then click **OK**.

   The **Receive Location Properties** window appears.
7. In the **Transport Type** field, select **DB2**, and then click **Configure**.

   The **DB2 Transport Properties** dialog box appears.
8. Configure the following properties:

Use this	To do this
Connection String	Enter the name of a connection string that will be used to connect to the DB2 database. To configure a new or existing Connection String, click the ellipsis (**...**). This starts the Data Source Wizard. To access Help, click **Help** on the wizard pages, or open the Host Integration Server Help and look in **Technical Reference - UI Help - Data Integration Help - Data Source Wizard**.
Document Root Element Name	The root element name that is used in the XML documents that are received from DB2.
Document Target Namespace	The target namespace that is used in the XML documents that are received from DB2.
SQL Command	The select or stored procedure command that is executed one time for each polling interval.

Update Command	The command that is executed after each row in the receive operation is processed. It can be either a delete statement that deletes the row from the table in the SQL command, or an update command that statically modifies one or more rows. When this option is specified, the SQL command must be a Select statement and must access a single table.
URI	A name identifying the receive port location. Default is DB2://.
Polling Interval	The number of units between polling requests. Allowed range is 1 - 65535.
Polling Unit of Measure	The unit of measure (seconds, minutes, or hours) used between polling requests. Default is seconds.
Message Batch Size	When an SQL command returns a result set to the DB2 receive adapter, the adapter submits one message to the BizTalk message engine for each row in the result set. This is referred to as a single row receive. The receive adapter can optionally return the result set in its entirety as a single message to the BizTalk message engine. Messages can also have a fixed number of rows in them (for example, one message contains 10 rows). Default is -1.

9. Click **OK** to return to the **Receive Location Properties** dialog box.
10. In the **Receive Handler** field, select the instance of the BizTalk Server host on which the receive location will run. The receive handler must be running on this host.
11. In the **Receive Pipeline** field, select the receive pipeline to use to receive messages at this receive location.
12. To configure a receive pipeline, click "**..**". For more information, click **Help** on the property pages.
13. To configure scheduling, click the **Schedule** tab.

    For more information, click **Help** on the **Schedule** tab.
14. When you are finished with configuration, click **OK** to close the **Receive Location Properties** dialog box and return to the BizTalk Server Administration console tree.
15. In the **Receive Locations** window, right-click the receive location in the **Name** column and select **Enable**.

How to Create a Schema for the DB2 Adapter

To create the XSD schemas for the BizTalk Adapter for DB2, you use the DB2 Schema Generation Wizard.

To generate the DB2 schema

1. Open your BizTalk Visual Studio project.
2. Right-click the project, point to **Add**, and then click **Add Generated Items**.
3. In the **Add Generated Items** dialog box, select **Add Adapter Metadata**.

   This starts the Add Adapter Wizard.
4. On the **Select Adapter** page, select **DB2**, and then click **Next**.

   This starts the DB2 Adapter Schema Generation Wizard.
5. On the **Database Information** page, create a connection string, or select an existing connection string.

   This can be Initial Catalog, Package Collection, (TCP Address and Port) or (APPC Local LU, Remote LU, and Mode), (User Name and Password), or (Integrated Security). Maximum length is 1024.
6. On the **Schema Information** page, define the default namespace, root elements, and port type to be used in the schema.

   If you select **Receive port**, only a request document root element name is needed. If you select **Send port**, both request and response document root element names are required.
7. On the **Statement Type Information** page, select the type of database command to be issued.

   If you selected receive ports on the previous page, you can choose either a SELECT SQL statement or a stored procedure. If you selected send ports on the previous page, you can choose to issue an updategram, stored procedure, or SELECT statement.
8. On the **Statement Information** page, enter the details about the DB2 database.

   Depending on the information entered on earlier pages, the following properties are available:

   a. **Receive Select Statement** If you chose to use a receive port with an SQL statement, you can either select, or browse to, the statement here.

   b. **Receive Stored Procedure** If you chose to use a receive port and issue a stored procedure, you can select a stored procedure from the current connection's catalog. You must enter values for all parameters on this page.

   c. **Send Updategram** If you chose to use a send port and updategrams, you can select an updategram operation here, and also the table and columns that will be present in the updategram.

   d. **Send Stored Procedure** If you chose to use a send port and issue a stored procedure, you can select a stored procedure from the current connection's catalog. You do not have to enter values for all parameters on this page.

   e. **Send Select Statement** If you chose to use a send port with an SQL SELECT statement, you can either select, or browse to, the statement here.

9. On the **Completing the DB2 Transport Schema Generation Wizard** page, click **Finish**.

How to Create a BizTalk Application Using the DB2 Adapter

After you create the schema, ports, and receive locations for the BizTalk Adapter for DB2, you can start coding your BizTalk application.

To create a BizTalk application using the DB2 Adapter

1. Create a BizTalk project to hold your BizTalk application.
2. Use the schema that you created in How to Create a Schema for the DB2 Adapter to describe the DB2 database to the BizTalk application.
3. Use the send port that you created in How to Create a Send Port for the DB2 Adapter to send data to the DB2 database.
4. If necessary, use the receive port and location that you created in How to Create a Receive Port and a Receive Location for the DB2 Adapter to receive data from the DB2 database.
5. Add any additional orchestrations, components, or code, as necessary.
6. Test your application.
7. After you finish testing your application, create an .msi package to move your application to a staging or live server.

Data Access Library

BizTalk Adapter for Host Files

The BizTalk Adapter for Host Files is a send and receive adapter that enables BizTalk orchestrations to interact with host systems. Specifically, the adapter enables send and receive operations over TCP/IP and APPC connections to host files that run on mainframe and AS/400 platforms. Based on Host Integration Server technology, the adapter uses Data Access Library metadata assemblies to configure connections, and the Microsoft .NET Framework data provider for host files to issue SQL commands and stored procedures.

The adapter serves two main functions:

- For **Send** operations (both One Way and Solicit Response), the adapter sends SQL commands and system commands to a host file instance, with the option of soliciting a response.

- For **Receive** operations (One Way only) the adapter creates an SQL command that polls host file objects and creates per-row messages, which are then submitted to the BizTalk message system.

In addition, the BizTalk Adapter for Host Files uses the standard BizTalk Adapter tracing tool as a troubleshooting mechanism.

Note
The BizTalk Adapter for Host Files is a non-transactional adapter. This means that once an action is performed, it cannot be u ndone or rolled back.

Installation Components

You can only install BizTalk Adapter for Host Files on a computer that is already running BizTalk Server and its prerequisites.

Note
To run the native 64-bit (X64) adapter, you must use a 64-bit (X64) BizTalk Server 2006 host instance.

Note
This adapter requires the SNA DDM Service. Before using the adapter, check to see that the SNA DDM Service is running by using either Services in Control Panel or the NET START SNADDM Windows command.

Note
All editions of BizTalk Server 2000, BizTalk Server 2002, and BizTalk Server 2004 can be installed on an x64 operating system but only the **BizTalk Server 2006** Enterprise and **BizTalk Server 2006** Developer editions support running a **BizTalk Server 2006** host instance using native 64-bit execution.

Required Components

The adapter installation package installs the following components on your BizTalk Server computer:

- BizTalk Adapter for Host Files
- Managed Provider for Host Files
- Data Access Library
- Nodeless Host Integration Server server installation and configuration

Optional Components

- Host Integration Server configured for APPC connections
- Microsoft Enterprise Single Sign-On

Apart from this installation, and the configuration steps that are outlined in the topics in this section, no additional registration is necessary.

How to Create a Metadata Assembly for the Host File Adapter

After you install the adapter, you can create a metadata assembly that describes your remote system to BizTalk Server.

To create a metadata assembly

1. Create a Host File project and application in Visual Studio.

   Part of the process of creating a Host File application in Visual Studio is describing the layout of the host file system. This process creates both a metadata assembly and a schema. The metadata assembly is a programmatic representation of the remote host file system, whereas the schema is an XML representation of the host file system. You will use the metadata assembly to describe the host file system to BizTalk Server.

   For more information about how to create a Host File application in Visual Studio, see How to Create an Application Using the Managed Data Provider for Host Files.

How to Create a Send Port for the Host File Adapter

You create a send port for the BizTalk Adapter for Host Files by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions on the Enterprise Single Sign-On (SSO) database.

To configure a send port

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a send port.
3. Right-click **Send Ports**, point to **New**, and then click **Static One-way Send Port** or **Solicit Response Send Port**.

   The **Send Port Properties** dialog box appears.
4. In the **Transport Type** field, select **Host File**.
5. Click **Configure**.

   The **Host File Transport Properties** dialog box appears.
6. Configure the following properties:

Use this	To do this
Connection String	The name of a connection string that is used to connect to the Host File database. To configure a new or existing connection string, click the ellipsis (**...**). This starts the Data Source Wizard. To access Help, click **Help** on the wizard pages, or open the Host Integration Server Help and look in **Technical Reference - UI Help - Data Integration Help - Data Source Wizard**.
Document Target Namespace	The target namespace that is used in the XML documents that are sent to the host.
Response Root Element Name	The root element name that is used in the XML documents that are received from the host. (This property may be empty for a one-way port.)
URI	Uniform resource identifier. A name to identify the send port location.

7. Click **OK** to return to the **Send Port Properties** dialog box.
8. In the **Send Handler** field, select the host instance on which the send adapter is running.
9. In the **Send Pipeline** field, select the pipeline that processes messages sent through this port.
10. To configure a Send Pipeline, click "**..**".

    For more information, click **Help** on the property pages.
11. You can configure additional properties by clicking the following tabs: **Transport Advanced Options**, **Backup Transport**, **Outbound Maps**, **Filters**, **Certificate**, and **Tracking**.

    For more information, click **Help** on these tabs.
12. When you are finished with configuration, click **OK** to close the **Send Port Properties** dialog box and return to the BizTalk Server Administration console tree.
13. In the **Send Ports** window, right click the send port in the **Name** column and select **Enlist**.
14. Right-click the send port in the **Name** column and select **Start**.

How to Create a Receive Port and a Receive Location for the Host File Adapter

You create a receive port and receive location for the BizTalk Adapter for Host Files by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions in the Single Sign-On (SSO) database.

To configure a receive port and a receive location

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a send port.
3. Right-click **Receive Ports**, point to **New**, and then click **Static One-way Receive Port**.

   The **Receive Port Properties** dialog box appears.
4. Configure the properties and then click **OK**.

   For more information, click **Help**.
5. In the console tree, right-click **Receive Locations**, point to **New**, and then click **One-way Receive Location**.

   The **Select a Receive Port** dialog box appears.
6. Select the receive port you created in step 3, and then click **OK**.

   The **Receive Location Properties** window appears.
7. In the **Transport Type** field, select **HostFiles**, and then click **Configure**.

   The **HostFiles Transport Properties** dialog box appears.
8. Configure the following properties:

Use this	To do this
Connection String	Enter the name of a connection string that will be used to connect to the host database. To configure a new or existing connection string, click the ellipsis (**...**). This starts the Data Source Wizard. To access Help, click **Help** on the wizard screens, or open the Host Integration Server Help and look in **Technical Reference - UI Help - Data Integration Help - Data Source Wizard**. When configuring a receive location or send port based on the BizTalk Adapter for Host Files, the metadata definition should be created as a metadata assembly and not an HCD file. For instructions on how to create a metadata assembly, see How to Create an Application Using the Managed Data Provider for Host Files.
Document Root Element Name	The root element name that is used in the XML documents that are received from the host.
Document Target Namespace	The target namespace that is used in the XML documents that are received from the host.
SQL Command	The Select command that is executed one time for each polling interval.

Update Command	The command that is executed after each row in the receive operation is processed. It can be either a delete statement that deletes the row from the table in the SQL command, or an update command that statically modifies one or more rows. When this option is specified, the SQL command must be a Select statement and access a single table. You can specify additional properties by clicking the ellipsis (**...**) button. This opens the **Change Command** dialog box, which provides three options: • **Do nothing** clears the other two options if selected. • **Delete after read** deletes the row after the adapter has read it. • **Update** lets you type an SQL command to be updated.
URI	Uniform resource identifier. A name identifying the receive port location.
Polling Interval	The number of units between polling requests. Allowed range is 1 - 65535.
Polling Unit of Measure	The unit of measure (seconds, minutes, or hours) used between polling requests. Default is seconds.

9. Click **OK** to return to the **Receive Location Properties** dialog box.
10. In the **Receive Handler** field, select the instance of the BizTalk Host on which the receive location will run. The receive handler must be running on this host.
11. In the **Receive Pipeline** field, select the receive pipeline to use to receive messages at this receive location.

    To configure a receive pipeline, click "**..**". For more information, click **Help** on the property pages.
12. To configure scheduling, click the **Schedule** tab.

    For more information, click **Help** on the **Schedule** tab.
13. When you are finished with configuration, click **OK** to close the **Receive Location Properties** dialog box and return to the BizTalk Server Administration console tree.
14. In the **Receive Locations** window, right-click the receive location in the **Name** column and select **Enable**.

BizTalk Adapter for Host Files

Data Access Library

Managed Data Provider for Host Files

How to Create a Schema for the Host File Adapter

You can use the Host File Schema Generation Wizard to create the XSD schemas for the BizTalk Adapter for Host Files. After you create the schema, you are ready to continue configuration on the BizTalk Server side.

To generate the Host File schema

1. Open your BizTalk Server Visual Studio project.
2. Right-click the project, point to **Add**, and then select **Add Generated Items**.
3. In the **Add Generated Items** dialog box, select **Add Adapter Metadata**.

   This starts the Add Adapter Wizard.
4. On the **Select Adapter** page, select **Host File**, and then click **Next**.

   This starts the Host File Adapter Schema Generation Wizard.
5. On the **Database Information** page, browse to an existing connection string or create a new one.

   This can be Initial Catalog, Package Collection, (TCP Address and Port) or (APPC Local LU, Remote LU, and Mode), (User Name and Password), or (Integrated Security). Maximum length is 1024.
6. On the **Schema Information** page, define the default namespace, root elements, and port type that you want to use in the schema.

   If you select **Receive port**, only a request document root element name is needed. If you select **Send port**, request and response document root element names are required.
7. On the **Statement Type Information** page, select the type of database command to be issued.

   If you selected send ports on the previous page, you can choose to issue an updategram, stored procedure, or SELECT statement. If you selected receive ports, this step is unnecessary.
8. On the **Statement Information** page, enter the details about the host file.

   Depending on the information entered on earlier pages, the following properties will be available. If you selected send port:

   - **Send Updategram** If you chose to use a send port and updategrams, you can select the updategram operation here, and also the table and columns that will be present in the updategram.
   - **Send System Command** If you chose to use a send port and issue a stored procedure, you can select a stored procedure from the current connection's catalog. You do not have to enter values for all parameters on this page.
   - **Send Select Statement** If you chose to use a send port with an SQL Select statement, you can either select or browse to the statement here.

   If you selected receive port:

   - **Receive Select Statement** If you chose to use a receive port with an SQL statement, you can either select or browse to the statement here.
   - **Send Updategram** If you chose to use a send port and updategrams, you can select the updategram operation here, and also the table and columns that will be present in the updategram.
   - **Send Stored Procedure** If you chose to use a send port and issue a stored procedure, you can select a stored procedure from the current connection's catalog. You do not have to enter values for all parameters on this page.
   - **Send Select Statement** If you chose to use a send port with an SQL Select statement, you can either select or browse to the statement here.

9. On the **Completing the Host File Transport Schema Generation Wizard** page, click **Finish**.

How to Create a BizTalk Application for the Host File Adapter

After you create the schema, you can code your BizTalk application. Your application will use the metadata assembly that you created in Visual Studio, in addition to the schema and ports that you created in previous steps.

To create a BizTalk application using the Host File Adapter

1. Create a BizTalk project to hold your BizTalk application.
2. Use the schema that you created in How to Create a Schema for the Host File Adapter to describe the Host File system to the BizTalk application.
3. Use the send port that you created in How to Create a Send Port for the Host File Adapter to send data to the host file system.
4. If necessary, use the receive port and location that you created in How to Create a Receive Port and a Receive Location for the Host File Adapter
5. Add any additional orchestrations, components, or code, as necessary.
6. Test your application.
7. After you finish testing your application, create an .msi package to move your application to a staging or live server.

   When you are creating a BizTalk Server .msi package, make sure that you include the host file metadata assembly that you created in How to Create a Metadata Assembly for the Host File Adapter.

BizTalk Adapter for Host Files

BizTalk Adapter for Host Applications

The Microsoft BizTalk Adapter for Host Applications is based on technology in Transaction Integrator (TI) that enables enterprises to connect BizTalk Server solutions to existing IBM mainframe zSeries (CICS and IMS) or midrange iSeries (RPG) server programs. The adapter offers an intuitive Visual Studio 2005 designer, including host COBOL and RPG source code import wizards, with which to generate XSD schemas for use in BizTalk projects. The administration tools are integrated with the BizTalk Server port configuration and deployment tools. Using this adapter, IT professionals can efficiently extend existing business rules in host programs with new solutions based on BizTalk Server 2006.

Note
A receive location is not available for this adapter.

A typical scenario involves the following steps:

- The IT professional installs the adapter.
- The IT professional configures the adapter and uses Transaction Integrator to define the Remote Environment.
- The developer creates the BizTalk application in Visual Studio. This involves defining the Remote Environment, building the TI assembly and schema, deploying, testing, and debugging the application, exporting the assemblies, and building the export package for use by BizTalk Server.
- Finally, the IT professional imports the developer's application into BizTalk Server, updates any necessary information, and deploys the application.

Tracing tools are available to debug your deployed application and improve its performance.

Some knowledge of Transaction Integrator is necessary. For an overview of TI basics, see the Transaction Integrator User's Guide.

In This Section

Installation Components

The following software must be installed on the appropriate computers.

Development Computer

The following software must be installed on the computer where the developer will create the BizTalk application:

- Windows Server 2003
- Visual Studio 2005
- SQL Server 2005
- BizTalk Server 2006
- BizTalk Adapter for Host Applications (or Host Integration Server)

Deployment Computer

The following software must be installed on the computer where the IT professional will deploy the BizTalk application:

- Windows Server 2003
- SQL Server 2005
- BizTalk Server 2006
- BizTalk Adapter for Host Applications

Installing the Adapter

If you installed Host Integration Server, the BizTalk Adapter for Host Applications was installed by default. If it was not, or if you have uninstalled it, rerun the Host Integration Server Setup program. When you reach the **Select Components** screen, select **Adapters** and then select **BizTalk Adapter for Host Applications**.

BizTalk Adapter for Host Applications

How to Configure SSO for the Host Application Adapter

When using the BizTalk Adapter for Host Applications with the BizTalk Server Service Account, it is necessary to create and map a Single Sign-On Affiliate Application.

To create and map the Affiliate Application

1. In the **Enterprise Single Sign-On Management Console**, create an SSO Affiliate Application. For more information, see How to Create an Affiliate Application.
2. Create a mapping for the Host Instance Account. For more information, see How to Create User Mappings.
3. In **TI Manager**, right-click the **Host Instance Account**, and then click **Properties**.
4. Click the **Security** tab.
5. In the **Affiliate Application** field, choose the SSO mapping you just created, and click **OK**.
6. In the BizTalk Server Administration console, right-click the **Send Port** for this adapter, and then click **Properties**.
7. On the **Properties** page, confirm that **SSO Affiliate Application** is set to **<Use RE settings>**.
8. Confirm that **Allow application to override selected authentication** is not selected.
9. Click **OK**.

How to Create a Send Port for the Host Application Adapter

You create a send port for the BizTalk Adapter for Host Applications by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions in the Single Sign-On (SSO) database.

To configure a send port

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a send port.
3. Right-click **Send Ports**, point to **New**, and then click **Solicit Response Send Port**.

   The **Send Port Properties** dialog box appears.
4. In the **Transport Type** field, select **HostApps**.
5. Click **Configure**.

   The **HostApps Transport Properties** dialog box appears.
6. Configure the following properties:

Use this	To do this
Host Type	Defines the type of host that the adapter instance will interact with. The Host Type is a three part name: "TI" <TI Programming model / RE Style> <RE Override name> • The first part of the name is always TI. • The second part is the TI RE Style. • The third part is the optional RE Override Name. You can change the host type or RE Override by clicking the ellipsis (**...**) to start the **Select Host Type and RE Override** dialog box.
TI Remote Environment Type	Displays a list of all available Remote Environment class types. Selecting <Any host type> will allow message processing with no restrictions.
RE Override	Enables the adapter administrator to change the Remote Environment destination at run time. This is useful if, in addition to the central production RE, a test or backup RE is required. If selected, this will apply to all messages that flow through the specific adapter instance. This option is only available when the TI Remote Environment Type is set to a valid RE Class, and is not available if the TI Remote Environment Type is set to <Any host type>.

Implicit Persistent Connections	Enables the adapter to use TI persistent connections in the case where a batch of messages is delivered to the adapter for processing. The adapter evaluates the messages in the batch to determine the viability of using a persistent connection. For example, persistent connections could be used in the following scenarios: • When TRM Link, ELM Link, CICS Link, IMS Connect or DPC are used, and all messages are associated with the same TI object. • When TRM User Data, ELM User Data, or CICS User Data is used, and all messages are associated with the same TI object and method. If it is selected, the adapter will sort the messages into logical groups to facilitate the use of persistent connections.
Use Transactions	Allows a remote environment to be used with or without transactions through multiple instances of this adapter.

7. Click **OK** to return to the **Send Port Properties** dialog box.
8. In the **Send Handler** field, select the host instance on which the send adapter is running.
9. In the **Send Pipeline** field, select the pipeline that processes messages that are sent through this port.
10. To configure a Send Pipeline, click "**..**".

    For more information, click **Help** on the property pages.
11. You can configure additional properties by clicking the following tabs: **Transport Advanced Options**, **Backup Transport**, **Outbound Maps**, **Filters**, **Certificate**, and **Tracking**.

    For more information, click **Help** on these tabs.
12. When you are finished with configuration, click **OK** to close the **Send Port Properties** dialog box and return to the BizTalk Server Administration console tree.
13. In the **Send Ports** window, right-click the send port in the **Name** column and select **Enlist**.
14. Right-click the send port in the **Name** column and select **Start**.

BizTalk Adapter for Host Applications

Creating an Application for the BizTalk Adapter for Host Applications

The following list describes the steps that you must follow to create an application that uses the BizTalk Adapter for Host Applications:

1. Set your mainframe environment and communications protocols to run your application.

2. Create a Visual Studio solution to contain all the necessary BizTalk and Host Integration Server projects for your application.

3. Create a Transaction Integrator (TI) project that will hold the interface definition of the host application.

   If necessary, you may modify the generated XML file to pass client context information.

4. Create a BizTalk project that will hold your BizTalk application, using the created interface definition and associated schema.

5. Create your BizTalk application, using the ports and settings that were defined earlier.

6. Associate the interface definition with the mainframe environment using TI Manager.

7. Deploy the schema.

8. Build the BizTalk Server deployment MSI package.

After you create the export package, you can move the solution to a staging or production server and import the package.

For more information, see Application Integration Programmer's Guide.

How to Create a Visual Studio Solution

How to Create a Transaction Integrator Project and Interface Definition

How to use a Client Context with the BizTalk Adapter for Host Applications

How to Create a BizTalk Project

Creating a BizTalk Application

How to Associate the Interface Definition with the Mainframe Environment

How to Export the Schema

How to Create a BizTalk Server Export Package

Mainframe Setup

The primary purpose of the BizTalk Adapter for Host Applications is to connect to an application that is running on a remote mainframe. Therefore, the first step in writing your BizTalk application is to confirm that the host mainframe is, in fact, running the specified application, and that you can access the mainframe from your system.

How to create, load, and troubleshoot a remote host application is beyond the scope of this topic. You should work with your mainframe developer to create and load an application onto the specified mainframe. You can also work with a mainframe system developer to access the mainframe from your system.

In addition, the SDK for the BizTalk Adapter for Host Applications includes a detailed readme on how to create and load a sample mainframe application. For more information, see [*installation directory*]\Microsoft Host Integration Server\SDK\Samples\AppInt\BizTalkHostApplications\. This directory contains instructions on how to set up a mainframe sample application, in addition to several variations on how to set different network protocols for the sample.

Creating an Application for the BizTalk Adapter for Host Applications

How to Create a Visual Studio Solution

After you create, debug, and confirm your access to the host application, you can start to create the application for the BizTalk Adapter for Host Applications. The first task you must perform is to create a Visual Studio solution. This solution will contain the BizTalk Server and Host Integration Server projects that will, in turn, contain the necessary components for your application.

To create a Visual Studio solution

1. In Visual Studio, click **File**, point to **New**, and then click **Project**.
2. In the **New Project** dialog box, in the Project types pane, click **Other Project Types**, and then click **Visual Studio Solutions**.
3. In the Templates pane, click **Blank Solution**.
4. Enter the name of your project in the **Name** field, and then click **OK**.

Creating an Application for the BizTalk Adapter for Host Applications

Mainframe Setup

How to Create a Transaction Integrator Project and Interface Definition

When you are creating an application for the BizTalk Adapter for Host Applications, you first create a Visual Studio solution to contain your projects, and then you create a Transaction Integrator (TI) project. Using the TI project, you will create an interface definition of the host application. Later, you will use the interface definition, together with an associated .xml schema, to describe the interface to your BizTalk application.

To create a TI project in Visual Studio

1. In your Visual Studio solution, click **File**, point to **Add**, and then click **New Project**.
2. In the **Add New Project** dialog box, in the **Project types** pane, click **Host Integration Projects**.
3. In the **Templates** pane, click **Transaction Integrator Project**.
4. Enter the name of your TI project in the **Name** field, enter the location to save the project in the **Location** field, and then click **OK**.

To add a .NET client library to the TI project

1. In Solution Explorer, right-click the name of your TI project, point to **Add**, and then click **Add .NET Client Library**.
2. In the **Add New Item** dialog box, confirm that .**NET Client Library** is selected in the **Templates** pane.
3. Type the name of the client library in the **Name** field, and then click **OK**.
4. On the **.NET Client Library Wizard Welcome** page, click **Next**.
5. On the **Library** page, in the **Type Restrictions** field, select **BAHA**.
6. Enter the relevant name, version number, and description, and then click **Next**.
7. On the **Remote Environment** page, enter the relevant information that describes the remote environment, click **Next**, and then click **Create**.

   If you do not know this information, you should speak to your mainframe systems developer.

To construct the interface definition

1. In Host Integration Server Designer, right-click the node of the .NET client library, point to **Import**, and then click **Host Definition**.
2. Use the Import COBOL Wizard to import a host definition file.

   By importing the host definition file into the .NET client library, HIS Designer also creates an XML schema data (XSD) file. This XSD file contains the interface definition you will use later in your BizTalk application. For more information about using the Import COBOL Wizard, see Import COBOL Wizard.
3. You may view the XSD file by clicking the **XSD Definition** tab in HIS Designer.
4. Click **File**, and then click **Save All**.

   The XSD file should be saved in the standard location for the project. Note that you will need this location in the next step, when you add the XSD file to your BizTalk project. For more information, see How to Create a BizTalk Project.

Creating an Application for the BizTalk Adapter for Host Applications

How to use a Client Context with the BizTalk Adapter for Host Applications

For Host Integration Server, the client context is a set of values that describe the context in which the client application is running in the Windows environment. By modifying the **ClientContext** keyword in the XML file associated with your BizTalk project, you can pass the client context information on to the remote application.

To use client context keywords in a BizTalk Adapter for Host Applications application

1. Generate an instance of the XML document that describes your assembly.

   For more information, see How to Create a Transaction Integrator Project and Interface Definition

2. In the XML document, edit the **TIClientContext** keyword.

   The **TIClientContext** keyword will appear in the XML document in the following format:

   ```
   <ns0:TIClientContext TIContextKeyword="TIContextKeyword_0" TIContextValue="TIContextValue_1" />
   ```

   Where "TIContextKeyword_0" and TIContextValue_1" represent the keyword and value pair, respectively.

   For the BizTalkAdapter for Host Applications, **TIClientContext** accepts USERID, PASSWORD, RecvTimeOut, and SendTimeOut as valid keywords.

   Note that you do not have to remove **TIClientContext** elements from your document if you are not using **ClientContext**.

3. When finished, save the XML file and exit.

Example

The following example describes an XML document generated by the Transaction Integrator Designer.

```
<ns0:DPC_WGB__GetBalance__WGBANK__Request xmlns:ns0="http://microsoft.com/HostApplications/
TI/WIP">
  <ns0:WGBANKInDocument>
   <ns0:ACCNUM>1234</ns0:ACCNUM>
   <ns0:name>Kim Akers</ns0:name>
  </ns0:WGBANKInDocument>
  <ns0:TIClientContext TIContextKeyword=" RecvTimeOut " TIContextValue="15" />
<ns0:TIClientContext TIContextKeyword="TIContextKeyword_0"TIContextValue="TIContextValue_1"
/>
</ns0:DPC_WGB__GetBalance__WGBANK__Request>
```

How to Create a BizTalk Project

After you create an XSD file for your application, you create a BizTalk project to contain the application. After you create the BizTalk project, you can add the XSD file as a standard item, and then use it to create your BizTalk application.

To create a BizTalk project for an application that uses the BizTalk Adapter for Host Applications

1. In Visual Studio, click **File**, point to **Add**, and then click **New Project**.
2. In the **Add New Project** dialog box, in the **Project Types** pane, click **BizTalk Projects**.
3. In the **Templates** pane, click **Empty BizTalk Server Project**.
4. Type the name of the project in the **Name** field, type the location of the project in the **Location** field, and then click **OK**.

To add the .xsd file to the BizTalk project

1. In Solution Explorer, right-click the name of your BizTalk project, select **Add**, and then click **Existing Item**.
2. In the **Add Existing Item** dialog box, navigate to the location where you saved the .xsd file in the previous step, click the .xsd file, and then click **Add**.

How to Associate the Interface Definition with the Mainframe Environment

After you create a BizTalk project for your application that uses the BizTalk Adapter for Host Applications, and then add the .xsd file to the project, you must identify your target mainframe, and then associate the interface definition with the mainframe environment.

To configure the remote environment using TI Manager

1. Start TI Manager.
2. Double-click **Transaction Integrator** in the console tree.
3. Right-click **Remote Environments**, point to **New**, and then click **Remote Environment**.
4. Use the New Remote Environment Wizard to describe the environment on your target mainframe.

   For more information about how to use the Remote Environment Wizard, see Creating and Managing Remote Environments Using TI Manager

To administer the TI .NET assembly metadata using TI Manager

1. Start TI Manager.
2. Double-click **Transaction Integrator** in the console tree.
3. In the **Windows-Initiated Processing** node, right-click **Objects**, point to **New**, and then click **Object**.
4. Use the Object Wizard to associate the TI assembly that you created earlier with the remote environment of your target mainframe.

   For more information about how to use the Object Wizard, see Object Wizard (for WIP).

How to Create a BizTalk Server Export Package

Concepts

Creating an Application for the BizTalk Adapter for Host Applications

How to Create a BizTalk Server Export Package

After you finish testing your BizTalk application in your development environment, you can put the associated dependencies into an export package. After you create the export package, you can then move your BizTalk application to a staging or live server.

Note
The process for creating an export package for a BizTalk application that uses the BizTalk Adapter for Host Applications is identical to creating any other export package that uses an adapter.

To create an export package for an application that uses the BizTalk Adapter for Host Applications

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Server 2006 Administration**, expand the BizTalk group, and then expand **Applications**.
3. Right-click the application that you want to export, point to **Export**, and then click **MSI file**.
4. On the **Welcome to the Export MSI File Wizard** page, click **Next**.
5. On the **Select Resources** page, select the artifacts to export into the .msi file, and then click **Next**.
6. If you are prompted, on the **Specify IIS Hosts** page, type the server name of the computer hosting the virtual directory that you want to include, and then click **Next**.

   You will be prompted to specify the server only if the virtual directory has not been previously added to the BizTalk Management database, such as when it was added to the application or was imported in an application.
7. On the **Dependencies** page, review the dependencies for the application, and then click **Next**.
8. On the **Destination** page, in **Destination application name**, type the application name.
9. In **MSI file to generate**, type the full path for the .msi file, and then click **Export**.
10. On the **Summary** page, note the location of the log file for this operation, and then click **Finish**.

Concepts

Creating an Application for the BizTalk Adapter for Host Applications

How to Deploy the BizTalk Server Application

After a developer has created and exported an application for the BizTalk Adapter for Host Applications, an IT professional can import it, update the connection properties, and deploy the application.

Before you import the application, you can find more information by completing the Importing Exported Packages tutorial. After you complete these procedures, you can perform any application-specific deployment tasks as necessary.

To import the BizTalk Server application

1. In the BizTalk Server Administration console, expand the **BizTalk Server 2006 Administration** node.
2. Expand the **BizTalk Group** node.
3. Right-click the **Applications** node, click **Import**, and then click **MSI file**.

   This starts the Import MSI Wizard.
4. Follow the instructions in the wizard. If you need help, you can click **Help** on each wizard page.

To update the connection properties

1. In the TI Manager Console, expand the **Remote Environments** folder.
2. Right-click the **Remote Environment** for this application, and then click **Properties**.

   - If you have a TCP/IP connection, select the **TCP/IP** tab, and either confirm or enter the appropriate information in the **IP/DNS Address** and **Port** fields.

   - If you have an SNA connection, select the **LU6.2** tab, and either confirm or enter the appropriate information in the **Local LU Alias**, **Remote LU Alias**, and **Mode Name** fields.

     You may have to obtain this information from your Mainframe or System Administrator.

BizTalk Adapter for Host Applications

BizTalk Adapter for WebSphere MQ

The Client-Based BizTalk Adapter for WebSphere MQ (MQSC Adapter) is a connectivity solution that enables you to use BizTalk Server in an enterprise with WebSphere MQ as the chosen messaging standard.

Previously, once-and-only-once delivery of messages between BizTalk Server and WebSphere MQ applications was provided by the Server-Based BizTalk Adapter for WebSphere MQ, which requires MQSeries Server on Windows as an intermediate server between BizTalk Server and non-Windows Queue Managers. To enable once-and-only-once delivery of messages, BizTalk Server and the adapter require WebSphere MQ to participate in a distributed transaction using MSDTC (Microsoft Distributed Transaction Coordinator). MSDTC support has been available only with the Server version of WebSphere MQ on Windows.

With BizTalk Server 2006, transactional messaging (once-and-only-once delivery) is also available through the MQSC Adapter. This is made possible by the MQSC Adapter working together with the WebSphere MQ Extended Transactional Client (MQ Extended-Client). Like the MQSeries Server, the MQ Extended Client supports distributed transactions using Microsoft Distributed Transaction Coordinator (MSDTC) on Windows. Therefore, the adapter can guarantee once-and-only-once delivery of messages by ensuring that both BizTalk Server and MQ Extended-Client participate in a distributed transaction.

When receiving messages from MQSeries and submitting them to BizTalk Server, the adapter starts an MSDTC transaction and performs an MQGet with SYNCPOINT so that MQSeries participates in the transaction. The adapter passes this same transaction context to BizTalk Server so that BizTalk Server participates in the same transaction when the adapter submits the message to it. After the message has been submitted, the adapter commits the transaction. When sending messages from BizTalk Server to MQSeries, the adapter starts the transaction and performs an MQPut operation with the SYNCPOINT option. BizTalk Server uses this same transaction to remove the message from the BizTalk Server MessageBox database, after which the adapter commits the transaction.

You can also configure the MQSC Adapter to support non-transactional messaging when integrating with MQSeries Queues. For this, the MQSC Adapter uses the WebSphere MQ Base-Client. In this case, the adapter only guarantees that no messages are lost. Duplication of messages can occur under failure conditions. Therefore, you should use this configuration option only if the application that is consuming the message from BizTalk Server or MQSeries Queues can handle duplication of messages. To prevent loss of messages, the MQSC adapter first does an MQGET with a browse lock by setting the MQGMO_BROWSE_FIRST and MQGMO_LOCK options. The adapter then submits the message to BizTalk Server. If the submitted message to BizTalk Server is successful, the adapter does a destructive MQGet with MQGMO_MSG_UNDER_CURSOR option. If a failure occurs while submitting the message to BizTalk Server, the adapter does an MQGet with MQGMO_UNLOCK so that additional operations can be performed on the message.

Both the Server-Based BizTalk Adapter for WebSphere MQ and the Client-Based BizTalk Adapter for WebSphere MQ offer their own advantages. The Client-Based Adapter was not designed to replace the Server-Based Adapter. Instead, it provides an additional option for integration between BizTalk Server and WebSphere MQ.

The following table compares the client-based MQSC adapter with the server-based MQSC adapter.

Feature	**Server-Based BizTalk Adapter for WebSphere MQ (MQS)**	**Non-Transactional Client-Based BizTalk Adapter for WebSphere MQ (MQSC)**	**Transactional Client-Based BizTalk Adapter for WebSphere MQ (MQSC)**
WebSphere MQ Dependency	Requires WebSphere MQ Server on Windows to communicate with WebSphere MQ Queue Managers on non-Windows Systems. This can be on BizTalk Server or on a remote server running Windows.	Requires WebSphere MQ Client to be installed on BizTalk Server to communicate directly to WebSphere MQ Queue Managers on remote systems.	Requires WebSphere MQ Extended Transactional Client to be installed on BizTalk Server to communicate directly to WebSphere MQ Queue Managers on remote systems.
Receive capability	Yes	Yes	Yes
Static send ports	Yes	Yes	Yes
Dynamic send ports	Yes	Yes	Yes

Polling queues on receive	Yes, with static MQGMO Wait Interval for three seconds.	Yes, with configurable MQGMO Wait Interval.	Yes, with configurable MQGMO Wait Interval.
Supports transactional or non-transactional scenarios	Only transactional scenarios are supported. Non-transactional configuration is available for test/debug mode, but not supported in production.	Non-transactional only.	Transactional only.
Guarantees once-and-only-once delivery of messages	Yes	No, in failure conditions, duplicate messages can occur either in BizTalk Server or in MQSeries queues. Application is responsible for handling duplicate messages.	Yes
Prevents loss of messages	Yes	Yes	Yes
Performance and scalability characteristics	Provides highest performance; better suited to handle heavy message loads.	Compared to server-based adapter, performance is low because of overhead built in to prevent loss of messages.	Performance is higher than non-transactional adapter, but lower than server-based adapter.
Receive-side conversion	When performing MQGET, MQGMO CONVERT option is specified when configured.	When performing MQGET, MQGMO CONVERT option is specified when configured.	When performing MQGET, MQGMO CONVERT option is specified when configured.
Send-side conversion	Can be configured to convert to code page of MQSeries Server on Windows.	Not applicable	Not applicable
Access to MQSeries headers from Orchestrations and Pipeline Components	Yes	Yes	Yes
Segmentation using Queue Manager capabilities	Yes	Yes	Yes
Security between BizTalk Server and MQSeries Server	COM+ application (MQSAgent) on MQSeries Server on Windows uses COM+ roles to allow users who can access it. On the wire, data is encrypted using Packet Privacy. MQSeries Server on Windows to remote MQSeries Server on non-Windows system can be configured to use SSL.	Configure Secure Sockets Layer (SSL) between MQSeries Client and Server	Configure SSL between MQSeries Client and Server
Dynamically receives from queue using solicit-response send port based on certain match options	Yes	No	No

MQSeries Channel configuration on BizTalk Server	No	Yes, uses Server Connection Channel.	Yes, uses Server-Connection Channel. To use SSL, Client Channel Definition file must be used.

MQSC Adapter Features

The Client-Based BizTalk Adapter for WebSphere MQ (MQSC Adapter) is designed for BizTalk Server and works with all the BizTalk Server components and tools. With the adapter, you can do the following:

- Communicate with remote Queue Managers that are running on Windows or other operating systems directly from BizTalk Server.
- Send messages to MQSeries Remote Queue Definitions, Local queues, Transmission queues, and Alias queues from BizTalk Server.
- Receive messages from MQSeries Transmission queues, Local queues, and Alias queues.
- Support clustered MQSeries Queue Managers.
- Support clustered BizTalk servers.
- Poll MQSeries Queues with wait interval.
- Configure Static, Dynamic, Solicit-Response send ports, and Static Receive Locations for this adapter.
- Map context properties to header properties for both transmitting and receiving messages. Gain easy programmatic access to MQSeries header properties (including MQMD, MQXQH, MQCIH, and MQIIH) through BizTalk context properties.
- Receive messages in batches from MQSeries queues.

The MQSC Adapter also does the following:

- Enables correlation with either BizTalk Server or MQSeries using the correlation identifier.
- Provides ordered delivery of messages.
- Provides Secure Sockets Layer (SSL) support for secure communication with remote MQSeries Queue Managers.

The MQSC Adapter can co-exist with the Server-Based Microsoft BizTalk Adapter for WebSphere MQ (MQSeries Adapter).

BizTalk Adapter for WebSphere MQ

How to Install the MQSC Adapter

The BizTalk Adapter for WebSphere MQ (MQSC Adapter) is installed as part of the BizTalk Adapters for Host Systems installation process.

To use the adapter with the IBM WebSphere MQ Client (Base-Client), you must also have the following software installed:

- Microsoft BizTalk Server 2006.
- Microsoft .NET Framework 2.0.
- IBM WebSphere MQ Client 5.3 with CSD10, **or** IBM Websphere MQ Client 6.0 with Fix Pack 6.0.1.1.

To use the MQSC adapter for Extended-Client support, you must also have the following software installed:

- IBM WebSphere MQ Client 5.3 with CSD10 and IBM WebSphere MQ Extended Transactional Client, **or** IBM WebSphere Client 6.0 with Fix Pack 6.0.1.1.

To install the MQSC Adapter

1. Run the Host Integration Server Setup.
2. On the component installation screen, expand **BizTalk Adapters**.
3. Select **BizTalk Adapter for WebSphere MQ (Client-Based)**.

As with other adapters, you can uninstall through the **Add or Remove Programs** utility in Control Panel.

Note
When you are using Extended-Client and configuring the adapter send port, receive port, and receive location, refer to How to Configure the MQSC Adapter for Transactional Messaging for more information

Refer to IBM documentation for more information about how to obtain and install WebSphere MQ Extended Transactional Client or WebSphere MQ Client. For information about how to obtain necessary fixes from IBM, refer to the README file

Important
Only x86 (32-bit) Windows operating systems that are supported by BizTalk Server 2006 are supported by the MQSC Adapter. WebSphere MQ on Windows is not supported on 64-bit Windows operating systems. This means that the MQSC Adapter is not supported on either X64 (64-bit) Windows or a 32-bit BizTalk Host Instance on x64.

BizTalk Adapter for WebSphere MQ

How to Add the MQSC Adapter to a BizTalk Server Installation

When you install the BizTalk Adapter for WebSphere MQ (MQSC Adapter), the BizTalk Adapters for Host Systems installation process adds the adapter to your BizTalk Server installation by default. Following installation, if for any reason the adapter is missing from the BizTalk Server 2006 Administration Console (for example, if it was deleted during testing), you can add it manually by using the following procedure.

To add the MQSC adapter

1. In the Console Root of the BizTalk Server 2006 Administration Console, expand the **BizTalk Server 2006 Administration** node.
2. Expand the **BizTalk Group** node.
3. Expand the **Platform Settings** node.
4. Right-click **Adapters**.
5. Click **New**.

   The Adapter Properties window is displayed.
6. In the **Name** field, type a name for the adapter.
7. In the **Adapter** field, select **MQSC** in the list.
8. In the **Description** box, type any text that is useful to you. (This is an optional step.)
9. Click **OK**.

Note
Adding the adapter requires that you restart the host instance.

BizTalk Adapter for WebSphere MQ

How to Configure a Send Port for the MQSC Adapter

You configure a send port for the BizTalk Adapter for WebSphere MQ by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions in the Single Sign-On (SSO) database.

To configure a send port

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a send port.
3. Right-click **Send Ports**, point to **New**, and then click **Static One-way Send Port**.
4. In the **Send Port Properties** window, select **mqsc** in the **Transport Type** list.
5. Click **Configure**.
6. In the adapter's **Transport Properties** window, configure the send port properties (refer to the tables at the end of this procedure).

Note
The following properties are required to configure a send port: **Channel Name** (This is a case-sensitive property.) **Connection Name** **Transport Type** **Queue** (This is a case-sensitive property.) **Queue Manager** (This is a case-sensitive property.)

   If you do not specify a **Channel Name** property, you must provide a client channel definition file to enable the WebSphere MQ Client installed on the BizTalk Server computer to communicate with remote queue managers. You must also provide a client channel definition file if you configure Secure Sockets Layer (SSL) to work with transactional messaging. For more information, see How to Configure a Client Channel Definition File.
7. When you have finished configuring the properties, click **OK**.
8. In the **Send Port Properties** window, in the **Send handler** list, select the host instance on which the send adapter is running.
9. In the **Send pipeline** list, select the pipeline that processes the messages sent through this port.
10. Click **OK**.
11. In the **Send Ports** window, right-click the send port in the **Name** column and select **Enlist**.
12. Right-click the send port in the **Name** column and select **Start**.

    In the **Advanced** section of the **Transport Properties** window, you can set the following send port properties.

Use this	To do this
SSO Affiliate	Sets the Single Sign-On (SSO) affiliate application. The user ID and password from SSO are used for the MQMD_UserIdentifier, and the MQIIH_Authenticator (or MQCIH_Authenticator) property respectively. This assumes that a valid SSO ticket exists. Default: Blank

Transaction Supported	When this property is set to **Yes**, the MQSC adapter works in conjunction with the WebSphere MQ Extended Transactional Client (Extended-Client) on the BizTalk Server computer to prevent loss of messages and to guarantee once-and-only-once delivery of messages. When it is set to **No**, duplication of messages may occur. In this case, the adapter uses the non-transactional WebSphere MQ Client (Base-Client) for integration with MQSeries. Default: No

In the **Channel Definition** section of the **Transport Properties** window, you can set the following properties.

Use this	To do this
Channel Name	Name of the channel defined on the MQSeries Server computer that the client communicates with. This must be a 'Server Connection' Channel type. Note that this is a case-sensitive property.
Connection Name	Name of the MQSeries Server that contains the Queue Manager and Queues that the MQSC Adapter sends messages to. For the TCP transport type, the format to be specified is SERVERNAME(PORT). The port number is equivalent to the port number defined in the Listener associated with the Queue Manager. The server name can also be specified as an IP address. For LU6.2, specify the LU Name or LU Pool Name configured in Host Integration Server.
Heart Beat	Number of seconds between checks to verify that the client/server connection is working. Default: 300
Password	Password that can be used by the MCA when attempting to initiate a secure LU 6.2 session with a remote MCA. The initial value of this optional property is null.
SSL Cipher Specification	Defines a single CipherSpec for an SSL connection that will be used by the end-point configured in the adapter. Both ends of a WebSphere MQ SSL channel definition must include the attribute, and the value specified here should match the name specified on the server end of the channel. The value is a string with a maximum length of 32 characters. Required only when SSL is configured for communication between the MQSeries Client and remote Queue Managers.
SSL Peer Name	Used to check the distinguished name (also known as DN) of the certificate from the peer queue manager or client at the other end of a WebSphere MQ channel. If the distinguished name that is received from the peer does not match this value, the channel does not start. Required only when SSL is configured for communication between the MQSeries Client and Queue Managers.
Transport Type	TCP and LU6.2 are supported. Default: TCP
User Id	MCA user identifier that is used by MQSeries MCA for authorization to access MQSeries resources. The initial value is null. This is an optional property. When this attribute is blank, the MCA uses its default user identifier.

In the **MQSeries** section of the **Transport Properties** window, you can set the following properties.

Use this	To do this

Segmentation Allowed	Set to **Yes** to tell MQSeries Queue Manager to create segmented messages when submitting large messages to MQSeries Queues. Default: **No**

In the **Queue Definition** section of the Transport Properties window, you can set the following properties.

Use this	To do this
Queue	MQSeries queue to which the adapter will send messages. Remote Queue Definitions, Local Queues, Alias Queues, and Transmission Queues are supported. Note that this is a case-sensitive property.
Queue Manager	Name of MQSeries Queue Manager that contains the queues to which the adapter will send messages. Clustered Queue Managers are supported. Note that this is a case-sensitive property.

13. Click **OK**.

BizTalk Adapter for WebSphere MQ

How to Configure a Receive Port and a Receive Location for the MQSC Adapter

You configure a receive port and receive location for the BizTalk Adapter for WebSphere MQ by using the BizTalk Server Administration console. You must be logged on with an account that is a member of the BizTalk Server Administrators group. In addition, you must have appropriate permissions in the Single Sign-On (SSO) database.

To configure a receive port and receive location

1. Click **Start**, point to **Programs**, point to **Microsoft BizTalk Server 2006**, and then click **BizTalk Server Administration**.
2. In the console tree, expand **BizTalk Group**, expand **Applications**, and then select the application for which you want to create a receive port.
3. Right-click **Receive Ports**, point to **New**, and then click **One-way Receive Port**.
4. In the **Receive Port Properties** window, configure properties for the port, and then click **OK**.
5. In the console tree, right-click **Receive Locations**, point to **New**, and then click **One-way Receive Location.**
6. In the **Select a Receive Port** window, click the receive port that you created in the previous step, and then click **OK**.
7. In the **Receive Location Properties** window, select the MQSC adapter as the Transport Type, and then click **Configure**.
8. In the adapter's **Transport Properties** window, configure the receive location's properties (refer to the tables at the end of this procedure).

Note
The following properties are required to configure a receive location: **Channel Name** (This is a case-sensitive property.) **Connection Name** **Transport Type** **Queue** (This is a case-sensitive property.) **Queue Manager** (This is a case-sensitive property.) If you do not specify a **Channel Name** property, you must provide a client channel definition file to enable the WebSp here MQ Client installed on the BizTalk Server computer to communicate with remote queue managers. You must also provide a client channel definition file if you configure Secure Sockets Layer (SSL) to work with transactional messagin g. For more information, see How to Configure a Client Channel Definition File.

9. When you have finished configuring the properties, click **OK**.
10. In the **Receive Location Properties** window, in the **Receive handler** list, select the instance of the BizTalk Server host on which the receive location will run.

    The receive handler must be running on this host.
11. In the **Receive pipeline** list, select the receive pipeline to use to receive messages at this receive location.
12. Click **OK**.
13. In the **Receive Locations** window, right-click the Receive Location in the **Name** column and select **Enable**.

    Receive Location Properties

    In the **Advanced** section of the **Transport Properties** window, you can set the following properties.

Use this	**To do this**

Data Offset for Headers	The adapter uses values from the MQSeries headers (the MQMD, MQXQH, MQIIH, and MQCIH structures) and populates corresponding values in the BizTalk Server context properties. By default, the adapter removes these MQSeries properties from the message body. Set to **No** to retain the properties in the message body. Default: **Yes**
Event Log Error Threshold	The maximum number of the same error to be logged for certain error conditions. The adapter continues operating and, if the adapter recovers, it logs the event in the Application log. Default: 10
Ordered	Set to **Yes** to maintain the order of the messages as they are received from the MQSeries queue and submitted to the BizTalk Server MessageBox. For the send side, the adapter sends the message to the queue in the same order that it receives it from the message box. Set to **No** to not maintain message order. For send-side ordering, if you are not using Orchestration, you must enable Ordered Delivery in the Transport Advanced Options of the send port configuration. For receive-side ordering, if you are using Orchestration, you must also set the **Ordered Delivery** property to **True** in your orchestration for the receive location. Ordered delivery can decrease performance; unless you require ordered delivery, it is not recommended. Default: **No**
Stop on error	Set to **Yes** to stop processing if there is an error. This option ends the transaction and disables the receive location if there is an error. Default: **No**
Suspend As Non Resumable	Set to **Yes** to move a message to the suspended queue when there is an error and indicate if it is resumable or not. Enabling this value does not preserve ordered delivery when there is an error, but does allow the receive location to continue receiving messages. Default: **No**
Transaction Supported	When set to **Yes**, the MQSC adapter works together with the WebSphere MQ Extended Transactional Client (Extended-Client) on the BizTalk Server computer to prevent loss of messages and to guarantee once-and-only-once delivery of messages. When set to **No**, duplication of messages may occur. In this case, the adapter uses the non-transactional WebSphere MQ Client (Base-Client) for integration with MQSeries. Default: **No**
Wait Interval	When MQGet is performed to retrieve messages from MQSeries Queue, MQGMO option for Wait Interval can be set. If there are no messages in the queue, the adapter waits for the specified time (in seconds) before closing the client request. As soon as messages arrive on the queue, the adapter starts retrieving the messages. Default: 3

In the **Channel Definition** section of the Transport Properties window, you can set the following properties.

Use this	To do this

Channel Name	Name of the channel defined on the MQSeries Server computer that the client communicates with. This must be a 'Server Connection' Channel type. Note that this is a case-sensitive property.
Connection Name	Name of the MQSeries Server that contains the Queue Manager and Queues that the MQSC Adapter receives messages from. For the TCP transport type, the format to specify is SERVERNAME(PORT). Port number is equivalent to the port number defined in the Listener associated with the Queue Manager. The server name can also be specified as an IP address. For LU6.2, specify the LU Name or LU Pool Name configured in Host Integration Server.
Heart Beat	Number of seconds between checks to verify that the client/server connection is working. Default: 300
Password	Password that can be used by the MCA when trying to initiate a secure LU 6.2 session with a remote MCA. The initial value of this optional property is null.
SSL Cipher Specification	Defines a single CipherSpec for an SSL connection that will be used by the end-point configured in the adapter. Both ends of a WebSphere MQ SSL channel definition must include the attribute, and the value specified here should match the name that is specified on the server end of the channel. The value is a string with a maximum length of 32 characters. Required only when SSL is configured for communication between the MQSeries Client and remote Queue Managers.
SSL Peer Name	Used to check the distinguished name (also known as DN) of the certificate from the peer queue manager or client at the other end of a WebSphere MQ channel. If the distinguished name that is received from the peer does not match this value, the channel does not start. Required only when SSL is configured for communication between the MQSeries Client and Queue Managers.
Transport Type	TCP and LU6.2 are supported. Default: TCP
User Id	MCA user identifier that is used by MQSeries MCA for authorization to access MQSeries resources. The initial value is null. This is an optional property. When this attribute is blank, the MCA uses its default user identifier.

In the **MQSeries** section of the Transport Properties window, you can set the following properties.

Use this	To do this
Character Set	Character set to which the message should be converted when messages are received from the MQSeries Que ue. If this property is set to a value other than None, the adapter sets the MQGMO CONVERT option when perf orming an MQGet. **None**: Do not convert. **UCS-2 and UTF-16**: Convert to these character sets. MQSeries does not distinguish between them. UTF-8: Convert to the UTF-8 character set. Default: None

Segmentation Allowed	Set MQSeries to assemble segmented messages or to get the message as is. Use No Action to read messages from the MQSeries queue without enabling segmentation. Use Complete Message to have MQSeries assemble segmented messages before passing them on to the adapter. Default: **No Action**

In the **Performance** section of the Transport Properties window, you can set the following properties.

Use this	To do this
Maximum Batch Size	Maximum size of a batch of messages in KB. This property and **Maximum Messages in Batch** work together so that the limit is whichever value the adapter reaches first. Default: 100
Maximum Messages in Batch	Maximum number of messages from 1 to 10,000 in a batch. This property and **Maximum Batch Size** work together so that the limit is whichever value the adapter reaches first. Default: 10
Threads	Number of threads used per receive location. Default: 2

In the **Queue Definition** section of the Transport Properties window, you can set the properties listed in the following table.

Use this	To do this
Queue	MQSeries queue from which the adapter will receive (MQGet) messages. Transmission Queues, Local Queues, Alias Queues are supported. Note that this is a case-sensitive property.
Queue Manager	Name of MQSeries Queue Manager that contains the Queues from which the adapter will retrieve messages. Clustered Queue Managers are supported. Note that this is a case-sensitive property.

14. Click **OK**.

BizTalk Adapter for WebSphere MQ

How to Configure a Client Channel Definition File

To specify a channel definition, you must provide a client channel definition file for WebSphere MQ Client components to use if the following are true:

- When configuring send and receive ports, you did not specify a **Channel Name** property.
- When configuring send and receive ports, you set the **Transaction Supported** property to Yes, and you configured Secure Sockets Layer (SSL) for client/server communication for WebSphere MQ.

To configure a client channel definition file

1. On your WebSphere MQ Server computer, create the client channel definition file.

   For information about how to create a client channel definition file, refer to IBM WebSphere MQ product documentation.

   After the file is defined, a binary format .TAB file is created. By default, this file is named AMQCLCHL.TAB, and it is typically located in the <*WebSphere MQ Server installation folder*>\qmgrs\<QueueManagerName>\@ipcc folder.

2. Move the AMQCLCHL.TAB file to the WebSphere MQ client computer on which BizTalk Server is installed, and define the MQCHLLIB and MQCHLTAB environment variables on this computer.

   - For MQCHLLIB, specify the folder that contains the AMQCLCHL.TAB file. By default, it is the WebSphere MQ client installation folder.
   - For MQCHLTAB, specify the name of the .TAB file (by default AMQCLCHL.TAB).

When you are setting up SSL using a client channel definition file, the key repository environment variable (MQSSLKEYR) must also be set on the WebSphere MQ client computer on which BizTalk Server is installed. For MQSSLKEYR, specify the path of the key repository for the client.

BizTalk Adapter for WebSphere MQ

How to Configure the MQSC Adapter for Transactional Messaging

After you install the IBM WebSphere MQ Extended Transactional Client on your BizTalk Server computer, the following additional configuration steps are necessary before you can implement transactional messaging with the BizTalk Adapter for WebSphere MQ.

- In the WebSphere MQ Server environment, give your Network Service account appropriate permissions, as described in the IBM Technote article 1223479. For security reasons, it is strongly recommended that you use the "Security Exit" so that you do not have to add "Network Service" account into the MQM group.

- On your BizTalk Server computer, add the MQSeries XA dll to the MSDTC registry. To the registry key **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSDTC\XADLL**, add the string value **amqmtsxatmc.dll** in the **Name** column and add its path to the **Data** column. Provide the path in the form **<WebSphere MQ Client installation folder>\bin\amqmtsxatmc.dll**; for example, **C:\Program Files\IBM\WebSphere MQ\bin\amqmtsxatmc.dll**.

- On your BizTalk Server computer, if you are using WebSphere MQ 5.3, give your Network Service account read/write access to the @SYSTEM folder, contained in <WebSphere MQ Client installation folder>\qmgrs\@SYSTEM. (You do not have to do this if you are using WebSphere MQ 6.0.)

- Make sure that MSDTC is enabled on the computer on which BizTalk Server is installed and that security is configured as described in the following procedure:

To enable MSDTC and configure security

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Component Services**.
2. In the Console Root of the Component Services Console, expand **Component Services**.
3. Expand **Computers**.
4. Right-click **My Computer**, and then click **Start MSDTC**.
5. Right-click **My Computer**, and then click **Properties**.
6. Click the **MSDTC** tab.
7. Under **Transaction Configuration**, click **Security Configuration**.
8. Under **Security Settings**, select the **Network DTC Access** and **Enable XA Transactions** check boxes.
9. Click **OK**.

BizTalk Adapter for WebSphere MQ

How to Configure SSL for the MQSC Adapter

The following procedures are designed to help you with configuring a Windows MQSeries Client to run with Secure Sockets Layer (SSL)-enabled MQSeries Server channels. The procedures describe configuration for one-way (Server) authentication.

Configuration is performed in the following steps:

- Set up the Queue Manager/Client to work without SSL.
- Add SSL to the configuration.
- Configure the MQSeries Client-Based Adapter properties for SSL.

Note
For more information, refer to IBM WebSphere MQ documentation. If you already have MQSeries client/server SSL working, you can go directly to the procedure for configuring the SSL properties in the adapter.

The following procedures assume that you are setting up a new Queue Manager. However, you can also apply these steps to existing Queue Managers.

To set up the Queue Manager/Client to work without SSL

1. Create a Queue Manager named QM1, and define a listener on the required port.
2. Define a SVRCONN channel TO.QM1.
3. Define a CLNTCONN channel TO.QM1.
4. Supply the name on the SVRCONN channel to which it will connect (TO.QM1), the transport type, the IP address/DNS name of the server, and the port number.
5. Define a local queue on the target Queue Manager named TESTQUEUE, which can be used for testing the client connections.
6. Copy the AMQCLCHL.TAB file from the server onto the client computer. (This file can be found in /var/mqm/qmgrs/<QueueManagerName>/@IPCC on most UNIX installations and /Program Files/<Websphere MQ Server installation folder>/qmgrs/<QueueManagerName>/@IPCC on most Windows installations.)
7. On the client computer, set the following environment variables:
   - MQCHLLIB=C:\sslclient\ssl\ (where MQCHLLIB is set to the path of the client channel table).
   - MQCHLTAB=AMQCLCHL.TAB (where MQCHLTAB is set to the name of the client channel table).

Note
There are defaults for these environment variables if you want to use them. See the WebSphere MQ Client manual for more information.

8. Test that the client connection works by running amqsputc.exe on your BizTalk Server computer: **amqsputc.exe TESTQUEUE**.

To add SSL to the configuration

1. Add the certificate to the Queue Manager's store (using Internet Explorer/the MQSeries user interface or amqmcert on Windows, or gsk6ikm or gsk6cmd on UNIX).
2. Alter the SVRCONN channel so the SSLCIPH is set (for example, to NULL_MD5) and set SSLCAUTH to OPTIONAL.

Note

SSLCAUTH is required for two-way authentication (client/server).

3. Alter the CLNTCONN channel so the SSLCIPH is set to the same as the SVRCONN channel (for example, to NULL_MD5).
4. Copy the new AMQCLCHL.TAB file from the server onto the client computer; the changes made for SSL can be picked up.
5. On the Windows client computer, ensure that the CA certificates are in the system key store (you can do this from Internet Explorer) and if they are not, import them into it (again, using Internet Explorer).
6. Export the following environment variable to specify the location and name of the client key store: **set MQSSLKEYR=C:\sslclient\ssl\key**.

Note

The key store **must** have the file name extension .sto and the environment variable **must not** specify it.

7. When you have the required CA certificates in the system store, you can set up a client key store.
   a. List the certificates in the system CA store: **amqmcert -l -k ca** and note the number(s) of the required CA certificate(s)

   b. Add the certificates to the client store: **amqmcert -a (certificate_number)**, where (certificate_number) is the number of each required certificate.

8. Test that the SSL Client connections work by using the amqsputc sample program and the test queue that you set up previously.

Note

You do not actually have to import CA certificates into the Windows system store before; for example, you can import t he certificates to the client certificate store straight from a file. See the IBM MQSeries System Admin guide for informat ion about amqmcert.

When the MQSeries Client-to-MQSeries Queue Manager SSL is working, the adapter can be configured on both receive locations and send ports to use SSL. The property values that were used in the test must be specified in the adapter configuration. The following adapter properties are relevant to both send port and receive locations:

SSL Cipher Specification defines a single CipherSpec for an SSL connection that will be used by the endpoint configured in the adapter. Both ends of a WebSphere MQ SSL channel definition must include the attribute, and the value specified here should match the name that was specified on the server end of the channel. The value is a string with a maximum length of 32 characters.

SSL Peer Name is used to check the distinguished name (also known as DN) of the certificate from the peer queue manager or client at the other end of a WebSphere MQ channel. If the distinguished name received from the peer does not match this value, the channel does not start.

BizTalk Adapter for WebSphere MQ

MQSC Adapter Schema

The BizTalk Adapter for WebSphere MQ uses the same property schema assembly (MQSeries.dll) that is available with the server-based MQSeries Adapter. Because the server-based MQSeries Adapter is available with BizTalk Server 2006, this assembly should be already deployed in the BizTalk Management Database.

In addition, an extension schema assembly is available with the MQSC Adapter. This property schema assembly is called MQSeriesEx.dll, and it contains properties that are valid only to the Client-Based MQSeries Adapter. The assembly is deployed into the BizTalk Management Database as part of the adapter installation.

For information about these context properties in both property schema assemblies (MQSeries.dll and MQSeriesEx.dll), refer to the Programming Guide section.

If these assemblies are not deployed, you can deploy them by using the btsdeploy command-line utility.

At the command prompt, type the following:

btsdeploy DEPLOY assembly=<*Path to MQSeries.dll or MQSeriesEx.dll***>**

Both assemblies can be found in the MQSC Adapter installation location.

Data Integration User's Guide

The Data Integration User's Guide contains information about the Data Access Tool (DAT). The DAT provides a single mechanism to help configure network, security, and database information. The DAT also helps you create packages on the DB2 system.

In This Section

Data Access Tool

Data Access

Data Access Tool

The Data Access Tool (DAT) is a new feature in Host Integration Server designed to streamline the process of creating and managing connections to data sources on host environments. Whereas this used to be divided into multiple feature sets and programs, the DAT provides a single mechanism to guide you through configuring network, security, and database information, and creating packages on the DB2 system.

The DAT consists of two items:

The **Data Source Browser** displays all data sources in familiar Microsoft Management Console (MMC) format for configuration and management.

The **Data Source Wizard** guides you step by step through the configuration process. The wizard dynamically adapts to both DB2 and File System data sources, and displays the appropriate screens.

Note
The Data Access Tool and DB2 data providers create DB2 packages for use by all DB2 users, by setting the execute privilege o n the DB2 packages to PUBLIC. It is recommended that you revoke execute privileges to PUBLIC on these packages, and then grant execute to selected DB2 users or groups.

In This Section

How to Edit a Configuration

Editing the configuration brings up the editor for the specific data source. In other words, OLE DB data sources trigger the Universal Data Links page, and ODBC data sources trigger the Data Access Tool Wizard.

To edit a configuration

1. In the **Data Source Browser** window, on the **Action** menu, click **Edit Data Source**.

   The **Data Source** property page appears.

2. When you are finished editing, click **OK**.

Data Access Tool

How to Display an Initialization String

This option displays the native initialization string, for example, an OLE DB connection string or an ODBC connection string, in the output window. This string can be copied from the output window and pasted into another text-based window.

To display an initialization string

1. In the **Data Source Browser** window, on the **Action** menu, click **Display Connection String**.

   The connection string appears for viewing or copying.

See Also
Other Resources
Data Access Tool

How to Test a Connection

You can test the connection to the data source and display information about it, such as the host platform and version. In a connection between an AS/400 and a DB2, a typical result of this operation might look like the following:

```
Successfully connected to data source 'My_SOURCE'.
Server class: DB2/400
Server version: 05.01.0000
```

Certain operations may require the user to enter a user name and password. If this is the case, the **Password** dialog box appears.

To test a connection

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Test Connection**.

Other Resources
Data Access Tool

How to Create Packages

The create package command creates Host Integration Server packages on a DB2 system. As the process runs, status messages are displayed in the results pane. As seen on an AS/400, the result of this operation is:

```
Connected to data source 'MY_SOURCE_IP'.
AUTOCOMMITTED package has been created.
READ COMMITTED package has been created.
READ UNCOMMITTED package has been created.
SERIALIZABLE package has been created.
REPEATABLE READ package has been created.
The package creation process has completed successfully.
```

To create packages

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Create Packages**.

   The **Create Packages** dialog box appears.

Data Access Tool

How to Run a Sample Query

You can perform a sample query against the host data source. The query retrieves a list of tables from the system catalogs using the default schema property configured in the data source. The data is displayed in the results pane as two tabs: an **Output** tab and a **Grid** tab.

To run a sample query

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Sample Query**.

Other Resources

Data Access Tool

How to Convert Data Sources

Converting data sources allows you to convert a DB2 data source from one provider type to another. Only acceptable provider type conversion is displayed. For example, converting from DB2 OLE DB to DB2 OLE DB is not enabled.

To convert a data source

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Convert To**, and then select a provider from the list.

Data Access Tool

How to Add a Table

This command displays the **Table** dialog box. You can also access this dialog box by selecting a table and clicking **Properties** from the context-sensitive menu.

To add a table

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Add Table**.

   The **Table** property page appears.
3. Enter the appropriate information in the **Table** property page.

   For more information about these properties, click **Help**.
4. When you are finished, click **OK**.

Data Access Tool

How to Create a New Data Source or Data Description

Clicking **New Data Source** initiates the Data Source Wizard. Clicking **New Data Description** creates an empty data description file and adds it to the tree view.

To create a new data source or data description

1. In the **Data Source Browser** window, click the **File** menu.
2. Click **New**, and then click **Data Source** or **Data Description**.

See Also
Other Resources
Data Access Tool

How to Open a File

Use this command to choose a .udl or .dsn file through a standard **File Open** dialog box. The command will open the data source using the Data Source Wizard.

To open a file

1. In the **Data Source Browser** window, click the **File** menu.
2. Click **Open Data Source**.

   The **File Open** dialog box appears.
3. Locate the appropriate data source and then click **Open**.

OLE DB Provider for AS/400 and VSAM

To use Microsoft OLE DB Provider for AS/400 and VSAM with an OLE DB consumer application, you must either create a universal data link (.udl) file and call this from your application, or call the provider using a connection string that includes the provider name. Microsoft Data Access Components (MDAC) includes Microsoft Data Link, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Link also supports finding and storing connections to OLE DB data sources.

For additional information about using .udl files or connection strings, see How to Create a Connection String for a .udl File or Configuring Data Descriptions in the Programmer's Guide.

Note
The SNAOLEDB provider runtime and Data Access Tool both support a full path to the HCD files. To maximize security, you s hould store HCD files in a secure local folder or share that only the developer and the runtime application can access.

How to Browse OLE DB Data Sources

Reference

Configuring a Data Source for OLE DB Provider for AS/400 and VSAM

Concepts

How to Add or Configure a Data Link for Windows

Data Description for AS/400 and VSAM

With the Microsoft OLE DB Provider for AS/400 and VSAM, you can directly access record-level data in mainframe VSAM, Partitioned Data Sets (PDS), and midrange OS/400 files from an application that uses OLE. The OLE database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere — file systems, e-mail folders, and databases. The OLE DB Provider for AS/400 and VSAM combines the universal data access of OLE DB with the record-level input/output (RLIO) protocol of the IBM Distributed Data Management (DDM) architecture.

In addition to describing tables that are used by the Microsoft OLE DB Provider for AS/400 and VSAM, you can describe tables for the File Transfer utility. To indicate that the File Transfer Utility should use a given table, click the **Properties** page for the specific table, and then select the **Use Table for File Transfer** check box. Leaving this box clear indicates that the table is to be used by the Microsoft OLE DB Provider for AS/400 and VSAM.

In addition to the sample applications provided on the Host Integration Server CD-ROM, many of the sample programs that ship as part of the Microsoft Data Access Components (MDAC) SDK can be used with the OLE DB Provider for AS/400 and VSAM. To use the OLE DB Provider for AS/400 and VSAM, you must specify **SNAOLEDB** for the provider name.

For more information about using the Host Data Description utility, see Host CCSID and Data Description in the OLE DB Providers Programmer's Guides.

OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 contains the following features:

- Interactive and scriptable Setup program
- SNA Trace Utility and Trace Viewer
- TCP/IP network connection
- Execution of dynamic SQL commands (DDL and DML), including CALL statement for stored procedures
- Customized Data Link property dialog boxes for creating and modifying file-persisted OLE DB data link files.

To use the Microsoft OLE DB Provider for DB2 with an OLE DB consumer application, you must either create a universal data link (.udl) file and call it from your application, or call the provider using a connection string that includes the provider name. Microsoft Data Access Components (MDAC) version 2.0 and later includes Microsoft Data Link, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Link also supports finding and storing connections to OLE DB data sources.

For more information about using .udl files or connection strings, see the OLE DB Provider for DB2 Programmer's Guide in the **OLE DB Providers Programmer's Guides**

How to Browse OLE DB Data Sources

By default, data links are created in the \Program files\Common files\System\Ole db\Data links folder. A shortcut is provided in the Host Integration Server program group.

To browse OLE DB data sources

1. Click **Start**, point to **Programs**, and then point to **Host Integration Server**.
2. Point to **Data Integration**, and then click **OLE DB Data Source Browser**.

   The list of data links appears.

Concepts

OLE DB Provider for DB2
OLE DB Provider for AS/400 and VSAM
Create Package Utility

Create Package Utility

Microsoft OLE DB Provider for DB2 and Microsoft ODBC Driver for DB2 are implemented as IBM Distributed Relational Database Architecture (DRDA) application requesters. These features use DB2 packages to issue dynamic SQL statements and call DB2 stored procedures. The provider and driver create packages dynamically in the location to which the user points using the Package Collection attribute in the data source definition.

By default, the provider automatically creates one package in the target collection, if one does not exist, at the time the user issues the first SQL statement (or calls SQL catalog to fetch schema information). The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value that is configured in the data source. The package is created for use by SQL statements issued under the same isolation level that is associated with the transaction isolation level property and parameter. If no transaction isolation level is specified, the default for mainframe DB2 is CS and for other platforms the default is NC.

Multiuser Environments

A problem can occur in multiuser environments. For example, if User A specifies a Package Collection value that represents a DB2 collection used by multiple users, but User A does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), the package is created for use only by User A. This means that User B might be unable to access the required package. The solution is for an administrative user who has package administrative rights (for example, PACKADM authority in DB2 for OS/390) to create a set of packages for use by all users.

Host Integration Server offers the Create Packages for DB2 utility, which an administrator can use to create packages. This utility can be run using a privileged User ID to create packages in collections accessed by multiple users. The utilities create the following sets of packages and grant EXECUTE privilege to PUBLIC for all:

- AUTOCOMMIT package (MSNC001)
- READ_UNCOMMITTED package (MSUR001)
- REPEATABLE_READ package, (MSRR001)
- READ_COMMITTED package, (MSCS001)
- SERIALIZABLE or REPEATABLE_READ package (MSRS001)

Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, DB2/400 QSYS.SYSPACKAGE, and DB2 UDB SYSIBM.SYSPACKAGE catalog tables.

Note
When you are upgrading to Host Integration Server from Microsoft SNA Server 4.0 Service Pack 2 or Service Pack 3, you mu st re-create any existing packages by running the CrtPkg utility.

ODBC Driver for DB2

Microsoft ODBC Driver for DB2 enables access over SNA LU 6.2 and TCP/IP networks to remote DB2 databases. This driver is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester that can connect to most DRDA-compliant DB2 systems, including MVS, OS/390, OS/400, AIX RS/6000, and Microsoft Windows.

You can use the driver interactively or from an application program to issue SQL statements and execute DB2 stored procedures. From Microsoft Office Excel, users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. From Microsoft Office Access, users can import from and export to DB2. Using Microsoft Internet Information Services (IIS), developers can publish DB2-stored information to users through a Web browser interface.

IP-DLC Link Service

This section describes the configuration and use of the IP-DLC Link Service.

In This Section

Introduction to the IP-DLC Link Service

This section describes the overall architecture of the Host Integration Server system with IP-DLC link service functionality.

IP-DLC is a Host Integration Server feature that provides SNA connectivity for applications using dependent and independent sessions over a native IP network. It implements the HPR/IP protocol, which is also known as HPR over IP or Enterprise Extender. Each SNA packet is transmitted natively across the IP network as a UDP datagram.

In This Section

System Overview

This topic outlines key points of the Host Integration Server implementation of the IP-DLC link service.

- The IP-DLC link service is configured and managed by the Host Integration Server administrator as for any other link service.

- To provide the support required for transporting dependent LU sessions across an APPN network, the IP-DLC link service runs the DLUR feature as defined by the SNA/APPN DLUR Architecture Reference. This provides dependent LU session support to a CS/390 host running the matching DLUS feature.

- The IP-DLC link service operates as a Branch Network Node (BrNN) as defined in the SNA/APPN Branch Extender Architecture Reference. When large numbers of Host Integration Server systems are connected to a mainframe, the Branch Network Node configuration ensures that the overhead of topology and network search traffic on the Host Integration Server and mainframe links is minimal—comparable to using Host Integration Server without the IP-DLC link service.

- Multiple IP-DLC link services can be configured, one for each local IP address on the Host Integration Server system.

- Multiple IP-DLC connections are supported for each IP-DLC link service. There is one IP-DLC connection for each PU local to Host Integration Server.

- Remote independent LUs are associated with an IP-DLC link service instead of a connection. All remote independent LUs accessible through an IP-DLC link service are associated with the single peer connection for the IP-DLC link service. All independent LU traffic is routed by the APPN network and may traverse any active HPR/IP link.

IP-DLC Link Service Concepts and Terminology

Supported Features

This topic lists the features that are supported over the IP-DLC link service.

Base SNA Features

The following existing Host Integration Server SNA features are supported over the IP-DLC link service:

- LU types 0, 1, 2, 3 and 6.2 (dependent and independent)
- LUA, FMI, APPC, and CPI-C APIs
- Dynamically Defined Dependent LUs (DDDLUs)
- Dynamic addition of local LUs, remote LUs, and connections
- Incoming and outgoing calls
- Connection Activation at Server startup, on demand or by administrator
- SNA data compression
- PU concentration with the upstream link over IP-DLC
- NetView RUNCMD/Alerts (note that the IP-DLC link service does not generate alerts)

Because the preceding SNA features are supported, it follows that the following applications are also supported over the IP-DLC link service:

- Host Integration Server-compatible 3270 emulators
- Host Integration Server-compatible 5250 emulators
- APPC - 3270 Session Viewer (including the LU-LU Test feature)
- Host Print Service
- Data Integration Services
- Local and remote administration
- TN3270 server
- TN5250 server
- MSMQ-MQSeries Bridge
- Transaction Integrator

Fault Tolerance Features

Note that because the IP-DLC link service uses the APPN and HPR/IP protocols, it is automatically able to take advantage of the following fault tolerance features:

- Ability to reroute sessions around a failure in the network provided that an alternative route exists.

- Ability for mainframe applications to be moved to a different processor with little or no impact to users when system or application failures occur on the mainframe.

Load Balancing Features

Load balancing for a single IP-DLC link service, with a single local IP address, over multiple adapter cards can be achieved using NIC Teaming at the MAC layer. The IP-DLC link service handles frames arriving out of sequence.

Security Features

Because the IP-DLC link service uses UDP/IP, the Windows IPSec feature can be used to provide end-to-end data security over the IP-DLC link service. Windows handles configuration of IPSec independently. No specific configuration is required for the IP-DLC link service.

Diagnostic Features

The diagnostics provided by the IP-DLC link service are used through the Host Integration Server Tracer Initiator and Trace Viewer facilities.

Scalability
Key Limitations
IP-DLC Link Service Concepts and Terminology

Scalability

The IP-DLC link service supports the Host Integration Server capacity of 30,000 simultaneous host sessions per server.

Note
Four nodes are required to achieve 30,000 simultaneous host sessions and a single node supports a maximum of 15,000 simultaneous host sessions.

Concepts

System Overview
Supported Features
Key Limitations
IP-DLC Link Service Concepts and Terminology

Key Limitations

The key limitations with the IP-DLC link service implementation are as follows:

- The IP-DLC link service cannot be run as a distributed link service (DLS).
- The PU Passthrough and Downstream connections are not supported over IP-DLC connections. It is not possible to have a one-to-one correspondence between upstream and downstream messages where the upstream connection is an IP-DLC connection.
- Each IP-DLC link service must use a different CP name from the SNA node service.
- Each IP-DLC link service requires a unique local IP address. If multiple IP-DLC link services are required, each must have its own unique local IP address.
- A single IP-DLC link service cannot be shared by multiple SNA node services. Each SNA node service must use a different IP-DLC link service for IP-DLC connectivity.

IP-DLC Link Service Concepts and Terminology

The following is a brief introduction to the terminology and concepts that are referred to in this section, including APPN and HPR.

Session

A session is a logical connection between two network accessible units (NAUs). The most common example of an NAU is a logical unit (LU) (for more information, see Logical Unit (LU) later in this topic).

Physical Unit (PU)

The component that manages and monitors the resources (such as attached links and adjacent link stations) associated with a node. This term applies to non-APPN nodes only.

Logical Unit (LU)

A logical unit (LU) is a port through which an application or end user accesses the SNA network to communicate with another application or end user. An LU may be capable of supporting many sessions with other LUs.

There are two types of LUs:

- Dependent LUs require assistance from a mainframe to establish a session with another LU. These are also sometimes referred to as old LUs.
- Independent LUs can establish a session with another LU without the assistance of a mainframe.

APPN

Advanced Peer-to-Peer Networking (APPN) is a network architecture that supports distributed network control. It makes networks easier to configure and use, provides centralized network management, and supports flexible connectivity.

APPN Nodes

APPN nodes include systems of various sizes, such as mainframes using CS/390, Solaris servers running DCLs SNAP-IX, PCs running IBM Communications Server for Windows NT/2000 and IBM AS/400.

In an APPN network, nodes can be one of the following types:

- Network Nodes (NN)
- End Nodes (EN)
- Branch Network Nodes (BrNN)
- Low-entry networking nodes (LEN nodes)

Each node in an APPN network is connected to at least one other node in the APPN network. Where supported, CP-CP (Control Point to Control Point) sessions are established over these connections to adjacent nodes (nodes in the same network that can establish direct connections without going through a third node). CP-CP sessions are used to exchange network topology information, request the location of network resources, and manage sessions. All of the nodes in an APPN network share a common network name.

Network Node

A Network Node provides distributed directory and routing services for all LUs in its domain, where its domain is all directly attached End Nodes and LEN nodes that are using the services of the Network Node. The Network Node is referred to as the Network Node Server (NNS) for those directly attached End Nodes and LEN nodes.

A Network Node provides the following services:

- LU-LU session services for its local LUs.
- Directory searches and route selection for all LUs in its domain.

- Intermediate session routing for sessions between LUs on different nodes.

- Routing for Management Services (MS) data, such as alerts, between a served End Node or LEN node and an MS focal point.

End Node

An End Node is an end point in an APPN network. It maintains directory information only for local resources. An APPN End Node can independently establish sessions between local LUs and LUs on adjacent nodes. For sessions with LUs on nodes not directly connected to the End Node, an End Node requests routing and directory information from its Network Node Server using CP-CP sessions.

End Nodes can register their local LUs with their Network Node Server. This capability means the network operator at the Network Node Server does not have to predefine the names of all LUs on the attached End Nodes to which the Network Node provides services.

An End Node can be attached to multiple network nodes, but it can have CP-CP sessions active with only one Network Node at a time: its Network Node Server. The other Network Nodes can be used only to provide intermediate routing for the end node or as substitute Network Node servers if the main Network Node Server becomes unavailable.

An End Node can also have a direct connection to another End Node or LEN node, but CP-CP sessions are never established between the two nodes.

LEN Node

A LEN Node is a type 2.1 node that uses independent LU 6.2 protocols, but does not support CP-CP sessions. It can be connected to a Network Node or End Node but does not support APPN functions. The existing SNA node of Host Integration Server is a LEN node.

A Network Node can provide routing services for an attached LEN node, enabling the LEN node to participate in an APPN network without requiring links to be defined between the LEN node and all of the nodes in the APPN network.

LUs in the APPN network with which the LEN node may want to establish sessions must be defined to the LEN node as if they reside on the LEN node's Network Node server. The LEN node establishes sessions with LUs defined to be contacted through its Network Node Server. The Network Node routes the session through the APPN network to the node in the network where the LU actually resides.

LUs on the LEN node must be predefined to the Network Node that serves the LEN node. LU resources on LEN nodes (unlike those on End Nodes) cannot be registered on the Network Node Server by the LEN node.

When a LEN node's only link is to an End Node, the LEN node can communicate only with LUs on the End Node through the direct link between the two nodes. This is because an End Node cannot provide intermediate routing.

Branch Network Node

The Branch Network Node (BrNN) combines the functions of a Network Node and an End Node. As the name implies, a BrNN can be used to subdivide a network into a backbone network and attached branch networks. The BrNN provides the following functions:

- To the backbone network, the BrNN appears as an End Node, connected to its Network Node Server (NNS) in the backbone network.

- The nodes in the backbone network are not aware of the nodes within the branch, reducing the amount of topology information that must be stored.

- Because the BrNN appears as an End Node, it does not receive topology information from the backbone network (topology information is transmitted only between Network Nodes) reducing the amount of network overhead traffic flowing into the branch network.The BrNN registers all resources in the branch with its NNS as though they were located on the BrNN itself. This means that the nodes in the backbone network can locate resources in the branch without having to be aware of the separate nodes in the branch.

- To the branch network, the BrNN appears as a Network Node, acting as the NNS for End Nodes and LEN Nodes in the branch.

High Performance Routing

High Performance Routing (HPR) is an extension of the APPN architecture. HPR provides the following functions:

- Rapid Transport Protocol (RTP) minimizes processing cycles and storage requirements for routing network layer packets through intermediate nodes on a session route.
- Automatic network routing (ANR) enables APPN networks to automatically reroute sessions if a portion of the originally computed route fails.

Dependent LU Requester/Server

Dependent LU Requester (DLUR) function enables sessions for dependent LUs to reside on remote nodes across an APPN network, instead of requiring a direct connection to the host.

DLUR works in conjunction with Dependent LU Server (DLUS) at the host. Together, they route sessions across the network from dependent LUs in the APPN network to the DLUS host. The route to the host can span multiple nodes and can take advantage of APPN's network management, dynamic resource location, and route calculation facilities.

If the local node is a Network Node, dependent LUs on downstream computers can also use pass-through DLUR, in the same way that LUs internal to the node do, to access the host across the network.

Managing IP-DLC Link Services

This section gives procedures for creating, configuring, viewing, and deleting IP-DLC link services.

In This Section

Creating an IP-DLC Link Service

You create and configure an IP-DLC link service as you would create any other link service.

To create an IP-DLC link service

1. In the SNA Manager, locate the computer on which you want to create the IP-DLC link service.
2. Right-click the **Link Services** folder under that computer.
3. On the context menu, click **New/Link Service.** The **Insert Link Service** dialog box appears.
4. From the list of available link services, select **IP-DLC Link Service**.
5. Click **Add** to load the **IP-DLC Link Service** properties dialog box.
6. To configure the new link service, follow the steps for Configuring an IP-DLC Link Service.

See Also

Other Resources

Managing IP-DLC Link Services

Viewing Link Services

As with other link services, you can view IP-DLC link services in the list view of the **Link Services** folder.

To view link services

1. In the scope pane of the Host Integration Server MMC snap-in, locate the computer with the link services that you want to view.
2. Expand the list for that computer.
3. Select the **Link Services** folder. The link services for that computer will appear in the right pane.

Other Resources

Managing IP-DLC Link Services

Viewing Link Service Properties

As with other link services, you can view IP-DLC link service properties by using the context menu in the list view of the **Link Services** folder.

To view link service properties

1. In the scope pane of the Host Integration Server MMC snap-in, locate the computer with the link services that you want to view.
2. Expand the list for that computer.
3. Select the **Link Services** folder.

   The link services for that computer appear in the right pane.
4. Right-click the appropriate link service, and then click **Properties**. The **Link Service Properties** page appears.
5. Click **Configure**.

   The properties for this IP-DLC link service appear, and can be viewed or edited.

See Also

Other Resources

Managing IP-DLC Link Services

Deleting Link Services

As with other link services, you can delete an IP-DLC link service in the MMC snap-in.

Note
When you delete a link service, all related connections will no longer be associated with any link service. A user might associate such a connection with any other IP-DLC link service that is associated with the node. Deleting a node associated with a link service will break association between these items.

To delete a link service

1. In the scope pane of the Host Integration Server MMC snap-in, locate the computer with the link services that you want to delete.
2. Expand the list for that computer.
3. Right-click the appropriate link service, and then click **Delete**.

Link Service and the LnkCfg Utility

LnkCfg is a useful command-line utility for deploying and managing link services. The format of the command line for configuring the link service is specified as follows.

LINKCFG LINKSVC "Title"

/SERVER:servername

/LSTYPE:"IP-DLC Link Service"

/PRIMARYNNS:NNSServer

/BACKUPNNS:NNSServer

[/LOCALADDRESS:ipaddress] or [/ADAPTER:adaptername]

/NETWORKNAME:networkname

/CPNAME:name

/NODEID:"xxx.xxxxx"

/LENNODE:lennode

The following table describes the command-line parameters.

Property	Description	Content
"Title"	Title of the link service.	1-128 characters.
/SERVER:servername	Name of the server.	Valid server name.
/PRIMARYNNS:NNSServer	Primary network node server.	DNS name or IP address.
/BACKUPNNS:NNSServer	Backup network node server.	DNS name or IP address.
/ADAPTER:adaptername	Name of the local adapter. /ADAPTER and /LOCALADDRESS arguments should not be used together.	Name of the physical or logical adapter on the computer.
/LOCALADDRESS:ipaddress	Local address. /ADAPTER and /LOCALADDRESS arguments should not be used together.	Valid IP address or server name.
/NETWORKNAME:networkname	Network name of the Branch Network Node implemented by the link service.	1-8 characters SNA Type A string.
/CPNAME:name	Control point name of the Branch Network Node implemented by the link service.	1-8 characters SNA Type A string.
/NODEID:"xxx.xxxxx"	Identity of the Branch Network Node implemented by the link service.	String in format HHH.HHHHH where H is a hexadecimal digit.
/LENNODE:lennode	Name of the associated LEN node.	Name of a LEN node deployed on the local computer.

Connections and the SnaCfg Utility

SnaCfg is a useful command-line utility for deploying and managing SNA Server configurations.

The following table describes the command-line parameters.

Property	Description	Validation
/conntype:type	Connection type.	IP-DLC.
/RemoteAddress:adr	Address of the remote DLUS service. This property is not accessible through the user interface. It provides a way of establishing a direct connection with DLUS rather than routing the connection through the NNS.	Valid IP address or DNS name.
/PrimNetworkName:name	Network name of the primary DLUS server.	1–8 characters, SNA Type A string.
/PrimCPName:name	Control point name of the primary DLUS server.	1–8 characters, SNA Type A string.
/BackupNetworkName:name	Network name of the backup DLUS server.	1–8 characters, SNA Type A string.
/BackupCPName:name	Control point name of the backup DLUS server.	1–8 characters, SNA Type A string.
/DLURRetryType:N	DLUR retry type.	0 indicates none 1 indicates infinite 2 indicates limited
/DLURRetryLimit:N	DLUR retry limit. This parameter is invalid unless the DLUR retry type is set to limited.	1–65534
/DLURRetryDelay:N	Delay after a DLUR retry. This parameter is invalid unless the DLUR retry type is set to limited.	1–65535
/RetryLimit:N	Number of the connection retries.	0 indicates unlimited 1–65534 number of retries
/RetryDelay:N	Delay after a connection retry.	0–327670, must be a factor of 5.
/XIDFormat:N	XID type.	Set to: 1 – "Format 3"

/RemoteNetName:name	This value is always set to the network name of the IP-DLC link service.	Must be left blank for a new connection.
/RemoteCPName:name	This value is always set to the control point name of the IP-DLC link service.	Must be left blank for a new connection.

Defining Dependent LUs

Secure Deployment of the IP-DLC Link Service

Secure Deployment of the IP-DLC Link Service

The IP-DLC link service takes advantage of the entire Host Integration Server secure deployment feature set, especially the following:

- A typical IP-DLC link service deployment scenario may use Internet Protocol security (IPSec), a firewall, or a virtual private network (VPN) as a security barrier between the Host Integration Server computer and the remote node. (A VPN is advisable if the HPR/IP link spans an insecure IP network.)

- Incoming frames from IP addresses that are not already defined in Host Integration Server are rejected. This isolates the main SNA node service from such attack.

- The IP-DLC link service checks the length of incoming datagrams before copying the data into internal data areas, and discards any that are too long.

- All configuration data—whether from registry entries, COM.cfg, or the SNA node service—is validated for correct value when first accessed. Particular consideration is given to validating lengths to avoid buffer overruns. If any errors are found, the IP-DLC link service logs an event and terminates.

SNA Service

The core of the power of Host Integration Server is its ability to provide a wide range of host connectivity services. Host Integration Server uses client/server architecture to distribute communications processing. This architecture maximizes the power of the host, Host Integration Server, and individual client computers. Within the context of Host Integration Server, a connection is the data communication path between a Host Integration Server computer and an IBM host (mainframe or AS/400). A connection is what makes it possible for a client computer on a local area network (LAN), using standard LAN protocols, to communicate with a host by means of one or more Host Integration Server computers. Each server supports up to 3,000 users operating 30,000 concurrent sessions, 8,000 split stock users per node, four nodes per server.

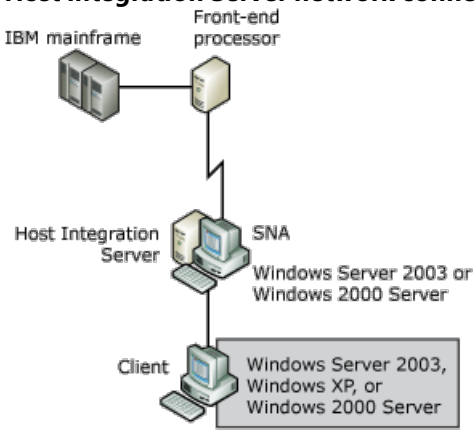
In This Section

Communication Between Host Integration Server Computers and a Host Computer

Within the context of Host Integration Server, a connection is the data communication path between a Host Integration Server computer and an IBM host (mainframe or AS/400). A connection corresponds to a physical unit (PU) definition on a mainframe or an APPC controller definition on an AS/400. The connection is what makes it possible for a personal computer on the LAN to communicate with a host by means of a Host Integration Server computer. Note that SNA connections do not use BISYNC, an older IBM standard for communications.

The following figure shows a Host Integration Server network connected to an IBM mainframe.

Host Integration Server network connected to IBM mainframe



For each physical adapter or connection, an appropriate link service is installed and configured within Host Integration Server. The link service is a Windows server service or device driver that is used to control server-to-host communication adapters supported by Host Integration Server. The link service provides the SNA data link-level protocol used by the Host Integration Server computer to communicate with the host.

After being configured, the link service is available for use not only on the configured Host Integration Server, but also on any Host Integration Server computer in the subdomain using the Distributed Link Service feature of Host Integration Server.

After a link service is configured, you can create connections. A link service may support multiple links to one or more hosts.

In SNA terms, the combination of a connection and the link service it uses is equivalent to a PU. In hierarchical SNA networks, Host Integration Server provides PU 2.0 functionality. For peer-oriented SNA networks, Host Integration Server provides PU 2.1 LEN node functionality.

Other Resources

SNA Service

Physical Unit (PU)

Although the name physical unit (PU) strongly implies a hardware component, a PU is an IBM naming convention for hardware and software combinations that perform a specific task in an SNA network. For example, PU 5 represents not only the mainframe itself, but also the mainframe software components (such as SSCP and VTAM) within the SNA network.

The following table lists the SNA defined PU types and a brief description of each.

PU number	Description
PU 1	Terminal Controller (IBM 6670, 3767)
PU 2	Cluster controller running configuration support programs (IBM 3174, 3274, 4701, 4702)
PU 2.1	Peer-to-Peer (APPN), used primarily in AS/400 networks
PU 4	IBM Front End Processor, usually running ACF and the Network Control Program (IBM 3754, 3725, 3720, 3745, 3746)
PU 5	IBM Host (mainframe) system

Other Resources

SNA Service

Logical Unit (LU)

A logical unit (LU) is a configurable unit of software that contains the information needed to specify the type of communications session with the host computer or peer system. Thus, an LU is a point of access to the Host Integration Server network. There are several types of LUs:

- APPC
- 3270
- Downstream
- Logical unit application (LUA)

LUs represent a set of functions that manage the exchange of data between users and applications, acting as intermediaries between the user and the network. Host Integration Server protocols identify several LUs on host computers that represent specific functions. The following table is a list of LU numbers and a brief functional description.

LU number	Description
LU 0 (also LU/A or LUA, logical unit application)	General purpose LU for development of specialized applications such as TN3270. Used for program-to-program communications in hierarchical networks.
LU 1	LU 1 handles the transmission of printer data to network and system printers in SNA character string format. IBM 3287-type printers and Host Integration Server Host Print service that allows you to redirect print data streams to LAN printers. Used to communicate with multiple-device terminals.
LU 2	IBM monochrome terminals 3278 (3270) IBM Color graphic terminals 3279/3179 Host Integration Server displays
LU 3	IBM 3284-style printers and Host Integration Server Host Print service, which allows you to redirect print data streams to LAN printers. LU 3 is a simple printing protocol that uses the 3270 data stream format to communicate with a single printer.
LU 4	IBM 6670 information distributor and is not supported through Host Integration Server.
LU 5	Not defined.
LU 6	LU 6.2 is most common revision. IBM 5250 devices and Host Integration Server local and remote APPC LUs. Provides peer-to-peer communication through Advanced Program-to-Program Communication (APPC) and (Common Programming Interface for Communications (CPI-C).
LU 7	IBM 5250 display terminal. Used mainly on System 3.x but not on AS/400 systems.

On Host Integration Server computers, you can configure LUs to emulate the 3270 data streams needed to communicate with the mainframes or 5250 data streams for AS/400 systems.

A 3270 LU is a dependent LU that requires the mainframe to function. It has a fixed designation, such as a display LU, printer LU, logical unit application (LUA) LU, or downstream LU. Each type of LU has a specific number assigned to it. A 3270 LU on Host Integration Server has an LU number, and a corresponding resource must be defined on the host computer. The 3270 LU name is arbitrary and does not have to match the name of the resource on the host.

Additional information about APPC is available later in this section.

SNA Service

Choosing a Connection Type

A Host Integration Server computer can use any of the types of connections described in this section. To choose a connection type for your servers, you should first contact the host administrator and find out the type of connection available to the mainframe or AS/400. If more than one type is available, choose a type based on comparisons of cost and speed.

For demonstration purposes, you can install the Demo SDLC link service, which receives messages from Host Integration Server and responds to them itself from a prerecorded script.

The various adapters in a computer must be configured to work together so that there are no interrupt, port address, or direct memory access (DMA) conflicts. When you install a new adapter in your computer, you may need to study the configuration of the new and old adapters to make sure that there are no conflicts.

The following connection types are available:

- 802.2 Data Link Control (DLC 802.2)

  Token ring, Ethernet, or Fiber Distributed Data Interface (FDDI) connections use the IEEE 802.2 protocol. With a mainframe, an 802.2 connection goes to a 37*xx* front-end processor (FEP) or a 3174 communications controller (or, rarely, to an adapter in the mainframe). With an AS/400 system, an 802.2 connection goes directly to the AS/400.

  These connections are generally faster than other connections, except for channel connections. The following table provides details.

Type of 802.2 connection	**Common speeds**
Token ring	4 megabits per second (Mbps) or 16 Mbps.
Ethernet/Fast Ethernet	10–100 Mbps.
FDDI	100 Mbps (or more); however, the FDDI line communicates through a front-end processor that is channel-attached to the mainframe, and this may limit the overall speed of communications.

  DLC 802.2 also has certain limitations. The 802.2 link service cannot support more than one 802.2 connection to the same MAC address and destination SAP (that is, to the same host) at the same time, whether the connections originate from the local or a remote SNA Server computer. The 802.2 protocol specification does not permit two distinct connections to have the same Source MAC, Source SAP, Destination MAC, and Destination SAP. The 802.2 link service is bound to a particular LAN adapter and source SAP value, and therefore uses the same source MAC and SAP for all connections. To support multiple connections, you can:

  - Connect to different network adapters on the host.
  - Configure multiple 802.2 link services, all bound to the same LAN adapter but specifying different source SAPs.
  - Support multiple connections to a given host through the same 802.2 link service. Verify that the host is configured to accept 802.2 connections on multiple SAPs. This can be configured to mainframe FEPs (but is rarely used). AS/400s support multiple SAPs by default. These SAP values are configured as the remote SAP value on the Host Integration Server connection, which is configured on the Host Integration Server computer using the distributed link service.

  This limitation applies to connections based on the 802.2 link service in general.

  When you make an 802.2 link service available to distributed link service on other Host Integration Server computers, it cannot be used by the local Host Integration Server computer, and is not visible in SNA Manager Console.

- Synchronous Data Link Control (SDLC)

SDLC uses a standard phone line, which can be leased or switched and can be point-to-point or multi-drop. An SDLC line is used with a modem or other type of data circuit -terminating equipment (DCE) at each end. With a mainframe, an SDLC line travels through a modem or other DCE to a 37*xx* front-end processor (FEP), 3174 communications controller, or integrated synchronous adapter. With an AS/400 system, an SDLC line goes through a modem or other DCE, and then directly to the AS/400.

An SDLC connection is slower than an 802.2 or channel connection. Common speeds for SDLC connections are listed in the following table.

Type of transmission	**Common speeds**
Analog (conventional phone line)	9600–56000 bits per second
Digital Data System (DDS)	56 kilobits per second (kbps) (sometimes 64 kbps)
Integrated Services Digital Network (ISDN)	56 kbps (can be more)
T1 carrier system (digital)	1.544 megabits per second (Mbps)
E1 carrier system (digital)	2.048 Mbps

SDLC connections are useful for wide-area connections between geographically disparate locations, or when bandwidth and usage requirements are low. Because of these factors, SDLC is ideally suited for branch-type deployment strategies.

Host Integration Server supports SDLC connections using the link support that is included with it or through an SDLC link service available through various third-party vendors. Not all supported SDLC adapters support all link speeds listed in preceding table.

- Distributed Link Service

  The distributed link service feature provides a method for a Host Integration Server computer to connect to a host using a link service installed on a different Host Integration Server computer. The network connecting SNA Server computers need not support any SNA link level protocol such as DLC 802.2 or SDLC.

  The distributed link service is configured in two parts: by installing the distributed link service on one SNA Server computer and by marking a real link service on another computer as distributable. The distributed link service acts as a proxy for sharing the distributable link service. It supports load balancing across multiple, distributed link services. It also supports hot backup because the distributed link service can select alternate remote servers when a remote link fails. It allows a branch SNA Server computer to connect to the host over a wide area network (WAN). This supports only routable internetworking protocols such as TCP/IP, rather than requiring an SNA WAN protocol such as SDLC or bridged DLC.

  Distributed link services provide the following benefits:

  - The branch-based Host Integration Server computers provide split-stack SNA gateway service for local client computers, simplifying configuration of the client computers. This conserves PUs and concentrates traffic on behalf of several client computers, which saves valuable network bandwidth.

  - The branch-based Host Integration Server computer communicates with the central-site Host Integration Server computers through a native TCP/IP connection, which eliminates DLC 802.2 time-out problems associated with traditional SNA encapsulation methods.

  - Because the central site servers provide the equivalent of PU pass-through service for the branch-based servers, the host operator sees each branch-based server as a PU and can manage the branches through standard NetView alerts and RunCmds.

  - The branch-based servers can connect to the host through multiple centralized servers, load-balancing among the multiple central-site servers at connect time.

- Should a central-site server fail for any reason, the branch-based servers will automatically establish a new connection through an alternate centralized server for hot backup.

- Should the WAN fail for any reason, the branch-based Host Integration Server computers can be configured to connect to the host through a direct dial-up SDLC connection as a backup that will be activated automatically upon the host connection failure. It is actually activated upon the first request after a failure.

- The routers at the branches only need to route TCP/IP, which provides for simplicity of WAN management and cost savings.

- Because the branch-based servers rely on WAN services provided by the leading networking vendors, the distributed link service will work over all existing and future WAN technologies, including leased lines, X.25, frame relay, and ATM networks.

- Unlike other native TCP/IP solutions such as TN3270, the distributed link service is not limited in SNA functionality. Each branch-based Host Integration Server computer provides full SNA access for the local personal computers, including PU 2.0, PU 2.1, and APPN LEN service, as well as LU 0, LU 1, LU 2, LU 3, and LU 6.2 support. Both mainframe and AS/400 access are supported.

- Although the majority of customers are moving to TCP/IP networks, the distributed link service also fully supports IPX protocols.

When Host Integration Server is set up to use more than one client/server protocol, distributed link service first attempts to establish communication between the servers using TCP/IP, if available. If that fails, distributed link service next attempts to connect using IPX/SPX. To designate a protocol other than TCP/IP as the primary protocol to be used by distributed link service, use the Registry Editor to add or modify the values in the Windows registry. For an example of the registry entry, see the *Host Integration Server Administrators Reference*.

By default, when you make a link service available to distributed link service on other servers, it will permit a connection from distributed link service running on any remote server that is configured to connect to it. This is similar to the level of access control permitted by traditional pass-through gateways. Any downstream device that is configured for the correct MAC address can use the gateway.

However, you can restrict access to the distributed link service, requiring the remote distributed link service to provide a valid Windows server username and password. The procedure requires coordination between the upstream and remote servers.

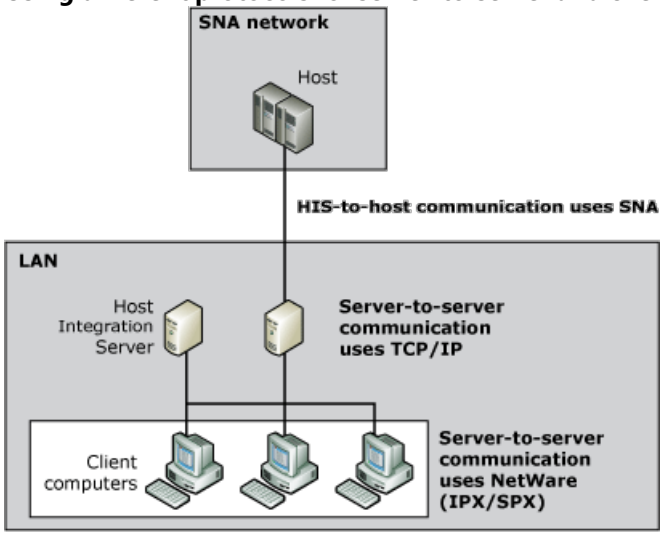
Communication Between Multiple Host Integration Server Computers

Host Integration Server computers communicate with each other using mail slot or datagram broadcast messages. They use the SnaBase service to keep track of names of servers, client computers, and available transaction programs (TPs), which are the programs used for communication through Advanced Program-to-Program Communications (APPC) or Common Programming Interface for Communications (CPI-C).

Microsoft Windows Server 2003 and Windows 2000 Server support multiple protocols simultaneously, but there is no need to send the same Host Integration Server broadcasts over all available protocols. Using the SNA Manager Console, you can specify the network protocol for server broadcasts. You must make sure that one protocol is available on all Host Integration Server computers in the SNA subdomain, and use that protocol for server broadcasts. For more information, see Configuring a Server Broadcast. The following figure shows a network in which TCP/IP is used for server-to-server communications and IPX/SPX is used for client-to-server communications.

Using different protocols for server-to-server and client-to-server communications



Separate protocol used for server-to-server and client-to-server communications

It is recommended that you use only one protocol for server broadcasts. Using multiple server-to-server transport protocols can add to network overhead because every server broadcast must be sent out through all the protocols selected.

Server broadcasts need to be configured only once for a subdomain; the configuration affects all servers in the subdomain.

The mean time between server broadcasts is specified in number of seconds, with the default being 60 seconds. Specifying a smaller value brings heavier demands on the network because the broadcasts occur more often.

SNA Service

Configuring a Server Broadcast

You can configure a server broadcast to ensure that your servers use the appropriate protocols for your network configuration.

To configure a server broadcast

1. In the SNA Manager tree, select the subdomain that you want to configure.
2. On the **Action** menu, click **Properties**.
3. Click the **Server Broadcasts** tab, fill in the options, and then click **OK** to exit.
4. On the **Action** menu, click **Save configuration**.

SNA Service

Communication Between Host Integration Server Computers and Client Computers

Client computers locate the resources of the Host Integration Server computer in either one of two ways:

- Sponsor connection
- Active Directory directory service

A sponsor connection is created when a client computer makes a request to communicate with a Host Integration Server computer and an initial connection is established. The first Host Integration Server computer to respond to the request (called the sponsor computer) provides the client computer with all the names of Host Integration Server computers in the subdomain. From these names, the client computer locates an available LU or LU pool.

In a similar way, a client computer that is configured to use Active Directory makes a request to the Active Directory database. Active Directory responds to the request and provides the client computer with all the names of Host Integration Server computers in the Organizational Unit.

For client/server protocols to operate properly with Host Integration Server, both client computers and servers must have the network software and the Host Integration Server software installed properly. The network protocols available for use by various client operating systems are listed in the following table.

Operating system on client computer	**Client/server protocols**
Windows Server 2003 or Windows 2000	Microsoft Networking (Named Pipes) Novell NetWare (IPX/SPX) TCP/IP

SNA Service

Host Integration Server Client and SNA Communications

When a client computer makes an SNA request, the client computer must direct that request to a domain or to one or more Host Integration Server computers. The appropriate way for a client computer to direct requests depends on the protocol used and the relative location of client computers and servers. The following table lists the ways that client computers direct SNA requests, and the information that will be requested by Setup during client software installation.

Network protocol used on client	**How the client directs SNA requests**	**Information to find out before running client setup**
Microsoft Networking	Either to the local domain (if the Host Integration Server computers are in the same domain as the client computer), or to one or two specific Host Integration Server computers in a remote domain.	Whether the client computer is in the same domain as the Host Integration Server computers, and if not, one or two names of Host Integration Server computers.
Novell NetWare (IPX/SPX)	To a specific domain. The Host Integration Server computers must be located in this domain for the client computer to locate them.	The name of the SNA subdomain in which the Host Integration Server computers are located.
TCP/IP	Either to a domain name or to a specific server name, depending on what is specified in the SNA Client Mode or Host Integration Server Location dialog box.	Contact your network administrator for additional information regarding a specific IP address for Host Integration Server.

When a client computer first makes a request for communication with the SNA network, it establishes an initial connection (the sponsor connection) with a Host Integration Server computer. The client computer then requests a logical unit (LU), either by name or by requesting an LU from a particular pool of LUs. If the request is for a particular LU, the sponsor server responds by providing the name of the Host Integration Server computer that contains the LU. If the request is for an LU pool, the sponsor server responds by providing the client computer with all the names of Host Integration Server computers in its subdomain that support the pool. From these names, the client computer picks a server at random.

Host Integration Server computers and client computers keep track of the names of servers in the SNA subdomain through the SnaBase service (formerly known as the network access protocol, or NAP). For client computers, the sponsor connections, along with the SnaBase provide a view into the server subdomain.

SNA Service

Host Print Service

Host Print service provides server-based 3270 and 5250 print emulation, allowing mainframe and AS/400 applications to print to a LAN printer supported by Microsoft Windows Server 2003 and Windows 2000. Host Integration Server Host Print service enables centralized control of LU print resources. You can administer all Host Print service functions using SNA Manager, including margin control, fonts, and characters per line. Host Print service also supports print-to-file with auto-incrementing file names. You can configure the file naming scheme for each printer LU.

The following three methods of printing host information are available:

- **Screen printing.** This method allows any 3270 or 5250 emulator to print what is on the display using print screen features of the client operating system. The printer output can be directed to a printer attached to the client computer or the network.

- **Client-redirected printing.** This method delivers an SNA host printer data stream (such as 3287) to the appropriate emulation application running on a Host Integration Client 2000 computer. The client software converts the data stream into data that can be printed locally or to a network printer.

- **Server-based redirected printing.** This method uses a server process to convert SNA host printer data streams into data that can be directed to a local or network printer.

In This Section

Using Host Print Services

Host Print service is a Windows Server service, and is found as SnaPrint in the Services utility in Windows Control Panel. To access network printers, the SnaPrint service must run in a domain account with administrative privileges. You must create this account before Host Integration Server Setup.

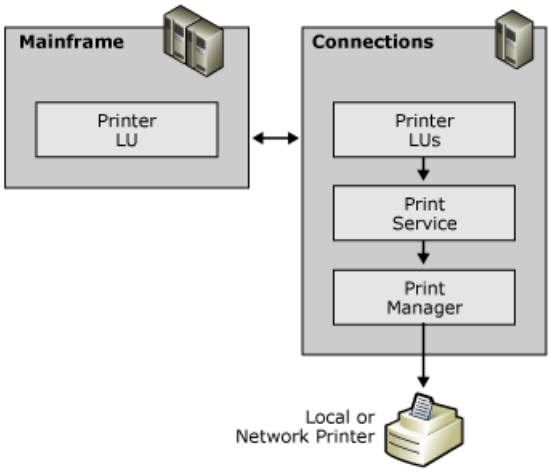
Host Print Service

Mainframe Printing

Mainframe printing supports both LU 1 and LU 3 data streams. It also includes pass-through support from the host for Intelligent Printer Data Stream (IPDS). Using IPDS, mainframe print jobs can be printed on LAN printers without changing either the print job or the host application.

Connections between mainframe printing and local printer



Host Print service provides print emulation for three LU types: LU 3, LU 1, and LU 6.2 (APPC). The LU type defines the characteristic of the host data stream. LU 3 and LU 1 printing use a 3270 data stream over a session to a mainframe. APPC printing uses a LU 6.2 data stream over a session to an IBM AS/400. The following sections provide an overview of LU 3 and LU 1 printing. APPC printing is discussed under the AS/400 section later in this section.

The Host Print service must run in a user account that has permission to access the defined network printer (or printers). For example, if you are printing to a printer attached to a Novell NetWare system, the Host Print service must run in an account that is recognized by NetWare.

Host Print Service

LU 3 Printing

LU 3 printing is the simplest of the three types of host printing. The LU 3 data stream closely resembles that for 3270-display emulation. It consists of a write command code and a write control character (WCC) followed by the print job. These print jobs contain printable characters and only four simple formatting orders (new line, form feed, carriage return, and end of medium). No other control of the print output is available. This form of printing is similar to printing a text file from a personal computer. If more print formatting is required, an LU 1 print session should be used. For more information, see the section LU 1 Printing.

In SNA Manager, the 3270 Print Session properties Page Layout tab includes specifications for the number of characters per line and the number of lines per inch. Host print jobs using the LU 3 data stream also provide defaults for these parameters. The defaults may be different depending on the settings.

For LU 3, the settings in the host print job normally override the Print Service session settings. However, if you leave the host settings at their defaults of 6 lines per inch and 132 columns per row, the Print service session settings are used.

After the defaults for lines per inch and page width have been determined, the Print service chooses a font for the print job that will accommodate this size print output on the paper loaded in the printer.

There are no transparent sections in LU 3 print jobs, so Transparency is ASCII does not apply. LU 3 print jobs do not have SCS codes, but do have NL, CR, FF, and LF characters and do have commands to allow you to position print data on the page. The Print service uses these to build an internal representation of the page before printing it out. When a PDT file is used, Print service uses the definitions of NL, CR, FF, and LF from the PDT file to allow it to format the printout correctly. If no PDT file is configured, Print service uses the Windows GDI.

Command Code

The write command codes are not unique values, but are identified by occupying the first byte in the Request Unit (the message format used in an SNA network, also known as an RU). In addition there can be only one command code per RU. For LU 3 printing, the most commonly used command code is Erase/Write '0xF5'. Read command codes, which would be normal for display sessions, are not valid for LU 3 printing, and will be rejected with a sense code of '1003'.

Write Control Character (WCC)

Following the write command code is the write control character (WCC). This byte is also identified by its position, second byte in the RU. With LU 3 printing, bits 2 and 3 of the WCC define the printout format.

Write Control Character (WCC) Codes

Bit	Explanation
0,1	Ignored by the printer.
2,3	Defines printout format.
none	00 NL or CR orders define the print line length, EM indicates the end of the message.
none	01 Indicates 40-character lines.
none	10 Indicates 64-character lines.
none	11 Indicates 80-character lines.
4	Start-printer bit.
6	Keyboard reset.
7	Reset MDT bit.

Format Control Orders

There are four control codes used only for printing known as Format Control Orders.

Format Control Orders

Abbreviation	Order	EBCDIC

NL	New Line	0x15
EM	End of Medium	0x19
FF	Form Feed	0x0C
CR	Carriage Return	0x0D

NL, CR, and EM are valid only when the write operation does not specify a line length format in the WCC byte. FF is valid in any write operation.

3270 Orders

The 3270 data stream can contain sequences, called 3270 Orders, which provide additional control functions. The two most commonly used in LU 3 printing are Set Buffer Address (SBA) and Repeat to Address (RA). Note that the buffer address used in these commands is relative to each write. The print buffer in LU 3 allows a maximum of 4 KB of data, and often only 2 KB. This may require multiple write commands to be sent for a full page of text. The first write command will start at the top of the page. Its first buffer address will also be at the top of the page. Subsequent writes will continue where the first left off. Their first buffer address will also start where the previous write ended, unless it was ended with a form feed. For the examples below, it is assumed that these are the first write commands.

SBA is indicated by a '0x11' followed by a two-byte buffer address. This order sets the cursor position to the location specified in the two-byte buffer address. In LU 3 printing, this sets the print position. The data following the SBA will be printed starting from this location. For example:

114040 Sets the print position to row 1 and column 1.

RA is indicated by a '0x3C' followed by a two-byte stop buffer position and the character to be repeated. This order causes a character to be repeated from the current buffer address up to but not including the stop buffer address specified in the RA. For example:

3C40D3C1 Repeats the character 'A' ('0xC1') to row 1 and column 20.

Data

For LU 3 printing the data or printable characters must have values between '0x40' and '0xFE'. The only valid values outside this range are the 3270 Orders.

Example: 15C1C2C3 Prints a new line followed by 'ABC'

Example: 1BC1C2C3 Rejected because '0x1B' is an invalid value

Sample Host Data

Following is sample data from a host along with an explanation of the data and resulting printout.

```
F5C81140 40151515 C1C2C3C4 15404040
E6E7E8E9 19
```

This sample data is analyzed in the following table.

3270 LU 3 Sample Data

Data	Interpretation
F5	Command code Write/Erase
C8	WCC with bits 2, 3 specifying that NL, EM and CR orders determine the print line length.
114040	SBA sets print position to row 1 column 1
15	New line

15	New line
15	New line
C1C2C3C4	EBCDIC hex values for ABCD
15	New line
404040	EBCDIC hex values for three spaces
E6E7E8E9	EBCDIC hex values for WXYZ
19	End Medium

Print output from the sample data in the preceding table. ABCD on top print line and WXYZ indented on lower line.

Host Print Service

LU 1 Printing

LU 1 printing allows the host to specify formatting for a print job. This is accomplished through the use of SNA Character String (SCS) control codes. The SCS codes encompass the 3270 format orders (FF, CR, and NL), as well as providing additional control codes to format the print output. Through the SCS codes, the host application can set the margins, characters per line, and lines per inch. In addition to the format of the print job, SCS code allows the host application to send a transparent section. By using an SCS code, the host can mark a section of data as transparent. This will cause the print emulator (the Host Print service in this case) to not scan this section for SCS control codes but to pass it to the print output untouched. Transparent sections are most commonly used to embed printer control codes, such as the HP PCL, in the print job. Unlike LU 3 printing, there is no write command code or WCC. The first byte of the RU is either an SCS code or data.

Data Stream Flags

The BIND sent by the host for a LU 1 session indicates what SCS control codes are valid for this session. These Data Stream Flags are set in byte 18 of the BIND.

Data Stream Flags

Bit	Value	Description
0		**Base SCS code support**
	0	**Base support** (NL & FF only)
	1	**Full Base** includes Base plus the following:
		BS (back space)
		CR (carriage return)
		LF (line feed)
		ENP (enable presentation)
		INP (inhibit presentation)
		HT (horizontal tab)
		VT (vertical tab)
1		**Set Horizontal Format** (SHF)
	0	not supported
	1	supported
2		**Set Vertical Format** (SVF)
	0	not supported
	1	supported
3		**Vertical Channel Select** (VCS)
	0	not supported
	1	supported

4		**Set Line Density** (SLD)
	0	not supported
	1	supported
5		**Reserved**
6		**Bell** (BEL)
	0	not supported
	1	supported
7		**Transparent** (TRN) & **Interchange Record Separator** (IRS)
	0	not supported
	1	supported

SCS Codes

The SCS control codes are fully documented in the IBM Host Print Guide (document number SC31-7145). All of the SCS control codes fall within the range of '0x00'–'0x3F.' These codes range from single byte codes, such as Subscript '0x38', to multiple byte codes followed by several parameters, such as Set Horizontal Format '0x2BC1...'

The following are some of the more common SCS control codes used.

Note
[L]=length and **(Abv)** represents one-byte parameters in the SCS control code.

Set Horizontal Format (SHF) — '0x2BC1[L](MPP)(LM)(RM)(T1)(. . .)(Tn)'

[L] — Length of the parameters, including the length byte

MPP — Maximum Presentation Position; defines the characters per line

LM — Left Margin; column value for the left most print position

RM — Right Margin; column value for the right most print position

T1 — Horizontal tab stop; column value for a tab stop

Tn — Additional tab stops, which can be added in any order

Example

2BC1068401840542

2BC1 — SHF

06 — length of the parameters is 6 bytes including the length byte

84 — MPP is set to 132 characters per line

01 — LM is set to column 1

84 — RM is set to column 132

05 — T1 is set to column 5

42 — T2 is set to column 66

Set Vertical Format (SVF) — '0x2BC2[L](MPL)(TM)(BM)(T1)(. . .)(Tn)'

[L] — Length of the parameters, including the length byte

MPL — Maximum Presentation Line; defines the lines per page

TM — Top Margin; line number of top most print position

BM — Bottom Margin; line number of the bottom most print position

T1 — Vertical Tab Stop; line number for a tab stop

Tn — Additional Tab Stops, which can be added in any order

Example

2BC20642053D0A21

2BC2 — SVF

06 — length is 6 bytes

42 — MPL is set to 66 lines per page

05 — TM is set to line 5

3D — BM is set to line 61

0A — T1 is set to line 10

21 — T2 is set to line 33

Set Line Density (SLD) — '0x2BC6[L](Point)'

[L] — length, including length byte. Value of '0x01' denotes default.

Point — Distance to be moved vertically for a single line. The number is indicated in typographic points (one point is equal to 1/72 inch). Setting a value of '0x0C' will result in 6 lines per inch, a value of '0x09' will result in 8 lines per inch. Value of '0x00' denotes default a value of 6 lines per inch.

Example

2BC6020C

2BC6 — SLD

02 — length is 2

0C — 12 points or 6 lines per inch

Set Print Density (SPD) '0x2BD2[L]29(CharDensity)(Resv)'

[L] — length, including length byte. Value of 0x02 denotes default characters per inch (cpi) of 10

CharDensity — value indicating the numbers of cpi

Resv — Reserved (not used)

Example

2BD204290A00

2BD2 — SPD

04 — length is 4 bytes

29 — type

0A — 10 cpi

00 — reserved

Transparent (TRN) — '0x35[L](P1)(. . .)(Pn)'

This SCS control code indicates a section of data that is not scanned for SCS codes, but passed to the print output untouched. The extent of the section of data is denoted by the length byte.

Example

35051B28313055

35 — TRN

05 — length of transparent section, not including the length byte

1B28313055 — transparent section, HP PCL code for PC-8 symbol set 'Esc(10U'

Note
In this example, the transparent section is in ASCII. This would require that the "Transparent is ASCII" box be selected in the Print Services printer session properties in the SNA Manager.

Sample Host Data

Following is sample data from a host along with an explanation of the data and resulting printout.

```
35021B45 2BC10684 01840542 2BC20642
04420A21 C1C2C3C4 15404040 E6E7E8E9
```

3270 LU 1 Sample Data

Data	Interpretation
35021B45	Transparent section, send 'Esc E', a Reset in HP PCL, to printer
2BC1068401840542	SHF, 132 characters per line, LM 1, RM 132
2BC2064204420A21	SVF, 66 lines per page, TM 4, BM 66
C1C2C3C4	EBCDIC hex values for ABCD
15	New line
404040	EBCDIC hex values for three spaces
E6E7E8E9	EBCDIC hex values for WXYZ

Print output from data in the preceding table. ABCD on the top print line and WXYZ indented on the lower line.

Host Print Service

Configuring Host Print Service

Configuring Host Print service involves the following steps:

- Creating Link Services
- Creating Connections
- Creating a 3270 Printer LU
- Configuring Host Print Service

In addition, a print demonstration using a script is available. The following procedures will create and configure the print demonstration:

Configuring Host Print service for a 3270 connection

1. In SNA Manager, expand the server on which you want to add print services.
2. Right-click **Print Service**, point to **New**, and then click **3270 Session**.
3. The **Properties** page for this session appears.
4. On the **General** tab, type a session name.
5. Click **Printer**, and then configure a printer.
6. Click the **3270** tab, choose an LU Name to use for this print session. If there are no LU names in the drop-down list, you will need to insert a printer LU on the 3270 connection to be used for this print session (To create a print LU, see the earlier procedure).
7. Configure other parameters as desired.
8. Click **OK** to add this print session.
9. In the console tree, right-click **Print Service**, and then click **Save Configuration**.
10. Right-click **Print Service** again, and then click **Start**.

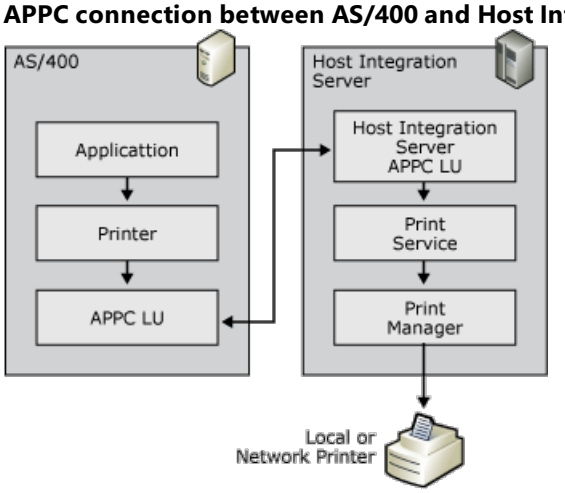
The Host Print service is configured with startup set to Manual. To start the Host Print service at system startup, go to the **Services** icon of Control Panel. Select the service name. Click **Startup**. Change the service activation type from Manual (the default) to Automatic for this service.

SNA Manager will only lock the configuration file when you initiate a configuration change. If the lock is obtained, the status bar will flash **'CONFIG LOCK'**. When you complete the change and save the configuration file, the lock will be released and the status bar will be cleared. The status bar will display **'OUT OF DATE'** on other servers in the domain. To refresh the status on the **'OUT OF DATE'** servers, SNA Manager must be closed and reopened.

AS/400 (APPC) Printing

APPC printing, like LU 1 printing, uses SCS control codes in the data stream. The set of SCS control codes available for use in APPC printing is more extensive, and allows more formatting options than the set described for LU 1 printing. The IBM AS/400 also provides an additional method for formatting print jobs called Host Print Transform (HPT). With HPT enabled, the AS/400 takes responsibility for rendering the print job into data the printer can understand.

APPC connection between AS/400 and Host Integration Server to send print job to local printer



Host Print Transform (HPT)

When SCS control codes are used by the host to format the print output, a print emulator is responsible for translating the SCS codes and characters into data that the printer can understand, through the Windows printer driver and Windows Print system. With HPT enabled, the AS/400 converts the data to printer control codes before sending the data to Host Integration Server. This output from the host requires no further processing after it leaves the AS/400. The print emulator's only responsibility is submitting the data to the printer.

HPT is enabled on the AS/400 in the Device description for the print session. When HPT is enabled, pre-rendered print jobs are sent to the Host Integration Server in marked ASCII Transparent (ATRN) sections using the SCS control code '0x03.' The ATRN control code provides the same function as the Transparent (TRN) control code detailed in the LU 1 printing section. In addition to indicating that the block of data that should be dealt with as transparent, ATRN also indicates that the data is ASCII; therefore it is not converted from EBCDIC to ASCII.

To enable the host transform feature using the default 5224 print device

1. Stop the print writer associated with the print device.
2. Vary off the print device.
3. Issue the following command:

   ```
   chgdevprt devd(<print device>) transform(*YES) mfrtypmdl(<LAN printer type>)
   ```

   Common LAN printer types include: *HP4, *HPIII, *HPII, *IBM4039. To see a complete list of available options, prompt (F4) on the MFRTYPMDL parameter.
4. Vary on the print device.
5. Start the print writer.

For more details on the Host Print Transform feature, see the "OS/400 Printer device programming" manual (SC41-3713), or the "AS/400 Printing IV" redbook (GG24-4389). Both are available from IBM.

SCS Codes

The SCS control codes are fully documented in the *IBM Host Print Guide* (document number SC31-7145). All of the SCS control codes fall within the range of '0x00'–'0x3F.' These codes range from single-byte codes, such as Subscript '0x38' to multiple-byte codes followed by several parameters, such as Set Horizontal Format '0x2BC1...'

The following are some of the more common SCS control codes used.

Note
[L]=length and **(Abv)** represents one-byte parameters in the SCS control code

ASCII Transparency (ATRN) — '0x03[L](P1)(. . .)(Pn)'

This SCS control code indicates a section of data that is not scanned for SCS codes, but passed to the print output untouched. In addition, this control code indicates that the data is ASCII. The extent of the section of data is denoted by the length byte. With HPT jobs, the length byte will commonly be '0xFF'.

Example

030441424344

03 — ATRN

04 — length of 4

41424344 — ASCII hex values for ABCD

SCS Control Code Formatted (Non-HPT)

If HPT is disabled in the Device description for the print session, SCS control codes will be used for the formatting of the print job. The SCS control codes, SHF, SVF, SLD, and SPD detailed earlier for LU 1 printing are also supported in APPC printing. Also commonly used in APPC printing is the SCS control code Presentation Position (PP) '0x34.' This control code allows the print position to be moved either horizontally or vertically, relative to the previous position or to an absolute position.

The following are the four forms of the Presentation Position SCS control code.

Absolute Horizontal Presentation Position (AHPP) '0x34C0(nn)'

nn — column number the print position is set to.

Example

34C00F

34C0 — AHPP

0F — column number 15

Relative Horizontal Presentation Position (RHPP) '0x34C8(nn)'

nn — number of columns to move from the current print position.

Example

34C80F

34C8 — RHPP

0F — 15 columns

Absolute Vertical Presentation Position (AVPP) '0x34C4(nn)'

nn — line number the print position is set to.

Example

34C40F

34C4 — AVPP

0F — line number 15

Relative Vertical Presentation Position (RVPP) '0x344C(nn)'

nn — number of lines to move from the current print position.

Example

344C0F

344C — RVPP

0F — 15 lines

Sample Host Data

Following is sample data from a host along with an explanation of the data and resulting printout.

```
2BC10684 01840542 2BC20642 04420A21
34C404 C1C2C3C4 344C01 34C004 E6E7E8E9
```

Data	Interpretation
2BC1068401840542	SHF, 132 characters per line, LM 1, RM 132
2BC2064204420A21	SVF, 66 lines per page, TM 4, BM 66
34C404	AVPP sets print position to line 4
C1C2C3C4	EBCDIC hex values for ABCD
344C01	RVPP sets print position down one line
34C004	AHPP sets print position to column 4
E6E7E8E9	EBCDIC hex values for WXYZ

Print output from data in preceding table. ABCD on top print line and WXYZ indented on lower line.

Host Print Service

How to Configure Host Print Service for an AS/400 Computer

Configuring AS/400 print service involves the following steps:

- Creating Link Services
- Creating Connections
- Creating LUs

To create a print LU

1. In SNA Manager, expand **SNA Service** for the server that you are working with, and then expand **Connections**.
2. Right-click the appropriate connection, point to **New**, and then click **Printer LU**.
3. Define your printer LU. You can keep the default for the **LU Number** or assign your own. Although the LU number is meaningful to the connection itself, the number is not very useful, so you can add a user-friendly name in the **LU Name** box.
4. Click **OK**.

To configure Host Print service for an AS/400 Connection

1. In SNA Manager, expand the server on which you want to add print services.
2. Right-click **Print Service**, point to **New**, and then click **APPC Session**.
3. The **Properties** page for this session appears.
4. On the **General** tab, type a session name, click **Printer**, and then configure a printer.
5. On the **APPC** tab, provide an **AS/400 Device Name**, a **Local LU Alias**, a **Mode Name**, and a **Remote LU** to use for this print session.
6. If the **AS/400 Device Name** you specify does not exist on the AS/400, it will be created.
7. On the **Security** tab, configure security for this print session.
8. Configure other parameters as desired.
9. Click **OK** to add this print session.
10. In the console tree, right-click **Print Service**, and then click **Save Configuration**.
11. Right-click **Print Service** again, and then click **Start**.

The Print Service feature of Host Integration Server supports print jobs from an AS/400 that contain basic formatting options. Some print jobs require special formatting. To properly print these jobs, the Host Print Transform feature of the AS/400 must be enabled. Host Print Transform is a feature of the AS/400 operating system (V3R1 and later) that translates print jobs in the SNA character string (SCS) data stream into an ASCII data stream (such as PCL). The data stream is specific to a particular make and model of ASCII printer, which must be defined at the time Host Print Transform is enabled.

Custom Host Code Page

Host Integration Server allows a custom host code page to be used for a printer session. The host code page is used for the translation between ASCII and EBCDIC. By default, a printer session will use the standard language code page provided by Windows Server 2003 or Windows 2000. As an alternative, a custom code page can be specified to allow a different translation. For example, using the default code page, the EBCDIC letter "A" ('0xC1') would be translated to an ASCII letter "A" ('0x41'). With a custom code page, it would be possible to have the EBCDIC "A" translated to any value. The custom code pages are text files that can be modified with a hex editor. Samples are included in the PRINTSERVERADDONS directory on the Host Integration Server CD-ROM. The code page file contains 512 bytes. The first 256 bytes represent what the EBCDIC characters are translated to. The second 256 bytes are what the ASCII characters are translated to. Logically each section is a 16-column by 16-row block.

```

The value being translated is matched to its new value using the first number in the hex value as the row and the second as the column. For example, to find what the EBCDIC character "Z" ('0xE9') is translated to in the sample code page count down to row E and over to column 9. This position has the value '0x5A', which is the ASCII value for a "Z".

Concepts

AS/400 (APPC) Printing

Formatting Print Jobs

Host Print service can format print jobs by either using the Windows Server 2003 or Windows 2000 printer driver or by using a Printer Definition Table.

By default, print jobs submitted by Host Print service to a Windows Server 2003 or Windows 2000 Server print queue rely on the Windows Server 2003 or Windows 2000 printer driver to format the print data and send to the physical printer. Formatting the print data is done by the Windows Graphical Device Interface (GDI).

In addition to the Windows GDI, Host Integration Server Host Print service supports the use of a Printer Definition Table (PDT), which bypasses the formatting function of the Windows Server 2003 or Windows 2000 printer driver. The PDT file provides a function similar to a printer driver, in that it translates Graphic Device Interface (GDI) calls to control codes specific for a printer.

Selecting PDT causes the Windows Server 2003 or Windows 2000 Host Print service to treat all received data as transparent. All data is passed directly to the printer, except SCS codes, which are treated differently. Using a PDT, the SCS codes will be translated using the PDT before they are passed to the printer. For more information about Printer Definition Files, see Printer Definition Files.

The PDT is created in two steps.

1. A source text file is created and called the Printer Definition File (PDF) that defines the codes that can be used to control the printer.

2. A program is used to compile the information in the PDF into a binary file, the PDT that is used by Host Print service.

For example, if the host sends a byte indicating a new line ('0x15'), the PDT could be used to convert this to a carriage return, line feed ('0x0D0A').

For more information about creating a PDT, see Printer Definition Files.

To enable GDI

1. In SNA Manager, expand the server, and then click **Print Service**.
2. Right-click a print service displayed in the details pane, and then click **Properties**.
3. Click the **Job Format** tab, and then select **GDI**.

To select a PDT for printing

1. In SNA Manager, expand the server, and then click **Print Service**.
2. Right-click a print service displayed in the details pane, and then click **Properties**.
3. Click the **Job Format** tab, select **PDT**, and then click **PDT File**. The **Select Compiled Printer Definition File** dialog box appears.
4. Select the PDT that you want to use, and then click **Open**.
5. Click **OK**.

Transparency

Transparency sets a flag that indicates that transparent data from the host is in ASCII and needs no translation from EBCDIC to ASCII. Selecting **Transparency is ASCII** causes the Windows Server 2003 or Windows 2000 Host Print service not to put the received data through an EBCDIC to ASCII translation table before printing.

Check **Transparency Custom Byte** to send the data stream in transparent mode. **Transparency Custom Byte** indicates the character designated to start a sequence of transparent data (the transparent data may or may not be ASCII). The IBM standard is 0x35, but if the host print job uses another value (for example, 0x36), this should be specified.

To select Transparency

1. In SNA Manager, expand the server, right-click **Print Service**, and then click **Properties**.
2. Click the **Advanced** tab, click **Transparency Custom Byte**,enter the byte data, and then click **OK**.

Tasks
Formatting Print Jobs

Printer Definition Files

Host Print service enables you to specify the capabilities of a printer to override the defaults provided by the Windows printer driver.

By default, jobs submitted by Host Print service to a Windows print queue rely on the printer's Windows driver to send to the physical printer the data required to perform such formatting tasks as breaking lines and starting a new page.

Applications that bypass the formatting function of the Windows printer driver can use codes specified in a printer definition file to control the physical printer for a particular printer session under Host Print service. To use the file, open the properties page of the printer session, click the **Printing** tab, select **PDT**, and then type the fully qualified path of the file in the box. For more information about using the PDT file, click **Help** on the printer session properties dialog box.

Creating a printer definition file consists of two steps: First, you create a source text file that defines the codes that can be used to control the printer. Second, you run a program to compile the information in the text file into a binary file that can be used by Host Print service.

In This Section

Creating the Source Text File

You can use any text editor (such as Notepad) to create the source text file. The conventional file extension for the source text file is .pdf (which stands for Printer Definition File).

The PDF file consists of two sections:

- The Macro Definition Section
- The Parameter Definition Section

All text bounded by the C-language comment markers (**/*** and ***/**) is treated as comments and ignored by the compiler.

The next two sections describe the PDF sections currently supported by Host Print service.

Macro Definition Section

The macro definition section is bounded by **BEGIN_MACROS** and **END_MACROS** statements and consists of lines with the following syntax.

macro_name **EQU** *control_character_list*

The macro name can be any alphanumeric string that does not contain spaces, and the control character list consists of one or more two-digit hexadecimal values representing the data to be sent to the printer.

For example, the following macro defines the NUL character.

```
NUL EQU 00
```

For an example macro definition, see Sample Source Text File.

Parameter Definition Section

The parameter definition section immediately follows the macro definition section and consists of one or more lines with the following syntax.

parameter_name **=** *value_list*

The parameter name can be any character string that does not contain spaces. The compiler ignores parameter names not supported by Host Print service.

The value list can be empty or can contain one or more of the following:

- A three-digit decimal value.
- A two-digit hexadecimal value.
- A one-char character value.
- The name of a macro specified in the macro definition section.

For example, the following shows a parameter defining the control sequence to be sent to the printer to begin a new line.

```
NEW_LINE = CRR LFF
```

In this example, CRR and LFF are the names of macros specified in the macro definition section.

Host Print service currently supports the following parameters (definitions of unsupported parameters are ignored).

Parameter name	**Description**
START_JOB	Control sequence to be sent at the start of a print job.
END_JOB	Control sequence to be sent at the end of a print job.
CARRIAGE_RETURN	Control sequence for a carriage return.
LINE_FEED	Control sequence for a line feed.
FORM_FEED	Control sequence for a form feed.
NEW_LINE	Control sequence for a new line.
SET_6_LINES_PER_INCH	Control sequence to specify 6 LPI.
SET_8_LINES_PER_INCH	Control sequence to specify 8 LPI.
START_HIGHLIGHT_INTENSE	Control sequence to begin bold printing.
END_HIGHLIGHT_INTENSE	Control sequence to end bold printing.
START_HIGHLIGHT_UNDERLINE	Control sequence to begin underline printing.
END_HIGHLIGHT_UNDERLINE	Control sequence to end underline printing.
KANJI_CODE?	Control sequence of Kanji code for a printer, either JIS or SHIFT_JIS.
KANJI_ON	Control sequence to start printing Kanji.
KANJI_OFF	Control sequence to end printing Kanji.
SET_PAGE_LENGTH	Control sequence to set number of lines per page.

LEFT_MARGIN	Control sequence to set left margin in number of characters.
RIGHT_MARGIN	Control sequence to set right margin in number of characters.
TOP_MARGIN	Control sequence to set top margin in number of lines.
SET_HORIZONTAL_POSITION	Control sequence to set row position.
SET_VARIABLE_LINE_DENSITY	Control sequence to set line density.
SET_VARIABLE_PRINT_DENSITY	Control sequence to set number of characters per inch.
SET_FONT_SIZE	Control sequence to set font size in points.

Printer Definition Files

Sample Source Text File

The sample PDF file, HPLJ2.PDF, is provided on the Host Integration Server CD-ROM in the \SDK\Samples\SNA\PrintDefFile directory.

See Also

Other Resources

Printer Definition Files

Compiling the Source Text File

After you have created the source text file, the next step is to compile the file using the Pdfcomp (PDFCOMP.EXE) utility located in the *platform*\SYSTEM\PRINTSRV directory of the Host Integration Server CD-ROM. To run Pdfcomp, type the following at the command prompt.

```
input_file output_file
```

You must specify the full name (including file extensions) of the input and output files.

For example, to compile the sample PDF file, copy PDFCOMP.EXE and HPLJ2.PDF to a directory on the server's hard disk, open a Command Prompt window and change the current directory to the directory containing the copied files. Then, type the following at the command prompt.

```
hplj2.pdf hplj2.pdt
```

This creates the binary PDT file in the current directory. Specifying this file in the properties of a printer session allows Host Print service to send preformatted data to the printer, bypassing the formatting function of the Windows printer driver.

Compilation of the PDF file into a PDT is not strictly necessary. If an uncompiled PDF file is selected in a Print Session under the SNA Manager, the compilation is performed automatically each time the print session is used. This feature has a performance overhead and is available mainly for ease of development. For production systems, it is strongly recommended that you pre-compile PDF files.

Printer Definition Files

TN Service

TN Service, which is based on the Telnet protocol, enables a user at one site to connect and interact with a remote system at another site using the TCP/IP network protocol. When connecting to a remote computer, the initiating computer acts as a terminal for the remote computer. Host Integration Server supports TN3270-style and TN5250-style sessions in addition to native Host Integration Server client 3270 and 5250 sessions.

In This Section

TN3270

TN3270 service utilizes the features of Host Integration Server to obtain mainframe access and to address issues such as security and redundancy. TN3270 service supports the TN3270, TN3287, and TN3270E protocols, providing terminal emulation and printing capabilities.

To provide for TN3270 service, in Host Integration Server you create connections and LU definitions that map to the mainframe. TN3270 communicates with Host Integration Server using the logical unit application (LUA) API. Therefore, all LUs configured for use with the TN3270 service must be LUA LUs. The LUA LUs and LUA pools defined for the Host Integration Server computers can then be assigned to the TN3270 service using the drag-and-drop method. When the system is activated, the LUA LUs become available for TN3270 clients to access mainframe applications.

Redundancy involves SNA local nodes and link services. Each Microsoft Windows Server 2003 or Windows 2000 domain can contain one or more SNA subdomains. LUA LUs from multiple servers can be assigned to the TN3270 service. This results in client sessions distributed among the participating servers in the subdomain, balancing the load. This also allows redundancy between Host Integration Server computers. If one server goes down, a client computer can then access LUA LUs on a different server.

Similarly, a server can be configured with redundant host links to increase fault tolerance and bandwidth.

In This Section

IP Settings

The IP settings assigned to an LUA LU or pool will allow TN3270 clients to connect to that LUA LU or pool. By default, the LUA LU or pool is not assigned an IP address or a subnet mask. This will allow any TN3270 client to use the LUA LUs or pools.

If you want to restrict an LUA LU or pool to one or more specific TN3270 clients, you should determine the IP address or host name of the client computers that will use these LUA LUs or pools. For client computers using Windows Server 2003 or Windows 2000, you can determine the IP address, subnet mask, and host name by typing **ipconfig/all** from the command prompt on the client computer.

If a workstation has a name that can be resolved using name resolution, it can be used in place of IP addresses. For example, if a workstation name is Giraffe and if the IP name list contains that name, it will map to the correct IP address. Name resolution works with WINS, DHCP, or similar name resolution services. For more information regarding WINS and DHCP, see your Windows Server 2003 or Windows 2000 documentation.

You can modify, delete, or add IP addresses and subnet masks within LUA LUs or pools. If you want to change the configuration of multiple LUA LUs, you can only change properties such as display types, the IP address, and subnet mask that the LUA LUs have in common. You cannot change properties such as the LUA LU name or number, because these values are unique for each LUA LU.

You can add new IP addresses and subnet masks to a range of LUA LUs. If the new IP address or subnet mask already exists on some of the LUA LUs, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the LUA LUs have in common and that appear on the IP address list.

Configuration changes are apparent only to users who establish a connection after the changes are saved. Users who were connected at the time the configuration changes were made will not be affected.

TN3270

Administering TN3270

Using SNA Manager, you can view client addresses, LU names, and the state of each defined client computer. The session status information is useful if you need to stop, pause, or modify TN3270.

You can monitor network activity, including the state of each LU. An LU or pool will display one of the following states.

State	Description
CONNECTED	The TN client has established a connection to TN3270 service.
SSCP-LU	The TN client has established a connection to VTAM.
LU-LU	The LU is bound to a host application.
TERM	The connected session is terminating.

To add LUs or pools to TN3270 service

1. Before LUs can be added to the TN3270 service, you must first create application (LUA) LUs on an appropriate connection.
2. 0Select the LUs on the connection.

   A contiguous range of LUs can be selected by using the mouse to select the first item in the range you want to add, holding down the SHIFT key, and using the mouse to select the last item in the range that you want to add.

   A noncontiguous range of LUs can be selected by using the mouse to select each item in the range that you want to add, while holding down the CTRL key.
3. Drag the LUs into the desired server icon in the TN3270 Service folder.

   The LU appears in the list frame when the server icon in the TN3270 Service folder is highlighted. The icon for the LUs will change to a TN icon both in the TN3270 service and in the connection list.

   By default, the LU will be assigned an IP address of 0.0.0.0 and a subnet mask of 0.0.0.0. This will allow any TN3270 client to use this LU.
4. Specify one or more client IP addresses for this LU.
5. On the **Action** menu, click **Save Configuration** to put the changes into effect.

By adding an LU, you are defining Host Integration Server resource access to TN3270 service and you are defining logmode entries that are associated with a Host Integration Server resource.

Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time that the configuration changes were made will not be affected.

You can modify, delete, or add IP addresses and subnet masks to LUA LUs. If you want to change the configuration of multiple LUA LUs, you can only change properties such as display types, the IP address, and subnet mask that the LUA LUs have in common. You cannot change properties such as the LUA LU name or number, because these values are unique for each LUA LU.

You can add new IP addresses and subnet masks to a range of LUA LUs. If the new IP address or subnet mask already exists on some of the LUA LUs, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the LUA LUs have in common and that appear on the IP address list.

You can assign a 3270 LU pool to a workstation, not an LUA pool. LUA pools can be assigned to the TN3270 service.

To edit a TN3270 LU configuration

1. In the **SNA Manager** console tree, select the LU that you want to view or modify.
2. Right-click the LU name, and then click **Properties**.

3. Click **OK** to exit.

TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client computer to connect to multiple host computers.

To override the default port value for a session

1. Select an LU.
2. Right click, and then click **Properties**. The **TN3270 LU Properties** dialog box appears.
3. Click **Use**, and then type a port number other than the default used for the server. The LU port assignment will override the default port assigned to the server.

To start, pause, continue, and stop TN3270 service

1. Right-click **TN3270**, and then click **Start** or **Stop**.

   - or -

2. In the **Services** utility of the Windows Server 2003 or Windows 2000 **Administrative Tools or Windows Control Panel**, select **TN3270 Service**, and right-click **Start**, **Pause**, **Continue**, or **Stop**.

The TN3270 service is set to start manually by default. You can change this to automatic if you are not running either the TN5250 service or the Telnet daemon on this server, or if you have configured the TCP ports for more than one of these services.

Once TN3270 service has stopped, it can no longer be accessed. You may need to start the TN3270 service after you have paused or stopped it. TN3270 service can be restarted only on the local system.

Pausing allows you to prevent new users from establishing a connection with TN3270 service without disconnecting current users. You can then view TN3270 service session status and notify connected users to disconnect from TN3270 service.

Before stopping TN3270 service, notify all connected users that they will be disconnected within a specified time period. Stop the service after expiration of your warning period.

Tips

- To start TN3270 service from a command prompt, type

  net start tn3270

- To pause TN3270 service from a command prompt, type

  net pause tn3270

- To continue TN3270 service from a command prompt, type

  net continue tn3270

- To stop TN3270 service from a command prompt, type

  net stop tn3270

TN3270, TN5250, and Telnet services all default to the well-known TCP port number 23. If you plan to install more than one of these services, perform the following steps.

To use TN3270 service with TN5250 service or Telnet service

1. Configure the services to use unique port numbers.
2. Reconfigure all your TN3270 clients or TN5250 clients to use the new port numbers.

To remove TN3270 service

1. To pause TN3270 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.
2. Pausing TN3270 service allows you to notify connected users to disconnect from TN3270 service before you stop and remove the application.
3. To stop TN3270 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.
4. Open **Control Panel**, and double-click **Add/Remove Programs**.
5. Click **Host Integration Server**, and then click **Change**. The **Add/Remove Application** dialog box appears.
6. In the **Add/Remove** dialog box, click **Add/Remove**.
7. Click the **TM3270 Service** icon, and then click **Entire Feature will be unavailable**.
8. Click **Continue**.

Note
You can remove TN3270 service anytime you want. However, removing TN3270 service deletes the TN3270 service files from your computer, including TN3270 service configuration data. To use TN3270 service again, you must run Host Integration Server Setup to reinstall TN3270 service files.

See Also
Concepts
TN3270 and Single Sign-On

TN3270 and Single Sign-On

The TN3270 service does not work with Single Sign-On. You should not enable the TN3270 service to run under a user account for which you have a Single Sign-On mapping. If you access the host through the TN3270 service by typing **MS$SAME** for your logon, you will get the user ID and password of the user under which the TN3270 service is running (for example, SNAUSER). If you use an Administrator-level account and change the password, SNA services will fail to start after the password change.

TN3270 Configuration

This section describes the management and configuration of certificates necessary for running TN3270 on Host Integration Server.

In This Section

Managing Certificates

Configuring Certificates

Managing Certificates

The SChannel API uses certificates to provide its security features.

In This Section

Server Authentication

Client Authentication

Obtaining and Creating Certificates

Server Authentication

For server authentication, the server requires a valid certificate with the following properties:

- Type X509
- Suitable for Server Authentication
- Associated private key
- Stored in the Personal or My certificate store for the service account used by the TN3270 service
- By default, a TN3270 server will look for a certificate with a Common Name (CN) matching the host name of the computer running the TN3270 server. This default can be changed by using a registry entry. For details, see Changing the Default Server Authentication Certificate Common Name (CN).

This certificate will be sent to the client as part of the handshake negotiation when the connection is established. For the client to accept the certificate:

- The certificate (and its issuing chain) must be current (for example, not outside of its valid dates).
- The issuing chain must lead to a certification authority (CA) that appears in the clients Trusted Root CA List.
- The certificate (or any part of its issuing chain) should not appear on a certificate revocation list (CRL) of its issuer.
- Most clients offer strict certificate checking, which if selected, will reject connections if the server certificates common name does not match its host name.

Note
If the certificate on the server is changed, the TN3270 server must be stopped and restarted.

Client Authentication

For client authentication, the client requires a valid certificate with the following properties:

- Type X509
- Suitable for Client Authentication
- Associated private key

You might not want to grant access to some of these certificate settings. It is recommended that you check the list of default Trusted Root Certification Authorities on the server, and remove any you do not want.

How the certificate is stored and selected depends on the client program. The certificate will be passed to the server as part of the handshake process. For the server to accept the certificate:

- The certificate (and its issuing chain) must be current.
- The issuing chain must lead to a CA that appears in the servers Trusted Root CA list.
- The certificate (or any part of its issuing chain) should not appear on a CRL of its issuer.

Concepts
Server Authentication
Obtaining and Creating Certificates

Obtaining and Creating Certificates

It is recommended that you use the Microsoft Certificate Services and certification authorities to manage certificates.

When a certificate is issued, it includes a certificate and a private key. When the certificate is transmitted for verification purposes, only the certificate part is sent (and not the private key). The server needs a certificate and a private key for the server authentication certificate. The server needs a copy of the client authentication certificate for its root CA.

Obtaining Certificates

Certificates are obtained from certification authorities. Because these CAs are widely trusted organizations, the certificate will be recognized widely.

Creating Certificates

Windows Server 2003 and Windows 2000 Server feature a certification authority program that allows a local CA to be set up. The local CA may depend on a certificate obtained from an external, well-trusted CA, or it may be a stand-alone CA.

This system can be used if the root certificate (on the CA program) is copied to the Trusted Root CAs store on all the computers using the certificates. The local CA can then issue client and server authentication certificates, and each will be recognized by the other.

Concepts

Server Authentication

Client Authentication

Configuring Certificates

The **TN3270 Server properties** dialog box contains a **Port/Security** tab, which allows you to configure the ports to be available to the TN3270 server. The security parameters are then configured on a port-by-port basis.

The following issues are required to implement security support:

- A client that attempts to connect to a port that has not been configured on the TN3270 server will be unsuccessful.
- The default port defined in SNA Manager does not affect the security configuration. Either a port security record is found (in which case it is used), or it is not found (in which case the client fails to connect).
- A port with security level Unsecured means that TLS/SSL will be fully disabled on that port. There will be no exchange of certificates on that port.
- All the changes made to the configuration are dynamic.
- Server authentication certificates may not be dynamically changed.

In This Section

Switching on Security and Changing Certificates

To support security, the TN server needs to load a server authentication certificate. This is done when a TN server receives a configuration requiring security (for example, at least one port is configured to a security level other than Unsecure) for the first time. After a certificate has been loaded successfully, the certificate cannot be changed without restarting the TN server.

If the certificate-loading process fails (for example, if the certificate is not found or is invalid), any ports requiring security will not be available to the TN server and an error will be logged. The user must then fix the certificate and try again.

Note
The certificate-loading process incorporates several stages, such as opening a certificate store, finding the certificate, and acquiring credentials based on the certificate. Obtaining credentials involves three steps:

- Opening the servers certificate store (using **CertOpenStore**)
- Obtaining the server authentication certificate (using **CertFindCertificateInStore**)
- Getting a credential for each security setting (using **AcquireCredentialHandle**)

The credential contains all the security options supported by the credential (such as maximum and minimum encryption strength, and algorithms supported). Client authentication is not a credential property. The credential is linked to the server authentication certificate.

If security is specified but the TN3270 server fails to get the credentials, any ports that are defined as secure will be unavailable to clients. An error will be logged and the user can try to reload the credentials again.

Concepts

Changing the Default Values of the Security Parameters

Changing the Default Server Authentication Certificate Common Name (CN)

Other Resources

Configuring Certificates

Changing the Default Values of the Security Parameters

By default, the security levels are:

- High = 168-bit encryption (minimum)
- Medium = 128-bit encryption (minimum)
- Low = 40-bit encryption (minimum)
- Unsecured = TLS/SSL fully disabled

The default values of the first three of these levels can be overridden by the following registry entries (stored in **HKEY_LOCAL_MACHINE/SYSTEM/CurrentControlSet/Services/TN3270/Parameters**):

- **SSLHighSecurity**
- **SSLMediumSecurity**
- **SSLLowSecurity**

Each registry entry will contain a numeric (DWORD) value. The registry is checked for entries only when the TN3270 server is started. For any changes in the registry entries to take effect, the TN3270 server must be restarted.

Configuring Certificates

TN5250

TN5250 acts as a gateway that allows an AS/400 access to TN5250 clients providing 5250 terminal emulation.

To provide for TN5250 service, you must create TN5250/AS400 definitions that map to the AS/400. TN5250/AS400 definitions include local and remote APPC LUs, the mode (the default is QPCSUPP), AS/400 user name and password, terminal type, and IP address and subnet mask.

TN5250 supports multiple sessions up to the limits of the mode used in the TN5250/AS400 definition.

IP Settings

IP settings assigned to TN5250/AS400 definitions allow TN5250 clients to connect to the AS/400. By default, the TN5250/AS400 definition is not assigned an IP address or a subnet mask. This will allow any TN5250 client to connect to the AS/400.

If you want to restrict the use of a TN5250/AS400 definition to one or more specific TN5250 clients, you should determine the IP addresses or host names of the client computers that will use the TN5250/AS400 definition. For client computers using Windows Server 2003 or Windows 2000, you can determine the IP address, subnet mask, and host name by typing **ipconfig/all** at the command prompt on the client computer.

If a workstation's name can be resolved using name resolution, it can be used in place of IP addresses. For example, if a workstation name is Giraffe, and if the IP name list contains that name, it will allow that workstation access. Name resolution works with WINS, DHCP, or similar name-resolution services. For more information about WINS and DHCP, see the Windows Server 2003 or Windows 2000 Help.

You can modify, delete, or add IP addresses and subnet masks within a TN5250/AS400 definition. If you want to change the configuration of multiple TN5250/AS400 definitions, you can only change the properties of items that the TN5250/AS400 definitions have in common. You cannot change the name of remote LUs.

You can add new IP addresses and subnet masks to multiple TN5250/AS400 definitions. If the new IP address or subnet mask already exists on some of the TN5250/AS400 definitions, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the TN5250/AS400 definitions have in common and that appear on the IP address list.

Configuration changes are apparent only to users who establish a connection after the changes are saved. Users who were connected at the time the configuration changes were made are not affected.

Tasks

TN5250 Administration

TN5250 Administration

The local LU, remote LU, and mode must match the configuration information in Host Integration Server.

To enable an APPC session with the AS/400, the user ID and password must be provided for conversation security. Contact your AS/400 administrator for the correct information.

The TN5250 requires TN5250/AS400 definition terminal names to allow TN5250 service to accept client requests from client computers emulating those types of terminals.

To set up Host Integration Server for TN5250 access

1. Open **SNA Manager** console tree.
2. Install and configure a link service, if this has not been done.
3. Insert a connection to an AS/400 that the TN5250 clients will access. Configure the connection with Remote End as Peer System.
4. Configure a local LU and a remote LU for access to an AS/400, making sure the mode for the remote LU is QPCSUPP.
5. On the **File** menu, click **Save Configuration** to put the changes into effect.

To add and configure LUs for TN5250 service

1. Before LUs can be added to the TN5250 service, you must first install a link service, add a connection to an AS/400 on this link service, and create local and remote LUs for accessing this AS/400.
2. Right-click **TN5250**, point to **New**, and then click **TN5250 AS/400 Definition**.
3. Configure the properties of this TN5250 AS/400 definition.

   If you do not specify an IP address for an LU, the default value will allow any TN5250 client computer access to this LU.

   Click **Help** for information on the property options.
4. Click **OK** to close the **AS/400 Definition Properties** dialog box.
5. On the **Action** menu, click **Save Configuration** to put the changes into effect.

Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time that the configuration changes were made will not be affected.

You can modify, delete, or add IP addresses and subnet masks to AS/400 definitions. If you want to change the configuration of multiple AS/400 definitions, you can only change properties such as display types, the IP address, and subnet mask that the AS/400 definitions have in common. You cannot change properties such as the local or remote LUs, because these values are unique for each AS/400 definition.

You can add new IP addresses and subnet masks to a range of AS/400 definitions. If the new IP address or subnet mask already exists on some of the AS/400 definitions, but not on others, the addition will occur without duplication in the ones that already have the IP address or subnet mask. You can also modify or delete the IP addresses that the AS/400 definitions have in common and that appear on the IP address list.

To edit an AS/400 definition for TN5250 service

1. In the SNA Manager console tree, select the TN5250 service AS/400 definition that you want to view or modify, right-click, and then click **Properties**.

To delete AS/400 definitions from TN5250 service

1. In the SNA Manager console tree, select the icon for the AS/400 definition that you want to delete.
2. Click **Delete**.
3. Click **Save** to save your configuration changes.

Note

Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time that the configuration changes were made will not be affected.

To start, pause, continue, and stop TN5250 service

1. Right-click **TN5250**, and then click **Start** or **Stop**.

   - or -

2. In the **Services** utility of the Windows Server 2003 or Windows 2000 **Administrative Tools**, select **TN5250 Service** and click **Start**, **Pause**, **Continue**, or **Stop**.

The TN5250 service is set to start manually by default. You can change this to automatic if you are not running either the TN5250 service on this server, or if you have configured the TCP ports for more than one of these services.

After TN5250 service has stopped, it can no longer be accessed. You may need to start the TN5250 service after you have paused or stopped it. TN5250 service can be restarted only on the local system.

Pausing allows you to prevent new users from establishing a connection with TN5250 service without disconnecting current users. You can then view session status in the Active TN5250 Sessions folder and notify connected users to disconnect from TN5250 service.

Before stopping TN5250 service, notify all connected users that they will be disconnected within a specified time period. Stop the service after expiration of your warning period.

Tips

- To start TN5250 service from a command prompt, type

  net start tn5250

- To pause TN5250 service from a command prompt, type

  net pause tn5250

- To continue TN5250 service from a command prompt, type

  net continue tn5250

- To stop TN5250 service from a command prompt, type

  net stop tn5250

Pausing or removing TN5250 service

1. To pause TN5250 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.

   Pausing TN5250 service allows you to notify connected users to disconnect from TN5250 service before you stop and remove the application.

2. To stop TN5250 service, use the **Services** utility in Windows Server 2003 or Windows 2000 Control Panel.
3. Open **Control Panel**, and then double-click **Add/Remove Programs**.
4. Click **Host Integration Server**, and then click **Change**. The **Add/Remove Programs** dialog box appears.
5. In the **Add/Remove Application** dialog box, click **Add/Remove**.
6. Click the **TN5250 Service** icon, and then click **Entire feature will be unavailable**.
7. Click **Continue**.

Note

You can remove TN5250 service anytime you want to do so. However, removing TN5250 service deletes the TN5250 service files from your computer, including TN5250 service configuration data. To use TN5250 service again, you must run Host Integration Server Setup to reinstall TN5250 service files.

TN5250

Active Directory Services

Microsoft Active Directory is the Microsoft Windows Server 2003 or Windows 2000 directory service.

A directory service is an object-oriented information database of network resources. It also provides the services that locate, use, and manage the database and the network resources. These network resources are known as objects and can include network servers, users, printers, computers, databases, and security policies.

Active Directory provides the following services and benefits:

- **Simplified administration.** Active Directory provides a single point of administration for all network resources. It also provides a single point of logon for network users.

- **Network security.** Security policies can be implemented and enforced to help keep information and resources safe, and at the same time, make information and resources available to the right people.

- **Scalability.** The Active Directory database can be expanded by dividing it into partitions. A partition is a logical division of objects. Using partitions, Active Directory can scale from small installations with a few objects, to large installations containing millions of objects.

- **Directory replication and distribution.** Replicating and distributing the directory to other servers in the network ensures its availability and redundancy.

- **Open standards.** Active Directory supports industry standard naming conventions, such as the Domain Name System (DNS), and protocols, such as the Lightweight Directory Access Protocol (LDAP). This allows Active Directory to be integrated into networks that already have a directory. It also allows you to unify and manage the multiple namespaces that may exist in the heterogeneous environments of corporate networks.

Complete Active Directory services information is available from many sources, including the Windows Server 2003 and Windows 2000 Help.

In This Section

How Host Integration Server Uses Active Directory

How to Configure Active Directory During Host Integration Server Installation

Host Integration Server Active Directory Administration

How Host Integration Server Uses Active Directory

Host Integration Server uses Active Directory by registering services and resources with the Active Directory schema. The benefits of using Active Directory include:

- Client configuration and resource location on the network is simplified.
- The limitation of 8,000 sponsor connections that existed in SNA Server 4.0 is eliminated.

Host Integration Server client computers must be configured to communicate to a Host Integration Server computer using either sponsor connections or Active Directory. A client computer cannot be set up to use both at the same time.

If a Host Integration Server computer is configured to use Active Directory, it must operate in an Organizational Unit (OU). If the Active Directory schema is new or otherwise does not have any OUs, Host Integration Server will create an OU for itself.

In addition, the following relationships between the SNA subdomain and the OU containing the Host Integration Server specific containers must be observed:

- Multiple Host Integration Server computers can exist within the same OU.
- Each OU containing a Host Integration Server must be a unique SNA subdomain.
- Two different SNA subdomains cannot exist within the same OU.
- An SNA subdomain cannot stretch across two OUs.
- If an OU contains multiple Host Integration Server computers, they must be part of the same SNA subdomain.
- The name of the OU and the name of the SNA subdomain within that OU can either be the same name or different names.

Active Directory Services

How to Configure Active Directory During Host Integration Server Installation

Host Integration Server participation in Active Directory is accomplished by the SNA service and the SNA Windows Management Instrumentation (SNAWMI) Provider. The SNA service is an installable option that can be selected during Host Integration Server Setup. The SNAWMI is always installed automatically when the SNA service is installed.

With Host Integration Server, there are two mechanisms that will deliver SNA client resource location. One is sponsor connections, which is the existing mechanism present in SNA Server 4.0. The second uses Windows Server 2003 or Windows 2000 Active Directory. If you want to use Active Directory instead of SNA subdomains, you must add the Host Integration Server schema to the Windows Server 2003 or Windows 2000 domain schema before installing Host Integration Server.

The Windows Server 2003 or Windows 2000 schema is extended by running a command-line utility found on the Host Integration Server CD-ROM. The following procedure adds the Host Integration Server schema to the Windows Server 2003 or Windows 2000 domain schema:

To extend the Active Directory schema

1. Make sure you are logged on to the server running Windows Server 2003 or Windows 2000 as **Administrator** or another user who is a member of both the Domain Admins and Schema Admins groups, and who has been delegated control to the domain. You can use the **Active Directory Users and Computers** administrative tool to verify user privileges and delegate control.
2. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
3. Select **Users**, select **Domain Admins**, right-click, and then click **Properties**.
4. Select the **Members** tab and **add** members to this group.
5. Select **Users**, select **Schema Admins**, right-click, and then click **Properties**.
6. Select the **Members** tab and **add** members to this group.
7. Expand **Domain Controllers**, select the domain, right-click, and then click **Delegate Control**.
8. Complete the wizard.
9. Insert the Host Integration Server CD-ROM into the CD-ROM drive of the computer running Windows Server 2003 or Windows 2000 Server .
10. Open a Command Prompt window.
11. Change drives to the CD-ROM drive.
12. Enter the following command.

```
addschma HIserver.schema
```

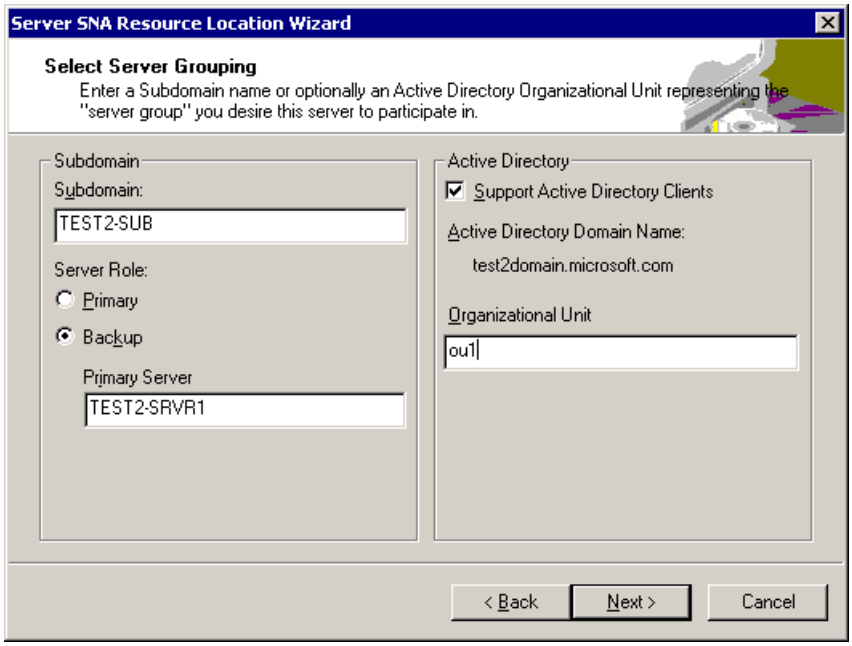
13. The resulting display will indicate if the command was successful.

Note

If you do not successfully add the Host Integration Server schema, you will not be able to use Active Directory, but you can sti ll configure a Host Integration Server client to use SNA subdomains and sponsor connections.

Configuring Host Integration Server to use Active Directory is performed during installation. The following figure shows the Setup screen where you can choose to install Active Directory support.

Select Server Grouping screen



Selecting Support Active Directory Clients, and then entering an Organizational Unit (OU) adds the following services to the ServerResources container for that OU:

- SNAServer Service
- SNAWMI Provider Service
- SNABase Service
- MngAgent Service

Active Directory Services

Host Integration Server Active Directory Administration

Administration of Host Integration Server Active Directory participation is done using the SNA Manager.

To access the Active Directory Server Configuration

1. In the SNA Manager tree, expand an SNA subdomain, select the server that you want to work with, right-click the server, and then click **Properties**.
2. In the **Properties** box, click **Change**. The **Server SNA Resource Location Wizard** appears.
3. Follow the on-screen prompts to install Active Directory support.

The **Server SNA Resource Location Wizard** is the same wizard that configures Host Integration Server following setup.

Note
Changes made to the **Server Properties** page require the SNABase Service to be restarted.

Active Directory Services

Host Configuration

For a connection to be established successfully between a host computer and a Host Integration Server computer, a number of software configuration settings (VTAM, NCP, or AS/400), and hardware characteristics must work together. These include the mainframe node ID settings, AS/400 name settings, addresses, BTU length, and link service settings.

The following table provides more details about important configuration items.

Element	Important items to consider
Host configuration settings (VTAM, NCP, or AS/400 settings) must match the **Connection and Server** settings on Host Integration Server	**Mainframe Node ID settings:** For most mainframes, IDBLK and IDNUM in the PU definition must be matched by the two parts of the Remote Node ID on the Host Integration Server connection. **AS/400 name settings:** For the AS/400, local and remote Control Point Names (CP names) and network names must match corresponding Host Integration Server settings (local names configured on the server and remote names on the connection). **Addresses:** For several connection types (802.2, X.25, and channel), host settings must be matched with equivalent settings on the Host Integration Server connection. For details, see the section about the type of connection you are configuring. **BTU length:** For the mainframe, this is set through MAXDATA in the PU definition. For the AS/400, this is set through MAXFRAME. These should equal the Max BTU Length on the Host Integration Server connection. **Other settings:** For some connections, other settings are also important. For example, for Synchronous Data Link Control (SDLC), the NRZ/NRZI settings on the host must match those on the Host Integration Server connection. For details about these and other settings, see the section about the type of connection you are configuring.
For SDLC and X.25 **Communications hardware:** line, modem (if applicable), and adapter characteristics must match the **Link service and connection** settings on the Host Integration Server	**Speed and duplexing:** For SDLC and X.25, note the speed and duplexing capabilities of the line, modem (or DCE), and adapter, and make sure that they will not be exceeded by the settings in the Host Integration Server link service and connection. Settings for fast transmission or for full duplexing cause greater demands on hardware. (Fast transmission plus full duplexing cause the greatest demands.) The hardware element with the smallest capacity will limit the capacity of the entire system. For example, with an SDLC adapter that lacks a coprocessor, you cannot use full-duplex transmissions at high speeds, even if the modem and line can handle them.

When you are configuring a new host connection or troubleshooting an existing connection, regardless of the connection type, the identifiers between the host and Host Integration Server must match. The following sections describe various configuration settings.

In This Section

Mainframe Connections Using XIDs

Node ID is the identifier used for exchange identifications (XIDs) with most mainframes. Check to make sure that the following items match; if they do not, Host Integration Server is not identifying itself in a way that the host can recognize.

Identifier used on mainframe	**Identifier to configure on Host Integration Server**
IDBLK and **IDNUM** in the PU definition	The two parts of the **Local Node ID** (configured on the connection)

Host Configuration

Mainframe Connections Not Using XIDs

There are some situations in which the mainframe does not use Node ID in exchange identifications (XIDs), but instead uses Network Name and Control Point Name. These situations include mainframes communicating through LU 6.2 and mainframes that call up Host Integration Server. (Host Integration Server accepts incoming calls on that mainframe connection.) In these situations, the following parameters must match.

Note
Use the following identifiers only when necessary. They are more complicated than needed for most mainframe connections and add the potential for error when used unnecessarily.

Identifier used on mainframe (in unusual cases only)	Identifier to configure on Host Integration Server
NETID in the VTAM Start command for the local SSCP	**Local Network Name** (configured on the server)
CPNAME in the PU definition	**Local Control Point Name** (configured on the server)
NETID and **SSCPNAME** in the VTAM Start command for the remote SSCP (VTAM system)	**Remote Network Name** and **Remote Control Point Name** (configured on the connection)

Host Configuration

AS/400 Connections

Network Name and Control Point Name (used together and called the fully qualified name) are the identifiers used when using exchange identification (XID) with AS/400 computers. Check to make sure that the following items match; if they do not, Host Host Integration Server is not identifying itself in a way that the AS/400 can recognize.

Identifier used on AS/400	**Identifier to configure on Host Integration Server**
RMTNETID (usually; often set to APPN); **RMTCPNAME**	**Local Network Name** and **Local Control Point Name** (configured on the server)
RMTNETID (often set to APPN); **CP Name** (shown in the **Display network attributes** screen)	**Remote Network Name** and **Remote Control Point Name** (configured on the connection)

Event log entries can be very helpful in diagnosing and correcting mismatched identifiers between Host Integration Server and host computers.

Host Configuration

Configuring VTAM for 3270 Access

When setting certain Host Integration Server parameters for a host connection, you must match values set on the host or on front-end processors for the host. Host values are configured in VTAM. Front-end processor values are configured in the Network Control Program (NCP).

The following table shows how parameters for Host Integration Server correspond to VTAM host parameters.

Host Integration Server parameter	VTAM parameter
Control Point Name (Local Node).	**CPNAME=** in the PU definition.
Network Name (Local Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the local SSCP (the VTAM system to which Host Integration Server is attached). Note that this is generally the same as the NETID for the remote SSCP.

Note

The local Control Point Name and Network Name are needed only if the Host Integration Server will accept incoming calls, or will be used for LU6.2 (APPC).

802.2 Connection Parameters

The following table shows how Host Integration Server parameters for 802.2 connections correspond to VTAM or Network Control Program (NCP) parameters. Asterisks (*) indicate required parameters.

Host Integration Server parameter	VTAM or NCP parameter
Local Node ID,* first three digits (block number).	**IDBLK=** parameter in the PU definition
Local Node ID,* last five digits (node number).	**IDNUM=** parameter in the PU definition
Network Name (Remote Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Control Point Name (Remote Node).	**SSCPNAME** parameter in the VTAM Start command f or the remote SSCP (VTAM system)
Remote Network Address* when connecting to a 3720, 3725, or 374 5 front-end processor.	**MACADDR=** parameter in the NCP Gen
Remote Network Address* when connecting to an IBM 9370 host.	**MACADDR**= parameter in the PORT definition
Remote SAP Address when connecting to an IBM 9370 host.	**SAPADDR**= parameter in the PU definition
Max BTU Length.	**MAXDATA**= parameter in the PU definition (set Max BTU Length ≤ MAXDATA)

* Required parameter in Host Integration Server

SDLC Connection Parameters

The following table shows how Host Integration Server parameters for Synchronous Data Link Control (SDLC) connections correspond to VTAM or Network Control Program (NCP) parameters. Asterisks (*) indicate required parameters.

Host Integration Server parameter	VTAM or NCP parameter
Local Node ID,* first three digits (block number).	**IDBLK=** parameter in the PU definition
Local Node ID,* last five digits (node number).	**IDNUM=** parameter in the PU definition
Network Name (Remote Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Control Point Name (Remote Node).	**SSCPNAME** parameter in the VTAM Start command f or the remote SSCP (VTAM system)
Max BTU Length.	**MAXDATA=** parameter in the PU definition (set Max BTU Length ≤ MAXDATA)
Encoding (NRZ or NRZI).	**NRZI=** setting in the LINE/GROUP definition (defaults to YES on host)
Local Poll Address.	**ADDR**= parameter in the PU definition

* Required parameter in Host Integration Server

X.25 Connection Parameters

The following table shows how Host Integration Server parameters for X.25 connections correspond to VTAM or Network Control Program (NCP) parameters. Asterisks (*) indicate required parameters.

Host Integration Server parameter	VTAM or NCP parameter
Local Node ID,* first three digits (block number).	**IDBLK=** parameter in the PU definition
Local Node ID,* last five digits (node number).	**IDNUM=** parameter in the PU definition
Network Name (Remote Node) Note that the Network Name for the local and remote nodes is generally the same.	**NETID** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Control Point Name (Remote Node).	**SSCPNAME** parameter in the VTAM Start command f or the remote SSCP (VTAM system)
Remote X.25 Address*.	**DIALNO=** parameter in the PORT definition
Max BTU Length.	**MAXDATA=** parameter in the PU definition (set Max BTU Length ≤ MAXDATA)

* Required parameter in Host Integration Server

Sample VTAM Parameters

VTAM parameters on host connections need to correspond to settings in Host Integration Server. Each connection needs its own specified values.

In This Section

Sample VTAM Parameters for a Token Ring Connection

The following is a sample of VTAM parameters that might be used for a Token Ring connection to an IBM 9370 host. The underlined values correspond to values specified in Host Integration Server Manager.

```
R01100   PORT
CUADDR=100,<U>MACADDR=400040004001</U>,LANCON=(5,2),X

MAXDATA=2012,MAXSTN=52,SAPADDR=04

SERVER01 PU     ADDR=C1, <U>IDBLK=05D, IDNUM=00001</U>,X

ANS=CONTINUE,<U>MAXDATA=0265</U>,MAXOUT=7,MAXPATH=7,X

PACING=0,VPACING=0,SSCPFM=USSSCS,X

LANACK=(0,0),LANCON=(5,2),LANINACT=4.8,LANRESP=(5,2), X

LANSDWDW=(7,1),LANSW=YES,MACADDR=400040001111,X

USSTAB=MSUSSTAB,DLOGMOD=D4C32792,X

PUTYPE=2,DISCNT=(NO),ISTATUS=ACTIVE,<U>SAPADDR=04</U>

T0110002 LU   <U>LOCADDR=002</U>
T0110003 LU   <U>LOCADDR=003</U>
T0110004 LU   <U>LOCADDR=004</U>
T0110005 LU   <U>LOCADDR=005</U>
P0110006 LU   <U>LOCADDR=006</U>,DLOGMOD=LU33286S
T0110007 LU   <U>LOCADDR=007</U>
T0110008 LU   <U>LOCADDR=008</U>
```

The following table shows the Host Integration Server parameters and values that correspond to the sample VTAM parameters.

Host Integration Server parameter	**Sample value**	**VTAM parameter**
Remote Network Address	400040004001	MACADDR= parameter in the PORT definition
Local Node ID, first three digits (block number)	05D	IDBLK**=** parameter in the PU definition
Local Node ID, last five digits (node number)	00001	IDNUM**=** parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length ≤ MAXDATA)
Remote SAP Address	04	SAPADDR= parameter in the PU definition
LU Numbers	2 through 8	LOCADDR= parameter in the LU definitions

Sample VTAM Parameters for an SDLC Connection

The following is a sample of VTAM parameters that might be used for a Synchronous Data Link Control (SDLC) connection to a host. The underlined values correspond to values specified in Host Integration Server Manager.

```
SERVER02 PU     <U>ADDR=C1,IDBLK=017,IDNUM=B8001</U>,DISCNT=NO,X
                VPACING=00,PACING=00,PUTYPE=2,<U>MAXDATA=265</U>,X
                DLOGMOD=D4C32792,USSTAB=MSUSSTAB
```

```
T01B8002 LU   <U>LOCADDR=002</U>
T01B8003 LU   <U>LOCADDR=003</U>
T01B8004 LU   <U>LOCADDR=004</U>
T01B8005 LU   <U>LOCADDR=005</U>
P01B8006 LU   <U>LOCADDR=006</U>,DLOGMOD=LU33286S
```

The following table shows the Host Integration Server parameters and values that correspond to the sample VTAM parameters.

Host Integration Server parameter	**Sample value**	**VTAM parameter**
Local Poll Address	C1	ADDR= parameter in the PU definition
Local Node ID, first three digits (block number)	017	IDBLK**=** parameter in the PU definition
Local Node ID, last five digits (node number)	B8001	IDNUM**=** parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length ≤ MAXDATA)
The encoding scheme (NRZ versus NRZI)	Not specified; defaults to NRZI= YES on host	The NRZI= setting in the LINE/GROUP definition
LU Numbers	2 through 6	LOCADDR= parameter in the LU definitions

Sample VTAM Parameters for an X.25 Connection

The following is a sample of VTAM parameters that might be used for an X.25 connection to a host. The underlined values correspond to values specified in Host Integration Server Manager.

```
PORTA00  PORT
CUADDR=(A00,A08),NETTYPE=1,CHARGACC=YES,CHARGE=NO,X

VCALLS=(,,001,006,,),<U>DIALNO=31370023061</U>,MAXOUT=7,
NETLEVEL=80,PMOD=8,PLENGTH=256,PWINDOW=3,
REPLYT0=3,RETRIES=7

SERVER03 PU
ADDR=C1,<U>IDBLK=05D</U>,<U>IDNUM=00025</U>,ANS=CONTINUE,X
<U>MAXDATA=265</U>,MAXOUT=7,MAXPATH=0,PACING=0,VPACING=0,X

SSCPFM=USSSCS,IRETRY=YES,USSTAB=MSUSSTAB,PUTYPE=2,X

DISCNT=YES,ISTATUS=ACTIVE
```

The following table shows the Host Integration Server parameters and values that correspond to the sample VTAM parameters.

Host Integration Server parameter	**Sample value**	**VTAM parameter**
Remote X.25 Address	31370023061	DIALNO= parameter in the PORT definition
Local Node ID, first three digits (block number)	05D	IDBLK=parameter in the PU definition

Local Node ID, last five digits (node number)	00025	IDNUM=parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length ≤ MAXDATA)

Sample VTAM Parameters Including CPNAME

The following is a sample of VTAM parameters that might be used for a Token Ring connection to an IBM 9370 host, when identification of the computer running Host Integration Server is based on Control Point Name (CPNAME). For this configuration, Format XIDs must be exchanged.

In the PU definition, IDBLK, IDNUM, MACADDR, and SAPADDR are not used. For this configuration to work on Host Integration Server, the Remote Node ID, Remote Network Name, and Remote Control Point Name should all be left blank. Additionally, the Local Node ID can be left at the default value (because it is not used).

In this sample, the underlined values correspond to values specified in Host Integration Server Manager.

```
R01100   PORT CUADDR=100,<U>MACADDR=400040004001</U>,LANCON=(5,2),          X
               MAXDATA=2012,MAXSTN=52,SAPADDR=04

SERVER01 PU   ADDR=C1,<U>CPNAME=SERVER01</U>,ANS=CONTINUE,                  X
              <U>MAXDATA=0265</U>,MAXOUT=7,MAXPATH=7,                       X
              PACING=0,VPACING=0,SSCPFM=USSSCS,                      X
              LANACK=(0,0),LANCON=(5,2),LANINACT=4.8,                X
              LANRESP=(5,2),LANSDWDW=(7,1),LANSW=YES,                X
              USSTAB=MSUSSTAB,DLOGMOD=D4C32792,                      X
              PUTYPE=2,DISCNT=(NO),ISTATUS=ACTIVE

T0110002 LU   <U>LOCADDR=002</U>
T0110003 LU   <U>LOCADDR=003</U>
T0110004 LU   <U>LOCADDR=004</U>
T0110005 LU   <U>LOCADDR=005</U>
P0110006 LU   <U>LOCADDR=006</U>,DLOGMOD=LU33286S
T0110007 LU   <U>LOCADDR=007</U>
T0110008 LU   <U>LOCADDR=008</U>
```

The following table shows the Host Integration Server parameters and values that correspond to the sample VTAM parameters.

Note

For this example, it is assumed that the local Network Name configured for the Host Integration Server matches the NETID parameter in the VTAM Start command for the local SSCP. (The VTAM system to which Host Integration Server is attached.)

Host Integration Server parameter	Sample value	VTAM parameter
Remote Network Address	400040004001	MACADDR= parameter in the PORT definition
Local Control Point Name (for the server)	SERVER01	CPNAME= parameter in the PU definition
Max BTU Length	265	MAXDATA= parameter in the PU definition (set Max BTU Length less than or equal to MAXDATA)
LU Numbers	2 through 8	LOCADDR= parameter in the LU definitions

Sample VTAM Parameters

Sample VTAM Parameters for Independent APPC

The lists in this section show sample VTAM parameters that might be used for communication using independent Advanced Program-to-Program Communications (APPC). The underlined values correspond to values specified in SNA Server Manager.

```
SERVER1  PU    ADDR=09,                                  X
               <U>IDBLK=05D</U>,                                 X
               <U>IDNUM=11111</U>,                               X
               <U>CPNAME=SNASERV</U>,                            X
               ISTATUS=ACTIVE                            X
               DLOGMOD=D4C32782,                         X
               MODETAB=ISTINCLM,                         X
               <U>MAXDATA=521</U>,                               X
               MAXPATH=1,                                X
               PUTYPE=2,                                 X
               SSCPFN=USSSCS,                            X
               MAXOUT=7,                                 X
               PASSLIM=4,                                X
               PACING=0,                                 X
               DISCNT=NO,                                X
               USSTAB=USSTAB

TRPATH    PATH DIALNO=2223331234567890,                  X
               GRPNM=AAA01,                              X
               GID=2

<U>LOCLU1</U>    LU   LOCADDR=0,                                   X
               ISTATUS=ACTIVE,<U>DLOGMOD=APPCMODE</U>,           X
               RESSCB=25,USSTAB=USSTAB,PACING=0,         X
               VPACING=0
```

In the preceding example, the LOCADDR= value for the LOCLU1 is 0. This is the correct value to use with independent APPC LUs.

The following table shows Host Integration Server parameters and values that correspond to the preceding sample VTAM parameters.

Host Integration Server parameter	**Sample va lue**	**VTAM parameter**
Connection: Local Node ID, first three digits (blo ck number)	05D	IDBLK**=** parameter in the PU definition
Connection: Local Node ID, last five digits (node number)	11111	IDNUM**=** parameter in the PU definition
Server: Control Point Name	SNASERV	CPNAME**=** parameter in the PU definition
Connection: Max BTU Length	521	MAXDATA= parameter in the PU definition (set Max BTU Lengt h ≤ MAXDATA)
Local APPC LU: LU Name	LOCLU1	Name in LU definition
APPC Partner LUs: Mode	APPCMODE	DLOGMOD= parameter in the LU definition

The following list shows mode table entries for use with independent APPC LUs.

```
*********************************************************
*           LOGMODE TABLE ENTRY FOR RESOURCES           *
*          CAPABLE OF ACTING AS LU 6.2 DEVICES          *

Sample VTAM Parameters

Configuring VTAM for APPC Access

Parameters on VTAM must match Advanced Program-to-Program Communications (APPC) parameters on Host Integration Server. To configure the needed parameters, consult with the host administrator for the matching VTAM parameters.

The following tables show Host Integration Server parameters and values that correspond to VTAM and CICS parameters. Note that the values given are samples only and may not work for your configuration.

The following table shows Host Integration Server parameters and values that correspond to sample VTAM parameters.

Host Integration Server parameter	**Sample value**	**VTAM parameter**
Connection: Local Node ID, first three digits (block number)	05D	IDBLK= parameter in the PU definition
Connection: Local Node ID, last five digits (node number)	11111	IDNUM= parameter in the PU definition
Server: Control Point Name	SNASERV	CPNAME= parameter in the PU definition
Connection: Max BTU Length	521	MAXDATA= parameter in the PU definition (set Max BTU Length ≤ MAXDATA)
Local APPC LU: LU Name	LOCLU1	Name in LU definition
LU 6.2 Partner LUs: Mode	APPCMODE	DLOGMOD= parameter in the LU definition

The mode named APPCMODE is an example of a mode configured for use with LU 6.2. The mode named SNASVCMG is included in Host Integration Server, because it is required for parallel session support. It does not need to be configured.

The following table shows Host Integration Server parameters and values that correspond to sample CICS parameters.

Host Integration Server parameter	**Sample value**	**CICS parameter**
LU Name for Local APPC LU	LOCLU1	Sessions
Mode name	APPCMODE	Modename
Parallel Session Limit in the mode	250	Maximum
Partner Min Contention Winner Limit in the mode	125	Maximum
Max Receive RU Size in the mode	00521	SENDSize
Max Send RU Size in the mode	00521	RECEIVESize
LU Name for remote APPC LU	CICSLU	APPLID

The parameter called Maximum has two values, 250 and 125, separated by commas. The first value (250) is the parallel session limit. The second value (125) is the host minimum contention winner limit. On Host Integration Server, this corresponds to Partner Min Contention Winner Limit in the mode. In addition, because the host is the contention winner on 125 sessions (out of a total of 250), Host Integration Server should be configured as the contention winner on the remaining 125 sessions. In this case, Host Integration Server mode would have the following values:

- Parallel Session Limit 250
- Minimum Contention Winner Limit 125
- Partner Min Contention Winner Limit 125
- Automatic Activation Limit 0

```

The following table shows Host Integration Server parameters and values that correspond to the preceding sample CICS parameters.

Host Integration Server parameter	Sample value	CICS parameter
LU Name for local APPC LU	LOCLU1	Sessions
Mode name	APPCMODE	Modename
Parallel Session Limit in the mode	250	Maximum
Partner Min Contention Winner Limit in the mode	125	Maximum
Max Receive RU Size in the mode	00521	SENDSize
Max Send RU Size in the mode	00521	RECEIVESize
LU Name for remote APPC LU	CICSLU	APPLID

In the sample CICS screen, the parameter called Maximum has two values, 250 and 125, separated by commas. The first value (250) is the parallel session limit. The second value (125) is the host minimum contention winner limit. On Host Integration Server, this corresponds to Partner Min Contention Winner Limit in the mode. In addition, because the host is the contention winner on 125 sessions (out of a total of 250), Host Integration Server should be configured as the contention winner on the remaining 125 sessions. In this case, Host Integration Server mode would have the following values:

- Parallel Session Limit 250
- Minimum Contention Winner Limit 125
- Partner Min Contention Winner Limit 125
- Automatic Activation Limit 0

The remaining screens in this section show more information about how CICS could be configured for independent APPC through VTAM.

Sample VTAM Parameters

Configuring NCP for Independent APPC

Parameters on Network Control Program (NCP) must match Advanced Program-to-Program Communications (APPC) parameters on Host Integration Server. To configure the needed parameters, consult with the host administrator for the matching NCP parameters.

This section provides information about NCP definitions used for supporting and defining independent LUs. The section is not intended to provide comprehensive information about NCP, which is described more thoroughly in IBM manuals such as:

- *Planning and Reference for NetView, NCP, VTAM* (CN4D1200)
- *NCP, SSP, and EP Resource Definition Guide* (CXDG7200)
- *NCP, SSP, and EP Resource Definition Reference* (CXDH1200)

You may need to study other IBM documentation as well. Some of the topics to study are:

- Independent LUs
- Type 2.1 node support
- Dynamic reconfiguration

Table of NCP Parameters That Affect Independent APPC

The following table shows basic recommendations for setting NCP parameters for independent APPC with Host Integration Server. The next sections describe the parameters in more detail.

NCP definition	NCP parameter	Recommendations
BUILD	ADDSESS	Must support the number of sessions needed.
Not applicable	AUXADDR	Must support the number of additional addresses needed.
Not applicable	MAXSESS	Use for setting the maximum sessions allowed for any LU. Corresponds to the sum of all the parallel session limits for all the modes with which a particular LU is partnered.
PUDRPOOL	NUMBER	Must support the number of servers accessing NCP.
LUDRPOOL	NUMILU	Must support the number of dynamically configurable LUs needed.
PU	NETID	Corresponds to the Local Network Name on Host Integration Server.
Not applicable	PUTYPE	For independent APPC, use PUTYPE=2.
Not applicable	XID	For independent APPC, use XID=YES.
LU	LOCADDR	For independent LUs with set definitions, use LOCADDR=0.

Not applicable	PACING	Use a value greater than or equal to the corresponding Host Integration Server parameter, the Pacing Receive Count in the mode.
Not applicable	VPACING	Use a value less than or equal to the corresponding Host Integration Server parameter, the Pacing Send Count in the mode.

BUILD Definition

The following parameters in the BUILD definition affect independent APPC:

ADDSESS= *value*

Is equivalent to the total number of sessions available to independent LUs. ADDSESS specifies the number of LU-LU session control blocks available for independent LUs. Note that session control blocks may be reserved for a particular LU by using RESSCB (reserved session control blocks) in the LU definition.

The sum of ADDSESS, AUXADDR, and NUMILU equals the total number of control blocks available for dynamic configuration of LUs. (For a description, see LUDRPOOL Definition, later in this topic.) This total should be high enough to support needed sessions, but low enough so that NCP does not exceed the storage capacity of the controller.

AUXADDR= *value*

Specifies the number of addresses that can be dynamically defined for both dependent and independent LUs. To allow for additional sessions between independent LUs, AUXADDR should be greater than ADDSESS. For more information about dynamic reconfiguration, see ADDSESS (the preceding description).

MAXSESS= *value*

Specifies the maximum number of LU-LU sessions that one independent LU can support. If you specify MAXSESS in an LU definition (as supported by NCP V6R2), the LU uses the value in the LU definition, not the BUILD definition. The limit set by MAXSESS prevents an independent LU from using too many unreserved session control blocks.

PUDRPOOL Definition

The following parameter in the PUDRPOOL definition affects independent APPC:

NUMBER= *value*

Specifies the number of physical units (PUs) that can be dynamically defined.

LUDRPOOL Definition

The following parameter in the LUDRPOOL definition affects independent APPC:

NUMILU= *value*

Specifies the number of independent LUs that can be added through dynamic reconfiguration. Find a value high enough to support needed sessions (including control-session overhead for parallel sessions), but low enough so that NCP does not exceed the storage capacity of the controller. Note that total LUs allowed by NUMILU plus NUMTYP1 plus NUMTYP2 is limited. The exact limit depends on your version of NCP.

PU Definition

The following parameters in the PU definition affect independent APPC:

NETID= *name*

Specifies the name of an adjacent network, and corresponds to the local Network Name on Host Integration Server. NETID allows the network names to differ between the host and Host Integration Server. This name is used in exchange identification (XID) negotiation.

PUTYPE=2

For independent APPC, use PUTYPE=2. When combined with XID=YES, this is equivalent to physical unit type 2.1.

XID=YES

For independent APPC, specify XID=YES, so that XIDs can be exchanged while in Normal Disconnected Mode (NDM).

LU Definition

The following parameters in the LU definition affect independent APPC:

LOCADDR=0

For independent LUs configured by an administrator (as contrasted with LUs dynamically configured by NCP), specify LOCADDR=0.

PACING= *value*

Specifies the number of frames for NCP to send to an independent LU before NCP waits for a pacing response. The value for PACING should generally be greater than or equal to the corresponding Host Integration Server mode parameter, Pacing Receive Count. This ensures a smooth flow of data from the host to the Host Integration Server. (Host Integration Server does not support adaptive pacing.)

VPACING= *value*

Specifies the number of frames for NCP to receive from an independent LU before NCP sends a pacing response; sometimes called the receive window size. The value for VPACING should generally be less than or equal to the corresponding Host Integration Server mode parameter, Pacing Send Count. This prevents delays in sending from the Host Integration Server to the host. (Host Integration Server does not support adaptive pacing.)

Sample VTAM Parameters

Configuring the AS/400 for 5250 Access

When setting Host Integration Server parameters for an AS/400 connection, you must match values set on the host. Check with the host administrator to obtain required information for AS/400 access.

The administrator of the AS/400 may allow configurations to be created automatically in response to incoming requests. Alternatively, the administrator may disable this feature, to ensure a higher level of security. Work with the documentation for the AS/400 or with the administrator to determine the appropriate methods for configuring the AS/400.

Note
If the administrator of the AS/400 has allowed configurations to be created automatically in response to incoming requests, t he parameters listed in this section need not be specified on the AS/400.

The following list shows command sequences on the AS/400 and the parameters to set after choosing those command sequences. You must be logged on with administrative privilege on the AS/400 to configure the listed parameters. For more detailed information, see the AS/400 documentation.

Communications > Network configuration > Configure communications and remote hardware > Work with lines

Find out the name of the line from the AS/400 administrator. To enable automatic configuration for the line, for Autocreate controller, specify *YES, and for Autodelete controller (a time-out value), specify *NONE, or a large value such as 7000 (minutes). To prevent automatic configuration for the line, for Autocreate controller, specify *NO.

If the configuration is not automatic, specify the following:

- APPN-capable *YES
- A Control Point Name and network identifier that match corresponding parameters in Host Integration Server
- APPN CP session support *YES

Communications > Network configuration > Configure communications and remote hardware > Work with communications controllers

In this context, communications controller means the Host Integration Server.

If the configuration is not automatic, specify the local address of the Host Integration Server computer.

Connecti on type	**Address as specified in AS /400 configuration**	**Method for finding out address on Host Integration Server**
802.2	LAN remote adapter address	At the command prompt, type **net config server**; then view the line labeled "Server is active on."
SDLC	Station address (STNADR)	Start Host Integration Server Manager and view the Poll Address specified for the S DLC connection. (For SDLC, both ends use same address.)
X.25	Network address	Start SNA Manager, access the **IBM X.25 Link Service Setup** dialog box, and view t he Local X.25 Address.

Guidelines for an AS/400 that Does Not Have PC Support

You can connect to an AS/400 for 5250 emulation even if the AS/400 does not have PC Support. However, to do this, you must create the mode QPCSUPP on the AS/400, along with other resources that would have been created by PC Support. A recommended way to do this is to create the QPCSUPP mode, create the QWCPCSUP class, and add the class QWCPCSUP to the system QCMN. For details about how to create these resources, see the online OS/400 documentation for the related commands: **crtmodd**, **crtcls**, and **addrtge**.

Changing Session Limits with a Single Mode Name

If the AS/400 requires different session limits on each LU (while the mode name stays the same), you must change the device description attached to the controller to reflect the correct number of sessions allowed for the LUs. For example, with a 5250

emulator, the mode name must be QPCSUPP. If you change the Parallel Session Limit on QPCSUPP for one LU-LU pair, all other LU-LU pairs that use the QPCSUPP mode will also be affected. Therefore, to change the session limit on some LUs but not others, you must change it at the AS/400.

The simplest way to get the correct number of sessions for the LUs on the AS/400 is to autocreate the controllers and devices, and then change the device description attached to the controller, so that the session limit is decreased. This is done by using the Change Device Description (**chgdevappc**) command. It needs to be done for each device description that needs to have different session limits. The AS/400 device settings that should be modified are Maximum Sessions (**maxssn**) and Maximum Conversations (**maxcnv**).

For 5250 emulation in the AS/400 environment, you must configure the following elements:

- Each Host Integration Server computer that will access the AS/400
- Connections
- Local APPC LUs
- Remote APPC LUs
- LU-LU pairs

Sample VTAM Parameters

Table of Parameters for AS/400 Communication

The following table summarizes details about configuring Host Integration Server for the AS/400 environment. In addition, for an X.25 connection using permanent virtual circuit (PVC), specify the PVC Alias.

SNA Server element	Parameter name in Host Integration Server	Instructions for configuring for the AS/400 environment
Server	Network Name (Local Node)	This generally corresponds to the RMTNETID setting on the AS/400. (APPN is often used.)
Server	Control Point Name (Local Node)	Corresponds to RMTCPNAME on the AS/400.
Connection	Remote End	Select Peer System as the Remote End for the connection.
Connection	Activation	Coordinate with the switched disconnect (SWTDSC) setting on the AS/400. If SWTDSC is *YES, select On Demand. If SWTDSC is *NO, select On Server Startup.
Connection	Local Node ID	Specify the Local Node ID, a required parameter for all connections. This corresponds to EXCHID on the AS/400.
Connection	Control Point Name (Remote Node)	Specify the AS/400 Control Point Name (CP name) as the remote Control Point Name for the connection.
Connection	Network Name (Remote Node)	Corresponds to the RMTNETID on the AS/400. (APPN is often used.)
Connection	802.2: Remote Network Address SDLC: Poll Address X.25: Remote X.25 Address	Corresponds to ADPTADR in the Line Description on the AS/400. Corresponds to STNADR in the Line Description on the AS/400. Specify the address of the AS/400.
Connection	Max BTU Length	Corresponds to the MAXFRAME setting on the AS/400.
Remote APPC LU	LU Name	Specify the Control Point Name of the AS/400 as the remote LU name.
Mode	Mode name	Choose the QPCSUPP mode for all LU-LU pairs to be used for AS/400 connectivity.
User or group listing	Default local APPC LU	Assign a Default local APPC LU to the user or group. If the user or group does not specify a local LU name when opening a session to an AS/400, this default local LU name will be used.
User or group listing	Default remote APPC LU	Assign a Default remote APPC LU which is the same as a default AS/400 to the user or group. If the user or group does not specify a remote LU (that is, an AS/400) when opening a session, the assigned AS/400 will be used.

Sample VTAM Parameters

Applications and Tools

Microsoft Host Integration Server includes several applications and tools to assist you in managing your environment. The following sections describe how to set up tracing on a Host Integration Server computer, and how to view trace files for information on the activity between components. They also discuss the performance-monitoring counters that provide basic stress testing for Host Integration Server.

In This Section

Network Management Support

The requirement to manage heterogeneous network environments containing mainframes, midrange systems, and personal computers is a big challenge. This section discusses two mainframe management tools, IBM NetView and Response Time Monitor, which are supported by Host Integration Server and can be used to manage your integrated network.

Host Integration Server can be managed either from the Host Integration Server computer (and other computers on the LAN) or from the mainframe using NetView. NetView is a centralized network management system that allows you to control SNA network resources, including Host Integration Server.

Using the IBM Response Time Monitor (RTM) provides additional management of Host Integration Server. RTM measures the length of time it takes for a host to respond to an incoming 3270 end-user request. Working in conjunction with NetView on the mainframe, RTM gathers data from 3270 terminal emulators and sends the information to the host through the NetView connection.

In This Section

How to Manage the SNA Environment Using NetView

The IBM NetView program sends and receives alerts and other information between a host (mainframe or AS/400) and the computers that connect to it. Host Integration Server supports NetView, bringing centralized SNA-based network management into local area network (LAN) environments. Using NetView, you can control any Host Integration Server computer that represents a physical unit (PU) in the SNA environment.

NetView can forward Host Integration Server alerts to the host system. In addition, NetView can be extended with the Windows NVAlert and NVRunCmd services. NVAlert provides the ability for the host system console to receive and display alerts generated by Windows and applications running on the Windows computer. NVRunCmd provides the ability to command Host Integration Server from the host system console.

The NVAlert and NVRunCmd services are installed when you install Host Integration Server. By default, the NVAlert configuration file, NVAlert.ini, is created and placed in the \Program Files\Host Integration Server\System folder. Also installed in the Windows Control Panel is the NVAlert service, and is configured with a startup setting of Manual.

If you plan to manage Host Integration Server most of the time using NetView from the mainframe, you should change the default startup configuration from Manual to Automatic. In Control Panel, click the **Services** icon, and then select the service you want to change. Click **Startup**, and then click **Automatic** as the **Startup Type**.

To configure NetView

1. In the Host Integration Server console tree, right-click the subdomain that you want to configure, and click **Properties**.
2. Click the **NetView** tab, and fill in the option.
3. Click **OK**, and save the configuration.

NVAlert runs as a background process, enabling alert messages generated by Windows or by Windows-based applications to be forwarded to a host system through NetView. To control the alert messages sent from the NVAlert service, modify the NVAlert.ini file to specify the Windows alerts that you want forwarded to the host system.

As events occur and are recorded in a log file, NVAlert compares each logged event to the list in the NVAlert.ini file. When an event matches one on the list, NVAlert forwards an alert as specified in NVAlert.ini to the host system.

If a problem occurs sending an alert, NVAlert follows a preset pattern of time-outs and retries. No additional alerts can be sent until the alert is successfully sent to the host.

NVAlert.ini File

Concepts

Sending Commands to Host Integration Server from the Mainframe

NVAlert.ini File

The following sections describe the structure and the required and optional lines of data for NVAlert.ini. For information about standard code points and values used by NetView, see your IBM NetView documentation.

Required Data Lines

You must precede each section of data lines that you add to NVAlert.ini with the following heading, including the square brackets **[ ]** as shown:

```
source.type.eventid
```

Use the Windows Event Log service to view the intended alert, and supply values as described in the following list. For information about the Event Log service, see your Windows documentation.

- For *source*, substitute the name that appears beneath the Source heading in the Windows Event Log service.
- For *type*, find the type listing (in the event detail in the Windows Event Log service), and substitute one of the following values:

Success	0
Information	1
Warning	2
Error	3
Success audit	4
Failure audit	5

- For *eventid*, use the decimal number that appears under the EventID heading in the Windows Event Log service.

Note
Choose alerts that will not exceed the basic transmission unit (BTU) of the connection over which the alerts will flow be cause the host cannot handle alerts exceeding this size.

After the heading, type data lines using the following syntax:

```
        =xx=xxxx=xxxx[,...]
```

In these lines, each letter *x* represents a hexadecimal digit specifying NetView code points. For the appropriate values to provide, see your IBM NetView documentation. The element characters [**,**...] indicate that the argument can be repeated, with commas separating the repetitions. Do not type the brackets.

Adding Optional Data Lines

To help you monitor the SNA environment or diagnose a problem, you can add additional data to the alerts sent to the mainframe. The following optional data lines can be added to an alert:

```
        =xxxx[,...]
```

```
=00,xx,string[;...]

=xxxx[,...]

=00,xx,string[;...]

=xxxx[,...]

=00,xx,string[;...]

=xxxx[,...]

=00,xx,string[;...]

=xxxx[,...]

=00,xx,string[;...]
```

Each letter *x* represents a hexadecimal digit specifying NetView code points. For the appropriate values, see your NetView documentation. The elements [**,**...] and [**;**...] indicate that the argument can be repeated, with commas or semicolons separating the repetitions. Do not type the brackets.

RecAct is an abbreviation for recommended action and *DetData* is an abbreviation for detailed data. You can use the DetData syntax to add blocks of detailed data to an alert.

- For *xx,* type the Data ID code point as described in the IBM *SNA Formats* manual (IBM document GA27-3136-12) or other NetView documentation.

- For *string*, provide a text string using the following variables:

%M	Module name.
%C	Computer name.
%I	Event ID.
%S*n*	String number *n* in the event log (*n* starts at zero).
%D*xxxx*, *yyyy*	Raw data of length *yyyy*, starting at buffer offset *xxxx*. Both *xxxx* and *yyyy* are hexadecimal values. Use this variable only if you do not specify any other variables.

Example of an Alert

The following is an example of a Windows-based alert and a description of each data line. The alert warns that a hard disk is nearly full and the description in the Windows Event Log service will read "The C: disk is at or near capacity. You may need to delete some files."

Sample alert and description

Data lines	Description
`[Srv.2.2013]`	Source is Srv, type is 2 (warning), and EventID is 2013
`AlertType=11`	Impending problem
`AlertDescription=5002`	Resource nearing capacity

`ProbableCauses=5001`	Media DASD device
`UserCauses=0102,F0A0`	Insufficient storage media space available
`UserDetData=00,95,%C`	Problem located on the indicated file server name (supplied through NetView value 95); event logged on indicated computer name (supplied through %C)

How to Manage the SNA Environment Using NetView

Sending Commands to Host Integration Server from the Mainframe

The NVRunCmd service enables you to launch processes on the Host Integration Server from the NetView console. Commands are sent to the Host Integration Server computer, carried out, and results are returned to the NetView console as long as the results contain only alphanumeric characters. The NVRunCmd service cannot send graphical information to the mainframe NetView console. For example, if you use NVRunCmd to run the **dir** command, a character-based display of the current folder is displayed in NetView. But if you use NVRunCmd to start a graphical application, no command output is sent to NetView.

NVRunCmd does not handle back-and-forth interactions, such as a confirmation generated by a Host Integration Server computer in response to a command. If a command forwarded by NVRunCmd requires confirmation before being carried out, the command process will not be completed, and will eventually time out.

NVRunCmd is configured during Host Integration Server Setup and runs as a background process, waiting for a command to be sent from a NetView console. When NVRunCmd receives a command, it determines whether the command is one that it can process, and returns either the results (in 256-byte segments) or a messagesaying that the command failed. NVRunCmd attempts to send the results back to the NetView console only once, and if the NetView console does not receive the results, the link or some other part of the communications has failed.

The pipe symbol (|) cannot be used to combine commands. For example, NVRunCmd cannot process the following command string:

```

```

The maximum amount of information that can be returned to the NetView console is 31,700 bytes. Any additional information returned by the command will be lost, with a message appended to the truncated data warning the user.

Configuring NVRundCmd Privileges

By default, the NVRunCmd service runs in the context of the local system's security. Therefore, some commands generate responses that are different from the responses generated by a user logged on the same Windows operating system. For example, the commands **net use** and **chdir**, typed without options, generate a response in the context of NVRunCmd, not the context for a logged-on user.

For better system security, use the Windows Control Panel to access the **Services** dialog box and configure **Startup** options for the NVRunCmd service. Associate the NVRunCmd service with a user account that has the privilege level that you want for NVRunCmd.

Sending a Command from the Host Console

To send a command to the intended Host Integration Server computer, you need to specify the corresponding PU in the **runcmd** command in the NetView console of the host system. Use the following syntax to launch a process on the Host Integration Server software. Commands are not case sensitive; commands entered in lower case are converted to upper case.

```
        servicepoint

        commandname
        parameters
```

- For *servicepoint*, type the name of the VTAM PU of the Host Integration Server computer (node) in which you want the command to run. Note that on the server, this value is configured as the control point name for the server.

- For *commandname*, type the command you want to run. The command must be alphanumeric because NetView cannot return graphical output.

- For *parameters*, type the parameters needed for running the command on the server.

Note
NVRunCmd does not use or need a defined NetView connection. You can use NVRunCmd from the host to each Host Integration Server computer in the subdomain separately. The NetView connection is needed only for sending alerts to NetView.

How to Manage the SNA Environment Using NetView

Monitoring Mainframe Response Times

The IBM response time monitor (RTM) measures the length of time it takes for a host to respond to an incoming 3270 end-user request. Responding to customer requests is a good indication of system performance. Monitoring the response time can be helpful diagnosing network and other system problems. RTM is a feature that works in conjunction with NetView on the mainframe. It gathers data from 3270 terminal emulators and sends the information to the host through the NetView connection for collection and analysis. Then you can view a graphical display of response times for a particular 3270 emulation session.

In This Section

Configuring RTM in Host Integration Server

Use the SNA manager console to configure how response times are measured and classified. Response time monitor (RTM) statistics for a specific logical unit (LU) are sent to the host that owns the LU, rather than to the connection designated for NetView data.

In This Section

How to Configure Response Time Monitor (RTM)

You can specify the times that RTM should send data and the trigger that causes it to register the host response. The configuration settings are on the **Response Time Monitor** tab of the **Properties** page for the selected SNA subdomain and are listed in the following table:

Note
For these settings to be meaningful, each emulator for your 3270 users must support RTM. If the host RTM settings are different, they override the Host Integration Server settings.

RTM Settings

Setting		**Definition**
RTM Data Sent At		Specifies when RTM data is sent to the host. You can send the data during one or both of the following situations:
	Counter Overflow	Sends the RTM data to the host when the number of host responses in a given time period overflows the size of the available counter.
	End of Session	Sends the RTM data to the host at the end of each LU-to-LU session.
RTM Timers Run Until		Specifies when the RTM registers a host response - when RTM stops the timers. (The timers are started when the local system sends data.) Possible stopping points are as follows:
	First Data Reaches Screen	Stops timing when data reaches the local screen.
	Host Unlocks Keyboard	Stops timing when the host unlocks the local keyboard.
	Host Lets User Send	Stops timing when the host lets the local computer send more data.
RTM Thresholds		Specify the cutoff times, in tenths of a second that the RTM saves its count of host responses and restarts the count. The range is 1–1000 in tenths of a second (from 0.1 seconds to 100.0 seconds). The defaults are 5, 10, 20, and 50 (0.5 seconds, 1.0 seconds, 2.0 seconds, and 5.0 seconds).

Although you can configure the RTM boundaries and definition that you want to use on your server, the host can override these values, either for an individual 3270 LU or for all LUs the host controls. The host can also specify whether to permit local display of RTM data, and, when Host Integration Server sends RTM data, it can disable collection of RTM statistics completely.

To configure Response Time Monitor (RTM)

1. In the Host Integration Server console tree, right-click the subdomain that you want to configure, and click **Properties**.
2. Click the **Response Time Monitor (RTM)** tab, and complete the options.
3. Click **OK**, and **save** the configuration.

Defining RTM Thresholds

Response time monitor (RTM) data is collected by comparing host response times against a series of four boundary values. Each time a host transaction occurs, the response time is compared with the boundary values, and the appropriate counter is incremented. There is a counter for each of the four intervals defined by the boundary values, and an overflow counter for response times above the largest boundary value.

You can change the default boundaries — 0.5, 1, 2, and 5 seconds — using the SNA manager console. You also can select which of three response time definitions to set as default.

The response time is measured from the time the user presses ENTER until one of the following events occurs:

- The first character of host data reaches the 3270 display.
- The keyboard is unlocked.
- The user is enabled to send data.

A host can override the default boundaries and other host response time settings for any or all logical units (LUs) it controls.

See Also
Concepts
Specifying When RTM Data is Sent
Indicating Lost RTM Data

Specifying When RTM Data is Sent

Response times are recorded for a specific logical unit (LU) rather than for a specific 3270 session. If a 3270 session ends and another session of the same or a different 3270 user starts using the same LU, the response time counters include responses from both sessions. To prevent the counters from collecting information from more than one 3270 session, you can reset the RTM counters on the LU before a new session begins. The counters are reset when the host requests the reset or when response time monitor (RTM) data is sent unsolicited by Host Integration Server. Usually when a host requests RTM data the counters are reset at the same time.

To ensure that RTM data relates only to the current 3270 session, you should select the **End-of-Session** checkbox when configuring RTM parameters for Host Integration Server. Note that the host can override this setting.

Defining RTM Thresholds

Indicating Lost RTM Data

Indicating Lost RTM Data

When Host Integration Server sends response time monitor (RTM) data to the host, it can indicate to the host that RTM data may have been lost, that is, some host response times were not included in the RTM data sent to the host. This indication is sent when:

- One of the RTM counters reaches its maximum value, and Host Integration Server is not configured to send RTM data unsolicited at counter overflow. When this occurs, Host Integration Server stops recording response times until the host requests the data or until end-of-session, if unsolicited sending at end-of-session is configured. The data is sent with an indication that data may have been lost due to counter overflow.

- Connection to the host for either Host Integration Server or the Windows servers ends abnormally. The first RTM data sent to the host after the connection is re-established includes the lost-data indicator to indicate that data may have been lost due to failure of the server.

- Host Integration Server is configured to send RTM data at the end-of-session, and a new 3270 session is started before the RTM data for the previous 3270 session on the same LU can be sent. Response times for the new session are discarded until the RTM data from the previous session is sent and the counters are reset. When RTM data is sent on the new session, it includes the lost data indicator.

Specifying When RTM Data is Sent

Additional Information About NetView and RTM

For additional information about NetView and RTM see Network Management The following topics are discussed:

- Connections used for the IBM NetView program and RTM facilities
- Link alerts
- Link statistics
- Application-generated alerts, and alerts generated through the NVAlert and NVRunCmd services
- Local logging of network management data

Using the SNA Trace Utility

The following information guides you through configuring and using the Host Integration Server SNA Trace Utility. The SNA Trace Utility is used to control trace files.

In This Section

Using the SNA Trace Utility

This section includes an overview of the Host Integration Server SNA Trace Utility and details the names and locations of the files generated by the trace application.

In This Section

SNA Trace Utility

The Host Integration Server SNA Trace Utility (snatrace.exe) is a graphical tool that allows you to enable or disable tracing options and set the SNA Trace Utility parameters.

After deciding the software components and types of tracing that can provide useful information, start the Host Integration Server SNA Trace Utility application and configure trace options for Host Integration Server computers.

If you are working to improve system performance or solve a difficulty with Host Integration Server components, reviewing trace files can assist in determining the source of the problem.

The SNA Trace Utility records activity between or within components of Host Integration Server. The files created provide detailed information about the exact sequence of events occurring within Host Integration Server components or between Host Integration Server computers and Host systems on the network.

Note
You must be an administrator on the local account to run the SNA Trace Utility.

Using the SNA Trace Utility

System Troubleshooting

When gathering information about system difficulties, it is best to start with information provided by the Windows Event Log and System Monitor, see Windows Utilities for additional information.

Event log information is generally more straightforward to interpret than trace information; use trace information only if event logs do not provide enough details.

When you report system problems to Microsoft Product Support (PSS), a technician may ask you for trace files and other system information:

- Trace files
- Windows Event Logs
- The current configuration file (Com.cfg)
- Dump files, which may be created by Host Integration Server when a system trap (exception error) occurs
- Datascope traces of protocol exchanges

Other Resources

Using the SNA Trace Utility

Trace File Names

Each trace file has two names associated with it, <*Filename*1>.atf and <*Filename*2>.atf.

Traces are written to the first file until it reaches the specified size, then to the second until it reaches that size, and so on alternating between the two files.

By default, the trace files are stored in the \Program Files\Host Integration Server\Traces folder, with an .atf file extension.

The following table lists the file names used by Trace:

Service	Type of tracing	File names used	File names used
SnaBase	Internal	Napint1.atf	Napint2.atf
	Message	Napmsg1.atf	Napmsg2.atf
SnaServer (PU 2.1 node)	Internal	Nodeint1.atf	Nodeint2.atf
	Message	Nodemsg1.atf	Nodemsg2.atf

Choosing a Trace Type

After selecting one or more Host Integration Server components to be traced, decide the type of tracing to apply.

The following table describes the types of tracing available:

Type of tracing	Activity traced	Applies to installed components
Internal*	Activity within a software component of Host Integration Server.	SnaBase, SnaServer (PU 2.1 node), SNA applications, link services and more.
Message	Messages passed into and out of a software component of Host Integration Server, including messages sent to and received from the network.	SnaBase, SnaServer (PU 2.1 node), SNA applications, link services and more.
API	Information passed into and out of a Host Integration Server DLL, as the DLL communicates with an application, such as the APPC DLL.	SNA applications and more.

* Internal tracing is intended for use by product support technicians. Interpreting internal traces and certain types of message traces requires a specialized knowledge base.

Using the SNA Trace Utility

Trace Types

Before setting up tracing, decide the software components you want to trace, and which types of tracing information will be useful.

Each type of tracing is enabled using the Host Integration Server Trace application.

Internal Trace types:

- Fatal Conditions
- Error Conditions
- Debug Conditions
- Function Entry/Exit
- State Transition
- Custom Conditions

Message Trace types:

- Internal Messages
- 3270 Messages
- LU 6.2 Messages

API Trace types:

- APPC API
- CPI-C API
- LUA API
- CSV API

TN3270 Internal Trace types:

- TN3270 Internal Trace

Interpreting Traces

The Host Integration Server Trace feature provides message, client API, SnaBase, Transaction Integrator, PU 2.1 node, and link service tracing.

The following table shows the information needed for interpreting each type.

Type of tracing	Software component traced	Area of expertise needed
APPC API	SNA applications	APPC programming
CPI-C API	SNA applications	CPI-C programming
LUA API	SNA applications	LUA programming
SNA Formats	SnaServer (PU 2.1 Node)	SNA formats
Data Link Control (messages)	SnaServer (PU 2.1 node) or link service	DLC interface
Level 2 Messages	Link service	Link service interface
3270 Messages	SNA Applications, SnaServer (PU 2.1 Node), or SnaBase	3270 emulator interface
Internal Messages	All software components for Host Integration Server	Intended for product support personnel
APPC Messages	SNA Applications, SnaServer (PU 2.1 Node), or SnaBase	Intended for product support personnel
Internal	All software components for Host Integration Server	Intended for product support personnel

Trace Types

Using Trace to Diagnose Problems

The following table shows examples of possible difficulties and the types of tracing that may be useful.

Problem	What to trace
Host Integration Server cannot connect to host.	For the SnaServer (PU 2.1 node), trace data link control and 3270 Messages.
SNA Manager does not reflect changes in network services.	For the SnaServer (PU 2.1 node), trace Internal Messages; for Manage Agent, enable internal tracing.
Windows-based client computer cannot connect to a Host Integration Server resource.	For any client computer, enable internal tracing For a 3270 or LUA client computer, trace 3270 messages For an APPC or CPI-C client computer, trace LU 6.2 messages.

Using the SNA Trace Utility

Running the SNA Trace Utility

You can run the SNA Trace Utility from either the SNA Manager or from a command prompt.

In This Section

Starting the SNA Trace Utility

The following topics explain how to start the SNA Trace Utility from the SNA Manager, from the Windows **Start** menu, or from a command prompt.

In This Section

How to Start the SNA Trace Utility from the SNA Manager

The following procedure details how to start the SNA Trace Utility from the SNA Manager

To start the SNA Trace Utility from the SNA Manager

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and then click **SNA Manager**.
3. Click **Tools**, and then click **SNA Trace Utility**.

How to Start the SNA Trace Utility from the Start Menu

The following procedure details how to start the SNA Trace Utility from the Windows Start menu.

To start the SNA Trace Utility from the Start menu

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and then point to **Application and Tools**.
3. Click **SNA Trace Utility**.

How to Start the SNA Trace Utility from a Command Prompt

The following procedure details how to start the SNA Trace Utility from a command prompt.

To start the SNA Trace Utility from a command prompt

1. From **Start**, click **Run**.
2. Type in **command**, and click **OK**.
3. Type in:

-or-

To run the SNA Trace Utility on a specific server

1. From **Start**, click **Run**.
2. Type in **command**, and click **OK**.
3. Type in:

Tracing Servers Components

The Host Integration Server Trace application can be started locally or remotely for a Host Integration Server computer. For a client computer, the Host Integration Server Trace application can only be started locally.

Important
All procedures listed in this section assume that Trace is running on a computer that has Host Integration Server installed and configured.

In This Section

Selecting Components to Trace

Before you can begin tracing files, you need to decide on the Host Integration Server components to trace.

The Trace application enables you to record internal or external activity for the following components:

- Enterprise Single Sign-On
- NVAlert
- NVRuncmd
- SNA applications
- SNA Manager Client
- SNA Manager Agent (MngAgent)
- SnaBase
- Installed link services
- SNANetMn
- SNAPrint
- SNAServer
- SNA Management
- DB2 Network Library
- SNADDM
- TN3270
- TN5250

Tracing for TN3270

You can enable or disable tracing for TN3270 using the Host Integration Server Trace application. Host Integration Server Trace provides API, internal, and message tracing.

Host Integration Server SNA Trace Utility places trace files for TN3270 in the \Host Integration Server\Tracesfolder by default.

The following table illustrates the TN3270 file names used by Host Integration Server Trace:

Service	Type of tracing	File names used	File names used
TN3270	API	Tn3api1.atf	Tn3api2.atf
	Internal	Tn3int1.atf	Tn3int2.atf
	Message	Tn3msg1.atf	Tn3imsg2.atf
	TN3270 internal trace	Tn_00.atf – Tn0a.atf	

Note

The TN3270 internal trace contains up to 1024 bytes of information and creates up to ten files. The names are Tn_00.atf to Tn_0a.atf.

Note

SNA Trace event monitoring will not stop the TN3270 internal trace.

Optimizing Performance

Network Considerations

Network Analyzer

Status and Performance

Host Integration Server and the Windows operating system offer several tools for helping you evaluate the demand on, and performance of, Host Integration Server computers and components.

You can use the following tools to quickly isolate problems:

Windows Utilities

The Windows Event Viewer allows you to monitor events on a server to troubleshoot various hardware and software problem. User Manager allows you to set up auditing and Server Manager allows you to set up administrative alerts to be sent to remote computers. For additional information on these utilities, refer to Windows documentation.

Host Integration Server Status (using the SNA Manager)

The Host Integration Server SNA Manager provides information about the current status of Host Integration Server resources, including logical units (LU), connections, and print sessions. This shared console provides a convenient and consistent environment for Host Integration Server, Transaction Integrator, and other console administration tools.

System Monitor

This Windows application enables you to measure the performance data for computers on the network. You can also monitor connections, LU sessions, and adapters.

Note
In Windows, the name of this utility is **System Monitor**, although it appears on the **Start** menu as **Performance**.

Using the SNA Trace Utility

The Host Integration Server Trace utility records activity between or within Host Integration Server components. Tracing provides detailed information of internal activities on Host Integration Server. It is helpful in isolating problems and is frequently used by product support personnel.

Status and Performance Information

Optimizing Performance

If more than one Host Integration Server computer is currently in use, you can evaluate the demand and performance on the servers in order to obtain a benchmark, and to estimate hardware requirements for future growth. The two primary tools for this kind of evaluation are the System Monitor, which is part of Windows, and the Host Integration Server Status available through the SNA manager.

System Monitor is a graphical tool included in Windows. The System Monitor allows you to collect performance data on your computer or on other computers in the network. For detailed instructions for using System Monitor, see the Windows documentation.

Studying activity on a moderately or heavily used server involves studying a complex set of processes and process interactions. Detailed interpretation of the data requires an understanding of how the operating system works, for example, how virtual memory is managed or how processor time is divided between competing processes.

Network Considerations

Your network adapter can have a large impact on the overall network performance. Advanced adapters provide good setup options to optimize the network I/O performance. Look for I/O buffering on the card itself, direct memory access (DMA) (adjustable data link control (DLC) (maximum frame size, and local area network (LAN) speed setting parameters.

Host Integration Server performance tuning involves adjusting the frame size, BTU size, and DLC-level pacing on the connection properties, as well as the request/response unit (RU) size and session-level pacing on the mode properties.

Additional tips:

- Your test data buffer must fit into one RU; if the RU size is too large, it will consume excess memory. 1200 bytes of screen paint data fits into an RU of 1484 bytes. This is the optimum for Ethernet. A 1920-byte data buffer would require two client/server message frames.

- The maximum BTU size needs to be at least the RU size + 9 bytes. For Ethernet, an RU of 1484 bytes and a BTU of 1493 bytes is good. For TokenRring, an RU of 4087 bytes and a BTU of 4096 bytes is a good starting point.

- The DLC level pacing is the most common tuning problem. To avoid deadlocks and timeouts, set the pacing between the two nodes so that the receiving window is one frame smaller than the partners send window. For example, node A can be set to send seven frames until it stops and waits for acknowledgement from node B; node B can be set to send an ACK after it receives six frames from node A, and vice versa. This guarantees successful DLC frame acknowledgements between the nodes.

- Setting the DLC receive acknowledgement to 1 or 2 would cause a receive ready (RR) to be sent after every second I-frame. This results in unnecessary control frame overhead on the LAN between the gateway and the server.

See Also
Other Resources
Performance Tuning

Network Analyzer

A network analyzer, is an important tool for checking the load and throughput on the network as well as verifying that there are no mismatched configurations in the test environment.

You can use a network analyzer to verify the transaction counts by monitoring the data link control (DLC) traffic to and from the computer being tested. You can filter traffic to count only incoming I-frames of a certain size and type. Using filtering, you can determine the number of accepted frames and ascertain the number of responses from the receiver servers.

Another important measurement that uses a network analyzer is following the network bandwidth usage. Ethernet, in particular, slows down drastically when usage rates grow beyond 40–50 percent. A Token Ring network is more predictable in throughput even on higher loads; however, going beyond 60 percent network load levels should be cause for attention. Finally, the network analyzer can be used to confirm proper tuning of local area network (LAN) protocols. DLC level pacing (send and receive window size), timeouts, and retransmissions could artificially limit LAN throughput, perhaps to the point that the LAN, rather than the system under test, is the performance-limiting component.

Looking at the captured messages will give a good indication of problems and where they are. If there are Receiver Not Ready (RNR) frames present, one of the nodes is overloading and then limiting the message flow in. You can minimize an excess number of Receiver Ready (RR) messages by adjusting the DLC level pacing for a larger send and receive window. Long elapsed times between the individual frames can highlight configuration problems. This indicates which of the components, client, gateway, or server, consume most of the processing time. A single client test is a good way to determine where the delays might be.

A typical time for message transmission in Host Integration Server is between 1–5 milliseconds, even on almost full CPU loads. A transmission time longer than 1–5 milliseconds indicates a configuration mismatch or lack of available RAM because the system is using the virtual memory on the hard drive.

Status and Performance Information

Host Integration Server Status

The Host Integration Server SNA Manager provides valuable status information for Host Integration Server computers within a SNA subdomain. You can view the status of connections, LUs, and print sessions.

In This Section

Status Information

The Host Integration Server SNA Manager provides several types of status messages that can supplement other performance information.

- You can see the status of servers, logical units (LUs), and connections (Active, Inactive, Pending, Stopping, Active [Out of Date], or Error) in the console tree by selecting the server of interest.

- You can view the number of users and the number of sessions by double-clicking the relevant server. This information can be especially useful when combined with data from System Monitor.

- Also on the SNA Manager, you can view the names of active 5250 users being supported by a particular local LU. If there is only one local LU per server, the names will include all users with active 5250 sessions on a particular server.

For example, click **Servers** in the console tree to view the status of a given SNA subdomain. The status of the servers in that subdomain will appear in the details pane.

See Also

Other Resources

Host Integration Server Status

Server Status

You can view the status of servers in a given subdomain, including the number of active users, and you can view the properties for a server to gather status information. There are six status types on the Host Integration Server SNA Manager:

- Active
- Inactive
- Pending
- Stopping
- Active [Out of Date]: Indicates that the Host Integration Server resource needs to be restarted to bring the internal parameters up to date with the latest configuration changes. First, select the affected Host Integration Server resource. Then, on the **Action** menu, click **Stop**, and then click **Start**.
- Error: Indicates that an unexpected condition has made the server inaccessible to the Host Integration Server SNA Manager.

You can also see the number of active users, 3270 sessions, Advanced Program-to-Program Communtications (APPC) sessions, and Logical Unit for Applications (LUA) sessions. If the server is active, the number of licensed users and licensed sessions is also shown.

Important
If the [Out of Date] message appears on the status bar at the bottom of the SNA Manager (as opposed to in the console tree), then the SNA Manager is out of synchronization with the rest of the SNA subdomain. The SNA Manager is out of date when another server saves the configuration file, so your copy of the file (which resides in RAM memory) is out of sync with the m aster configuration file. To synchronize your copy of the configuration file, go to the **Action** menu, and click **Refresh**.

Host Integration Server Status

Connection Status

The Host Integration Server SNA Manager offers six different messages that indicate the status of a connection:

- Active
- Pending
- Stopping
- Inactive
- On Demand: Indicates that the connection is available to be started when needed. On Demand connections can also have all of the statuses listed above.
- Incoming: Indicates that the connection is available to receive incoming calls. Incoming connections can also have all of the statuses listed above.

To view a connection status, simply select the appropriate connection in the SNA Manager.

Other Resources

Host Integration Server Status

Non-APPC LU Status

The status of a non-Advanced Program-to-Program Communications (APPC) logical unit (LU) can be:

- Inactive
- In Session
- System Services Control Point (SSCP). This indicates that the LU is in use, but is not yet bound to a specific host application.
- Available: Indicates the LU is recognized by the host as an available LU.
- Pending: Indicates that a user is trying to access the LU, but either the connection is inactive or the mainframe does not recognize the LU.
- Unavailable: Applies to downstream LUs only.

To view the status of an LU, select the LU in the SNA Manager.

See Also

Other Resources

Host Integration Server Status

APPC LU Status

The status of an Advanced Program-to-Program Communications (APPC) logical unit (LU) will either be Inactive or will show the number of active sessions.

To view the status of an APPC LU, select the appropriate LU in the SNA Manager.

See Also
Other Resources
Host Integration Server Status

Print Session Status

There are several different messages that show the status of a Host Integration Server print session:

- Active
- Inactive
- Pending
- In Session: Indicates the print server session is active, and the logical unit (LU) is bound. For Advanced Program-to-Program Communications (APPC), a conversation is allocated.
- Offline: Indicates the print session has been created, but the print server is not aware of it.
- Paused: Indicates the print server session is active, but the printing has been paused.

To view the status of a print session, simply select the print session in SNA Manager.

Note
The status shown by the SNA Manager and the Diagnostic tool (DISPLAY.EXE) may appear to be different for a given item (for example, LU status). This is because the SNA Manager shows the currently active sessions. The Display tool shows what was negotiated during CNOS setup.

Windows Utilities

Microsoft Windows has several built-in utilities that can assist you in tracking system usage, problems, and performance. These utilities can provide the administrator with valuable information about any computer on the network.

In This Section

Windows Event Viewer

You can use information from Windows Event Logs as you test a configuration or diagnose problems.

In This Section

Event Viewer

Windows Event Logs can tell you the sequence and type of events that led up to a particular state or situation.

The Event Logs for Windows include:

- System Event Log
- Security Event Log
- Application Event Log
- Directory Service
- File Replication Service

The Event Viewer will display the following information about system events:

- Type
- Date
- Time
- Source
- Category
- Event ID
- User
- Computer

From the View menu you can:

- View All events
- Filter Events
- View newest event first
- View oldest event first
- Find events
- Display event details
- Refresh events window.

See Also

Other Resources

Windows Event Viewer

How to Start Event Viewer

Event Logs can be viewed using the Windows Event Viewer.

You can start the Event Viewer from the SNA Manager or from the operating system.

To start Event Viewer with the SNA Manager

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and click **SNA Manager**.
3. When the **SNA Manager** starts, click **Tools**.
4. Click **Event Viewer**.

To start Event Viewer with Windows

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Event Viewer**.

See Also

Other Resources

Windows Event Viewer

How to Change Event Viewer Settings

In Windows, you can adjust Event Viewer settings by right-clicking the log and clicking **Properties**.

You can adjust the following Event Log settings:

- Maximum log size
- Overwrite events as needed
- Overwrite events older than *x* days
- Do not overwrite events (Clear log manually)
- Using a low-speed connection (Windows)

To change Event Viewer settings

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Event Viewer**.
3. Right-click the appropriate log file (**Application**, **Security**, **System**, **Directory Service**, or **File Replication Service**).
4. Click **Properties**.

See Also
Other Resources
Windows Event Viewer

How to Save Event Logs

You can save event logs for later reference or for historical data. Event log files can be saved as event files (*.evt), text files (*.txt). or comma-delimited text files (*.txt).

To save event logs

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Event Viewer**.
3. Right-click the appropriate log file (**Application**, **Security**, **System**, **Directory Service**, or **File Replication Service**).
4. Click **Save Log File As**.
5. Type a name for the file, and click **Save**.

See Also

Other Resources

Windows Event Viewer

How to Clear Event Logs

In Windows, you can clear the event logs by selecting **Clear all Events** on the **Action** menu after selecting the appropriate log file. You have the option of saving the event log before you clear it.

To clear event logs

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Event Viewer**.
3. Select the appropriate log file (**Application**, **Security**, **System**, **Directory Service**, or **File Replication Service**).
4. Click the **Action** menu, and then click **Clear all Events**.
5. You will be prompted to save the file.

Note
There is no verification for clearing the event log.

See Also

Other Resources

Windows Event Viewer

How to Select Computers in Event Viewer

In Windows, you can select any computer in your network to view its event logs in Event Viewer.

To select computers in Event Viewer

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Event Viewer**.
3. Right-click **Event Viewer** (top level).
4. Select **Connect to another computer**.
5. Type the computer name on which to view Event Logs, and click **OK**.

Other Resources

Windows Event Viewer

How to Filter Events

In Windows, you can specify the type of information you want the event logs to record. The information can include the following:

- Event types
- Event source
- Category
- Event ID
- User
- Computer
- Events for various time/dates

To filter events

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Event Viewer**.
3. Right-click the appropriate log file (**Application**, **Security**, **System**, **Directory Service**, or **File Replication Service**).
4. Select **Properties**, and click the **Filter Tab**.
5. Type the appropriate information that you want to filter, and then click **OK**.

Other Resources

Windows Event Viewer

How to Find Events

You can specify what type of event to find based on the following criteria:

- Event type
- Source
- Category
- Event ID
- Computer
- User
- Description
- Direction (up or down from the currently selected event)

How to find events

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Event Viewer**.
2. Right-click the appropriate log file (**Application**, **Security**, **System**, **Directory Service**, or **File Replication Service**).
3. Click the **View** menu, and select **Find**.
4. Enter the appropriate information that you want to find.
5. Click **Find Next**.
6. Click **Close** when you are finished.

Setting Audit Policy

You can set the audit policies within the operating system. The audit policies control which events will be logged to the event log files.

In This Section

Audit Policies

How to Set Audit Policy

Audit Policies

Auditing security events and then placing entries in the computers security log can track selected activities of users. Use the audit policy to determine the types of security events that are logged.

Because the security log is limited in size, choose to log only those events necessary. The maximum size of the computer's security log is defined in Event Viewer.

Entries in a security log can be reviewed using Windows Event Viewer.

How to Set Audit Policy

The following procedure details how to set an audit policies with Windows.

To set an audit policy

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Local Security Policy**.
3. Expand **Local Policies**, and select **Audit Policy**.
4. Make appropriate changes to audit policies.

Audit Policies

System Monitor

This section details the Windows System Monitor.

In This Section

System Monitor Overview

Using the Windows System Monitor, you can view reports on CPU load, memory usage, and interrupt rate, as well as the overall throughput of Host Integration Server traffic on the network. Restrained use of the system monitor is recommended because the tool itself can cause extra stress on the servers CPU. Specifically, this can happen if tracking all the details of many logical units (LUs) over the network from another server. Try to limit the system monitor to providing summary statistics only.

Also, try to check the CPU loads of your receiver servers and stress client computers during a practice run to make sure they are not overloaded. If the client computers are Windows computers, you can use the System Monitor application in Windows to check the CPU load on the client machines.

Host Integration Server services are fully integrated with the Windows operating system. This allows the services, connections, and processes associated with Host Integration Server to be assigned to the System Monitor. You can evaluate the demand and performance of one or more Host Integration Server-based computers to obtain a benchmark and to estimate hardware requirements for future growth.

You can use the Windows System Monitor to look at the resource use of specific components and program processes. With the system monitor, you can create charts and reports that gauge a computer's efficiency; identify and troubleshoot possible problems such as unbalanced resource use, insufficient hardware, or poor program design; and plan for additional hardware needs.

Using the System Monitor, you can configure object counters and instances to assist in evaluating Host Integration Server performance. Specific counters and instances appear when a particular service is installed and running on the server.

For detailed instructions about using the System Monitor, see your Windows Server documentation.

Useful Performance Counters
Performance Counters on Transaction Integrator
Maximizing Communications Throughput

Useful Performance Counters

Performance counters allow you to see where computer resources are being used. The counters described below provide valuable information for evaluating the demand on, and performance of, Host Integration Server components.

- **Memory: Pages/sec**

  In order to understand memory load on a Windows Server, you must first understand paging, which is a technique for implementing virtual memory. Paging is switching blocks (pages) of program instructions or data back and forth between memory and disk. Paging is carried out as needed by the virtual memory manager in Windows.

  Pages/sec is the number of pages read from the disk or written to the disk because they were not in memory when needed (that is, the number of page faults that required disk access). The counter includes paging traffic generated when the cache accesses file data for applications.

  Pages/sec is the primary counter for determining whether your server is paging excessively. As this counter goes up, server responsiveness slows because of the time required for disk access (reading or writing). A server dedicated to communications should be equipped with enough physical memory so that little paging is required.

  The highest acceptable value for pages/sec varies from system to system. One way to judge whether system load is causing too much paging is to observe whether processor activity drops significantly as paging increases. This indicates that the system is occupied with switching pages rather than with actually processing instructions.

  The primary ways to correct excessive paging are to add more physical memory to the server or to decrease the demand on the server. Demand can be decreased by narrowing the variety of tasks that a server must perform or by decreasing the number of users accessing a server. For example, an overloaded multipurpose server with file, print, and Host Integration Server demands, could be dedicated to Host Integration Server traffic only, or user loads placed on one server could be divided between two servers (load balancing). In any case of memory overload, adding physical memory may provide the needed performance increase.

  A secondary way to decrease the impact of paging is to upgrade the disk system. This includes installing a faster disk, installing a second disk, using RAID striping, or similar upgrades. This upgrading does not decrease paging (pages/sec), but speeds up the paging process itself. For example, replacing a slow IDE disk with a faster SCSI disk may make a given paging rate, perhaps 20 – 40 pages/sec acceptable.

- **System: %Total Processor Time and Processor: %Processor Time**

  System: %Total Processor Time is the percentage of elapsed time during which the system processors are busy. It can be viewed as the fraction of total processor time spent doing useful work. Values of 60 – 80 percent during typical loads are good values because they allow some reserve for peak loads. However, when the processor stays at 100 percent for periods of time, this may indicate a processor bottleneck. On a multiprocessor system, you can view **Processor: %Processor Time** for each processor to see how the load is distributed among processors.

  One useful way to view **Total Processor Time** values is in Chart view, along with counters indicating increases and decreases in user load. For user load, such counters include **Host Integration Server Logical Unit Sessions: Throughput Bytes/Sec**, and **Host Integration Server Adapter <*adaptername*>: Throughput Frames/Sec.** These two counters are available only when there is Host Integration Server activity. For example, you might notice that during a period of peak demand for logical unit sessions, Total Processor Time reaches 100 percent and stays there. This could indicate that the Host Integration Server computer is reaching peak capacity and that any additional demand might require additional processors or additional servers.

  It may also be helpful to view **System: %Total Processor** Time along with any other counters related to the servers major functions. For example, when a Host Integration Server computer is also a file server, the **Server: Server Sessions** counter can be helpful. Other counters that may help you analyze the sources of processor activity are **Process: %Processor Time** for processes you think are relevant, as well as **System: Total Interrupts/sec**. Also, if your client computers are using NetWare, consider looking at **NWLink SPX: Connections Open**. Similarly, if your client computers use TCP/IP, consider looking at **TCP: Connections Established**.

- **System: Total Interrupts/sec and Processor: Interrupts/sec**

  System: Total Interrupts/sec is the rate at which the computer is receiving and servicing device interrupts. Device interrupts are the signals that a device sends to a processor to indicate that a task is complete or the device requires attention. Some devices that may generate interrupts are adapters, network adapters, the system timer (clock), and the mouse. **System: Total Interrupts/sec** provides an indication of how busy these devices are on a computer-wide basis.

  Similarly, for each processor, **Processor: Interrupts/sec** is the rate at which the processor is receiving device interrupts.

  Normal thread execution is suspended during interrupts. An interrupt may cause the processor to switch to another, higher-priority thread. Clock interrupts are periodic and frequent (on the order of 100 per second); they create a background of interrupt activity.

  These counters can help indicate the general demand on a server, and may be useful when combined with processor and memory data, such as **System: %Total Processor Time and Memory: Pages/sec.**

- **SNA Connections: Throughput Bytes/Sec**

- **SNA Logical Unit Sessions: Throughput Bytes/Sec**

- **SNA Adapter adaptername: Throughput Frames/Sec**

  These counters provide an indication of Host Integration Server activity. When observing these counters, it may also be useful to start the SNA Manager and double-click the same server being observed in System Monitor. You can see the number of users and sessions that correlate with a particular level of Host Integration Server activity. This information, combined with data about the processor and memory load, can help you understand the load and performance on your servers. Low throughput does not necessarily mean poor performance, but instead may simply indicate that current activity is low.

  Measurement of frames/second may provide a better indicator of server load than bytes per second, because server overhead for interrupt handling and message processing increases per frame, not per byte. In other words, a large frame with many bytes requires about the same overhead as a small frame with fewer bytes.

- **SNA Connections: Data Bytes Received/Sec**

- **SNA Connections: Data Bytes Transmitted/Sec**

- **SNA Logical Unit Sessions: Data Bytes Received/Sec**

- **SNA Logical Unit Sessions: Data Bytes Transmitted/Sec**

- **SNA Adapter adaptername: Data Bytes Received/Sec**

- **SNA Adapter adaptername: Data Bytes Transmitted/Sec**

- **SNA Adapter adaptername: Frames Received/Sec**

- **SNA Adapter adaptername: Frames Transmitted/Sec**

- **SNA Adapter adaptername: Throughput Bytes/Sec**

  These counters provide additional detail about Host Integration Server activity when used with the previous three counters.

- **SNA Adapter adaptername: Adapter Failures**

- **SNA Adapter adaptername: Connection Failures**

- **SNA Adapter adaptername: Successful Connects**

  These counters may be useful for detecting patterns in which connections or adapters fail for short periods and then return to normal. Event Logs can provide more information about causes of failure. You might also want to set up System Monitor alerts with these counters, so that an alert is triggered if too many failures occur.

Performance Counters on Transaction Integrator

The following performance counters are available for Transaction Integrator.

Average Method Call Time
This counter measures the average time it takes Transaction Integrator to process method calls made by the client application. The time begins when Transaction Integrator recognizes the request from the client application (the Invoke call). The time ends when Transaction Integrator returns control to the client application. This counter is not specific to any Transaction Integrator programming model. This counter is represented in terms of seconds of elapsed time.

Bytes received from host/sec
This counter indicates the number of bytes received from the mainframe by Transaction Integrator. This counter is not specific to any Transaction Integrator programming model. For the CICS Link model, the number reported will be slightly more than the amount of user data due to link model protocol header data. This number is represented in terms of bytes per second.

Bytes sent to host/sec
This counter indicates the number of bytes sent from Transaction Integrator to the mainframe. This counter is not specific to any Transaction Integrator programming model. For the CICS Link model, the number reported will be slightly more than the amount of user data due to link model protocol header data. This number is represented in terms of bytes per second.

Host response time CICS Link
This counter measures the average time the host spends processing the transaction programs unit of work when the CICS Link model is being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after Transaction Integrator sends the final data buffer and ends when the first response buffer is received by Transaction Integrator. This counter is represented in terms of seconds of elapsed time.

Host response time CICS Non-link or IMS
This counter measures the average time the host spends processing the transaction programs unit of work when either the CICS Non-link or IMS models are being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after Transaction Integrator sends the final data buffer and ends when the first response buffer is received by Transaction Integrator. This counter is represented in terms of seconds of elapsed time.

Link calls/sec
This counter measures the number of method calls that use the CICS Link programming model. This number is in terms of calls per second.

Non-link calls/sec
This counter measures the number of method calls that use the CICS Non-link or IMS programming model. This number is represented in terms of calls per second.

Total calls/sec
This counter indicates the total number of method calls that Transaction Integrator has processed. This counter is not specific to any Transaction Integrator programming model. This number is represented in terms of calls per second.

Total errors/sec
This counter indicates the total number of method calls that have returned a non-zero HRESULT indication to the client application. This counter is not specific to any Transaction Integrator programming model. This number is represented in terms of errors per second.

Transaction Integrator Performance Guide

Maximizing Communications Throughput

Servers used primarily for communications need to provide fast throughput, but do not need to provide fast file access as a file server would. Faster throughput will result if portions of memory are set aside for communications programs such as Host Integration Server or Microsoft SQL Server.

Such dedicated memory includes nonpaged memory, or portions of memory that are never switched to disk, but remain available for immediate use at all times. This helps support fast throughput. If more memory is dedicated to Host Integration Server or similar programs, less memory is available for file sharing.

With Windows operating systems, you can view or change network throughput options. For Host Integration Server, you may not need to change the throughput option. Setup automatically sets the option to maximize throughput for network applications.

Servers used primarily for communications run many important background processes. Background processes are processes not related to user actions in the current window. These servers generally do not need to run foreground processes at maximum speed. Therefore, making the operating system more responsive to background processes and somewhat less responsive to foreground processes can increase Host Integration Server throughput. Setting background or foreground responsiveness is known as tasking.

A server that is less responsive to foreground processes will run local applications such as word processing software, spreadsheets, or the SNA Manager more slowly. Tasking is most appropriate for servers used primarily to support client computers, not servers used locally as desktop computers.

The options available for tasking are:

- Best Foreground Application Response Time
- Foreground Application More Responsive than Background
- Foreground and Background Applications Equally Responsive

Choose the one that is best suited to your network configuration.

How to Start System Monitor

You can start the Windows System Monitor in several ways. The following procedures describe how to start the system monitor from the operating system and from the SNA Manager.

To start System Monitor with the SNA Manager

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and click **SNA Manager**.
3. Once the **SNA Manager** starts, click **Tools**.
4. Click **System Monitor**.

To start System Monitor with Windows

1. Click **Start**, and point to **Programs**.
2. Point to **Administrative Tools**, and then click **Performance**.

System Monitor Overview

How to Configure System Monitor

Configuring System Monitor consists of adding counters to the System Monitor user interface. You can also set up administrative alerts to be generated by System Monitor. For more information about using System Monitor, see the Windows operating system Help.

The following procedure details how to add counters to System Monitor with the Windows operating system.

To add System Monitor counters

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server**, and click **SNA Manager**.
3. Once the **SNA Manager** starts, click **Tools**.
4. Click **Performance Monitor**.
5. Click **Add** (Plus sign).
6. Select the object for which to gather performance data (**SNA Connections** for example).
7. Select the counter.
8. Select the instance.
9. Click **Add**.
10. Repeat steps 6 – 9 for each counter you add.
11. Click **Done** to return to the **Performance Monitor**.

Note
Using Windows, if you load System Monitor from a Terminal Server client session, the performance counters for Host Integration Server and the MSMQ-MQSeries Bridge do not appear. When you are using the System Monitor in Terminal Server client session, you have to use "\\ComputerName\" instead of "\\ComputerName" for the computer field in order to be able to access the Host Integration Server or MSMQ-MQSeries bridge counters.

How to Save Performance Data

When you capture performance data, you can save the data for future use.

To save System Monitor data

1. Click **Start**, and point to **Programs**.
2. Point to **Host Integration Server** and then click **SNA Manager**.
3. Once the **SNA Manager** starts, click **Tools**.
4. Click **Performance Monitor**.
5. Click **Add** (Plus sign).
6. Select the object for which to gather performance data (**SNA Connections** for example).
7. Select the counter.
8. Select the instance.
9. Click **Add**.
10. Repeat steps 6 through 9 for each counter you add.
11. Click **Done** to return to the **System Monitor**.
12. Collect the desired data, click **Console**, and then click **Save As**.
13. Type a file name, and click **Save**.

Messaging User's Guide

Microsoft MSMQ-MQSeries Bridge is an adaptable system that can be customized. You can set up MSMQ-MQSeries Bridge to operate on almost any Message Queuing (also known as MSMQ) or IBM MQSeries network configuration.

In This Section

Using MSMQ-MQSeries Bridge

The topics in this section describe the procedures for using MSMQ-MQSeries Bridge. In addition, Help buttons located on the MSMQ-MQSeries Bridge user interface are linked to topics specific to their context.

In This Section

MSMQ-MQSeries Bridge Overview

MSMQ-MQSeries Bridge is an external gateway between two otherwise incompatible message queuing systems. MSMQ-MQSeries Bridge provides a seamless interface between Message Queuing on computers running Microsoft Windows Server 2003 or Windows 2000 Server and IBM MQSeries running on mainframes and other systems.

See Also

Other Resources

Using MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Operation

MSMQ-MQSeries Bridge is an interface between Message Queuing and MQSeries, so that you can send messages between Message Queuing applications and MQSeries queues.

MSMQ-MQSeries Bridge operates entirely in the background. In the MSMQ to MQSeries direction, a Message Queuing application can send a message to an MQSeries queue by a standard MQSendMessage() application programming interface (API) call or ActiveX control.

An MQSeries application can receive the message from the MQSeries queue by a standard MQGET() API call. In the MQSeries to MSMQ direction, the opposite relations apply. Neither application needs to be aware that the message has crossed between environments.

The MSMQ-MQSeries Bridge interface extends the features of Message Queuing and MQSeries across the combined environment. MSMQ-MQSeries Bridge fully supports connectionless, asynchronous messaging.

Using MSMQ-MQSeries Bridge, you can route messages to each messaging system even if the two systems are not connected to the network at the same time.

See Also

Other Resources

Using MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Benefits

Using MSMQ-MQSeries Bridge, your applications can send messages between IBM MQSeries and Message Queuing easily and efficiently. MSMQ-MQSeries Bridge extends connectionless, store-and-forward messaging across messaging systems and computing platforms throughout your network.

MSMQ-MQSeries Bridge offers:

Compatibility
Each messaging system sends and receives data in its native format. MSMQ-MQSeries Bridge converts the message formats automatically between the systems.

Adaptability
Your applications can send messages using standard Message Queuing or MQSeries API calls. You do not need to recode existing applications to use MSMQ-MQSeries Bridge.

Reliability
MSMQ-MQSeries Bridge supports transactions and deliver-once features, ensuring that messages are properly delivered following recovery from a system failure.

Performance
You can customize MSMQ-MQSeries Bridge for optimal performance in your network environment.

Management
Using MSMQ-MQSeries Bridge Manager, you can configure and manage all MSMQ-MQSeries Bridge computers in your enterprise network from a central location.

See Also
Other Resources
Using MSMQ-MQSeries Bridge

Message Queuing and MQSeries Features

The Message Queuing and MQSeries message queuing systems offer the following features:

Connectionless, asynchronous messaging
The communicating applications do not need to log on to the remote system or establish a session with each other. The computers on which the applications run do not need to be connected at the instant when messages are written or read. Applications can continue running without waiting for transmission to be completed.

Guaranteed delivery and deliver once
Message Queuing and MQSeries provide mechanisms by which an application can guarantee and confirm that messages are delivered, and prevent duplicate delivery.

Message prioritization
A sending application can specify the order in which the receiving application will get the messages.

User-defined message structure
The message body may contain a single byte (or no message contents at all), a text string, or a long and complex data structure. The message body may be structured or encrypted in any syntax that the communicating applications understand.

Transaction support
Send-message or receive-message operations can participate in a transaction, and can be coordinated with other operations such as database updates. The entire transaction is canceled and rolled back if any of the operations fail.

Application programming interface (API)
MSMQ and MQSeries operate on the Application Layer of the ISO Reference Model for Open System Interconnection. They act as a simple interface between an application program and the network, freeing the application programmer from concern about network or communication details.

See Also
Other Resources
Using MSMQ-MQSeries Bridge

Reference Material

Before installing or programming MSMQ-MQSeries Bridge, you should be familiar with the principles of message queuing and with at least one message queuing environment (Message Queuing or MQSeries).

For background information, refer to the *Host Integration Server Programmer's Guide*, Message Queuing documentation, and the IBM MQSeries documentation.

Using MSMQ-MQSeries Bridge

How MSMQ-MQSeries Bridge Works

The following topics detail how MSMQ-MQSeries Bridge works.

In This Section

MSMQ-MQSeries Bridge Concepts

With MSMQ-MQSeries Bridge, Message Queuing (also known as MSMQ) and MQSeries applications can send messages to each other, between the message queuing systems.

MSMQ-MQSeries Bridge achieves this by mapping the messages and the data fields of the sending system and the values associated with those fields, to the fields and values of the receiving environment.

After the mapping and conversion, MSMQ-MQSeries Bridge completes the process by routing the message across the combined Message Queuing and MQSeries networks.

See Also

Other Resources

How MSMQ-MQSeries Bridge Works

Message Queuing Concepts

Message queuing enables programs to share data across a network without necessarily having a synchronized connection linking the sending and receiving applications at the same instant. The programs do this by putting the data, or message, on a message queue, which is then retrieved by the receiving application.

Two basic concepts of both Message Queuing and MQSeries are message and message queue:

Message
A message is a set of data that needs to be transmitted from one application to another application, on the same or a different computer in a network.

Message queue
A message queue is the location where messages are stored, which can be written and read by applications.

See Also
Other Resources
How MSMQ-MQSeries Bridge Works

Message Fields or Properties

A message may contain one or more fields, such as the message buffer or body, label, priority, or sender ID. The following applies to fields or properties:

- In MQSeries, the fields are members of a fixed data structure.
- In Message Queuing, the fields are known as properties. A message can contain any number of properties (even zero). In practice, an application assembles a message from one or more properties in a dynamic data structure.

See Also

Other Resources

How MSMQ-MQSeries Bridge Works

Sending and Receiving Messages

To create a message, an application specifies the message fields or properties and supplies the field values. The application then issues a Message Queuing or MQSeries API call to send the message.

The Message Queuing or MQSeries Queue Manager (server) transmits the message to the destination message queue. If the destination location is not connected to the network when the message is sent, the message queuing system stores the message at an interim location. The system forwards the message automatically when a connection is established.

To receive a message, an application issues an API call that reads the message from the queue.

Receiving a message

How MSMQ-MQSeries Bridge Works

System Components

The MSMQ-MQSeries Bridge system can contain two main components:

MSMQ-MQSeries Bridge
Converts and transmits messages between the Message Queuing and MQSeries environments.

MSMQ-MQSeries Bridge Manager
Configures, monitors, and controls the messaging traffic through MSMQ-MQSeries Bridge.

See Also
Other Resources
How MSMQ-MQSeries Bridge Works

Message Conversion

MSMQ-MQSeries Bridge maps the fields or properties of a message to the corresponding fields or properties of the destination message queuing system. For example, if you send a message from MQSeries to Message Queuing, MSMQ-MQSeries Bridge analyzes the fields of the MQSeries message and maps each value to its Message Queuing counterpart. In cases where one system needs an additional field that does not exist in the other, MSMQ-MQSeries Bridge provides the field during the conversion process.

For example, if a Message Queuing message includes the PROPID_M_TIME_TO_BE_RECEIVED property with a specific value, MSMQ-MQSeries Bridge maps this property to the MQSeries MQMD.Expiry property and multiplies the value by 10 to change the units from seconds to tenths of seconds.

MSMQ-MQSeries Bridge does not restrict the content of a message. The message body may contain its own internal structure, which is recognized only by the sending and receiving applications and is not interpreted in any way by MSMQ-MQSeries Bridge.

For detailed information about how MSMQ-MQSeries Bridge maps and converts properties from Message Queuing to MQSeries and from MQSeries to Message Queuing, see the *Host Integration Server Programmer's Guide*.

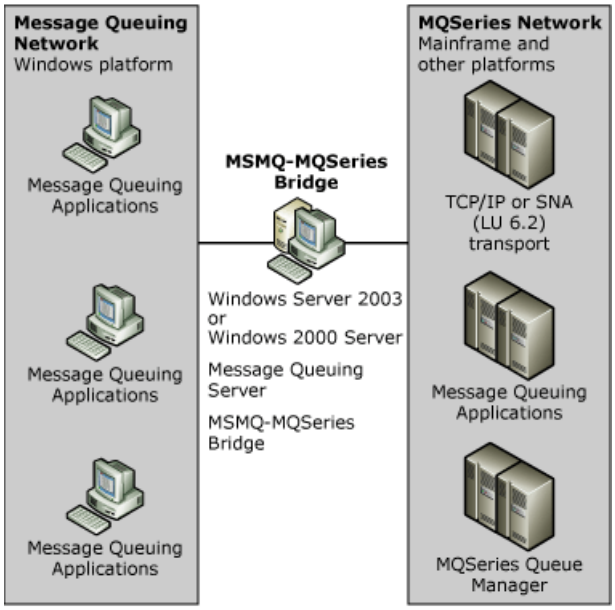
How MSMQ-MQSeries Bridge Works

Network Architecture

MSMQ-MQSeries Bridge is used in conjunction with Message Queuing and MQSeries networks. MSMQ-MQSeries Bridge is a Message Queuing Connector application.

MSMQ-MQSeries Bridge is installed on a Microsoft Windows Server 2003, Enterprise Edition or Windows 2000 Server Enterprise Edition system that serves as a connection point between the networks. A Message Queuing routing server must be installed on the same computer as MSMQ-MQSeries Bridge, and the computer must be connected by a TCP/IP or LU 6.2 link to an MQSeries Queue Manager.

MSMQ-MQSeries Bridge connects Message Queuing and MQSeries



See Also

Other Resources

How MSMQ-MQSeries Bridge Works

Multiple Connections

You can connect any number of Message Queuing or MQSeries systems or networks using MSMQ-MQSeries Bridge. For example, you can connect:

- A single MSMQ-MQSeries Bridge to several MQSeries Queue Managers
- A single MQSeries Queue Manager to several MSMQ-MQSeries Bridges
- Several MSMQ-MQSeries Bridges to several MQSeries Queue Managers

See Also
Other Resources
How MSMQ-MQSeries Bridge Works

Sending Messages From Message Queuing to MQSeries

To send a message from Message Queuing to MQSeries, you must define a Message Queuing foreign computer representing the MQSeries Queue Manager, and the MQSeries destination queue must already exist. If this is not the case, see Installing and Configuring MSMQ-MQSeries Bridge.

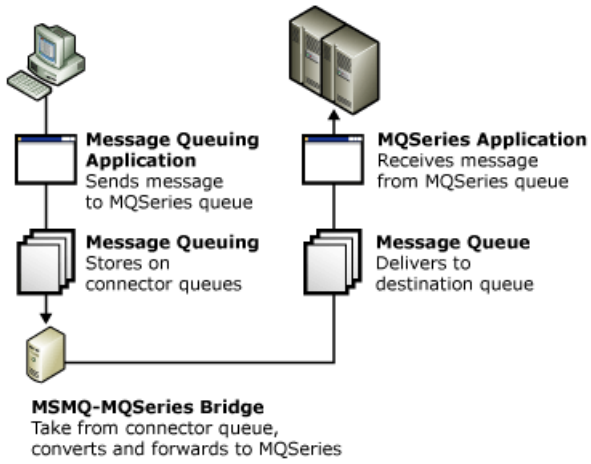
The messaging process is as follows:

- A Message Queuing application issues a Message Queuing MQCreateQueue() API call to create a foreign queue, located on the foreign computer and representing the MQSeries destination queue. Alternatively, you can create the foreign queue using Message Queuing, and in Windows Server 2003 or Windows 2000 the foreign queue is a part of Users and Computers.

- The application calls MQOpenQueue() to open the foreign queue.

- The application calls MQSendMessage() to send a message to the foreign queue. Message Queuing routes the message and stores it temporarily on a Message Queuing connector queue.

  Sending a message from Message Queuing to MQSeries



- MSMQ-MQSeries Bridge takes the message from the connector queue and converts the message properties to the MQSeries message structure. MSMQ-MQSeries Bridge routes the message to the MQSeries destination queue.

- An MQSeries application issues an MQSeries MQGET() API call to receive the message from the MQSeries queue.

Message Queuing processes the message from the initial MQSendMessage() call until it is placed on the connector queue. MSMQ-MQSeries Bridge converts and transmits the message to MQSeries, which handles the transmission from that point on.

See Also
Other Resources
How MSMQ-MQSeries Bridge Works

Sending Messages From MQSeries to Message Queuing

The path for sending a message from MQSeries to Message Queuing is essentially the inverse of Message Queuing to MQSeries, with a few differences. You must define appropriate MQSeries aliases, transmission queues, and channels for the Message Queuing destination queue or the Message Queuing server, and the Message Queuing destination queue must already exist.

For additional information, see Typical Configuration.

The messaging steps are as follows:

- An MQSeries application issues an MQOPEN() API call for a remote queue representing the Message Queuing destination queue.
- The MQSeries application calls MQPUT() to send a message to the remote queue. MQSeries transmits the message and stores it temporarily on an MQSeries transmission queue located at the MQSeries Queue Manager.
- MSMQ-MQSeries Bridge takes the message from the transmission queue and converts the message structure to Message Queuing message properties. MSMQ-MQSeries Bridge transmits the message to the Message Queuing destination queue.
- A Message Queuing application issues a Message Queuing MQReceiveMessage() API call to receive the message from the Message Queuing queue.

Sending a message from MQSeries to Message Queuing

How MSMQ-MQSeries Bridge Works

Transactional and Nontransactional Message Pipes

Using MSMQ-MQSeries Bridge, you can send messages through transactional or nontransactional message pipes.

If you send a message by a transactional message pipe, MSMQ-MQSeries Bridge supports the deliver-once feature of Message Queuing and MQSeries. This feature ensures that each message is delivered exactly once to the receiving application, but entails some overhead.

Choosing a nontransactional message pipe may improve performance, but a message may be delivered more than once in the event of a system failure during transmission.

Message Queuing messages in the foreign transactional queue will go through transactional message pipes, while Message Queuing messages in the foreign nontransactional queue will go through the nontransactional message pipes.

In the MQSeries to Message Queuing direction, you can send a message by transactional or nontransactional message pipe by specifying the appropriate remote queue manager alias as follows:

"**BRIDGEQMNAME**" refers to transactional message pipe.

"**BRIDGEQMNAME%**" refers to nontransactional message pipe.

In the Message Queuing to MQSeries direction, MSMQ-MQSeries Bridge sends transacted messages by normal service and untransacted messages by high service. In the MQSeries to Message Queuing direction, you can send a message by normal or high service by specifying an appropriate alias as the remote queue manager address.

How MSMQ-MQSeries Bridge Works

MSMQ-MQSeries Bridge Setup and Configuration

The following sections detail the setup and configuration of MSMQ-MQSeries Bridge.

After installing, you must configure the Message Queuing (also known as MSMQ), MQSeries, and MSMQ-MQSeries Bridge systems.

The configuration process is equivalent to building a bridge, enabling MSMQ-MQSeries Bridge to transfer messages.

In This Section

MSMQ-MQSeries Bridge Setup Requirements

The following information details the steps required to set up MSMQ-MQSeries Bridge. The installation process is straightforward, but rolling out a full installation may take some time in a complex network configuration.

This section helps you get started quickly and presents a step-by-step procedure for an initial MSMQ-MQSeries Bridge configuration.

In This Section

MSMQ-MQSeries Bridge Minimal Configuration

The minimal configuration enables MSMQ and MQSeries applications to communicate with one another, so the benefits of MSMQ-MQSeries Bridge are immediate. The minimal configuration requirements are:

- One installation of MSMQ-MQSeries Bridge on a computer running Windows Server 2003 or Windows 2000 Server.
- One installation of Message Queuing on the same computer as MSMQ-MQSeries Bridge. (Message Queuing with routing in Windows Server 2003 or Windows 2000 Server.)
- One installation of MQSeries Queue Manager on any supported platform.

Other Resources

MSMQ-MQSeries Bridge Setup Requirements

Where You Work When Installing MSMQ-MQSeries Bridge

To install MSMQ-MQSeries Bridge, you must work on two computers:

- The Message Queuing and MSMQ-MQSeries Bridge computer.
- The MQSeries computer, where the MQSeries Queue Manager is installed.

There are several steps and data transfers that must be performed on each computer.

See Also

Other Resources

MSMQ-MQSeries Bridge Setup Requirements

Gathering Required Information

Before you proceed, gather the following information. You will need this information later in the configuration process:

- Computer name (example: MSBRIDGE1).
- Directory in which the MQSeries Client for Windows Server 2003, Windows 2000, or Windows NT® is installed (example: c:\MQCLIENT).
- Connection information
    - For TCP/IP, the computer name or IP address (example: IBMNT) and the port number (example: 1414).
    - For SNA, the LU 6.2 Side Information Record (CPI-C Symbolic Destination Name).
- Name of the MQSeries Queue Manager (example: IBMNT).

Note
All MQSeries names must be in uppercase (for example, MSBRIDGE1, and not Msbridge1).

MSMQ-MQSeries Bridge Prerequisites

Prerequisites for Computers Running Windows Server 2003 or Windows 2000

The following software should already be installed on the computer where you will install MSMQ-MQSeries Bridge Server or Administrator Client:

Server Prerequisites

- Windows Server 2003 or Windows 2000 Server
- Message Queuing server (not in a workgroup) with routing enabled
- IBM MQSeries Client for Windows NT or IBM MQSeries for Windows NT (with server and client installed)
- TCP/IP or SNA (LU 6.2) link to an MQSeries Queue Manager (QM)

Administrator Client Prerequisites

- Windows Server 2003, Windows 2000 Professional, or Windows 2000 Server with Terminal Services
- Message Queuing set up (not in a workgroup)

MSMQ-MQSeries Bridge Properties

How to Add a Connected Network

To add a connected network (CN)

1. Right-click the MSMQ-MQSeries Bridge computer to which the CN is connected.
2. Select **New CN** from the pop-up menu, and select the CN name from the list.

   Along with the new CN, the following four message pipes are added to the console tree.

Message pipe	Description
MSMQ->MQS Transactional	Message Queuing to MQSeries transactional message.
MSMQ->MQS Nontransactional	Message Queuing to MQSeries nontransactional message.
MQS->MSMQ Transactional	MQSeries to Message Queuing transactional message.
MQS->MSMQ Nontransactional	MQSeries to Message Queuing nontransactional message.

3. Right-click the new CN and each message pipe to set their properties.

Naming Message Queuing and MQSeries Entities

You must choose names for certain Message Queuing and MQSeries entities that you define during the configuration process. For more information, see the topics in this section.

Note
The names are identical to or derived from other names that you already recorded. This naming system is recommended bec ause it helps you maintain your system easily.

In This Section

Message Queuing Names

MQSeries Names

Message Queuing Names

You will need the following information when creating your Message Queuing names.

- Name of a connected network or foreign site (example: IBMNT_CN).
- Name of the Queue Manager on the foreign computer (example: IBMQM).
- Name of a foreign queue (example: IBM.NT.QUEUE).
- Name of a Message Queuing queue to which you will send test messages (example: MSBRDIGE1.QUEUE).

See Also
Concepts
MQSeries Names

MQSeries Names

You will need the following information when creating your MQSeries names.

- MQI channel name (example: IBMNT_CN).
- Transmission queue name for normal service (example: MSBRIDGE1.XMITQ).
- Transmission queue name for high service (example: MSBRIDGE1.XMITQ.HIGH).
- Name of an MQSeries queue to which you will send test messages (example: IBM.NT.QUEUE).

Installing and Configuring MSMQ-MQSeries Bridge

The following topics detail how to configure MSMQ-MQSeries Bridge components:

In This Section

How to Install the MSMQ-MQSeries Bridge Software

The procedure for installing the MSMQ-MQSeries Bridge software is the same whether you are installing the Server or the Administrator Client.

Choosing Server installs MSMQ-MQSeries Bridge and MSMQ-MQSeries Bridge Manager. Choosing Administrator Client installs only MSMQ-MQSeries Bridge Manager.

To install MSMQ-MQSeries Bridge

1. Insert the Host Integration Server CD-ROM.
2. From the Host Integration Server startup page, click **Install Server** or **Install Administrator Client** and follow the directions on the screen.
3. When the setup is complete, you can optionally view the **Readme** file and launch MSMQ-MQSeries Bridge Manager. Click **Finish** to complete the installation.

See Also

Other Resources

Installing and Configuring MSMQ-MQSeries Bridge

Transport Considerations

When the TCP/IP protocol is used between the MQSeries Client and MQSeries Queue Manager, check the **Keep Alive** and **Keep Alive Time** settings in the MQSeries Queue Manager initialization file (Qm.ini). **Keep Alive** should be set to **YES** and the **Keep Alive Time** should be no more than half the message pipes retry delay. This enables the MQSeries Listener to release the resources of a broken connection before MSMQ-MQSeries Bridge retries the connection.

The message pipes retry delay can be found by right-clicking a message pipe in MSMQ-MQSeries Bridge Manager. Select **Properties**,and then select the **Cache** tab.

Installing and Configuring MSMQ-MQSeries Bridge

Configuring MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000

Configuring MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000 is a three-stage process requiring Message Queuing 2.0 or later, MSMQ-MQSeries Bridge, and MQSeries to be configured in that order. Configuring Message Queuing 2.0 on Windows Server 2003 or Windows 2000 is the only stage that is different from that described for configuring MSMQ-MQSeries Bridge on Windows NT 4.0.

Message Queuing 2.0 and MSMQ-MQSeries Bridge

Message Queuing 2.0 is built into Windows Server 2003 and Windows 2000 and offers the following additional functionality:

- Integration with the Microsoft Active Directory directory service, removing the need to use a separate SQL Server™ computer to maintain the MQIS.
- Mixed-mode operation, enabling Message Queuing 1.0 and Message Queuing 2.0 environments to coexist together.
- Performance improvements, particularly in the area of transactions.
- Workgroup Mode, enabling computers running Windows Server 2003 or Windows 2000 to use Message Queuing 2.0 without the need for Active Directory.

MSMQ-MQSeries Bridge is capable of running on Windows Server 2003 or Windows 2000. MSMQ-MQSeries Bridge can be installed on any of the computers running Windows Server 2003 or Windows 2000.

To use MSMQ-MQSeries Bridge on Windows Server 2003 or Windows 2000, install:

- Windows Server 2003 or Windows 2000 Server.
- Message Queuing server (not in a workgroup) with routing enabled.
- IBM MQSeries Client for Windows NT, Version 2.0, 5.0, or 5.1, or IBM MQSeries for Windows NT, version 2.0, 5.0, or 5.1 (both Server and Client)
- MSMQ-MQSeries Bridge (from Host Integration Server)

There are some changes in Message Queuing 2.0 that are relevant to MSMQ-MQSeries Bridge. These are:

- Foreign Connected Network has been replaced with the term Foreign Site. This is in keeping with Active Directory terminology. Therefore, in Windows Server 2003 or Windows 2000 a CN refers to a foreign site.
- The Message Queuing 2.0 COM API has changed. Many more of the Message Queuing message properties are now exposed through the Message Queuing COM API. In particular, the extension property (PROPID_M_EXTENSION) is now accessible from Visual Basic®, making it easier to override MSMQ-MQSeries Bridge conversions.
- Creating foreign sites and foreign computers is achieved using Active Directory Sites and Services.

Configuring Message Queuing 2.0 on Windows Server 2003 or Windows 2000

This section assumes that Message Queuing 2.0 has been installed (with routing enabled) on a computer running Windows Server 2003 or Windows 2000 on which you plan to install MSMQ-MQSeries Bridge. Using Active Directory Users and Computers, it should be possible to see the Message Queuing object:

Domain Controllers

Computer Name (Your computer name)

Message Queuing

If this is not the case, check that the view is set to Advanced Features. If the Message Queuing object still does not appear, Message Queuing 2.0 is not installed. Check the Windows Server 2003 or Windows 2000 Message Queuing Help to ensure the Message Queuing 2.0 prerequisites are met before installing Message Queuing 2.0.

From **Control Panel**, select **Add Remove Components** and install the **Message Queuing Services**. During the installation of Message Queuing 2.0, ensure that you select **Enable Routing**. This will enable you to define a foreign site (foreign connected network) and define routing links to the foreign site, which are required to set up an MSMQ-MQSeries Bridge.

Active Directory is used to configure Message Queuing 2.0 for use with MSMQ-MQSeries Bridge. This requires permissions to make changes to Active Directory. For example, when creating a routing link, the default is that only users of the Enterprise Administrators group can make these changes. Check to ensure you have the appropriate permissions to make the required Active Directory changes before commencing Message Queuing 2.0 configuration.

How to Define a Foreign Site in Windows Server 2003 or Windows 2000

Use the following procedure to define a foreign site in Windows Server 2003 or Windows 2000.

To define a foreign site

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node**.
2. Under **Services**, right-click **MsmqServices** and select **New Foreign Site**.
3. Enter the name for the foreign site. This is the name of the Foreign Connected Network in Message Queuing 1.0. The same naming conventions apply to the foreign site name as to the Foreign Connected Network name for Message Queuing 1.0.
4. Click **OK**.

Other Resources

Installing and Configuring MSMQ-MQSeries Bridge

How to Add a Foreign Computer Representing MQSeries in Windows Server 2003 or Windows 2000

Use the following procedure to add a foreign computer representing MQSeries in Windows 2003 Server or Windows 2000.

To add a foreign computer

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node**.
2. Under **Services**, right-click **MsmqServices** and select **New Foreign Computer**.
3. Enter the **Name** for the Foreign Computer. This name must be the same as that of the MQSeries Queue Manager.

   Note

   Windows Server2003 and Windows2000 do not allow the dot (.) character in computer names. If your MQSeries Queue Manager name contains a dot, you can replace it with a dash (-) and MSMQ-MQSeries Bridge will map the dash back to a dot when routing the message to its MQSeries destination.

4. Select the name for the **Site**,and click **OK**. This is the name of the foreign site that was just created.
5. Click **OK**.

Installing and Configuring MSMQ-MQSeries Bridge

How to Set the Foreign Site Permission in Windows Server 2003 or Windows 2000

Use the following procedure to modify the permissions for the foreign site.

To set the foreign site permissions

1. From **Active Directory Sites and Services**, expand the **Sites** folder, and select the foreign site created earlier.
2. Right-click the foreign site, and then select **Properties**.
3. Select the **Security** tab, and select **Everyone**. If MSMQ-MQSeries Bridge was installed using a local account, enable **Open Connector Queue**. Otherwise, select the account name used during setup.

See Also

Other Resources

Installing and Configuring MSMQ-MQSeries Bridge

How to Create a Foreign Queue in Windows Server 2003 or Windows 2000

Use the following procedures to create a foreign queue.

To define the MQSeries queues

1. From **Active Directory Users and Computers**, select **View**, select **Advanced Features**, select **View**, and then select **Users, Groups and Computers As Containers**.
2. Expand the **Computers** folder and select the foreign computer that was previously created.
3. Right-click the Message Queuing object, select **New**, and then select **MSMQ Queue**.
4. Type the name for the queue and click **OK**.

   The name must be the same as that of the MQSeries Queue.
5. Or, if you want to create a queue to accept transactional messages, type a name, select the **Transactional** check box, and then click **OK**.

A routing link is required to enable Message Queuing 2.0 to route messages between the current Windows Server 2003 or Windows 2000 site and the newly created Foreign Site that is used for MQSeries. Use the following procedure to create a routing link.

To create a routing link

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node** (if not already selected).
2. Under **Services**, right-click **MsmqServices**, select **New**, and then select **MSMQ Routing Link**.
3. Set Site 1 to the name of the foreign site that was previously created. Set Site 2 to the name of the current Windows Server 2003 or Windows 2000 site.
4. Set the **Routing link cost** at 1 and then click **OK**. Using a value greater than 1 is only relevant when multiple routing links are defined between sites, and you want to enforce one route over another. Do not set this value to zero, because it will cause routing of Message Queuing messages to the foreign site to fail.

A site gate is an Message Queuing server that is configured to route messages between sites on behalf of other clients. The Message Queuing server that will be defined as the site gate is the computer that will run MSMQ-MQSeries Bridge. This site gate will use the routing link that was just created. Use the following procedure to define a site gate.

To define a site gate

1. From **Active Directory Sites and Services**, select **View**, and then select **Show Services Node** (if not already selected).
2. Under **Services**, right-click **MsmqServices**. The routing link that was previously created should appear in the right pane window.
3. **Right-click** the routing link, and select **Properties**.
4. Select the **Site Gates** tab.
5. In **Site Servers**, select the name of the computer that will run MSMQ-MQSeries Bridge, and then click **Add**.
6. Click **OK**.

The Message Queuing server, which is the same computer running Windows Server 2003 or Windows 2000 as MSMQ-MQSeries Bridge, must be added to the foreign site created earlier.

To add the site queuing server to the foreign site

1. From **Active Directory Users and Computers**, select **View**, select **Advanced Features**, select **View**, and then select **Users, Groups and Computers as containers**.
2. Expand the Domain Controllersor Computers/<*Your server name*>/MSMQ folder.

3. Right-click the **Message Queuing** object, and select **Properties**.
4. Select the **Sites** tab.
5. Select the foreign site created earlier, and then click **Add** to add this server to the foreign site.
6. Click **OK**.

On the computer running Windows Server 2003 or Windows 2000, open MSMQ-MQSeries Bridge Manager. In MSMQ-MQSeries Bridge Manager, perform the following steps.

To change the configuration in MSMQ-Series Bridge Manager

1. Expand the **Enterprise** icon.
2. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon, click **Stop**, and then click **OK**.
3. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon and click **Properties**.
4. On the **MQI Channels** tab, click **Add**.
5. Enter the **Channel Name**.
6. Enter the **Queue Manager** name.
7. For **Transport Type**, select **TCP/IP** or **SNA LU6.2**.
8. On the **Address** tab, if you connect by TCP/IP, specify the IP address or computer name for **Address** and the port number for **Port**.

   For SNA LU 6.2, specify the LU 6.2 Side Information Record.
9. Click **OK** twice.

   A message appears warning you about changing the MQI Channel configuration. Click **OK** to bypass this message.

   See the other topics in this section for more information about configuration.

How to Run the MQSeries Server Definition File

On the MQSeries computer, run the MQSeries Server definition file that you transferred from MSMQ-MQSeries Bridge Manager.

To run the MQSeries server definition file

1. At the command prompt, run the `MQSC` command, for example:

   ```
   
   ```

   Note

   Substitute the MQSeries Queue Manager name for `IBMNT`.

2. The MQSeries Queue Manager is now configured. Review the Servreport.out file to be sure that the definitions ran successfully.

Installing and Configuring MSMQ-MQSeries Bridge

How to Run the MQSeries Client Definition File

On the MQSeries Queue Manager computer, run the MQSeries Client definition file that you transferred from MSMQ-MQSeries Bridge Manager.

To run the MQSeries client definition file

1. At the command prompt, run the MQSC command, for example:

   ```
   
   ```

2. The MQSC command creates a channel file called Amqclchl.tab, located in the directory MQMDirectory/QMGRS/<QueueManagerName>/@IPCC (the exact location may differ on various platforms).
3. Review the Clientreport.out file to be sure that the definitions ran successfully.
4. Transfer the Amqclchl.tab file to the MQSeries Client directory on the Windows computer. If you transfer by FTP, be sure to specify the Binary transfer option.

Other Resources

Installing and Configuring MSMQ-MQSeries Bridge

How to Configure the MQSeries Client

To complete the MQSeries configuration, return to the computer running Windows where MSMQ-MQSeries Bridge is installed.

To configure the MQSeries client

1. On the computer running Windows Server 2003 or Windows 2000, right-click **My Computer**, click **Properties**, select the **Advanced** tab, and then click **Environment Variable**.
2. Verify the following variables are in the **System Variables**.

   If they are not, set them correctly.

   MQCHLLIB should be the directory path of the channel file (by default, the MQSeries Client directory).

   MQCHLTAB should be the file name of the channel file (by default, Amqclchl.tab).
3. Check that the environment variable MQSERVER is not defined.
4. Click **OK**.

Installing and Configuring MSMQ-MQSeries Bridge

Testing the Installation

You can use the test programs provided in the server installation to test the MSMQ-MQSeries Bridge operation. By default, the test programs are installed to C:\Program Files\Host Integration Server\system.

For additional information about testing the MSMQ-MQSeries Bridge configuration, see the following topics.

In This Section

Creating the Test Queues

Create a Message Queuing and an MQSeries queue to receive the test messages. Alternatively, you can use queues that already exist on the computers running Windows and MQSeries.

To create a new Message Queuing queue on Windows Server 2003 or Windows 2000, see Create a Foreign Queue in Windows Server 2003 or Windows 2000.

Note
Use `IBMNT` for your MQSeries Queue Manager name. Use `IBM.NT.QUEUE` for the MQSeries queue name. **See Also**

Test the Installation

How to Test the MQSeries Client Definitions

Use the following procedure to start the MQSRRECV program.

To test the MQSeries client definitions

1. To start the program, open the command prompt and go to the MSMQ-MQSeries Bridge `samples` directory (by default, C:\Program Files\Host Integration Server\system).
2. Start the program by typing the following command:

   ```
   
   ```

   Note

   For `IBMNT`, use the MQSeries Queue Manager name. For `IBM.NT.QUEUE`, use the MQSeries queue name.

3. If the program starts successfully, it displays the message:

   ```
   Use <CTRL-C> to stop!
   ```

If you do not receive this message, confirm the channel file steps. You can view the channel file in Windows Notepad. If the file does not exist or it contains no entries, delete the Amqclchl.tab file from the MQSeries Server and execute the channel file steps again.

If the program still fails to start, override the channel file settings by issuing the following command:

```

```

An example for TCP/IP is:

```

```

An SNA example is:

```

```

Where `MQSCPIC` is the side information record name (CPI-C Symbolic Destination Name).

Then try `MQSRRECV` again. If the program now starts, either the channel file was not found, or it does not contain a correct MQI channel definition. If `MQSRRECV` still does not start, check that the listener on the MQSeries computer is started for the correct port. If not, start the listener and try again.

Press CTRL+C to stop the `MQSRRECV` program.

Testing the Installation

How to Start MSMQ-MQSeries Bridge

Open MSMQ-MQSeries Bridge Manager and then use the following procedure.

To start MSMQ-MQSeries bridge

1. Right-click the **Microsoft MSMQ-MQSeries Bridge Service** icon and click **Start**.
2. In the Manager display, all four message pipes should start (the icons should have a green arrow).

If the message pipes do not start, check the event log.

The `MQS->MSMQ` message pipes may fail in the following situations:

- Another MSMQ-MQSeries Bridge computer is currently using the same transmission queue.
- Microsoft MSMQ-MQSeries Bridge is terminated abnormally, causing the MQSeries server to behave as if MSMQ-MQSeries Bridge is still using the corresponding XMIT queue. If this happens, you must restart MQSeries Queue Manager, or configure the **Keep Alive** option in your MQSeries server. (For further information, see your MQSeries documentation.)

Testing the Installation

How to Send Test Messages from Message Queuing to MQSeries

On the computer running Windows, perform the following procedure to send test messages.

To send test messages from message queuing to MQSeries

1. Open two MS-DOS windows. Change both windows to the server installation directory (by default, C:\Program Files\Host Integration Server\System).
2. Start the MQSeries receiver program in the first window.

Note
Use `IBMNT` for your MQSeries Queue Manager name. Use `IBMNT` for the MQSeries queue name.

3. In the second window, send 10 messages from Message Queuing to MQSeries:

Note
Use `IBMNT` for your foreign computer name. Use `IBMNT.QUEUE` for the MQSeries queue name.

4. If the test succeeds, the first window displays the 10 messages that it receives.
5. Stop the `MQSRRECV` program by pressing CTRL+C in the first window.

How to Send Test Messages from MQSeries to Message Queuing

On the computer running Windows, perform the following procedure to send test messages.

To send test messages from MQSeries to Message Queuing

1. Open two MS-DOS windows. Go to the default installation directory (default is C:\Program Files\Host Integration Server\System).
2. In the first window, start the Message Queuing receiver program.
3. Send from MQSeries with the following command:

```
```

4. Receive in Message Queuing with the following command:

```
    >MSMQRecv MSBRIDGE1\MSBRIDGE1.QUEUE
```

Typical Configuration

The topics in this section detail the configuration of MSMQ-MQSeries Bridge.

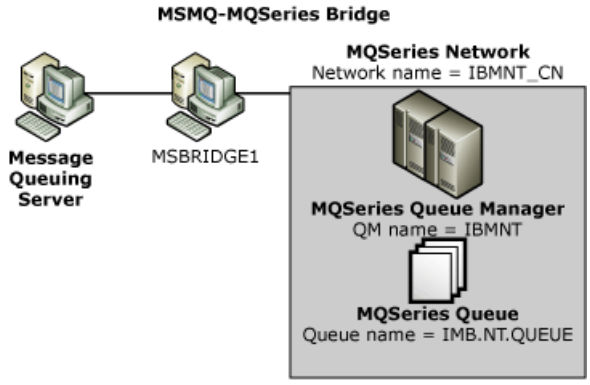
In This Section

Typical Configuration Diagram

Examine the diagram for an overview of a typical configuration. The names in the diagram (such as MSBRIDGE1, IBMNT_CN, and IBMNT) are arbitrary, but you must use the same name for the same entity at different locations in the configuration.

For example, if the MSMQ-MQSeries Bridge computer is called MSBRIDGE1, you must reference this same name in MSMQ-MQSeries Bridge Manager and in MQSeries.

A typical configuration



Settings for a Typical Configuration

Typical Configuration Settings

The following tables show settings for a typical configuration.

Define in Message Queuing		
	Foreign Connected Network or Foreign Site	IBMNT_CN
	Foreign computer	IBMNT
	Foreign queue	IBM.NT.QUEUE

Define in MSMQ-MQSeries Bridge		
MSMQ-MQSeries Bridge properties	MQI channel	IBMNT_CN
	Transport type	TCP/IP or LU6.2
Foreign Connected Network or Foreign Site properties	CN name	IBMNT_CN
	MQSeries QM	IBMNT
	Reply to QM	MSBRIDGE1
Message pipe properties	MQSeries Message Queuing	Normal
	MQSeries Message Queuing	High
Transmission queue	IBM.NT_CN.XMITQ	IBMNT_CN.XMITQ.HIGH

Import or define in MQSeries		
	Transactional Service	Nontransactional Service
Transmission queue	IBMNT_CN.XMITQ	IBMNT_CN.XMITQ.HIGH
Queue manager alias	MSBRIDGE1	MSBRIDGE1%
	Model queue	Q2Q_SYNC_Q
	MQI channel	MQS_CN
	Transport type	TCP/IP or LU6.2

MSMQ-MQSeries Bridge Manager

For information about MSMQ-MQSeries Bridge Manager, see the following topics.

In This Section

MSMQ-MQSeries Bridge Manager Overview

Using MSMQ-MQSeries Bridge Manager, you can control and monitor MSMQ-MQSeries Bridge operations. For example, you can use MSMQ-MQSeries Bridge Manager to:

- Start, stop, or pause the operation of an MSMQ-MQSeries Bridge, a CN, or a message pipe.
- Observe the quantity and type of traffic between Message Queuing and MQSeries.
- Determine how many messages are on MQSeries transmission queues or Message Queuing connector queues waiting to be transmitted.

This topic explains how to use and customize MSMQ-MQSeries Bridge Manager for these purposes.

Note
You can also use MSMQ-MQSeries Bridge Manager to configure your MSMQ-MQSeries Bridge system. This is an essential st ep in the MSMQ-MQSeries Bridge installation. For complete information, see MSMQ-MQSeries Bridge configuration.

MSMQ-MQSeries Bridge Display

The following table shows the MSMQ-MQSeries Bridge Manager column name and description.

Column name	Description
MQS H Threads	Number of MQSeries to Message Queuing threads at nontransactional message pipe
MQS N Threads	Number of MQSeries to Message Queuing threads at transactional message pipe
Message Queuing H Threads	Number of Message Queuing to MQSeries threads at nontransactional message pipe
Message Queuing N Threads	Number of Message Queuing to MQSeries threads at transactional message pipe
Lifetime	Time since MSMQ-MQSeries Bridge started
Path	Computer name
Status	MSMQ-MQSeries Bridge status (running, paused, or stopped)
DLQ Depth	Number of messages on the MSMQ-MQSeries Bridge non-transacted dead letter queue
XDLQ Depth	Number of messages on the MSMQ-MQSeries Bridge transacted dead letter queue

MSMQ-MQSeries Bridge Manager

Message Pipe Display

The following table shows the message pipe column name and description.

Column name	Description
Acc Size	Accumulated size (in bytes) of all messages transmitted since the message pipe started
Lifetime	Time since the message pipe started
Messages Sent	Total number of messages that have been sent since the message pipe started
Msgs/Sec	Messages per second (the current throughput of the pipe)
Q Depth	Queue depth (number of messages in the queue) waiting to be transmitted
Q Name	Name of the MQSeries transmission queue or Message Queuing connector queue associated with the message pipe
Retries	Number of times that MSMQ-MQSeries Bridge has tried to activate the message pipe
Startup	Whether the message pipe is enabled or disabled at MSMQ-MQSeries Bridge startup
Status	Message pipe status (running, paused, pending, recovering, stopped, or error)

MSMQ-MQSeries Bridge Manager

How to Customize the Column Display

Use the following procedure to add or remove a column in the details pane of MSMQ-MQSeries Bridge Manager.

To customize the column display

1. From the **View** menu, select **Columns**.
2. Select the tab for the type of object (**MSMQ-MQSeries Bridge**, **CN**,or **Message Pipe**).
3. To add a column to the display, select its name in the **Available Columns** list, and click **Add**.
4. To remove a column, select its name in the **Show the following** list, and click **Remove**.
5. To change the sequence of the column display, select columns in the **Show the following** list, and click the UP ARROW key or the DOWN ARROW key.
6. Click **OK**.

MSMQ-MQSeries Bridge Manager

Controlling MSMQ-MQSeries Bridge

To control the operation of an object, right-click the object in MSMQ-MQSeries Bridge Manager, and select the appropriate command. Some of the commands are also available on the main **Manager** menu.

For additional information, see the following topics.

In This Section

Starting, Stopping, or Pausing an Object

At MSMQ-MQSeries Bridge startup, the connected network (CN) and message pipes start automatically if you selected the **Startup Enabled** option in the object properties.

To change the status of an object, right-click that object in MSMQ-MQSeries Bridge Manager. Select one of the following options.

Option	Description
Stop	Stops the operation and resets the object's counters (lifetime, messages sent, and accumulated size).
Start	Starts a stopped object.
Pause	Pauses an operation, retaining the object's counters.
Resume	Resumes operation after **Pause**.

The command affects the selected object and all objects below it on the tree. For example, starting a CN starts all its **Enabled** message pipes.

Controlling MSMQ-MQSeries Bridge

Configuration Backup

MSMQ-MQSeries Bridge stores the MQSeries configuration and the MSMQ-MQSeries Bridge configuration in the registry. You can back up those configurations by using Regedit.exe provided in your Windows Server 2003, Windows 2000, or Windows NT system.

The registry location depends on whether you are running Windows NT in a cluster or non-cluster environment, as follows.

MSMQ-MQSeries configuration	Registry key to backup
Non-cluster environment	HKLM\Software\Microsoft\MQBridge\Server
Cluster environment	HKLM\Cluster\Software\Microsoft\MQBridge\Server

Controlling MSMQ-MQSeries Bridge

Additional Information About MSMQ-MQSeries Bridge

The following topics provide additional information about MSMQ-MQSeries Bridge.

In This Section

Using a Dash (-) in Message Queuing Computer Names

If a Message Queuing computer name contains the dash (-) character, IBM MQSeries will not be able to address it as a remote queue manager because IBM MQSeries does not support queue manager names with dashes.

MSMQ-MQSeries Bridge provides a feature to resolve this problem through name replacement. In IBM MQSeries, you can refer to the remote queue manager name with a dot (.) instead of a dash, and when the message arrives, MSMQ-MQSeries Bridge changes the dot back to a dash.

To enable this option, see the Advanced Tab.

See Also

Other Resources

Additional Information About MSMQ-MQSeries Bridge

Using a Dot (.) in Remote MQSeries Queue Manager Names on Windows Server 2003 or Windows 2000

Windows Server 2003 or Windows 2000 does not support computer names containing the dot (.) character. As a result, dots cannot be used when naming a remote IBM MQSeries QM.

MSMQ-MQSeries Bridge provides a feature to resolve this problem through name replacement. In Windows Server 2003 or Windows 2000, you can refer to the remote IBM MQSeries QM name with a dash (-) instead of a dot, and when the message arrives, MSMQ-MQSeries Bridge changes the dash back to a dot.

This feature is enabled by default. To disable the feature, set the following registry value:

Key: HKLM\Software\Microsoft\MQBridge\Server

Value: DisableDash2DotTranslation(REG_DWORD) = 1

Additional Information About MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Dead Letter Queue

MSMQ-MQSeries Bridge creates two dead letter queues for storing messages that are not deliverable. **MQBridge Dead Letter Queue** is for messages through the nontransactional message pipe, and **MQBridge Xact Dead Letter Queue** is for messages through the transactional message pipe.

In Windows Server 2003 or Windows 2000, these two queues are located in **Active Directory Users and Computers** under **Domain Controllers** or **Computers\<MSMQ-MQSeries Bridge Computer>\msmq**.

Other Resources

Additional Information About MSMQ-MQSeries Bridge

Notes on the Current Release of MSMQ-MQSeries Bridge

The following are additional notes to support the current release of MSMQ-MQSeries Bridge in Host Integration Server.

MSMQ-MQSeries Bridge Manager Supports Queue Names in Uppercase Characters

MSMQ-MQSeries Bridge does not differentiate uppercase vs. lowercase foreign queue names and foreign queue manager names. It converts them all to uppercase. MSMQ-MQSeries Bridge can only send messages to MQSeries queue managers and queues that have uppercase names.

MSMQ-MQSeries Bridge Encryption Delays on Windows Server 2003 or Windows 2000

There is a noticeable delay for changes to take place when enabling or disabling MSMQ-MQSeries Bridge encryption. It is recommended that you wait 5 to 15 minutes after changing the **Enable/Disable** option for encryption, before expecting MSMQ-MQSeries Bridge to function correctly.

Converting an MSMQ-MQSeries Bridge Resource Into a Cluster Resource

In Windows Server 2003 or Windows 2000, clusters are Active-Active. You must perform the following steps after installation to convert an MSMQ-MQSeries Bridge resource into a cluster resource:

1. In the Program Files\Host Integration Server\System directory by default, at the command line, type:

   ```
   BCLUSTER
   ```

2. When the dialog box appears, click **Add Bridge Resource**.

3. In MSMQ-MQSeries Bridge Manager, right-click the **Microsoft MSMQ-MQSeries Bridge Service** cluster resource and select **Bring online**.

In Windows Server 2003 or Windows 2000, you can also run the cluster on the local node only. To do this, run BCLUSTER as described in the preceding procedure, and click **Remove Resource**.

When moving from local node to cluster node, it is necessary to stop Microsoft MSMQ-MQSeries Bridge on all local nodes before you can bring the Microsoft MSMQ-MQSeries Bridge cluster resource online. This restriction only applies when running on Windows Server 2003 or Windows 2000.

Granting Access for Users Created During Install

When installing MSMQ-MQSeries Bridge on a computer running Windows Server 2003 or Windows 2000, if you choose to automatically create a user, that user will be denied access when attempting to start MSMQ-MQSeries Bridge.

You may also receive the following error in the event log: "Access to MSMQ connector queue is denied." While you should have sufficient rights for the operation of Microsoft MSMQ-MQSeries Bridge, it may be necessary to manually configure the Domain Administrators group security for the foreign site or sites to have full control.

To grant user access

1. In **Active Directory**, go to **Active Directory Sites and Services**.
2. Right-click the foreign site.
3. Click the **Security** tab, and click **Domain Admins**.
4. In the **Permissions** box, select the **Full Control Allow** box.
5. Click **OK**.

MSMQ-MQSeries Bridge Quick Setup for Windows Server 2003 or Windows 2000

Use the following steps to set up a foreign site in Windows Server 2003 or Windows 2000 (previously known as a foreign connected network in Windows NT 4.0).

1. Install Message Queuing with routing.

2. Use **Active Directory Sites and Service** to create a new foreign site and new foreign computer. It is located in the Services\MsmqServices folder (right-click).

3. Create a routing link between the foreign site and the default first site name by right-clicking the Services\MsmqServices folder. Click **New**, and then click **MSMQ Routing Link**.

4. In **Routing link cost**, enter a number between 1-999, where 1 has the highest priority. Do not enter 0; it means no link.

5. Select **Property**, choose the **Site Gates** tab, and then add the MSMQ-MQSeries Bridge computer to be a member of the routing link site gates.

6. In **Active Directory Users and Computers**, under **Domain Controllers** or **Computers\<MSMQ-MQSeries Bridge Computer>\msmq**, select **Property** and then select the **Sites** tab. Add the computer to the foreign site created earlier.

7. Recycle Message Queuing on all domain controllers.

Testing the MQSeries Client/Server Connection Before Using Message Queuing Applications

The connection between the MQSeries Client and the MQSeries Server should be tested using the AMQSPUTC and AMQSGETC tools from IBM. To perform this test, use the following procedure.

1. Configure the MQSeries Server by using the server and client definition files generated by MSMQ-MQSeries Bridge.

2. Place the .tab file (by default, Amqclchl.tab) in the client location.

3. Use AMQSPUTC and AMQSGETC to test the connection.

Enabling MSMQ-MQSeries Bridge Encryption

Before you can enable encryption, you must first run the Add Schema program.

1. Log on as Schema Administrator. (This is usually the same as a Domain Administrator.)

2. In the Program Files\Host Integration Server\System directory (by default), type the following at the command line:

```
Addschma hiserver.schema
```

3. In MSMQ-MQSeries Bridge Manager, expand **Enterprise**, expand **Computers**, and expand the computer name.

4. Right-click **Microsoft MSMQ-MQSeries Bridge Service**, click **Properties**, and then click the **Advanced** tab.

5. Select the **Support MSMQ to Bridge Encryption** box.

6. Click **OK**, click **Yes**, and then click **OK**.

7. Restart the Microsoft MSMQ-MQSeries Bridge.

To disable encryption, return to the **Advanced** tab and clear the **Support MSMQ to Bridge Encryption** box, and then recycle Microsoft MSMQ-MQSeries Bridge.

MSMQ-MQSeries Bridge Rejects MSMQ Messages with MQMSG_AUTH_LEVEL_MSMQ20 Authentication

Windows Server 2003 or Windows 2000 Server Message Queuing 2.0 introduces a new authentication signature,

MQMSG_AUTH_LEVEL_MSMQ20, and is not supported for a connector queue. The result is that messages are rejected without being processed.

Additional Information About MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Terminology

The following terms are used in MSMQ-MQSeries Bridge.

Term	Definition
CN	Foreign Connected Network in Windows NT 4.0, and Foreign Site in Windows Server 2003 or Windows 2000.
DLQ and **XDLQ**	MQBridge Dead Letter Queue and MQBridge Xact Dead Letter Queue. (For more information, see MSMQ-MQSeries Bridge Dead Letter Queue.)
MCA	Message Channel Agent. (For details, see IBM MQSeries documentation.)
MQI	Message Queue Interface (For details, see IBM MQSeries documentation.)
MQS	IBM MQSeries.
Message Queuing	Also known as MSMQ. Formerly known as Microsoft Message Queuing, Message Queuing Services, or Message Queue Server.
Nontransactional Message Pipe	Option allowing possible duplicate delivery of a message.
QM	Queue Manager.
Transactional Message Pipe	Option guaranteeing delivery of a message one time and only one time.

Security User's Guide

Enterprise Single Sign-On (SSO) provides services to enable single sign-on for end users in enterprise application integration (EAI) solutions. The SSO system maps Microsoft Windows accounts to back-end credentials. SSO simplifies the management of user IDs and passwords, both for users and administrators. It enables users to access back-end systems and applications by logging on only one time to the Windows network.

Note
Performance monitoring is available in this release. If you are running Enterprise SSO on a 64-bit Windows computer, you must also use the 64-bit Perfmon tool in order to use the ESSO Perfmon counters.

In This Section

Operations

Understanding Enterprise Single Sign-On

To understand Enterprise Single Sign-On (SSO), it is useful to look at the three types of Single Sign-On services available today: Windows integrated, extranet, and intranet. These are described in the following sections, with Enterprise Single Sign-On falling into the third category.

Windows Integrated Single Sign-On

These services enable you to connect to multiple applications within your network that use a common authentication mechanism. These services request and verify your credentials after you log into the network, and use your credentials to determine the actions that you can perform based on your user rights. For example, if applications integrate using Kerberos, after the system authenticates your user credentials, you can access any resource in the network that is integrated with Kerberos.

Extranet Single Sign-On (Web SSO)

These services enable you to access resources over the Internet by using a single set of user credentials. The user provides a set of credentials to log on to different Web sites that belong to different organizations. An example of this type of Single Sign-On is the Microsoft Passport Network for consumer-based applications. For federated scenarios, Active Directory Federation Services enables Web SSO.

Server-Based Intranet Single Sign-On

These services enable you to integrate multiple heterogeneous applications and systems in the enterprise environment. These applications and systems might not use common authentication. Each application has its own user directory store. For example, in an organization, Windows uses Active Directory directory service to authenticate users, and mainframes use IBM's Resource Access Control Facility (RACF) to authenticate the same users. Within the enterprise, middleware applications integrate the front-end and back-end applications. Enterprise Single Sign-On enables users in the enterprise to connect to both the front end and back end while using only one set of credentials. It enables both Windows Initiated Single Sign-On (in which the initial request is made from the Windows domain environment) and Host Initiated Single Sign-On (in which the initial request is made from a non-Windows domain environment) to access a resource in the Windows domain.

In addition, Password Synchronization simplifies administration of the SSO database, and keeps passwords in sync across user directories. You can do this by using password synchronization adapters, which you can configure and manage using the Password Synchronization tools.

Enterprise Single Sign-On System

Enterprise Single Sign-On provides services to store and transmit encrypted user credentials across local and network boundaries, including domain boundaries. SSO stores the credentials in the Credential database. Because SSO provides a generic single sign-on solution, middleware applications and custom adapters can take advantage of SSO to securely store and transmit user credentials across the environment. End users do not have to remember different credentials for different applications.

SSO System Components

The Single Sign-On system consists of a Credential database, a master secret server, and one or more Single Sign-On servers.

The SSO system contains affiliate applications that an administrator defines. An affiliate application is a logical entity that represents a system or sub-system such as a host, back-end system, or line-of-business application to which you are connecting using Enterprise Single Sign-On. Each affiliate application has multiple user mappings; for example, it has the mappings between the credentials for a user in Active Directory and their corresponding RACF credentials.

The Credential database is the SQL Server database that stores the information about the affiliate applications, as well as all the encrypted user credentials to all the affiliate applications.

The master secret server is the Enterprise Single Sign-On server that stores the master secret. All other Single Sign-On servers in the system obtain the master secret from the master secret server.

The SSO system also contains one or more SSO servers. These servers do the mapping between the Windows and back-end credentials and look up the credentials in the Credential database. Administrators use them to maintain the SSO system.

Note
You can have only one master secret server and only one Credential database in your SSO system. The Credential database c an be remote to the master secret server.

Note

Enterprise Single Sign-On has limited functionality in a workgroup environment, supporting only config store scenarios. A domain environment is required for Single Sign-On scenarios, Password Sync scenarios, and ESSO Management Agent scenarios with MIIS.

In This Section

- Enterprise Single Sign-On User Groups
- SSO Components
- SSO Server
- Master Secret Server
- SSO Affiliate Applications
- SSO Mappings
- SSO Tickets
- Configuring Enterprise Single Sign-On

Enterprise Single Sign-On User Groups

To configure and manage the Enterprise Single Sign-On (SSO) system, you must create certain Windows groups and accounts for each of these roles. When configuring the access accounts in Enterprise SSO, you can specify more than one account for each of these roles. This section describes these roles.

Important
It is strongly recommended that you use domain groups when configuring SSO.

Note
For security purposes, the SSO system does not allow for built-in accounts.

Single Sign-On Administrators

SSO administrators have the highest level user rights in the SSO system. They can do the following:

- Create and manage the Credential database.
- Create and manage the master secret.
- Enable and disable the SSO system.
- Create password synchronization adapters.
- Enable and disable password synchronization in the SSO system.
- Enable and disable host-initiated SSO.
- Perform all administration tasks.

The SSO administrators account can be either a Windows group account or an individual account. The SSO administrators account can also be either a domain or local group or individual account. When you use an individual account, you cannot change it to another individual account. Therefore, it is recommended that you do not use an individual account. You can change this account to a group account as long as the original account is a member of the new group.

Important
The service account that runs the Enterprise Single Sign-On service must be a member of this group. To help secure your env ironment, ensure that no other service is using the same service account.

Single Sign-On Affiliate Administrators

The SSO affiliate administrator defines the affiliate applications that the SSO system contains. Affiliate applications are a logical entity that represents the back-end system to which you are connecting using SSO. SSO affiliate administrators can do the following:

- Create and manage affiliate applications.
- Specify the application administrators account for each affiliate application.
- Perform all the administration tasks that the application administrators and application users can.

The SSO Affiliate Administrator account can be either a Windows group account or an individual account. The SSO Affiliate Administrator account can also be either a domain or local group or account.

Application Administrators

There is one application administrators group per affiliate application.

Members of this group can do the following:

- Change the application users group account.
- Create, delete, and manage credential mappings for all users of the specific affiliate application.
- Set credentials for any user in that specific affiliate application users group account.
- Perform all the administration tasks that the application users can.

Application Users

There is one application users group account for each affiliate application. This group contains the list of end users in an Enterprise SSO environment. Members of this group can do the following:

- Look up their credentials in the affiliate application.
- Manage their credential mappings in the affiliate application.

Note
Remember to be vigilant when assigning groups. It is possible, for example, to use a Host Integration Server security user group for the SSO application users group. Before you do this, be certain that all users need all access that will then be available to them.

Managing User Mappings

SSO Components

The sub services of the Enterprise Single Sign-On (SSO) service are as follows:

- **Mapping.** Maps the user account in the Windows system to the user accounts in the back-end systems (affiliate applications).
- **Lookup.** Looks up the user credentials in the Credential database in the back-end system. This is the SSO runtime component.
- **Administration.** Manages the affiliate applications and the mappings for each affiliate application.
- **Secret.** Generates the master secret and distributes it to the other SSO servers in the system. It is only active on the Single Sign-On server that is acting as the master secret server.
- **Password Synchronization.** Simplifies administration of the SSO credential database, and keeps passwords in sync across user directories.

Installing Enterprise Single Sign-On

SSO Server

The Enterprise Single Sign-On (SSO) server can perform any of the following tasks:

- **Functions as the master secret server.** The master secret server holds the master secret, or encryption key, used to encrypt all the credentials in the SSO system. Though the master secret server can act as a server for lookups and administration, it is recommended that you use this server to act only as a master secret server for security reasons. For more information about the functions the master secret server performs, see Master Secret Server.

- **Performs administrative operations.** SSO administrators can use any of the Single Sign-On Servers to perform administrative tasks such as managing affiliate applications, setting user credentials, and managing user mappings.

- **Performs lookup operations.** The SSO server uses the runtime component to look up the user credentials.

- **Issues and Redeems Tickets.** The SSO server also issues and redeems SSO tickets, which applications can use to get user credentials.

- **Password Synchronization.** You can create and manage password synchronization adapters on the SSO Server.

Password Synchronization

Master Secret Server

The *master secret server* is the Enterprise Single Sign-On (SSO) server that stores the master secret (encryption key). The master secret server generates the master secret when an SSO administrator requests it. The master secret server stores the encrypted master secret in the registry. Only Single Sign-On administrators can access the master secret.

The other Single Sign-On servers check every 30 seconds to see whether the master secret has changed. If it has changed, they read it securely; otherwise, they continue to use the master secret they already have cached in memory. The SSO service uses the master secret to encrypt and decrypt the user credentials.

You cannot use the SSO system until an SSO administrator configures the master secret server and generates the master secret. The master secret server generates the master secret during configuration. Only SSO administrators can generate the master secret. An SSO administrator must configure the master secret server and the Credential database before an application can use the SSO service.

Important
After you generate the master secret, it is strongly recommended that you back it up and store it in a secure location.

When an SSO administrator needs to regenerate the master secret, for example, if the SSO administrator wants to change the master secret periodically, the master secret server stores both the old and new master secret. The master secret server then goes through all the mappings, decrypts them using the old master secret, and encrypts them again using the new master secret.

If the master secret server fails, all runtime operations that are already running continue to run, but SSO servers are not able to encrypt new credentials.

Important
There can be only one master secret server in your SSO system. Therefore, it is strongly recommended you cluster the maste r secret server. For more information, see How to Cluster the Master Secret Server.

Managing the Master Secret

SSO Affiliate Applications

The Enterprise Single Sign-On (SSO) affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line-of-business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

When the SSO administrator or the SSO affiliate administrator defines an affiliate application, they must also determine who will administer the affiliate application (the application administrator), who the users of the affiliate application are (the application users), and what parameters the SSO system will use to authenticate the users of this affiliate application (the user ID, passwords, PINs, and so on). For more information about application administrators and application users, see Enterprise Single Sign-On User Groups.

Affiliate Application Types

Enterprise SSO defines several different application types. The different application types support different types of mappings between the Windows account and the account on the non-Windows system.

The application types are as follows:

Individual Individual applications support one-to-one mappings between the Windows account and the non-Windows account. In an Individual type application, one Windows account is mapped to one, and only one, non-Windows account. The mapping can be used in either direction, from Windows to non-Windows, or from non-Windows to Windows, or both, depending on the flags that have been set for this application. Thus, Individual applications can be used for Windows-initiated SSO, Host-initiated SSO, or both.

Group Group applications support mappings between one Windows group to one single non-Windows account. The Application Users account is used to define the Windows group that will be used for this Group application. Only one mapping can be defined for a Group application, and that mapping must be between the Windows group and the single non-Windows account that will be used by all members of this Windows group to access the non-Windows system. Group applications can only be used for Windows initiated SSO.

Host Group Host Group applications are conceptually the reverse of Group applications. They support mappings between a defined group of non-Windows accounts to a single Windows account. The single Windows account that will be used by the non-Windows accounts is defined by the Application Users account for the application. The group of non-Windows accounts that is allowed to access this application is defined by creating a mapping for each non-Windows account. Host Group applications can only be used for Host initiated SSO.

Designing an Affiliate Application

Before creating an affiliate application, the SSO affiliate administrator or the SSO administrator must make the following decisions:

1. **What will this affiliate application represent?** You must know the non-Windows application that the affiliate application will represent in the SSO system. For example:

   Application name: APP1

   Description: Application for Pay stub department

   Contact: administrator@companyname.com

2. **Who will administer this affiliate application?** You must determine who the administrators are for this affiliate application. These form the Windows administrators group for this affiliate application; for example, Domain\APP1AdminGroup.

3. **Who will use this affiliate application?** You must determine who the end users are for this affiliate application. These users represent the Windows users group for this affiliate application; for example, Domain\DomainUsers. In the case of the application for Pay stubs, you might want all users to access their pay stub information, so you can specify the domain users group as the user group for this application.

4. **What credentials does the affiliate application use to authenticate its users?** Different applications use different credentials to authenticate users. For example, some applications might use user IDs, passwords, PINs, or a combination

of these. You must also determine whether the system needs to mask these credentials as the user provides them.

5. **Will you use individual mappings or a group mapping for this affiliate application?** Does each Windows user have an account in the back-end system, or does the back-end system have one account for all Windows users? In the case of the pay stub system, each user has an account to access individual pay stub information, and you would need to use individual mappings.

After you create an affiliate application, you cannot modify the following properties:

- Name of the affiliate application.
- Fields associated with the affiliate application.
- Affiliate application type (host group, individual, or configuration store).
- Administration account same as affiliate administrators group. (If you select this property, the affiliate administrators group is used as the application administrators account for this affiliate application.)

Affiliate Application Properties

The following table lists the properties that you must define for each affiliate application that you create.

Property	Description
Application name	Name of the affiliate application. You cannot change this property after you create the affiliate application.
Description	Brief description of the affiliate application.
Contact	The main contact for this affiliate application that users can use. (Can be an e-mail address.)
appUserAccount	The Windows group that contains the user accounts of end users who will use this affiliate application.
appAdminAccount	The Windows group that contains the administrator accounts that will manage this affiliate application. Note You do not need to define this property if you set the adminAccountSame to Yes.

Application Flag	Description
enableApp	The status of this affiliate application.
groupApp	Determines whether this application uses a group mapping (Yes) or individual mappings (No). You cannot change this property after you create the application.
configStoreApp	Determines whether this affiliate application is a Configuration Store type application (Yes). You cannot change this property after you create the application.
hostInitiatedSSO	Enable this if it is a host-initiated SSO type application. Default is No.
windowsInitiatedSSO	Enable this if it is a Windows initiated SSO type application. Default is Yes.
validatePassword	This applies only to host-initiated SSO applications. When the application tries to retrieve credentials, it must provide the password in the Credential database, which is used for validation by SSO services. Default is Yes.

disableCredCache	The SSO server stores credentials in a cache to expedite access. Default is No.
allowTickets	Determines whether the SSO system uses tickets for this affiliate application. Note You must be an SSO administrator to set this flag.
validateTickets	Determines whether the SSO system validates tickets when the user redeems them. Note You must be an SSO administrator to set this flag.
appTicketTimeOut	Specifies a ticket time-out specific to the affiliate application. You can set this only when updating an affiliate application, not when creating it. If ticketing is enabled for this application and this property is not, the time-out specified at the SSO System (Global) level is used. Note You must be an SSO administrator to set this flag.
timeoutTickets	Determines whether tickets have an expiration time. Default is No. Note You must be an SSO administrator to set this flag.
allowLocalAccounts	Determines whether you allow the use of local groups and accounts in the SSO system. You can only configure this flag to Yes in single-computer scenarios.
adminAccountSame	Determines whether to use the SSO affiliate administrator group as the application administrator group. You cannot change this property after you create the application. Note You must be an SSO administrator to set this flag.

Application Fields	**Description**	**Description**
Field [0]	<*credential*>: Masked/Unmasked	Determines the type of credential (user ID, password, smartcard) that end users must provide to connect to the affiliate application, and whether this credential is masked (that is, whether the characters that the user types are displayed on the screen). You can enter as many fields as there are credentials for the affiliate application, but the first field must be the user ID. You cannot change this property after you create the application.

Other Resources

Managing Affiliate Applications

Managing User Mappings

SSO Mappings

When an Enterprise Single Sign-On (SSO) administrator or an SSO affiliate administrator defines an affiliate application, the administrator can define it either as an application that uses individual mappings, or as an application that uses a group mapping.

Individual Mappings

SSO individual mappings enable administrators and users to create a one-to-one mapping between Windows users and their corresponding non-Windows credentials. When individual mappings are used, users can manage their own mappings. The SSO system maintains the one-to-one relation for the user's Windows account and the user's non-Windows account.

Windows end users can create and manage their own mappings for individual type applications. The same affiliate application can act as a Windows-initiated SSO and a Host-initiated SSO type application.

Important
Mappings can be created only for Windows domain accounts. Local accounts cannot be mapped.

Note
Only individual users can obtain the credentials to their individual accounts when individual mappings are used.

Group Mapping

SSO group mapping consists of mapping a Windows group, which contains multiple Windows users, to a single account in the affiliate application.

You can also specify multiple accounts for the SSO Application Users role. Each account that you specify can be associated with an external account.

For example, it is possible to map a domain user (domain\userA) to one set of external credentials (ExternalUser1). The same domain\userA could also be a member of Domain Group (domain\group1) and this group could be mapped to a different set of external credentials (ExternalUser2). In this case, it is important that the administrator (who must be an Application Administrator or above) specifies the correct order for the Application Users accounts.

The mapping for the first account (in the Order) of which the caller is a member is the one that will be used. In this case, if mapping for domain\userA to ExternalUser1 is set to Order 0, SSO will return this set of credentials for domain\UserA.

Only an application administrator, SSO affiliate administrator, or SSO administrator can create a group mapping.

You cannot specify the same group application for Windows-initiated SSO and Host-initiated SSO.

Important
Mappings can be created only for Windows domain accounts. Local accounts cannot be mapped.

Important
When you use group mappings, the members of the group can obtain the credential information for the group mapping.

Managing User Mappings

SSO Tickets

In an enterprise environment, where a user interacts with various systems and applications, it is very likely that the environment does not maintain the user context through multiple processes, products, and computers. This user context is crucial to providing single sign-on capabilities because it is necessary to verify who initiated the original request. To overcome this problem, Enterprise Single Sign-On (SSO) provides an SSO ticket (not a Kerberos ticket) that applications can use to obtain the credentials that correspond to the user who made the original request. By default, SSO tickets are not enabled. For more information about enabling tickets, see How to Configure the Enterprise Single Sign-On Tickets.

The SSO system issues a ticket when requested by an authenticated Windows user. The SSO system can only issue a ticket for the user making the request (you cannot request a ticket for other users). A ticket contains the encrypted domain and user name of the current user, and the ticket expiration time. After the SSO system issues a ticket, the ticket expires in two minutes by default. SSO administrators can modify the expiration time for tickets. For more information, How to Configure the Enterprise Single Sign-On Tickets.

After an application verifies the identity of the original requester, the application redeems the ticket to obtain the credentials of the user who initiated the request to the affiliate application. An application can redeem tickets from the SSO system in one of three ways:

- **Redeem only.** When an application initiates a request to redeem a ticket, the request must contain the name of the affiliate application to connect to, and the ticket itself. Only application administrators for the specific affiliate application, SSO affiliate administrators, or SSO administrators can redeem a ticket. You should use **Redeem only** when there is a trusted sub-system between the application that issued the ticket and the application that is redeeming the ticket. Only an application administrator for the specified affiliate application can redeem the ticket for a user.

- **Validate and redeem.** Tickets contain information about the user for whom the SSO system is performing the credential look-up. In this case, the SSO service verifies that the sender of the original message and the user of the ticket are the same before the system redeems the ticket.

An SSO administrator can disable ticket time-outs on a per-affiliate application basis. However, this is not recommended, as the ticket would never expire for this application. In scenarios that require that you disable ticket time-outs, ensure that there is a secure end-to-end trusted sub-system maintained between the front-end where the SSO system issues the ticket to the adapter where the SSO ticket redeems the ticket.

An SSO affiliate administrator can specify that tickets are allowed and that validation of the ticket is required on a per affiliate application basis. However, if the SSO administrator specifies at the SSO system level that the validation of tickets is required, the SSO affiliate administrator cannot turn off this option at the affiliate application level.

Important
When using SSO ticketing, you must ensure that the ticket time-out value is long enough to last between the time when the t icket is issued to the time that it is redeemed.

Managing User Mappings

Configuring Enterprise Single Sign-On

You can configure Enterprise Single Sign-On (SSO) using command-line utilities, user interface (UI) tools, or COM or Microsoft .NET Framework interfaces.

SSO Command-line Utilities

You use three different command-line utilities to perform Enterprise Single Sign-On tasks:

SSOConfig. Enables an SSO administrator to configure the Credential database and to manage the master secret.

Note
The Configuration Wizard creates the Credential database and the master secret server.

SSOManage. Enables SSO administrators, SSO affiliate administrators, and application administrators to update the Credential database to add, delete, and manage applications, to administer user mappings, and to set credentials for the affiliate application users. Some operations can be performed only by the SSO administrators, or, only by the SSO administrators and SSO affiliate administrators.

SSOClient. Enables Single Sign-On users to manage their own user mappings and set their credentials.

For more information about the SSO accounts, see Enterprise Single Sign-On User Groups.

SSO UI Tools

Enterprise SSO MMC Snap-in. Enables SSO administrators, SSO affiliate administrators, and application administrators to update the SSO database, to add, delete, and manage applications, to administer user mappings, and to set credentials for the affiliate application users. Some operations can be performed only by the SSO administrators, or only by the SSO administrators and SSO affiliate administrators. All operations that can be performed by the application administrators can also be performed by the SSO administrators and SSO affiliate administrators.

SSO Client Utility. Enables end users to manage their own mappings and set their credentials using the UI tool.

SSO COM and .NET interfaces

Enterprise Single Sign-On provides COM and Microsoft .NET Framework programmatic interfaces that enable you to create custom components, and to create scripts to facilitate the administration of the SSO system.

Using Enterprise Single Sign-On

Installing Enterprise Single Sign-On

The following sections contain information about the installation of the Enterprise Single Sign-On feature. Because of this feature's complex relationships to other features and systems, and because of its importance to system security, you should read this section carefully before you install Enterprise Single Sign-On.

It is also recommended that you review the latest software prerequisites for installing Enterprise Single Sign-On.

In This Section

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Older versions of Host Integration Server, such as Host Integration Server 2000 and SNA Server 4.0, provided both Single Sign-On and password synchronization through their host security feature. This feature was based around the host security domain, which contained user mappings to map credentials between Windows and host systems.

In Host Integration Server, the Enterprise Single Sign-On (SSO) feature replaces host security as the source of Single Sign-On and password synchronization. Although some concepts are shared between the old and new features, there are important differences. In addition to the increased functionality, there are two primary conceptual differences in the new features:

- Host security domains are replaced by affiliate applications.
- Security credential data is now stored in a SQL Server database.

To migrate your existing host security data into the new SSO environment, use the Migration Utility. This is a command-line tool (hissomig.exe) that migrates all necessary data from the old version to the new, enabling you to continue using Single Sign-On without modifying your applications.

The topics in this section walk you through the migration process. It is important to follow these steps in the order given.

In This Section

Back up the Existing Security Data

For safety purposes, you should back up your existing security data before you migrate to Enterprise Single Sign-On.

For information about how to do this, see the documentation for your particular product version (for example, Host Integration Server 2000 or SNA Server 4.0).

SSO Security Recommendations

Other Resources

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Export the Encryption Key

If you are migrating from Host Integration Server 2000, you must export the encryption key. The encryption key is a security device that Host Integration Server 2000 uses to encrypt user passwords. It must be backed up because the migration utility will need it as part of the migration process.

To export the encryption key

1. Click **Start**, click **Run**, and then type **cmd**.
2. Locate the Host Integration Server 2000 installation directory.
3. Type **udbkey /showkey >hostseckey.bak** to back up the key into a file.
4. Protect the file securely.

Other Resources

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Install Enterprise Single Sign-On

After you back up the security data and export the encryption key in preparation for upgrading, it is time to install Enterprise Single Sign-On. You have several installation options. For more information, see Installing Enterprise Single Sign-On.

See Also

Other Resources

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Copy the Migration Utility to the Master Secret Server

The Migration Utility is not installed with the rest of Host Integration Server. You must manually copy it to the master secret server.

To copy the Migration Utility

1. Click **Start**, click **Run**, and then type **cmd** and press Enter.
2. Type **copy hisssomig.exe from <cddrive>\support\utilities\ to c:\hostsec** and press Enter.

See Also

Other Resources

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Run the Migration Utility

You can migrate your existing host security data into the new Single Sign-On (SSO) environment by using the hissomig.exe command-line utility. Migration is essentially a two-step process:

1. First, the tool **exports** data from the host security domain into an XML file. This file also contains validation data for the migration process. If mappings or file names conflict, an administrator can resolve them before the next step.

2. Second, the tool **imports** data into the Single Sign-On (SSO) environment, and updates the Host Integration Server credential database appropriately.

The Migration Utility has the following restrictions:

- You must be an SSO administrator and have at least read privileges to the SNAUDB database to perform migration.

- Both importing and exporting must be done on the master secret server.

Note
The XML file that is generated during migration is not deleted. Because this file contains security data, it is important that you manually delete the file as soon as migration is finished.

To export from Host Integration Server

1. Stop the Host Account Cache service.
2. Click **Start**, click **Run**, and then type **cmd** and press Enter.
3. Type **hissomig –export –servername <server> -output <XML file>** where <*server*> is the fully qualified name, NetBIOS name, or IP address of the Host Integration Server primary domain controller, and <*XML file*> is the full path of the XML file to which the data will be exported.

   For example:

   hissomig –export –servername SERVER1 -output c:\hostsecdb.xml
4. Press Enter.
5. Restart the Host Account Cache service.

To export from SNA Server 4.0

1. Stop the Host Account Cache service.
2. Click **Start**, click **Run**, and then type **cmd** and press Enter.
3. Type **hisssomig –export –dbfile <database file> -output <XML file>** where <*database file*> is the full path of the SNA 4.0 Host Security database file, and <*XML file*> is the full path of the XML file to which the data will be exported.

   For example:

   hisssomig –export –dbfile Y:\Program Files\SNA Server\hostsec\dbfile.dbs -output c:\hostsecdb.xml
4. Press Enter.
5. Restart the Host Account Cache service.

To import into Host Integration Server

1. Click **Start**, click **Run**, and then type **cmd** and press Enter.
2. Type **hisssomig –import –key <key> -input <XML file>** where <*key*> is the full path of the file that contains the encryption key, and <*XML file*> is the full path of the XML file from which the data will be imported.

   For example:

hisssomig –import –key Z:\hostseckey.bak -input c:\hostsecdb.xml

3. Press Enter.

Other commands for Migration Utility

The following is a list of commands for the Migration Utility. These commands are also displayed during migration if you attempt to run the utility with incorrect data.

Command	Comment
-servername	Name of server that holds the Host Integration Server Host Security primary host account cache database.
-dbfile	Full path of the SNA 4.0 Host Security database file.
-key	Full path of the file that contains the encryption key.
-username	User name that is used for encryption.
-password	Password for the user name that is used for encryption.
-output	Full path of the XML file to which the data will be exported.
-input	Full path of the XML file from which the data will be imported.
-log	Creates migration log in the directory specified. For example: **-log c:SSO\log**

Other Resources

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Upgrading from an Earlier Version of SSO

If you are installing the Enterprise Single Sign-on (SSO) feature, and you already have an earlier version deployed on your computer (for example, from Host Integration Server CTP, or Microsoft BizTalk Server), you must follow these steps.

- Back up the SSODB to a secure location.
- Back up the master secret key on the master secret server.
- Update the master secret server by running Host Integration Server Setup, selecting **Custom Installation**, and then selecting **Enterprise Single Sign-On**. After selecting **Enable Enterprise Single Sign-On on this computer**, select **Join an existing SSO system**.

You do not have to update the other SSO servers (non-master secret servers) from your BizTalk Server installation. However, if you want the new Enterprise Single Sign-On features to be available on those servers, you must update them by using the same procedures outlined earlier.

If you have a Beta version of Enterprise SSO installed as part of a Host Integration Server CTP release, you can use the same mechanism to upgrade those servers.

Note
These considerations also apply if you are installing Microsoft BizTalk Server 2006 on a computer that has an existing installation of Host Integration Server Enterprise Single Sign-On, and you want to update the servers.

Processing Servers for Enterprise Single Sign-On

In a multicomputer environment, after the master secret server and Single Sign-On (SSO) database have been created, you can install Enterprise Single Sign-On on subsequent computers. These are typically the computers on which either BizTalk Server or Host Integration Server is installed as well.

The initial installation process is the same as on the first computer. Configuration, however, becomes slightly different. Because the master secret server and the SSO database are already in place, select **Join** when the Configuration Wizard asks the question, **Create a new SSO system or Join an existing system?**

Note
During configuration, it is possible for a group on one computer to join an SSO database on a different computer that is not i n the database configured for that group. Although this is possible, it is not recommended.

Upgrading from Host Integration Server 2000 or SNA Server 4.0

Standard Installation Options

Host Integration Server takes advantage of the Enterprise Single Sign-On (SSO) capabilities for securely storing critical information.

By default, Enterprise Single Sign-On is not installed with the rest of Host Integration Server. You can install it by using the following procedure.

Note
When Enterprise Single Sign-on (Server component) is installed, configuration must be performed. The first step to set up an SSO system is to configure the master secret server. It is recommended that you set up a stand-alone master secret server. You can do this by only selecting Enterprise Single Sign-On from the custom feature tree in Host Integration Server Setup. It is also recommended that any computer that is running Enterprise Single Sign-On have a time synchronization service running. This keeps the computer time in sync with the rest of the system. This is necessary for SSO ticketing services to function correctly.

To install Enterprise Single Sign-On

1. Insert your Host Integration Server CD and run the Setup program again.
2. Select **Custom Installation**, and then select the appropriate option from the following list:

   When you run the HIS Server package, you have the following options:

   - **Enterprise Single Sign-On Master Secret Server —** Acts as the master secret server in the SSO system. This is the first server in the SSO system that must be deployed. This enables you to create the SSO Credential Database.
   - **Enterprise Single Sign-On Administration —** Administration and client tools for mapping and connecting to Enterprise Single Sign-On services.
   - **Server Runtime —** Core services to enable single sign-on and to store/access configuration data securely.
   - **Enterprise Single Sign-On Services with Password Synchronization —** Services to enable the Password Synchronization feature in the Enterprise SSO system. These services also integrate with the Microsoft Password Change Notification Service. Once you have installed the core Enterprise Single Sign-On services, you can install the Password Synchronization feature of Enterprise SSO from the Host Integration Server package by starting Setup (\Platform\SSO\Setup.exe) and selecting the **Password Synchronization** feature.
   - **Enterprise Single Sign-On Services —** Provides the core services to enable single sign-on and to store/access configuration data securely. Can act as the master secret server in the SSO system.
   - **Enterprise Single Sign-On Services with Password Synchronization —** Provides the services to enable the Password Synchronization feature in the Enterprise SSO System. These services also integrate with the Microsoft Password Change Notification Service.
   - **Enterprise Single Sign-On Administration —** Administration and client tools for mapping and connecting to Enterprise Single Sign-On services.

   When you run the HIS Client package, you have the following options:

   - **Enterprise Single Sign-On Administration —** Administration and client tools for managing and connecting to Enterprise Single Sign-On services.
   - **Enterprise Single Sign-On Client —** Client tools for end users to manage their mappings.

High-Availability Installation Options

How to Install the Enterprise Single Sign-On Administration Component

You can install the Enterprise Single Sign-On (SSO) Administration component as a stand-alone feature. This is useful if you need to administer the SSO system remotely. The hardware and software requirements are the same as for a typical Enterprise SSO installation.

After you install the administration component, you must use either ssomanage.exe or the SSO Administration MMC Snap-In to specify the SSO server that will be used for management. Both processes are included in the procedure that follows.

Note
While the SSO Administration feature in Host Integration Server is compatible with the server version of SSO in BizTalk Server 2006, the administrative components of Enterprise SSO in BizTalk Server 2006 are not compatible with the server version of Enterprise SSO in Host Integration Server.

Installing the SSO administrative utility (ssomanage.exe) does not create shortcuts on the **Start** menu that let you access the command-line utilities. To run the SSO administrative utilities after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On.

The Enterprise SSO Administration feature also includes an MMC Snap-in. The Snap-in is installed on Windows Server 2003 and Windows XP. It is not supported on Windows 2000. You must also have MMC 3.0 installed on your computer for the Snap-in to function.

To open the Enterprise SSO MMC Snap-in, click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.

To install the Enterprise Single Sign-On administrative component

1. Perform a custom installation of Host Integration Server, selecting only the Enterprise Single Sign-On administration component.
2. When the installation program finishes, click **Start**, click **Run**, and then type **cmd**.
3. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Do one of the following:

   - Type **ssomanage –server** to specify the SSO server that you want to connect to when you perform administration operations.

   OR

   Type **ssomanage -serverall** to specify the SSO server that all users of this computer will connect to when performing administration operations.

   OR

   Open the ENTSSO Administration MMC Snap-In. The Select SSO Server dialog will appear. Enter or browse to the SSO Server desired. To specify the SSO Server for all users on the machine, select **Set SSO Server for all users**.

Installing Enterprise Single Sign-On

How to Install the Enterprise Single Sign-On Client Utility

The stand-alone Single Sign-On (SSO) client utility (ssoclient.exe) enables end users to configure their client mappings in the credential database. You can install the client utility from a self-extracting file (SSOClientInstall.exe), which is installed with the SSO administration feature. Administrators can also make the installer package available to client users by placing a copy of the installer package on a network share.

To install the SSO client utility, you must be running one of the following operating systems on the client computer:

- Windows Server 2003
- Windows 2000 Server with Service Pack 4, or Windows XP Professional with Service Pack 1
- .NET Framework 2.0 (only necessary for the managed interoperability component of the SSO client utility)

Installing the SSO client utility does not create shortcuts on the **Start** menu for you to access the command-line utilities. To run the SSO client utility after installation, you must open a command prompt and navigate to the SSO directory located at Program Files\Common Files\Enterprise Single Sign-On.

To install the SSO client utility

1. Double-click the installer package, SSOClientInstall.

Note
Ask your Enterprise Single Sign-On administrator for the location of this file in your enterprise.

   The WinZip Self-Extractor program appears.
2. Select the folder where you want to unzip the files, and then click **Unzip**.

   It is recommended that you unzip the files in a temporary folder.

   The **Enterprise Single Sign-On Client Setup** program appears.
3. On the **Welcome to the Enterprise Single Sign-On Client** page, click **Next**.
4. On the **License Agreement** page, click **I accept the terms of this license agreement**, and then click **Next**.
5. On the **User Information** page, type your user name, organization name, and then click **Next**.
6. On the **Start Installation** page, click **Install**.
7. On the **Completing the Enterprise Single Sign-On Client Wizard** page, click **Finish**.
8. Specify the SSO server by doing either of the following:

   - Type **ssomanage –server** to specify the SSO server that you want to connect to when you perform administration operations. You can also type **ssomanage -serverall** to specify the SSO server that all users of this computer will connect to when performing administration operations.

     OR

   - Open the ENTSSO Administration MMC Snap-In. The Select SSO Server dialog will appear. Enter or browse to the SSO Server desired. To specify the SSO Server for all users on the machine, select **Set SSO Server for all users**.

Installing Enterprise Single Sign-On

High-Availability Installation Options

Topics in this section describe installation focused on high availability of Enterprise Single Sign-On, such as multicomputer deployment.

In This Section

How to Cluster the Master Secret Server

How to Cluster the SQL Server

How to Configure Enterprise Single Sign-On in a Multicomputer Scenario

How to Cluster the Master Secret Server

It is strongly recommended that you follow the instructions in this section to cluster the Enterprise Single Sign-On (SSO) service on the master secret server successfully.

Before you start configuring SSO in a cluster environment, it is recommended that you understand how clustering works. For more information, see http://go.microsoft.com/fwlink/?LinkId=33180.

When you cluster the master secret server, the Single Sign-On Servers communicate to the active clustered instance of the master secret server. Similarly, the active clustered instance communicates with the Credential database.

You must be an SSO administrator to perform this procedure.

Caution
You cannot install the master secret server on a Network Load Balancing (NLB) cluster.

To cluster the master secret server

1. Perform a custom installation to install the master secret server on the first node of the cluster (for example, ClusterNode1).
2. In the **Configuration Wizard**, on the **Configuration Questions** page, in the **Is this the master secret server?** list, select **Yes**, and then click **Next**.
3. Specify the service account credentials for SSO service. This must be a member of the SSO Administrators group account.
4. Specify the location of the SQL Server and SSO Credential database (SSODB).
5. Back up the master secret on the active node.
6. Perform a custom installation to install the master secret server on the second node of the cluster (ClusterNode2).
7. Use the **Configuration Wizard** to configure an Enterprise SSO Server on the second node of the cluster. This time, however, select **No** when you reach the question in step 2, because this is not the initial installation of the master secret server.
8. Click **Next**, and then complete the **Configuration Wizard**.
9. Stop the SSO service by typing **net stop entsso** at the command line.
10. Change the master secret server name in the SSO Credential database to the cluster name. For example, if the cluster is named MSS_CLUSTER, change the name from ClusterNode1 to MSS_CLUSTER.
11. Use a text editor to copy and paste the following code into an .xml file (for example: MSS CLUSTER.xml) and save the file:

    ```
    <sso>
      <globalInfo>
         <secretServer>MSS_CLUSTER</secretServer>
    </globalInfo>
       </sso>
    ```

12. At the command line, navigate to the Enterprise Single Sign-On installation directory. The default is Program Files\Common Files\Enterprise Single Sign-On.
13. Type **ssomanage -updatedb <filename>** where *filename* is the name of the .xml file in the previous step. This updates the master secret server name in the database.

    Ignore any run-time errors. The Microsoft Distributed Transaction Coordinator (DTC) was not configured to run on a cluster, and may be unable to start.
14. Open a command prompt on master secret server 1 and type **comclust -a**.
15. From the **Services** console, right-click **Distributed Transaction Coordinator**, and then click **Restart**.

16. Open a command line on master secret server 2 and type **comclust -a**.
17. From the **Services** console, right-click **Distributed Transaction Coordinator**, and then click **Restart**.
18. Open **Cluster Administrator**, and then click the cluster group that has the master secret server cluster.
19. On the **File** menu, point to **New**, and then click **Resource**.

    The New Resource window opens.

    Under **Name**, type the name of the SSO resource (for example, **ENTSSO**).

    Under **Resource Type**, select **Generic Service**.
20. In the **Possible Owners** window, include each cluster node as a possible owner of the ENTSSO resource.
21. After you create the **ENTSSO** resource, right-click **ENTSSO**, and click **Properties**.
22. In the **Cluster Properties** dialog box, click the **Security** tab, and verify that the user under which the application is running has sufficient user rights (not a local administrator) to access the cluster.
23. Open **Cluster Administrator**, right-click the cluster group that has the master secret server cluster, and then click **Move group**.

    This moves the master secret server resources from the first node to the second node.
24. Click **Start**, click **Run**, and then type **cmd**.
25. At the command prompt, navigate to the Enterprise Single Sign-On installation directory. The default is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
26. Type **ssoconfig -restoresecret <restore file>**, where <*restore file*> is the path and name of the back-up file that contains the master secret.

How to Configure Enterprise Single Sign-On in a Multicomputer Scenario

This section contains instructions for configuring Enterprise Single Sign-On (SSO) in a three-computer scenario.

In the following scenario, computer A is the master secret server, computer B is the Single Sign-On server, and computer C holds the Credential database. Computer B can act as a runtime server, as an administration server (administration sub services of SSO use this server for managing the Credential database), or as a mapping server (administration and client sub services of SSO use this server to manage mappings).

If you want to add more SSO servers to your environment, follow the steps for configuring computer B. Any new SSO servers will point to the existing Credential database, and cannot be the master secret server.

Note
It is recommended that you configure the master secret server on a different computer from the Single Sign-On server and t he Credential database.

To configure the master secret server and create the Credential database on Computer A

1. Perform a custom installation of Host Integration Server, and install only the Enterprise Single Sign-On runtime component.
2. Run the Configuration Wizard to configure SSO on the master secret server.

   On the **Configuration Questions** page, in the **Is this the master secret server** list, select **Yes**, and then click **Next**.
3. On the **Windows Accounts** page, specify the service account credentials for the SSO service. This must be a member of the SSO Administrators group.
4. On the **Database Configurations** page, specify the location of the SQL server (computer C) and the name of the Credential database (SSODB).
5. Back up the master secret.

   For more information, see How to Back Up the Master Secret.

To configure the SSO server on Computer B

1. Install Enterprise Single Sign-On on Computer B.

Note
This can be a Host Integration Server computer, or an SSO-only server (SSO runtime components).

2. Run the Configuration Wizard to configure SSO.

   On the **Configuration Questions** page, in the **Is this the master secret server** list, select **No**, and then click **Next**.
3. On the **Windows Accounts** page, specify the service account credentials for the SSO service. This must be a member of the SSO Administrators group.
4. On the **Database Configurations** page, point to the location of the SQL server (computer C) and the name of the Credential database (SSODB).

How to Remove Enterprise Single Sign-On

If you remove Host Integration Server, Enterprise Single Sign-On (SSO) is no longer configured, but it is not removed. You must remove SSO separately. You can also restore configuration information including the master secret to reuse existing data. For more information, see How to Restore the Master Secret.

To remove Enterprise Single Sign-On

1. Back up the master secret key.

   For more information, see How to Back Up the Master Secret.

2. Uninstall Host Integration Server.
3. Click **Start**, point to **Settings**, and then click **Control Panel**.
4. Click **Add or Remove Programs**.
5. In **Add or Remove Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **Remove**.
6. Click **Yes** when you are prompted to confirm the removal of Microsoft Enterprise Single Sign-On.

How to Configure SSO Using the Configuration Wizard

Use the **Enterprise Single Sign-On (SSO)** page to configure your SSO settings.

Note
You will not be able to reconfigure SSO in the configuration manager after you have configured it.

Use this	To do this
Enable Enterprise Single Sign-On on this computer	Select **Enable Enterprise Single Sign-On on this computer** to configure this server with SSO settings.
Create a new SSO system	Select **Create a new SSO system** if this is the first SSO server you are configuring in your SSO system. This also creates and configures the SSO Credential database. You must also back up the secret on this secret server. Caution You should configure the master secret server as a stand-alone server. You must be an SSO administrator while performing this configuration task. Note Only one master secret server can be associated with one SSO group. Associating two master secret servers to the same SSO group is not supported.
Join an existing SSO system	Select **Join an existing SSO system** to connect to an existing SSO system.
Data stores	The **Data stores** list provides an editable view of the data stores used for the SSO database.
Windows service	The **Windows service** list provides an editable view of the account used to run the Enterprise Single Sign-On service.
Windows accounts	The **Windows accounts** list provides an editable view of the SSO Administrators and SSO Affiliate Administrators Windows groups.

Use the **Enterprise Single Sign-On Secret Backup** page to save the master secret to an encrypted backup file in the event that disaster recovery is needed.

Use this	To do this
Secret backup password	Type the password for the backup file.
Confirm password	Confirm the password for the backup file.
Password reminder	Type a reminder for the password you enter.
Backup file location	Provide a file name and file path to the secret backup file. By default it is stored at <drive>:\Program Files\Common Files\Enterprise Single Sign-On\.

Considerations for Configuring SSO

When you configure Enterprise SSO, consider the following:

- When configuring the SSO Windows accounts using local accounts, you must specify the account name without the

computer name.

- When using a local SQL Server named instance as data store, you must use LocalMachineName\InstanceName instead of LocalMachineName\InstanceName, PortNumber.

- It is possible to configure the Enterprise SSO service account as the Network Service account. To do so, you must first add the Network Service account to the SSO Administrators group and reboot the computer for the change to take effect.

Important
While it is possible to do this, it is not a good security practice, as the Network Service account is a low privilege account.

How to Set the Enterprise Single Sign-On Server

Every time that you use the command line management utility, ssomanage, you must first point the user to the Single Sign-On (SSO) server that you want to connect to.

You can do this in one of two ways:

- Individual users can point themselves to the correct Single Sign-On server.
- A local computer administrator for the Single Sign-On server can point all the members of the Single Sign-On Users account to this server.

To set the Enterprise Single Sign-On server using the MMC Snap-In

1. Click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the MMC Snap-In under the **Console Root**, right-click **Enterprise Single Sign-On**, and then click **Select**.
3. Browse to the desired server.
4. If appropriate, select the **Set SSO Server for all users** check box.
5. Click **OK**.

To set the Enterprise Single Sign-On server for a single user

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –server <Single Sign-On Server>**, where <*Single Sign-On Server*> is the computer name of the Single Sign-On server that the user wants to connect to.

To set the Enterprise Single Sign-On server for all users

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –serverall <Single Sign-On Server>**, where <*Single Sign-On Server*> is the computer name of the Single Sign-On server that all members of the Single Sign-On Users account will be pointed to.

To determine the Enterprise Single Sign-On Server to which a user is connected

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –showserver**.

Note
This command displays the settings for the current user and also for other users if they exist.

Using Enterprise Single Sign-On

How to Enable Enterprise Single Sign-On

The enabling command enables the entire Enterprise Single Sign-On (SSO) system. After you run the enabling command, there is a short delay before all Single Sign-On servers are enabled, because each server polls the Credential database for the latest global information.

If you want to configure affiliate applications and mappings in the SSO system, you must also create an affiliate application. After an SSO affiliate administrator creates an affiliate application, an application administrator can make changes to it, and application users (end users) can create their own mappings. For more information, see Managing Affiliate Applications and Managing User Mappings.

To enable the SSO system using the MMC Snap-In

1. Click **Start**, click **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Enable**.

To enable the SSO system using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –enablesso**.

To enable SSO to create affiliate applications and mappings

1. Log on as an SSO administrator or SSO affiliate administrator to the SSO Server, or on a computer that has the SSO administration sub services of SSO.
2. Click **Start**, click **Run**, and then type **cmd**.
3. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage -enablesso** to enable the Enterprise Single Sign-On service.
5. Log on as an SSO affiliate administrator.
6. Type **ssomanage -createapps <application file>** to create an affiliate application, where <*application file*> is the XML file that contains definitions for the affiliate applications.

How to Change the Master Secret Server

After you set up the master secret server and configure the Credential database, you can change the master secret server if the original master secret server fails and cannot be recovered. To change the master secret server, you must promote a Single Sign-On (SSO) server to become the master secret server.

To change the master secret server using the MMC Snap-in

1. Click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane, right-click **System**, and then click **Properties**.

   The master secret server is displayed on the **General** tab of the **SSO System Properties** dialog box.
3. Click **Change** to select a new master secret server.

To promote a Single Sign-On server to master secret server

1. Create an XML file that includes the name of the SSO server that you want to promote to master secret server. For example:

```
<sso>
  <globalInfo>
     <secretServer>SSO Server name</secretServer>
  </globalInfo>
</sso>
```

2. Click **Start**, click **Run**, and then type **cmd**.
3. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssomanage –updatedb <update file>**, where <*update file*> is the name of the XML file that you create in step 1.
5. Restart the master secret server.
6. Type **ssoconfig –restoresecret <restore file>**, where <*restore file*> is the path and name of the file where the master secret is stored.

Using Enterprise Single Sign-On

How to Update the Credential Database

You use the commands described here to change the global information in the Credential database, such as the master secret server identification, the account names, auditing in the database, ticket time-out, credential cache time-out, and so on.

Changing Time-outs for the SSO System

You can modify two time-outs at the Enterprise Single Sign-On (SSO) system level:

Ticket timeout. This property specifies the length of time for which a ticket that SSO issues is valid. To satisfy most of the scenarios in an enterprise that use SSO, the default ticket time-out is two minutes. The SSO administrator can change this based on the application requirements.

Credential Cache timeout. This property specifies the credential cache time-out for all SSO servers. SSO servers cache the credentials after the first lookup. By default, the credential cache time-out is 60 minutes. The SSO administrator can change this to an appropriate value based on the security requirements.

You change both of these time-outs by updating the Credential database.

The following is an example XML file for updating the Credential database:

```
<sso>
<globalnfo>
<ssoAdminAccount>Domain\Accountname</ssoAdminAccount>
<ssoAffiliateAdminAccount>Domain\Accountname</ssoAffiliateAdminAccount>
<secretServer>ComputerA</secretServer>
<auditDeletedApps>1000</auditDeletedApps>
<auditDeletedMappings>1000</auditDeletedMappings>
<auditCredentialLookups>1000</auditCredentialLookups>
<ticketTimeout>2</ticketTimeout>
<credCacheTimeout>60</credCacheTimeout>
</globalInfo>
</sso>
```

To change time-outs using the Microsoft Management Console (MMC) Snap-In

1. Click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Properties**.
4. On the **SSO System Properties** dialog box, click the **General** tab.
5. Enter the appropriate settings, and then click **OK**.

To update the SSO database using the MMC Snap-In

1. Click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Update**.

To update the Credential database using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updatedb <update file>**, where <*update file*> is the path and name of the file.

How to Display the Credential Database Information

You can view Single Sign-On (SSO) credential database information by using the ssomanage command.

To display the SSO database information using the Microsoft Management Console (MMC) Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Properties**.
4. Click the tabs in the **SSO System Properties** dialog box to view SSO database information.

To display the Credential database information using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –displaydb**.

To display the Credential database that the SSO server is connected to

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –showdb**.

The following table describes the values that are displayed.

Property	**Value**
SQL Server	*<SQL Server name>*
SQL Server database	*<SQL Server database name>*
Single Sign-On Secret Server name	*<Single Sign-On Server name>*
Single Sign-On Administrators account	Domain\account name
Single Sign-On Affiliate Administrators account	Domain\account name
Size of audit table for deleted applications (number of audit entries)	1000 (default)
Size of audit table for deleted user mappings (number of audit entries)	1000 (default)
Size of audit table for external credential lookups (number of audit entries)	1000 (default)
Ticket timeout (in minutes)	2 (default) This value can be an integer between 1 to 525600
Credential cache timeout (in minutes)	60 (default)
Single Sign-On Status	Enabled/disabled
Tickets allowed	Yes/No (default)

Validate tickets	Yes (default)/No

How to Configure the Enterprise Single Sign-On Tickets

Other Resources

Using Enterprise Single Sign-On

How to Configure the Enterprise Single Sign-On Tickets

You can use the Microsoft Management Console (MMC) Snap-In or the command line to control ticket behavior for the entire Single Sign-On (SSO) system, including whether to allow tickets, and whether the system must validate the tickets. You can use **Yes**, **No**, **On**, or **Off** to indicate whether to allow or validate tickets. These words are case independent, and they must be used regardless of your language settings.

If you have the SSO Administration feature installed on a remote computer, you can perform remote IssueTicket operation. Note that all traffic between the SSO Administration module and the Runtime module (ENTSSO service) is encrypted.

By using the command-line utility, ssomanage.exe, you can specify the ticket time-out at the affiliate application level only when an update of the application is performed, not at creation time. Only an SSO Administrator can configure tickets at the SSO system level and at the affiliate application level. If ticketing is disabled at the system level, it cannot be used at the affiliate application level either. You can enable tickets at the system level and disable them at the affiliate application level. If validation is enabled at the system level, validation of tickets is required at the affiliate application level also. You can disable validation at the system level and enable it at the affiliate application level.

If ticket time-out is specified both at the system level and the affiliate application level, the one specified at the affiliate application level is used to determine the ticket expiry time.

For more information about tickets and ticket validation, see SSO Tickets.

To configure the SSO tickets using the MMC Snap-In for the Affiliate Application

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Affiliate Applications** node.
3. Right-click **Affiliate Application**, and then click **Properties**.
4. Click the **Options** tab.
5. Select **Allow Tickets** and configure the ticket time-out as appropriate.

To configure the SSO system-level tickets using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –tickets <allowed yes/no> <validate yes/no>**, where <*allowed yes/no*> indicates whether tickets will be allowed or not, and <*validate yes/no*> indicates whether tickets must be validated after they are redeemed.

Note
You can use **yes**, **no**, **on**, or **off** to indicate whether to allow or validate tickets. These words are case independent, and t hey must be used regardless of your language settings.

How to Audit Enterprise Single Sign-On

Use this command to set both the positive and negative auditing levels. Single Sign-On (SSO) administrators can set the positive and negative audit levels that suit their corporate policies. You can set positive and negative audits to one of the following levels:

- 0 = None
- 1 = Low
- 2 = Medium
- 3 = High - This level issues as many audit messages as possible.

The default value for positive auditing is 0 (none), and the default value for negative auditing is 1(low).

To change the database-level auditing, you must update the Credential database using an XML file. The following is an example XML file that is used for updating the Credential database:

```
<sso>
<globalnfo>
<auditDeletedApps>1000</auditDeletedApps>
<auditDeletedMappings>1000</auditDeletedMappings>
<auditCredentialLookups>1000</auditCredentialLookups>
</globalInfo>
</sso>
```

To audit Single Sign-On using the Microsoft Management Console (MMC) Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Properties**.
4. In the **SSO System Properties** dialog box, click the **Audits** tab.
5. Enter the appropriate settings, and then click **OK**.

To audit Single Sign-On using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoconfig –auditlevel < positive level> <negative level>**, where <*positive level*> is the level of auditing when actions succeed, and <*negative auditing*> is the level of auditing when actions fail.

To audit the Credential database

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updatedb <update file>**, where <*update file*> is the path and name of the file.

How to Enable SSL for Enterprise Single Sign-On

Use the following command to enable Secure Sockets Layer (SSL) between all the Enterprise Single Sign-On (SSO) servers and the Credential database.

To enable SSL for Enterprise Single Sign-On

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –setssl <yes/no>**, where <*yes/no*> indicates whether you want to enable SSL in the SSO system.

Managing the Master Secret

The master secret is the key that is used to encrypt all the information stored in the Credential database. If the master secret server crashes and you lose the secret, you cannot retrieve the information stored in the Credential database. Therefore, it is very important to back up the master secret as soon as you generate it.

In This Section

- How to Generate the Master Secret
- How to Back Up the Master Secret
- How to Restore the Master Secret

How to Generate the Master Secret

You must have administrator rights on the master secret server in order to generate the master secret. In addition, you must perform this task from the master secret server.

The first server where you install Enterprise Single Sign-On (SSO) becomes the master secret server.

Important
There can be only one master secret server in your SSO system.

Note
When Enterprise Single Sign-On is installed as part of the Host Integration Server installation, the master secret is generated as part of the Configuration Wizard. You only need to perform this task if you want to generate a new master secret.

To generate the master secret using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO Microsoft Management Console (MMC) Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Generate Master Secret**.

To generate the master secret using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoconfig –generatesecret <backup file>**, where <*backup file*> is the name of the file that contains the master secret.

   You will be prompted to enter a password to protect the file you just created.

Managing the Master Secret

How to Back Up the Master Secret

You can back up the master secret from the master secret server onto an NTFS file system or removable media, such as a floppy disk.

You must be a Single Sign-On administrator and a Windows administrator to perform this task. The Single Sign-On (SSO) system will prompt you for a password. To restore the secret later, you must specify the same password.

Caution
If the master secret server crashes and you lose the key, or if the key becomes corrupted, you will not be able to retrieve data stored in the Credential database. You must back up the master secret, or you risk losing data from the Credential database.

To back up the master secret using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO Microsoft Management Console (MMC) Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Back up Master Secret**.

To back up the master secret using the command line

1. On the **Start** menu, click **Programs**, and then click **Accessories**. Right-click **Command Prompt**, and then click **Run As...**.
2. Select the appropriate Administrator, and then click **OK**.
3. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssoconfig –backupsecret <backup file>**, where <*backup file*> is the path and name of the file where the master secret will be backed up, for example, **A:\ssobackup.bak**.
5. Provide a password to help protect this file.

   You will be prompted to confirm the password and to provide a password hint to help you remember this password.

Important
You must save and store the backup file in a secure location.

How to Restore the Master Secret

As part of data recovery procedures, you might have to restore the master secret to reuse existing data. To perform this task, you must log on to the master secret server by using an account that is both a Windows administrator and a Single Sign-On (SSO) administrator.

To restore the master secret using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO Microsoft Management Console (MMC) Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Restore Master Secret**.

To restore the master secret using the command line

1. On the **Start** menu, click **Programs**, and then click **Accessories**. Right-click **Command Prompt**, and then click **Run As...**.
2. Select the appropriate Administrator, and then click **OK**.
3. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **ssoconfig –restoresecret <restore file>**, where <*restore file*> is the path and name of the file where the master secret is stored.

Specifying Single Sign-On Administrators and Affiliate Administrators Accounts

The Enterprise Single Sign-On (SSO) Administrators and Affiliate Administrators accounts can be host group or individual accounts. You must create these accounts before you configure the SSO system. When you are using domain accounts, you must create the SSO Administrators and SSO Affiliate Administrators accounts as domain global security groups in the domain controller. You must be a domain administrator to create these accounts.

You must specify the Single Sign-On Administrators and Affiliate Administrators accounts in the Credential database. The following example shows XML code that can be used to update the Credential database:

```
<sso>
<globalInfo>
<ssoAdminAccount>Domain\Accountname</ssoAdminAccount>
<ssoAffiliateAdminAccount>Domain\Accountname</ssoAffiliateAdminAccount>
</globalInfo>
</sso>
```

Note

The Configuration Wizard automatically specifies the SSO Administrator and SSO Affiliate Administrator groups in the Credential database.

Before you update the Credential database with the SSO Administrators group, you must disable the Single Sign-On system. You can use the Microsoft Management Console (MMC) Snap-In or the command line to do this.

To disable the Enterprise Single Sign-On system using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Disable**.

To disable the Enterprise Single Sign-On system using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –disablesso**.

To update the SSO database using the MMC Snap-In

1. Click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Update**.

To update the Credential database using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updatedb <update file>**, where <*update file*> is the path and name of the XML file.

To enable the Enterprise Single Sign-On system using the MMC Snap-In

1. Click **Start**, point to **Programs**, point to **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.

2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Enable**.

To enable the Enterprise Single Sign-On system using the command line

1. Click **Start**, click **Run**, and then type **cmd**.
2. At the command line, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –enablesso**.

Managing Affiliate Applications

This section provides information on how to create and configure affiliate applications.

In This Section

- How to Create an Affiliate Application
- How to Delete an Affiliate Application
- How to Update the Properties of an Affiliate Application
- How to Enable an Affiliate Application
- How to Disable an Affiliate Application
- How to List Affiliate Applications
- How to List the Properties of an Affiliate Application
- How to Clear the Application Cache
- How to Set the Enterprise SSO Server Using the Client Utility
- How to Display the Enterprise SSO Server Using the Client Utility
- How to Set Credentials for the Affiliate Application Using the Client Utility

How to Create an Affiliate Application

You can use the MMC Snap-In or the **createapps** command to create one or more applications, as specified by the XML file. The following is an example XML file for Windows-Initiated Single Sign-On (SSO):

```
<sso>
<application name="SAP">
<description>The SAP application</description>
<contact>someone@example.com</contact>
<appuserAccount>domain\AppUserAccount</appuserAccount>
<appAdminAccount>domain\AppAdminAccount</appAdminAccount>
<field ordinal="0" label="User Id" masked="no" />
<field ordinal="1" label="Password" masked="yes" />
<flags groupApp="no" configStoreApp="no" allowTickets="no" validateTickets="yes" allowLocal
Accounts="no" timeoutTickets="yes" adminAccountSame="no" enableApp="no" />
</application>
</sso>
```

After you create an affiliate application, you cannot modify the following properties:

- Name of the affiliate application.
- Fields associated with the affiliate application.
- Affiliate application type (host group, individual, or configuration store).
- Administration account same as affiliate administrators group. (Specifying this flag will always use the affiliate administrators group as the administrator account for this affiliate application.)

Important

You can use local accounts for the administration account and user account by setting the allowLocalAccounts flag to yes. However, you should only use this flag in single-computer scenarios.

Security Note

You must be an SSO administrator or SSO affiliate administrator to perform this task.

Note

If you are performing the configuration on a Domain Controller, and the Domain Local scope groups are specified for Application Administrators or Application Users while creating Affiliate Applications, it is recommended that you enable the local account flag. To do this:

- In the MMC Snap-in, select Allow local accounts for access accounts during the creation process.
- From the command line, specify allowLocalAccounts=yes in the XML file for Affiliate Application creation.

After you create the affiliate application, you must enable it. For more information, see How to Enable an Affiliate Application.

To create an affiliate application using the Microsoft Management Console (MMC) Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **Affiliate Applications**, and then click **New**.

4. Follow the instructions in the **Create New Affiliate Application** wizard.

To create an affiliate application using the command line

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createapps <application file name>**, where <*application file name*> is the XML file.

Managing Affiliate Applications

How to Delete an Affiliate Application

Use the MMC Snap-In or the **deleteapps** command to delete the specified affiliate application from the Credential database.

Important
When you delete an affiliate application, the SSO system automatically deletes all mappings associated with it.

Security Note
You must be an SSO administrator or SSO affiliate administrator to perform this task.

To delete an affiliate application using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click the affiliate application, and then click **Delete**.

To delete an affiliate application using the command line

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –deleteapp <application name>**, where <*application name*> is the name of the affiliate application you want to remove from the Credential database.

How to Update the Properties of an Affiliate Application

Use the MMC Snap-In or the **updateapps** command to update one or more application properties, as specified by the XML file. You must be an affiliate administrator to perform this task. The following is an example XML file that lists the fields you can update.

```
<SSO>
<application name="SSOApplication">
<description>An SSO Application</description>
<contact>someone@companyname.com</contact>
<appUserAccount>DomainName\AppUserGroup</appUserAccount>
<appAdminAccount>DomainName\AppAdminGroup</appAdminAccount>
<flags allowTickets="no" validateTickets="yes"  timeoutTickets="yes" enableApp="no" />
</application>
</SSO>
```

After you create an affiliate application, you cannot modify the following properties:

- Name of the affiliate application.
- Fields associated with the affiliate application.
- Affiliate application type (host group, individual, or configuration store).
- Administration account same as affiliate administrators group. (Specifying this flag will always use the affiliate administrators group as the administrator account for this affiliate application).

Important
You can use local accounts for the administration account and user account by setting the allowLocalAccounts flag to y es. However, you can only use this flag in single-computer scenarios.

Note
You must be an SSO administrator, SSO affiliate administrator, or application administrator to perform this task.

Note
You must be an SSO administrator to modify the ticketing flags (validateTickets and timeoutTickets).

Note
You must be an SSO administrator or an SSO affiliate administrator to modify the application administration account.

To update the properties of an affiliate application using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click the affililate application, and then click **Update**.

To update the properties of an affiliate application using the command line

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory. The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –updateapps <application file name>**, where the *application file name* is the XML file.

How to List Affiliate Applications

Use the **listapps** command to list all the affiliate applications. If the user is a member of the Application Administrators account, this command only displays the application for which the user is an administrator.

To list affiliate applications using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On (SSO) installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -listapps [all]** where *all* is an optional parameter that will also display applications using the Configuration Store feature.

   If the user who runs this command is an Application administrator, it only lists the applications for which that user is an administrator. If the user who runs this command is an Affiliate Administrator or an SSO Administrator, it lists all the affiliate applications.

To list affiliate applications using the client utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –listapps** to list the affiliate applications.

   This lists only the affiliate applications that the user who is performing this task is a member of. That is, the user must belong to the application user group account for that affiliate application.

Managing User Mappings

This section provides information about how to create and configure the Enterprise Single Sign-On (SSO) mappings.

Administrators use the **ssomanage** utility to manage mappings, and the application users use the **ssoclient** utility to manage their mappings.

Note
Application administrators can manage mappings associated with affiliate applications for which they are an administrator, while SSO affiliate administrators and the SSO administrators can manage all mappings associated with all affiliate applicati ons.

In This Section

- How to List User Mappings
- How to Create User Mappings
- How to Delete User Mappings
- How to Set Credentials for a User Mapping
- How to Enable a User Mapping
- How to Disable a User Mapping

How to List User Mappings

Use the **listmappings** command to list all the existing mappings for the specified user. You must be a Single Sign-On (SSO) Administrator, Application Administrator, SSO Affiliate Administrator, or user to do this task.

Enabled user mappings appear as (E) <*domain*>\<*username*>, whereas disabled user mappings appear as (D) <*domain*>\<*username*>.

To list user mappings using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. To list all the mappings that a given user has in the affiliate applications that the user belongs to, type:

   ssomanage –listmappings <domain>\<username>

   where <*domain*> is the Windows domain for the user account, and <*username*> is the Windows user name for which you want to list the user mappings. If the user is an Affiliate Administrator or an SSO Administrator, this command lists all the mappings for that user in all the affiliate applications.

   Or
4. To list all the user mappings for a given application, type **ssomanage –listmappings <application name>**.

   Or
5. If you are an application administrator, and you want to list all the mappings a given user has in the affiliate applications for which you are an administrator, type **ssomanage –listmappings <domain>\<username> <application name>**.

To list user mappings using the client utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –listmappings** to list all the mappings you have.

Managing User Mappings

How to Create User Mappings

Use the **createmappings** command to create one or more user mappings, as specified in the XML file. The following is an example XML file.

```
<sso>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name1</externalApplication>
<externalUserId>App1UserName</externalUserId>
</mapping>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name2</externalApplication>
<externalUserId>App2UserName</externalUserId>
</mapping>
</sso>
```

If a user account is changed, you must use this command to create a mapping for the new user account. You should also remove the old user mapping. For more information about removing a mapping, see How to Delete User Mappings.

After you create a user mapping, you must enable it before you can use this mapping in the Single Sign-On (SSO) system. For more information, see How to Enable a User Mapping.

Important
Only domain groups are supported for user mappings.

To create user mappings using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createmappings <mappings file name>**, where <*mappings file name*> is the name of the file that contains the user mappings that you want to create.

To create user mappings using the client utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –setcredentials <application name >**, where <*application name* > is the name of the affiliate application that the user wants to create a mapping for.

How to Delete User Mappings

Use these commands to delete one or more user mappings, as specified in the XML file. The following is an example XML file.

```
<sso>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name1</externalApplication>
<externalUserId>App1UserName</externalUserId>
</mapping>
<mapping>
<windowsDomain>domain</windowsDomain>
<windowsUserId>WindowsUserName</windowsUserId>
<externalApplication>Application name2</externalApplication>
<externalUserId>App2UserName</externalUserId>
</mapping>
</sso>
```

If a user is not a member of the Application Users account, or does not exist in Active Directory, you should use this command to remove the user mapping from the Credential database.

If a user account is changed, you must use this command to remove the old user mapping, and then create a new user mapping for the new user account. For more information about creating a mapping, see How to Create User Mappings.

To delete user mappings using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –deletemappings <mappings file name>**, where <*mappings file name*> is the name of the file that contains the user mappings that you want to delete.

To delete a specific user mapping using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –deletemapping <domain>\<username> <application name>**, where <*domain*> is the Windows domain for the user account, <*username*> is the Windows user name, and <*application name*> is the specific application for which you want to remove the user mapping.

To delete a user mapping using the client utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –deletemapping <application name>**, where <*application name*> is the name of the affiliate application for which you want to remove the user mapping.

How to Set Credentials for a User Mapping

Use the **setcredentials** command to set the credentials for a user to access a specific application.

This command does not display the password as you type it.

If the user mapping already exists, this command sets the credentials for the existing mapping. If you have not created the user mapping, the SSO system prompts you for the user ID for the application.

To set credentials for an user mapping

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –setcredentials <domain>\<username> <applicationname>**, where <*domain*> is the Windows domain for the user account, <*username*> is the Windows user name, and <*applicationname*> is the specific application for which you want to set the credentials.
4. When the SSO system prompts you for the user credentials, enter the user password for this application.
5. If you have not created the user mapping, the SSO system prompts you for the user ID for the application.

To set credentials for a user mapping from client utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient -setcredentials <application name>**,where <*application name*> is the name of the affiliate application for which you want to remove the user mapping.

How to Enable a User Mapping

You must enable a user mapping before it you can use the mapping in the Single Sign-On (SSO) system.

When you enable a user mapping, it appears as (E) <*domain*>\<*username*> when you list the user mappings.

To enable a user mapping using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –enablemapping <domain>\<username> <application name>**, where <*domain*> is the Windows domain for the user account, <*username*> is the Windows user name for which you want to enable the credentials, and <*application name*> is the name of the affiliate application for which you want to remove the user mapping, and then press ENTER.

To enable a user mapping using the client utility

1. Click **Start**, click **Run**, type **cmd**, and then press ENTER.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –enablemapping <application name>**, where <*application name*> is the name of the affiliate application for which you want to remove the user mapping.

How to Disable a User Mapping

You can disable a user mapping when you want to turn off all operations associated with a given mapping. You must disable a user mapping before you can remove it.

When you disable a user mapping, it will appear as (D) <*domain*>\<*username*> when you list the user mappings.

To disable a user mapping using the administration utility

1. Click **Start**, click **Run**, type **cmd**, and then press **ENTER**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –disablemapping <domain>\<username><application name>**, where <*domain*> is the Windows domain for the user account, <*username*> is the Windows user name for which you want to disable the credentials, and <*application name*> is the name of the affiliate application for which you want to remove the user mapping.

To disable a user mapping using the client utility

1. Click **Start**, click **Run**, type **cmd**, and then press **ENTER**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default installation directory is <*drive*>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoclient –disablemapping <application name>**, where <*application name*> is the name of the affiliate application for which you want to remove the user mapping.

Host Initiated Single Sign-On

Host-initiated Single Sign-On (SSO) enables a request from the host system to access a resource on a Windows system. The host system (for example, an RACF account) exists in a non-Windows environment and under the context of a non-Windows user. The Single Sign-On Credential Store maps host accounts to Windows accounts, enabling this access.

The following topics describe configuration that is specific to Host-initiated SSO.

In This Section

- Configuration Requirements for Host Initiated SSO
- Enabling and Disabling Host Initiated SSO
- Creating Affiliate Applications for Host Initiated SSO
- Validating Passwords for Host Initiated SSO
- Managing User Mappings for Host Initiated SSO
- Troubleshooting Host Initiated SSO

Configuration Requirements for Host Initiated SSO

Although Enterprise Single Sign-On (SSO) and host-initiated SSO have certain aspects in common, certain platform and Active Directory requirements are unique to host-initiated SSO. This topic discusses those requirements, and lists the steps to check or create them on your system.

- Host-initiated SSO can be executed only on a native Windows Server 2003 domain environment.
- The service account for SSO Service that is performing host-initiated SSO must be configured to have Trusted Computing Base (TCB) privileges. (You can configure this for the service account in the domain security policy.)

In addition, certain requirements are necessary when using Transaction Integrator for Host-Initiated Processing (TI for HIP). TI for HIP uses host-initiated SSO to achieve Single Sign-On for non-Windows users.

For example, a service account for TI for HIP service runs under a service account *domainname**hipsvc*. This service can host applications that want to access remote or local resources on Windows with the Windows account that corresponds to the non-Windows account.

The *domainname**hipsvc* account must belong to the Application Administrator group account for the affiliate application that is being used for Single Sign-On.

The *domainname**hipsvc* account must have constrained delegation privileges to use host-initiated Single Sign-On. This can be configured by the domain administrator in Active Directory. Delegation can be configured for accounts that have registered service principal names (SPN). Constrained delegation allows the service account to access only components that are specified by the administrator.

To check your domain function level

1. In the **Active Directory Domains and Trusts** Microsoft Management Console (MMC) snap-in, right-click the **Active Directory Domains and Trusts** node, and then click **Raise Forest Functional Level**.
2. Verify that the functional level is **Windows Server 2003**. If it is not, refer to your Active Directory documentation before you attempt to change the setting.

To create an SPN

1. Download the **setspn** utility from the following location: http://go.microsoft.com/fwlink/?LinkId=148820
2. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
3. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
4. Type **setpsn -a hipsvc\computername.domain.com domain\hissvc**

   where *hipsvc**computername.domain.com* is the service that will perform the operation and the computer it is running on, and *domain**hissvc* is the service account for hipsvc.

After you do this, you can configure constrained delegation in Active Directory for this service account (domain\hissvc) to access the appropriate resource in the network.
To give TCB privileges for the SSO service account

1. Under **Domain Security Policy - Local Policies - User Rights Assignment**, add the SSO Service account to the **Act as part of operating system** policy.

   For more information about Kerberos Protocol Transition and Constrained Delegation, visit http://go.microsoft.com/fwlink/?LinkId=148816.

Host Initiated Single Sign-On

Enabling and Disabling Host Initiated SSO

By default, host initiated Single Sign-On (SSO) is not enabled in the Single Sign-On system, and must be enabled by the SSO Administrator.

To enable host initiated SSO using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Properties**.
4. Click the **Options** tab.
5. Select the **Enable host initiated SSO** box, and click **OK**.

To enable host initiated SSO using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -enable hisso**.

Disabling SSO applies to the entire SSO system, and all operations related to host initiated SSO are turned off.
To disable host initiated SSO using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **System**, and then click **Properties**.
4. Click the **Options** tab.
5. Clear the **Enable host initiated SSO** box, and click **OK**.

To disable host initiated SSO using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -disable hisso** as appropriate.

Host Initiated Single Sign-On

Creating Affiliate Applications for Host Initiated SSO

You can define two types of applications:

- **Individual** There is a one-to-one relationship between Windows users and non-Windows users.
- **Host Group** Multiple non-Windows users can be mapped to the same Windows account.

To create an affiliate application using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. Right-click **Affiliate Applications**, and then click **New** to start the **Create New Affiliate Application Wizard**.
4. Use the wizard to select the properties of your affiliate application.

To create an individual type affiliate application using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createapps <AffApp.xml>**, where *AffApp.xml* is the name of the xml file.

   The following is a sample file:

```
<?xml version="1.0"?>
<SSO>
  <application name="SSOApp_Host1">
    <description>An Individual Type Affiliate Application for Host Initiated SSO</desc
ription>
    <contact>someone@companyname.com</contact>
    <appUserAccount>DomainName\AppUserGroup_HISSO</appUserAccount>
    <appAdminAccount>DomainName\AppAdminGroup_HISSO</appAdminAccount>
    <field ordinal="0" label="User ID" masked="no" />
    <field ordinal="1" label="Password" masked="yes" />
    <flags windowsInitiatedSSO="no" enableApp="yes" />
  </application>
</SSO>
```

To create a host group type affiliate application

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createapps <AffApp.xml>**, where *AffApp.xml* is the name of the xml file.

   The following is a sample file:

```
<?xml version="1.0"?>
<SSO>
  <application name="SSOApp_HostGroupApp1">
    <description>A Group Type Affiliate Application for Host Initiated SSO associating
multiple non-Windows user to a single Windows user account(DomainName\WindowsUserAccou
nt1)</description>
```

```
    <contact>someone@companyname.com</contact>
    <windowsAccount>DomainName\WindowsUserAccount1</windowsAccount>
    <appAdminAccount>DomainName\AppAdminGroup_HISSO</appAdminAccount>
    <field ordinal="0" label="User ID" masked="no" />
    <field ordinal="1" label="Password" masked="yes" />
    <flags  enableApp="yes" />
  </application>
</SSO>
```

To create an affiliate application supporting both Windows initiated SSO and host initiated SSO

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createapps <AffApp.xml>**, where **AffApp.xml** is the name of the XML file.

   The following is a sample file:

```
<?xml version="1.0" ?>
- <SSO>
- <application name="SSOApp1">
  <description>An Individual Type Affiliate Application for both Host Initiated SSO an
d Windows Initiated SSO</description>
  <contact>someone@companyname.com</contact>
  <appUserAccount>DomainName\AppUserGroup</appUserAccount>
  <appAdminAccount>DomainName\AppAdminGroup</appAdminAccount>
  <field ordinal="0" label="User ID" masked="no" />
  <field ordinal="1" label="Password" masked="yes" />
  <flags  enableApp="yes" />
  </application>
  </SSO>
```

Other Resources

Host Initiated Single Sign-On

Validating Passwords for Host Initiated SSO

When an affiliate application for host initiated Single Sign-On (SSO) is created, password validation for the non-Windows user is enabled by default. This means that when applications call SSO to obtain the Windows user token to access resources, they must provide the non-Windows user account and the non-Windows password. If the password does not match the password in the SSO credential database for that non-Windows user, access is denied. If necessary, the password validation feature can be disabled for the affiliate application. The password validation feature applies to both individual and host group type affiliate applications for host initiated SSO.

The following is an example XML file for individual type host initiated SSO affiliate applications:

```
<sso>
<application name="SAP">
<description>The SAP application</description>
<contact>someone@example.com</contact>
<appuserAccount>domain\AppUserGroupAccount</appuserAccount>
<appAdminAccount>domain\AppAdminGroupAccount</appAdminAccount>
<field ordinal="0" label="User Id" masked="no" />
<field ordinal="1" label="Password" masked="yes" />
<flags groupApp="no"  configStoreApp="no" allowTickets="no" validateTickets="yes" allowLoca
lAccounts="no" timeoutTickets="yes" adminAccountSame="no" enableApp="no" />
</application>
</sso>
```

In the case of individual applications for host initiated SSO, the appUserAccount is a group account that contains the list of Windows domain account users that have a one-to-one mapping with their corresponding non-Windows accounts.

The following is an example XML file for host group type host initiated SSO affiliate application:

```
<sso>
<application name="SAP">
<description>The SAP application</description>
<contact>someone@example.com</contact>
<appuserAccount>domain\AppUserAccount</appuserAccount>
<appAdminAccount>domain\AppAdminGroupAccount</appAdminAccount>
<field ordinal="0" label="User Id" masked="no" />
<field ordinal="1" label="Password" masked="yes" />
<flags  configStoreApp="no" allowTickets="no" validateTickets="yes" allowLocalAccounts="no"
timeoutTickets="yes" adminAccountSame="no" enableApp="no" />
</application>
</sso>
```

In group applications for host initiated SSO, the appUserAccount must be an individual user account. It is this account that all non-Windows accounts are mapped to.

Host Initiated Single Sign-On

Managing User Mappings for Host Initiated SSO

Use the following procedures to create mappings, set credentials (whenever the Validate Password feature is enabled for the affiliate application), and enable/disable mapping.

To manage user mappings for host initiated SSO using the MMC Snap-In

1. Click **Start**, point to **Programs**, click **Microsoft Enterprise Single Sign-On**, and then click **SSO Administration**.
2. In the scope pane of the ENTSSO MMC Snap-In, expand the **Enterprise Single Sign-On** node.
3. In the scope pane, click **Affiliate Applications**.
4. In the details pane, right-click the affiliate application, and then select the appropriate menu item for your action.

To create mappings in host initiated SSO using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage –createmappings <mapping file>**, where <*mapping file*> is the name of the XML file.

   The following is a sample mapping file:

```
<SSO>
  <mapping>
    <windowsDomain>DomainName</windowsDomain>
    <windowsUserId>UserA</windowsUserId>
    <externalApplication>SSOApplication</externalApplication>
<externalUserId>ExternalUserID that corresponds to UserA</externalUserId>
  </mapping>
</SSO>
```

To set credentials for individual type affiliate applications using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory. The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -setcredentials <Windows account name> <application name>**.

To set credentials for host group type affiliate applications using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command line, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -setcredentials <external account name> <application name>**.

To enable mappings for individual type affiliate applications using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -enablemapping <Windows account name> <application name>**.

To disable mappings for individual type affiliate applications using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -disablemapping <Windows account name> <application name>**.

To enable mappings for host group type affiliate applications using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -enablemapping <external account name> <application name>**.

To enable mappings for individual type affiliate applications using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -disablemapping <external account name> <application name>**.

Host Initiated Single Sign-On

Troubleshooting Host Initiated SSO

The primary method of troubleshooting host initiated Single Sign-On (SSO) is tracing.

Tracing

Use the Trace command-line utility to enable tracing in SSO.

Note
For the trace command to function, the file tracelog.exe must be in the following directory: \<drive\>:\Program Files\Common Files\Enterprise Single Sign-On. You can download this file from the following location: http://go.microsoft.com/fwlink/?LinkId=33023

To use the trace utility

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **Trace –start –high** to set the tracing level to high and begin the trace.
4. Run the scenario with host initiated SSO.
5. Type **Trace –stop** to end the trace.
6. A .bin file is generated in the directory above, which you can send to Microsoft for analysis.

Host Initiated Single Sign-On

How to Use the ENTSSO Management Agent

This version of Enterprise Single Sign-On (SSO) contains a Management Agent (MA) for Microsoft Identity Integration Server (MIIS), which integrates Enterprise SSO with the account synchronization capabilities of MIIS. This enables an MIIS administrator to manage SSO mappings in the SSO Credential Database.

In Enterprise SSO, mappings are created between Windows Domain accounts (*domainname**username*) and external credentials. If you have an Active Directory Management Agent, and the Management Agent for the external Data Source (example: RACF MA), you can use the Enterprise SSO MA (ENTSSO MA) to manage mappings in the SSO Credential Database. ENTSSO MA is a *Call-Based Export* Management Agent only.

You configure the Management Agent in three separate parts:

- A configuration file (ENTSSO.xml)
- The MIIS user interface
- The ENTSSO user interface

The topics in this section describe the configuration process.

In This Section

How to Configure the XML File

How to Configure MIIS for ENTSSO MA

How to Configure ENTSSO for MIIS Password Sync

See Also

Other Resources

Security User's Guide

How to Configure the XML File

When you install Enterprise Single Sign-On (SSO), an XML file named ENTSSO.xml is installed in your Extensions directory. By editing the file, you define the configuration for all instances of the ENTSSO Management Agent (MA).

The file is similar to the following:

```
<?xml version="1.0" encoding="utf-8"?>
<sso>

  <SourceMA name="RACFMA1" objectType="person" attribute="uid"/>
  <SourceMA name="ACF2" objectType="person" attribute="uid"/>

  <ENTSSOMA name ="ENTSSOMA1" adma="ADMA1" deleteAll="true">
    <Application name="AppForRACF1A" sourceMA="RACFMA1" create="true" delete="true"/>
    <Application name="AppForRACF1B" sourceMA="RACFMA1" create="true" delete="false"/>
  </ENTSSOMA>

  <ENTSSOMA name ="ENTSSOMA2" adma="ADMA1" deleteAll="true">
    <Application name="AppForACF2" sourceMA="ACF2"/>
  </ENTSSOMA>

</sso>
```

XML Elements and Attributes

The following list describes the elements and attributes that you define in the XML file. Note that all element and attribute names in this file are case sensitive.

Element: ENTSSO - Defines the configuration of a single ENTSSO MA instance. Multiple ENTSSO elements are allowed.

Attribute: name - Defines the instance name of the ENTSSO Management Agent, and must match the name of the ENTSSO Management Agent instance in Microsoft Identity Integration Server (MIIS).

Attribute: adma - Defines the instance name of the Active Directory Management Agent that will be used by this ENTSSO Management Agent instance. The Active Directory Management Agent provides the Windows domain name and Windows user name for the mapping. This Active Directory Management Agent instance name must match the name of an Active Directory Management Agent instance in MIIS.

Attribute: deleteAll - Optional; default is **true**. If this is set to **true**, and a Windows identity is deleted, all mappings with that Windows identity are deleted from all ENTSSO applications.

Element: Application - Defines the relationship between an SSO affiliate application and an external Management Agent. Multiple **Application** elements are allowed.

Attribute: name - Defines the name of the SSO affiliate application. This application must already exist within the ENTSSO system.

Attribute: sourceMA - Defines the instance name for the source (external) Management Agent that will be used to provide the external UserId in the mapping for this application. This external Management Agent instance name must match the name of an external MA instance in MIIS.

Attribute: create - Optional; default is **true**. Defines whether mappings should be created for this application.

Attribute: delete - Optional; default is **true**. Defines whether mappings should be deleted for this application.

Element: SourceMA - Optional. Identifies the object type and attribute names for a specific source (external) Management Agent instance. If this element is not present for a specific Management Agent, then the default object type ("person") and attribute names ("uid") are assumed. Multiple **SourceMA** elements are allowed.

Attribute: name - The name of the source (external) Management Agent. This name must match at least one of the **sourceMA** attribute names from the **Application** elements.

Attribute: objectType - Optional; default is **person**. If the object type name that provides the external UserId is not **person**, it should be specified here.

Attribute: attribute - Optional; default is **uid**. If the attribute name that provides the external UserId is not **uid**, you can specify it here.

Security User's Guide

How to Configure MIIS for ENTSSO MA

When you install the Enterprise Single Sign-On (SSO) Administration feature (either the full version or the Admin-only version) on a computer running Microsoft Identity Integration Server (MIIS), the ENTSSO Management Agent is automatically installed. This means that when you open MIIS, nearly all of the configuration has already been done. The only part missing is the connection information.

Before starting this procedure, make sure you have the following information available:

- ENTSSO Server name.
- UserId and password of the Windows account under which the ENTSSO Management Agent will communicate with the SSO Server.

To configure the Management Agent within MIIS

1. Open MIIS, and open the **Identity Manager**.
2. Open the **Create Management Agent** dialog box.
3. Select **Enterprise Single Sign-On** in the list.

   This starts the **Create Management Agent Wizard**.
4. On the **Configure Connection Information** page, in the **Connect To:** field, enter the name of the SSO Server.
5. Enter the name of the ENTSSO Management Agent. This name must match the name specified in your ENTSSO.xml file.
6. In the **User** field, specify the domain account that the ENTSSO Management Agent uses to manage mappings in the SSO Credential Database.

   This account should be either a member of the SSO Affiliate Administrators or SSO Administrators accounts within the SSO System.
7. In the **Password** field, enter the password for that user.
8. Click **Next**, accepting the defaults until you reach the **Configure Extensions** page.
9. Near **Connection information** for password extension, click **Settings**.

   The **Connection Settings** dialog box appears.
10. In the **Connect To** box, enter the appropriate account. This account must be the same as the service account for the ENTSSO service running on the computer specified.
11. In the **User** and **Password** fields, enter the user name and password for the account.
12. Click **OK**.
13. In the **MIIS Create Management Agent**, click **Finish**.
14. While still in the **Identity Manager**, click the **Tools** menu, and then click **Options**.

    The **Options** dialog box appears.
15. Select **Enable metaverse rules extension**.
16. In the **Rules extension name field**, enter **Microsoft.EnterpriseSingleSignOn.ManagementAgent.dll**.
17. Click **OK** and close MIIS.

Example

If you already have a Metaverse rules extension that you want to use, you can copy the following code example and edit it appropriately.

```
// <copyright file="MVWrapper.cs" company="Microsoft">
// Microsoft Enterprise Single Sign-On
```

```
// Copyright (c) Microsoft Corporation.  All rights reserved.
// </copyright>

using System;
using System.Collections.Generic;
using System.Text;
using Microsoft.EnterpriseSingleSignOn.ManagementAgent;
using Microsoft.MetadirectoryServices;
using System.Diagnostics;

// This sample code illustrates how to call the Enterprise
// Single Sign-On (ENTSSO) MV rules
// extension from your own MV rules extension.
// A reference is required to
// Microsoft.EnterpriseSingleSignOn.ManagementAgent.dll.

namespace MVWrapper
{
    public class MVWrapper : IMVSynchronization
    {
        MVSync mvSync = null;

        public void Initialize()
        {
            Debug.WriteLine("IMVSynchronization.Initialize");

            mvSync = new MVSync();

            mvSync.Initialize();
        }

        public void Provision(MVEntry mventry)
        {
            Debug.WriteLine("IMVSynchronization.Provision");

            mvSync.Provision(mventry);
        }

        public bool ShouldDeleteFromMV(CSEntry csentry, MVEntry mventry)
        {
            Debug.WriteLine("IMVSynchronization.ShouldDeleteFromMV");

            return mvSync.ShouldDeleteFromMV(csentry, mventry);
        }

        public void Terminate()
        {
            Debug.WriteLine("IMVSynchronization.Terminate");

            mvSync.Terminate();

            mvSync = null;
        }
    }
}
```

How to Use the ENTSSO Management Agent

How to Configure ENTSSO for MIIS Password Sync

After configuring the XML file and Microsoft Identity Integration Server (MIIS), the remaining configuration steps take place in the Enterprise Single Sign-On (ENTSSO) system.

To allow Password Sync from MIIS

1. In Enterprise Single Sign-On, click the **Servers** node.
2. Right-click the appropriate server, and click **Properties**.
3. Click the **Password Sync** tab.
4. Select **Allow password sync from MIIS**.
5. Click **OK**.

To enable Password Sync on the system level

1. In Enterprise Single Sign-On, right-click the **System** node.
2. Click **Properties**.

   The **Properties** dialog box appears.
3. Click the **Options** tab.
4. In the **Enable Password Sync** field, select **From Windows to Adapters**.

Additional Configuration

Finally, you must configure one of the following:

- A Password Sync Adapter that accepts Windows Password Sync.
- Direct Password Sync enabled on at least one application.

For information about how to do this, refer to your Password Sync documentation.

To configure the EntSSO MA for MIIS Password Sync

1. On the ENTSSO Management Agent **Properties** page, click **Configure Extensions**.
2. In the **Connection information for password extension** field, click **Settings**.
3. In the **Connect To** field enter the name of the computer that will receive the password changes.

   The computer name must be in the same format that was used when creating the Service Principal Name (SPN) for the ENTSSO service on the domain.

   For example:

   Short format - SPN = ENTSSO/ABCD1411, then enter ABCD1411

   Long format - SPN = ENTSSO/ABCD1411.CompanyName.com then enter ABCD1411.CompanyName.com

Additional Configuration Steps

1. Click **Start**, point to **All Programs**, point to **Microsoft Identity Integration Server**, and then click **Identity Manager**.
2. On the **Tools** menu, click **Options**.
3. Select **Enable Password Synchronization**.
4. In the **Management Agents view**, select **ADMA**.
5. In the **Action** pane, select **Properties**.
6. On the **Properties** page, select **Configure Directory Partitions**, and then select **Enable this partition as a password synchronization source**.

7. Click **Targets**, and then select ENTSSOMA2 to enable it to receive password changes from MIIS. Deselect ENTSSOMA. Click **OK**, and then click **OK** again.
8. In the **Management Agent** view, select **ENTSSOMA2**. In the right-hand pane, select **Properties**. On the **Properties** page, click **Configure Extensions**.
9. Confirm that **Enable password management** is selected, and then click **Settings**.
10. In the **Connection Settings** dialog, specify the following:
    - Connect To: INTSVR1.fabrikam.com
    - User: fabrikam\ssosvcact
    - Password: ssosvcact

Note
This account should match the ENTSSO service account configured on INTSVR1.fabrikam.com.

11. Click **OK**, and then click **OK** again.
12. You can also disable password sync for MIIS. To do this, in **Identity Manager**, click the **Tools** menu, click **Options**, and then deselect **Enable Password Synchronization**.

    The following restrictions will apply:

    - For Password Sync to function properly, SPN must be configured on the ENTSSO service account that the ENTSSO Management Agent will communicate with.
    - Communication between MIIS and the ENTSSO server requires Kerberos.
    - When configuring Password Extension in the MIIS connection configuration for the ENTSSO Management Agent, the account specified must match the service account for the ENTSSO server that will receive passwords from MIIS.

How to Use the ENTSSO Management Agent

How to Use the Servers Snap-In

This version of Enterprise Single Sign-On (SSO) includes the ENTSSO Servers Snap-In, which allows you to view, monitor, and perform certain actions on your ENTSSO Server through the Windows interface.

Note
If your system has a firewall and your server name uses the FQDN format, you may not be able to contact the server. Instead, you must specify the NetBIOS name or the associated IP address.

To use the ENTSSO Servers Snap-In

1. Open Enterprise Single Sign-On.
2. In the Scope pane, click the **Servers** node.

   The following information is displayed in the Results pane.

   - **Name**: Name specified.
   - **Status**: Status of the ENTSSO service (Online, Offline, Pending, Started, Stopped, Start Pending, Stop Pending).
   - **Date**: Date when information was obtained.
   - **Time**: Time when information was obtained.
   - **SSO Server**: Fully qualified name of server.
   - **Service Account**: ENTSSO service account.
   - **SSO Database**: ENTSSO Credential Database with which this server is communicating.
   - **Secret Server**: Indicates whether the Secret Server module is running.
   - **Password Sync**: Indicates whether Password Sync is installed.
   - **Computer**: NETBIOS name of computer.
   - **Event counts**: Info/Warning/Errors event count. Resetting this will start the counter from 0.
   - **Version of SSO installed**: Version number of ENTSSO.exe. Also indicates whether this is 32-bit (x86) or 64-bit (x64).

To start or stop the server service

- In the ENTSSO Servers Snap-In, right-click the server and click **Start** or **Stop**.

To display information for one server

- In the Server tree, click the server.

  The information is displayed in the results pane.

To add a server

- Right-click in the Scope pane, and then click **Add Server**.

  The **Add Server** dialog box appears. Type or browse to the server you want to add.

  In certain Workgroup environments, clicking the **Browse** button will cause this dialog box to close. Instead of using the **Browse** button, simply type the server name in the box.

To view or change server properties

- In the Server tree, right-click the server, and click **Properties**.

  The **Server Properties** dialog box appears. You can view or change information in the following tabs:

  - **Audit Levels**
  - **SSO Database**
  - **SSO Service**
  - **Password Sync**
  - **Advanced**

Security User's Guide

How to Use Direct Password Sync

This version of Enterprise Single Sign-On includes the Direct Password Sync from Windows feature. This enables you to bypass a Password Sync Adapter and update the password in the ENTSSO Credential Database directly from Windows.

Direct Password Sync from Windows is useful in the following situations:

- Your enterprise system requires Windows to Windows mapping.
- You need to update the External User's password in the Credential Database directly when a password change occurs for the Windows user. You can change the password on the back-end system (that corresponds to the external user) by using other mechanisms. For example, you can use Microsoft Identity Integration Server to update passwords in Resource Access Control Facility (RACF) on an IBM Mainframe using the RACF Management Agent.

To enable Direct Password Sync

1. Open Enterprise Single Sign-On.
2. In the scope pane, click **Affiliate Applications**.
3. Right-click the appropriate **Affiliate Application**.
4. Click **Properties**.

   The **Affiliate Applications Properties** dialog box appears.
5. Click the **Options** tab.
6. Select the **Direct Password Sync from Windows** check box.
7. Click **OK**.

How to Use the Mapping Wizard

This version of Enterprise Single Sign-On includes the Mapping Wizard, which allows you to easily create mappings for affiliate applications.

Note
You can only use the Mapping Wizard if the External UserID is based on the Windows domain account.

To start the Mapping Wizard

1. Open Enterprise Single Sign-On.
2. In the scope pane, click **Affiliate Applications**.
3. Right click the appropriate affiliate application.
4. Click **Create Mappings**.

   The Mapping Wizard appears.

To use the Mapping Wizard

1. **Welcome to the Mapping Wizard**
   - Verify that this is the correct affiliate application, and click **Next**.
2. **Mappings File Option** page
   - ENTSSO manages mappings through an XML file. You can choose to create a new file or use an existing one.
3. **Files Location** page
   - Select the files to be used.
   - You must click **Validate** to validate the files before proceeding. The validation status appears in the **Status** window.
4. **Accounts** page
   - Choose one or more accounts to generate the new mappings file, and click **Validate**.
5. **External User Name** page
   - Define how the external user name is generated from the Windows user account. As you make selections in the boxes, you can see how the names will appear in the **Example** box.
6. **Generate** page
   - Click **Start** to generate the mappings file. (You will have an opportunity on the next page to view or edit the file as necessary before mappings are created.) Results are displayed in the three windows below.
   - The **Number** of mappings in selected accounts is an approximation, because accounts may be nested in other accounts.
   - Click **View Log File** to examine any errors or warnings that might have occurred.
7. **Options** page

- Your file has been created. Click **View/Edit Mappings File** if desired.
- Click **Enable mappings** if you want the mappings to be automatically enabled. (If you do not click this, you will have to enable them manually.)
- Click **Set Password** to automatically set the password for these mappings.

8. **Create** page
   - Before creating the mappings, click **View Mappings File** if desired.
   - When you are ready, click **Start** to perform the mapping operation. Your status is displayed in the three boxes below.
   - Click **View Log File** to examine any errors or warnings that might have occurred.

9. **Completing the Mapping Wizard screen**
   - Select any options desired, and then click **Finish**.

Using Enterprise Single Sign-On

How to Use Password Filters

The ENTSSO Password Synchronization feature synchronizes passwords between Microsoft Windows Active Directory and non-Windows systems. However, many external systems have password policy requirements which differ from those in Active Directory. (For example, an IBM system may require a password to be upper case and limited to 8 characters.) This forces ENTSSO to use the "lowest common denominator" between the two systems, limiting password security.

The ENTSSO Password Filter feature addresses this limitation. A Password Filter is merely a Password Sync Adapter with additional properties defined. These additional properties (such as maximum or minimum length, case, and character restrictions) serve to filter the passwords so that they meet the criteria of the external system.

Note that when you create a Password Filter, the Administrator group specified is automatically used as the SSO Administrators account. If you change the SSO Administrator group, you will need to make sure the Password Filter is also updated with the new SSO Administrators account.

Note
As with all elements of the ENTSSO system, Password Filters contain highly sensitive information and should be exposed to t he minimum number of people possible.

To Create a Password Filter

1. In the **SSO Management Console**, right-click the **Password Management** node, and then click **Create Filter**.

   The **Password Filter Wizard** appears.

2. Follow the directions on the Wizard to create the Password Filter.

To Assign an Affiliate Application to a Password Filter

1. Right-click the appropriate filter, and then click **Assign**....
2. Select the appropriate **Affiliate Application**.

Secure Deployment of Enterprise Single Sign-On

This section outlines a typical scenario for secure deployment of Enterprise Single Sign-On (SSO). For detailed procedures on the actions to take in SQL Server, see your SQL Server documentation.

In This Section

Deployment Overview

The system in this example is deployed over three domains, and contains the following computers:

Domain ORCH.com

- ORCH domain controller
- HIS1, the HISSO server
- HIS2, the master secret server
- HIS3, the Admin database

Domain SQL.com

- SQL domain controller
- SQL2, the SSO database

Domain HIS.com

- HIS domain controller
- HIS4 database

The key points defining this deployment are as follows:

- Domain ORCH.com and domain SQL.com have a two-way selective trust relationship.
- Domain ORCH.com is configured as native Windows Server 2003 server functional level.
- All SSO services are running on an ORCH.com domain user account (Orch\SSOSvcUser). The user is configured to have access permission on the SQL2 machine in the SQL.com domain. The user is configured for protocol transition and constrain delegation within the ORCH.com domain.
- Another ORCH.com domain user (Orch\TestAppUser) is set for running test programs. This user is also configured for protocol transition and constrain delegation.

For a description of the deployment process, see Deployment Process

Secure Deployment of Enterprise Single Sign-On

Deployment Process

The following steps give a high-level overview of secure deployment of Enterprise Single Sign-On (SSO). For detailed procedures on the actions to take in SQL Server, see the SQL Server documentation.

1. On the SQL Server domain controller, use the **New Trust Wizard** to create a trust with the following properties:

    - **Name:** ORCH.com
    - **Direction:** Two-way
    - **Sides:** This domain only
    - **Outgoing Trust Authentication Level - Local Domain:** Selective authentication
    - **Password:** Choose a password
    - **Confirm Outgoing Trust:** Yes
    - **Confirm Incoming Trust:** No

2. On the ORCH.com domain controller, use the **New Trust Wizard** to create a trust with the following properties:

    - **Name:** SQL.com
    - **Direction:** Two-way
    - **Sides:** This domain only
    - **Outgoing Trust Authentication Level - Local Domain:** Selective authentication
    - **Password:** Must be the same as password for ORCH.com
    - **Confirm Outgoing Trust:** Yes
    - **Confirm Incoming Trust:** No

3. On the ORCH.com domain controller, set the domain-wide trust for Incoming from SQL.COM.
4. On the SQL.com domain controller, set the domain-wide trust for Outgoing from ORCH.COM.
5. On the ORCH.com domain controller, raise the domain functional level to Windows Server 2003.
6. In the ORCH domain, create the following new users:

    - ORCH\SSOSvcUser
    - ORCH\TestAppUser
    - ORCH\AffAppUser

7. Add **Act as part of the operating system** to SSOSvcUser and TestAppUser.

8. Add **Allowed to Authenticate** privilege to ORCH\TestAdmin.

9. Add ORCH\SSOSvcUser to SQL2 in the SQL domain. This step requires using Advanced View in Active Directory Microsoft Management Console (MMC).

10. On the SQL2 computer, create the following two new logons:

    - ORCH\TestAdmin
    - ORCH\SSOSvcUser

11. On the SQL2 domain, create two domain global groups:

    - ORCH\SSOAdminGroup
    - ORCH\SSOAffAdminGroup

12. Add **Allowed to Authenticate** privilege to the ORCH\SSOAdminGroup group.

13. On the SQL2 database, create the following new logon:

    - ORCH\SSOAdminGroup

14. Install the master secret server as follows:

    - Log onto NTS5 using ORCH\TestAdmin.
    - Install Enterprise SSO, using SQL2 as the master secret server.

15. Log on to HIS1 using ORCH\TestAdmin, and install Enterprise Single Sign-On. Configure ESSO as SSO join HIS2, using database server name SQL2.

16. Install the Enterprise Single Sign-On Admin utility on HIS3 using ORCH\TestAdmin.

17. Add the following users to the following groups:

    - Add ORCH\TestAppUser to ORCH\SSOAdminGroup
    - Add ORCH\AffAppUser to ORCH\TestAffUserGroup

18. Install SQL Server 2000a Enterprise on HIS3, and add logon ORCH\AffAppUser.

19. On the HIS1 machine, open a command prompt and use the following commands to set constrain delegation and protocol transition:

    - **setspn -A MSSQLSvc/HIS3.ORCH.com:1433 ORCH\SSOSvcUser**
    - **setspn -A MSSQLSvc/HIS3.ORCH.com:1433 ORCH\TestAppUser**

20. On the **ORCH\SSOSvcUser** and **ORCH\TestAppUser** property pages, set the proper delegation for both user accounts by selecting the following options:

    - **Trust this user for delegation to specified services only**
    - **Use any authentication protocol**

21. Using ORCH\TestAdmin on the HIS1 computer, perform the following:

    - Add ORCH\TestAppUser to Remote Desktop User Group.
    - Grant **Impersonate after authenticated** privilege to ORCH\SSOSvcUser.
    - Grant **Impersonate after authenticated** privilege to ORCH\TestAppUser.

22. Verify your deployment by logging on to HIS1 using ORCH\TestAppUser and running the following application configuration:

    Run LogonExternalUser Test.

```
<SSO>
   <application name="TestApp">
      <description>An SSO Test Affiliate Application</description>
      <contact>AffAppUser@ESSOV2.EBiz.Com</contact>
      <appUserAccount>ORCH\TestAffAdminGroup</appUserAccount>
      <appAdminAccount>ORCH\TestAffUserGroup</appAdminAccount>
      <field ordinal="0" label="User ID" masked="no" />
      <field ordinal="1" label="Password" masked="yes" />
      <flags
         groupApp="no"
         configStoreApp="no"
         allowTickets="no"
         validateTickets="yes"
         allowLocalGroups="yes"
         ticketTimeout="yes"
         adminGroupSame="no"
         enableApp="yes"
         hostInitiatedSSO="yes"
         validatePassword="yes"/>
   </application>
</SSO>
```

Deployment Overview

Password Synchronization

The purpose of Password Synchronization is to simplify administration of the Single Sign-On (SSO) credential database, and to keep passwords in sync across user directories. You can accomplish these two tasks by using password synchronization adapters. The topics in this section describe the command-line utility for creating and managing those adapters.

There are three types of password synchronization sub-features.

The first type is **Windows to External** (for example, Active Directory to RACF). In this scenario, a Windows user's password change is captured and sent to the Enterprise SSO server that is assigned to receive password changes from domain controllers. This server then forwards the password change to an external system, and the mapping in the SSO credential database is kept in sync with the change made on the external system.

The second type is **External to Windows - Full synchronization**. In this scenario, a password is captured on the External system and sent to the Enterprise Single Sign-On server that is assigned for Password Synchronization. It then updates the password in the SSO credential database, and also updates the Windows user's password in Active Directory.

The third type is **External to Windows - Partial synchronization**. In this scenario, a password is captured on the External system and sent to the Enterprise Single Sign-On server that is assigned for Password Synchronization. It then updates the password in the SSO credential database.

In This Section

Installing Password Synchronization

As with the other Single Sign-On (SSO) features, Password Synchronization is not installed in the default Host Integration Server installation, and must be specifically selected during Setup.

To install Password Synchronization

1. Run the Host Integration Server Setup program, and select **Custom Installation**.
2. Under the **Security Integration** feature, select the **Enterprise Single Sign-On Password Synchronization** sub feature.
3. Complete the installation.

You also need Password Synchronization adapters to send and receive password changes to the external system. Other topics in this section describe how to configure your own adapters. For more information, see Administering Password Synchronization. You can also view a list of currently available adapters at the following location: http://go.microsoft.com/fwlink/?LinkId=68145. You can contact support aliases to obtain information about these Password Synchronization adapters.

Finally, to capture password changes made in Active Directory, in addition to installing the ENTSSO Password Sync feature, you must install components on the domain controllers to capture password changes. Both the Windows Password Capture component and Password Change Notification Service (PCNS) must be installed on all domain controllers from which you will be capturing passwords. You can find these components in the following location:

http://www.microsoft.com/downloads/details.aspx?FamilyID=C0964F2E-FA9F-4FC7-AC13-C43928EFEE9D&displaylang=en

Read the accompanying documentation before you proceed with the installation on the domain controller.

Password Synchronization

Administering Password Synchronization

You can administer Password Synchronization in Enterprise Single Sign-On (SSO) through either the Microsoft Management Console (MMC) Snap-In or the command line. This topic describes how to perform various administration tasks with adapters.

The MMC Snap-In displays a list of adapters and their properties. You can right-click an adapter and use the menu to perform the following commands:

- Create adapters
- Set properties
- Update
- Delete
- Enable
- Disable
- Add applications to an adapter
- Delete applications from an adapter
- Reset notification
- Add an adapter to an adapter group
- Delete an adapter from an adapter group

You can also use the SSOPS command-line utility to administer your password synchronization. Most of the commands in this section are intended for use by an administrator only.

For many commands, the command output is displayed on the screen in two columns. Because certain screen settings could cause truncation of data, for best results you should change the screen buffer size/Windows size to 120 characters.

The following table lists the SSOPS commands. Procedures and additional explanation are located throughout the rest of this topic.

Command	**Function**
-list	Lists existing adapters.
-display	Displays adapter information.
-create	Creates new adapters.
-setprops	Sets properties for adapter.
-update	Updates existing adapters.
-delete	Deletes an existing adapter.
-enable	Enables adapter.
-disable	Disables adapter.

-addapp	Adds application for adapter.
-deleteapp	Deletes application for adapter.
-reset	Resets notification or damping queues.
-addtogroup	Adds adapter to adapter group.
-deletefromgroup	Deletes adapter from adapter group.

To list existing adapters

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -list** and press ENTER.

   Adapters and descriptions are listed. (E) denotes that the adapter is enabled, (D) denotes that it is disabled.

To display adapter information

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -display <adapter name>** and press ENTER.

   The screen output displays information for the specified adapter.

   In addition to name, type, description, computer, and accounts, the following information is displayed.

Adapter Flag	**Details**
Adapter enabled	Determines whether the adapter is enabled. Flag: SSO_FLAG_ENABLED Attribute Name: enableApp Default: No
Allow local accounts	Determines whether the App Admin or App Users accounts can be local accounts. Flag: SSO_FLAG_APP_ALLOW_LOCAL Attribute Name: allowLocalAccounts Default: No
Receive password changes from adapter	Determines whether the adapter is allowed to receive external password changes. Flag: SSO_FLAG_PARTIAL_SYNC_FROM_EXTERNAL_TO_DB Attribute Name: syncFromAdapter Default: No

Verify old password	Determines whether the adapter will verify the old password when an external password change is received. If this flag is set, when an external password change is received, the external adapter must supply the old external password in addition to the new external password. The old external password is then compared with the existing external password in the SSO database for that external account. If they match, the password change is accepted. If they do not match, the password change is rejected. Flag: SSO_FLAG_SYNC_VERIFY_EXTERNAL_CREDS Attribute Name: verifyOldPassword Default: Yes
Change Windows password	Determines whether the Windows password will also be changed when an external password change is received (full sync). ENTSSO always uses the old Windows password stored in the SSO database to change the Windows password to the new value (Windows requires both the old and new password to change a user's password). Therefore, this must be initialized before the Windows password change can succeed. If password sync is configured for a particular mapping, when the external credentials are set via administrative tools (ssomanage or ssoclient -setcredentials), the Windows password that is stored in the SSO database is also set. Flag: SSO_FLAG_FULL_SYNC_FROM_EXTERNAL_TO_WINDOWS Attribute Name: changeWindowsPassword Default: No
Send Windows password changes to adapter	Determines whether Windows password changes are sent to the external adapter. Flag: SSO_FLAG_FULL_SYNC_FROM_WINDOWS_TO_EXTERNAL Attribute Name: syncToAdapter Default: No
Send old password to adapter	If Yes, the old password value (from the SSO database) is also sent to the external adapter in addition to the new password value. Some external systems might require both the old and new password values to change the password. Flag: SSO_FLAG_SYNC_PROVIDE_OLD_EXTERNAL_CREDS Attribute Name: sendOldPassword Default: No
Allow mapping conflicts	Determines whether the adapter will allow mapping conflicts. A mapping conflict occurs when mappings are not unique. In a single SSO Individual application, mappings are always one-to-one: one Windows account is mapped to exactly one external account and vice versa. However, it is possible to assign more than one application to an adapter. Thus, it is possible to have a mapping in one application that conflicts with a mapping in the other. The purpose of this flag is to prevent this from occurring. It is more secure to not allow mapping conflicts unless there is a specific, well understood requirement for this behavior. Flag: SSO_FLAG_SYNC_ALLOW_MAPPING_CONFLICTS Attribute Name: allowMappingConflicts Default: No

Adapter Description	**Details**
Notification retry count	Default is 1.
Notification retry delay (in mins)	Default is 5.

Maximum pending notifications	Default is 8.
Store notifications (when offline)	True/False.
Server name	Server name.
Port number	Port number.
Applications for this adapter	List of applications currently assigned to the adapter.

To create new adapters

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -create <adapter file>** and press ENTER.

   The screen output displays information for the newly created adapter.

To set properties for an adapter

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -setprops <adapter name>** and press ENTER.

   The screen output displays the properties for the specified adapter. You can edit them if necessary, but new values are not validated.

To update existing adapters

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -update <adapter file>** and press ENTER.

   Use this command to update the settings and flags for a specified adapter. Do not use this command to set properties; use the **-setprops** command instead.

To delete an existing adapter

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -delete <adapter name>** and press ENTER.

   The specified adapter is deleted.

To enable an adapter

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.

3. Type **ssops -enable <adapter name>** and press ENTER.

   The specified adapter is enabled.

To disable an adapter

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -disable <adapter name>** and press ENTER.

   The specified adapter is disabled.

To add an application to an adapter

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command line, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -addapp <adapter name> <application name>** and press ENTER.

   The specified SSO application is assigned to the specified adapter. This means that the passwords for the mappings in that application are now synchronized using this adapter.

   Although multiple applications can be assigned to one adapter, any given application can only be assigned to one adapter.

To delete an application from an adapter

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -deleteapp <application name>** and press ENTER.

   The specified SSO application is removed from an adapter. (Because an application can only be assigned to one adapter, you do not have to specify the adapter name.)

To reset notification

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -reset <adapter name | all | damping>** and press ENTER.

   This command clears the damping table and/or notification queues for a single adapter or all adapters, as specified. The damping table stores a 10-minute history of password changes. Before the Enterprise SSO system accepts or sends a password change, it checks the damping table to see whether it has performed the same change recently. If it has, the new change is discarded.

To add an adapter to an adapter group

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -addtogroup <adapter name> <adapter group>** and press ENTER.

   This command adds the specified adapter to the specified adapter group. Although an adapter can belong to only one adapter group, an adapter group can contain multiple adapters.

To delete an adapter from an adapter group

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssops -deletefromgroup <adapter name> <adapter group>** and press ENTER.

   This command deletes the specified adapter from the specified adapter group.

Password Synchronization

Configuring Password Synchronization

Use the SSOCONFIG command-line utility to configure your password synchronization settings. You can use this tool to specify directories for replay files and also change maximum password synchronization age.

To specify the directory for replay files

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoconfig -replayfiles <replay files directory> | -default** and press ENTER.

Note Replay files are not deleted when you change the service account. If you change this account, you must delete the replay files manually.

To display or change maximum password synchronization age

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssoconfig -syncage <maximum password age in hours>** and press ENTER.

Note
The SSOCONFIG utility uses the time on the computer that is running SQL Server as its system time. Remember this when you are using any commands related to time.

Password Synchronization

Managing Password Synchronization

Use the SSOMANAGE command-line utility to enable or disable Single Sign-On (SSO) features, and to display current SSO database settings.

To manage features or display settings using the MMC Snap-In

1. Right-click the appropriate feature or database.
2. Click the appropriate command.

To enable SSO features using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -enable** and press ENTER.

To disable SSO features using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -disable** and press ENTER.

To display current database settings using the command line

1. Click **Start**, click **Run**, type **cmd**, and then click **OK**.
2. At the command prompt, go to the Enterprise Single Sign-On installation directory.

   The default is <drive>:\Program Files\Common Files\Enterprise Single Sign-On.
3. Type **ssomanage -displaydb** and press ENTER.

Password Synchronization

SSO Security Recommendations

This section contains recommendations for how to help secure your Enterprise Single Sign-On (SSO) system.

With the Enterprise Single Sign-On (SSO) system, users can connect to different systems by using only one set of credentials. Host Integration Server uses the SSO system as a store for sensitive information. Although it automatically installs whenever you install the Host Integration Server runtime, you can also install Enterprise Single Sign-On as a stand-alone component, independent of your Host Integration Server environment. It is recommended you follow these guidelines for securing and deploying the Enterprise SSO services and resources in your environment.

General Deployment Recommendations for SSO

- You must have a time server in your environment to ensure all SSO servers are synchronized. If the clocks on the SSO servers are not synchronized, this could compromise the security of your environment.

- Considering there is only one master secret server in your entire environment, it is recommended that you use an active-passive cluster configuration for the master secret server. For more information about clustering the master secret server, see How to Cluster the Master Secret Server.

- The master secret server holds the encryption key the SSO system uses to encrypt the information in the SSO database. It is recommended that you do not install or configure any other products or services on this computer.

Note
The computer where you install and configure the master secret server does not have to be a server.

- The master secret server should have access to a removable media or NTFS file system folder in order to back up and restore the master secret. If you use removable media, ensure that you take appropriate measures to protect the removable media. If you back up the master secret to an NTFS file system, ensure that you protect the file and the folder. Only the SSO Administrator should have access to this file.

- You should back up the master secret as soon as the master secret server generates it. This is so that you can recover the data in the SSO database in the event the master secret server fails. For more information about backing up the master secret, see Managing the Master Secret.

- Back up your current secret, or generate a new secret regularly, for example, once a month. Without the secret, you cannot retrieve information from the SSO database. For more information about backing up and restoring the master secret, see Managing the Master Secret.

Security Recommendations for SSO Groups and Accounts

- It is recommended that you use Windows groups, and not single user accounts, especially for the SSO Administrator and SSO Affiliate Administrator groups. These groups must have at least two user accounts as members of the group at all times.

- The SSO runtime service accounts and the SSO administrator user accounts should be different accounts, even when they are members of the same SSO Administrators group. The SSO Administrator users who perform administrative tasks such as generating and backing up the secret must be Windows administrators, whereas the SSO runtime service accounts do not need to be Windows administrators.

Security Note
Windows administrator user rights do not supersede the user rights of the SSO administrator. To perform any SSO ad ministration-level task, you must be a member of SSO Administrators group even if you already are a Windows admini strator.

- If you use the SSO ticketing feature, you must use domain accounts that the computers in the processing domain (domain where the SSO servers are) recognize.

- It is recommended that you use a unique service account for the SSO service corresponding to the master secret server.

- The SSO Administrator account is a highly privileged account in the SSO system, which is also the SQL Server administrator account for the SQL server that has the SSO database. You should have dedicated accounts for SSO administrators, and should not use these accounts for any other purposes. You should limit the membership to the SSO Administrators group only to those accounts responsible for running and maintaining the SSO system.

Security Recommendations for an SSO Deployment

- If your network supports Kerberos authentication, you should register all SSO servers. When you use Kerberos authentication between the master secret server and the SSO database, you must configure Service Principal Names (SPN) on the SQL server where the SSO database is located. For more information about configuring Service Principal Names, see the Microsoft Download Web site at http://go.microsoft.com/fwlink/?LinkId=20797.

- When you are running Windows Server 2003, if the master secret server is on a different domain from the other SSO servers and from the SSO database, you must disable RPC security (as used for Data Transaction Coordinator (DTC) authentication between computers) on the master secret server, on the SSO servers (processing computers in the processing domain), and on the SSO database. RPC security is a new DTC feature in Windows Server 2003. When you disable RPC security, the DTC authentication security level for RPC calls goes back to one available in Microsoft Windows 2000 Server. For more information about disabling RPC security, see the Microsoft Help and Support Web site at http://go.microsoft.com/fwlink/?LinkId=24774.

- SSO administrators should regularly monitor the event log in the master secret server and the SSO server for SSO auditing events.

- In addition to firewalls, it is recommended that you use Internet Protocol security (IPsec) or Secure Sockets Layer (SSL) between all the SSO servers and the SSO database. For more information about SSL, see the Microsoft Help and Support Web site at http://go.microsoft.com/fwlink/?LinkId=16731.

Perimeter Network

When running Internet Information Services (IIS) and Enterprise Single Sign-On, follow these recommendations:

- If IIS is in a perimeter network (also known as demilitarized zone, DMZ, and screened subnet), provide another server running IIS behind the firewall to connect to the SSO system.

- Do not open the remote procedure calls (RPC) port on IIS.

SQL Server Access

All SSO servers access the SQL Server Credential database. For more information about how to help secure SQL Server databases, see http://go.microsoft.com/fwlink/?LinkId=33175.

It is recommended that you use Secure Sockets Layer (SSL) and/or Internet Protocol security (IPsec) to help secure the transmission of data between the SSO servers and the Credential database. For more information about using SSL, see http://go.microsoft.com/fwlink/?LinkId=33176.

To enable SSL for only the connection between the SSO server and the Credential database, you can set SSL support on every SSO server using the ssoconfig utility. This option enables SSO to always use SSL when accessing the Credential database. For more information, see How to Enable SSL for Enterprise Single Sign-On.

Strong Passwords

It is very important that you use strong passwords for all accounts, especially the accounts that are members of the SSO Administrators group, because these users have control over the entire SSO system.

SSO Administrator Accounts

It is recommended that you use different service accounts for the SSO services running on different computers. You should not use the SSO administrator account that performs administration operations such as generating and backing up the secret for

the SSO service. Although the SSO service accounts should not be local administrators on that computer, the SSO administrator who is performing administration operations must be a local administrator on the computer for some operations.

Master Secret Server

It is highly recommended that you secure and lock down the master secret server. You should not use this server as a processing server. The only purpose of this server should be to hold the master secret. You should ensure the physical security of this computer and only SSO Administrators should have access to this computer.

Kerberos

SSO supports Kerberos, and it is recommended that you set up Kerberos for SSO. To set up Kerberos with SSO, you must register a Secure Principal Name (SPN) for the SSO service. By default, when you set up Kerberos, SSO uses that SPN to authenticate the components using the SSO Service. It is recommended you set up Kerberos authentication between the SSO administrative sub services and the SSO server. You can also user Kerberos authentication between the SSO servers and between the SSO servers and the SQL Server where the Credential database is.

To set up and verify Kerberos, you use the utilities **setspn** and **kerbtray**. For more information about these utilities, see http://go.microsoft.com/fwlink/?LinkId=33178 and http://go.microsoft.com/fwlink/?LinkId=33179.

Delegation

When you are using Windows Server 2003, you can use constrained delegation, but it is recommended that you do not use delegation to perform the tasks of the Single Sign-On administrator. Similarly, it is recommended that you do not delegate additional tasks or user rights to the Single Sign-On administrator.

Auditing

Auditing is a critical mechanism for tracking information in your environment. Enterprise Single Sign-On (SSO) audits all operations performed in the Credential database. SSO uses event logs and audit logs of the database itself. SSO provides two audit levels for the Single Sign-On servers:

- Positive auditing levels audit successful operations.
- Negative auditing levels audit operations that fail.

SSO administrators can set the positive and negative audit levels that suit their corporate policies.

You can set positive and negative audits to one of the following levels:

- 0 = None - This level issues no audit messages.
- 1 = Low
- 2 = Medium
- 3 = High - This level issues as many audit messages as possible.

The default value for positive auditing is 0 (none), and the default value for negative auditing is 1(low). You may want to change these values depending on the level of auditing you want for your SSO system.

Important
Enterprise Single Sign-On auditing issues messages that are generated by the Single Sign-On service. This is not a security a udit, and the SSO system does not save the information in the Security log of the Event Log. The SSO system saves the SSO a udit messages directly to the Application Event Log.

Database-Level Auditing

For database-level auditing, the SSO system tracks the operations performed on the Credential database in the audit tables in the database. The size of these audit tables are defined at the SSO system level. You can audit for affiliate applications that are deleted, for mappings that are deleted, and for credential look-ups that are performed. By default, the audit size is set to 1000 entries. SSO administrators can change this size to meet their corporate policies.

Using Enterprise Single Sign-On Accounts

This section contains best practices when you are using domain and local groups and individual accounts in the Enterprise Single Sign-On (SSO) system.

Domain Windows Groups and Accounts

When you are working with domain Windows groups, the following recommendations apply:

- Use domain groups and domain accounts.
- Use a domain group for SSO administrators. You should not specify an individual domain account as the SSO administrator, because you cannot change this account from one individual account to another individual account.
- Although you can specify an individual domain account as the SSO affiliate administrator, you should use a domain group.
- Although you can specify an individual domain account as the application administrator, you should use a domain group.
- You must use domain groups for the application users account. The SSO applications users account does not support an individual account.

Transaction Integrator User's Guide

This section contains information about using Transaction Integrator (TI). Transaction Integrator is the synchronous COM+ or .NET Framework application integration solution in Host Integration Server. TI enables you to integrate mainframe-based transaction programs (TP) and AS/400 transactions with component-based Windows Server System applications when the following conditions are true:

- A synchronous or transactional solution is needed.
- Both the client and server systems are running at the time the call is made.

If you need an application integration solution that does not require the client and server systems to be running at the time the call is made, use an asynchronous messaging solution such as the MSMQ-MQSeries Bridge instead of TI. In an asynchronous solution, the middle-tier queuing system is running at the time the client issues a request message, the server retrieves the message and sends back the reply, and then the client receives the reply back from the middle tier.

With TI, you can integrate existing mainframe-based TPs with Windows-based COM, distributed COM (DCOM), or applications built on the .NET Framework. You might not even have to modify your TP if you have separated the business logic from the presentation logic. The wizards in TI guide you through the modification process, step by step.

With TI, you can preserve existing CICS and IMS TPs as you move to a three-tier client/server or Web-to-host computing environment. By using TI to invoke mainframe transactions, you can program in the visual object-oriented environments and programming languages that you know while you maintain access to host transactions.

TI supports both SNA connectivity and TCP/IP connectivity without requiring a host footprint or costly host transaction rewrites. You can choose SNA connectivity if you need two-phase commit (2PC), or choose TCP/IP connectivity if you need direct throughput. IBM has not implemented 2PC for the TCP/IP protocol, but for those cases where 2PC is not necessary, TCP/IP can give you direct connectivity.

True integration of online transaction processing (OLTP) with COM- or .NET-compliant systems means the integration of CICS and IMS with Windows-based solutions. CICS and IMS are widely used in the mainframe arena to create distributed OLTP solutions such as customer tracking and order entry. TI integrates CICS and IMS with COM by creating COM interfaces or .NET interfaces to the CICS and IMS transactions and then running the CICS and IMS transactions on the mainframe from Windows.

A TI component in a COM+ application works in concert with the TI run-time environment, Microsoft Distributed Transaction Coordinator (MS DTC), and the associated remote environment (RE) to drive a CICS or IMS TP. Together, they accomplish these tasks:

- Activate the host (mainframe) TP.
- Pass the parameters specified by the TI component to the TP.
- Run the TP.
- Return the results to the TI component.

When you deploy a TI component (a type library .tlb file) in a COM+ application, that COM+ application becomes a TI *Automation server*. When a client application invokes a method in that TI Automation server, Windows automatically starts the TI run-time environment in the associated remote environment to invoke the mainframe transaction that is associated with that TI method. Component Services in Windows 2000 automatically handles any class factory, early or late binding, or other internal operations needed. The invoked mainframe transaction can call other transactions on the mainframe before it returns the result to the COM-based client application through the TI Automation server.

In This Section

Getting Started with TI

This section explains some of the basics of using Transaction Integrator.

In This Section

Remotely Administering Transaction Integrator

Transaction Integrator (TI) does not support remote installation or configuration, and it does not support remote administration of Windows-initiated processing (WIP) except through use of the Windows Remote Desktop. TI does support remote administration of host-initiated processing through the use of TI Manager and the Remote Desktop. TI also supports the use of remote SQL Server databases.

Remote Installation and Configuration

TI must be installed and configured locally, and it does not support remote installation or configuration. The only way to install TI Manager and the TI runtime is by using the **Host Integration Server Installation Wizard**, and selecting **Application Integration** on the options page. You cannot install TI Manager or the TI runtime programmatically.

Remote Administration of Windows-Initiated Processing

You can administer Windows-initiated processing only from the local computer, and TI does not support remote administration for WIP. Each computer that has TI installed and configured and that is used for WIP is administratively separate from any other computer that also has TI installed. If you need to administer WIP when you are away from the local computer, you must use the Windows Remote Desktop feature to access TI Manager and the TI runtime.

Remote Administration of Host-Initiated Processing

You can administer the host-initiated processing remotely, but only from a computer that also has TI installed on it and uses the same HIP configuration database. For example, if three servers each have TI installed on them, and all three are configured to use the same HIP database, then you can remotely administer any of the three servers from either of the other two servers. You cannot remotely administer the TI runtime from another server that has TI installed but uses a different HIP configuration database. For example, if you have a fourth server that also has TI installed but uses a different HIP configuration database from the three servers in the previous example, you cannot remotely administer the TI runtime on any of the three other servers. Neither can you remotely administer the fourth server from any of the other three servers.

If you need to administer HIP when you are away from a computer that is configured to use the same HIP configuration database, you must use the Windows Remote Desktop feature to access TI Manager and the TI runtime.

Use of Remote Databases

You can also configure TI to use a remote SQL Server database. The SQL Server database is used to store TI host-initiated processing (HIP) configuration data. Use the **Microsoft Host Integration Server Configuration Wizard** to specify the database server to use.

To configure a remote database

1. Click **Start**, point to **Programs**, point to **Microsoft Host Integration Server**, and then click **Configuration Wizard**.
2. Follow the directions on the screen.
3. On the **Database configurations** wizard page, select **Transaction Integrator Configuration Database**.
4. Click **Edit**.
5. In the **Transaction Integrator Configuration Database Properties** dialog box, select the remote server and database to be used.
6. Click **OK**, and then click **Next**.
7. Continue to follow the directions on the screen.

After you click **Finish** in the Wizard, TI installs the HIP database on the designated remote server.

Transaction Integrator Manager Console

Transaction Integrator is administered through the Transaction Integrator (TI) Manager management console. Microsoft Management Console (MMC) is a framework for hosting administrative tools called *snap-ins*. In general, a console can contain tools, folders or other containers, Web pages, and other administrative items. These items are displayed in the left pane of the console, or the *console tree*. MMC provides a single user interface for integrating various Microsoft and third-party management tools. You can create custom consoles combining your choice of the various registered snap-ins; for example, you might put the SNA Manager and Transaction Integrator snap-ins together in a single console.

The TI Manager management console consists of a left pane that displays the console tree and a right pane that displays the properties of the objects in the left pane. The topmost node in the console tree is the **Console Root**, and as you add snap-ins to MMC, they appear under the **Console Root**.

Console Root Nodes

When you first open TI Manager, the console root has three major nodes (or snap-ins):

- **Transaction Integrator**. This node is the entry point to the TI Manager administrative tool.

- **Component Services**. This node is the entry point to the Component Services administrative tool. The Component Services administrative tool enables you to configure and administer COM components and COM+ applications, including installing and configuring COM+ applications, setting security at the application level, and creating and maintaining COM+ partitions. The Component Services administrative tool is designed both for system administrators and for developers. For example, developers can configure routine component and application behavior, such as participation in transactions and object pooling.

- **Internet Information Services**. This node appears in the console only if Internet Information Services (IIS) is installed on the computer. The **Internet Information Services** node is the entry point to the IIS administrative tool.

Transaction Integrator Node

The **Transaction Integrator** node contains two major subnodes:

- **Host-Initiated Processing**. You can use this node to view the major elements that are used in a host-initiated processing (HIP) environment.

- **Windows-Initiated Processing**. You can use this node to view the major elements that are used in a Windows-initiated processing (WIP) environment.

Transaction Integrator Manager Help

Using Windows-Initiated Processing

The following topics explain how to use Windows-initiated processing (WIP) over TCP/IP and over SNA.

In This Section

Where to Begin

Transaction Integrator (TI) enables you to integrate mainframe-based transaction programs (TP) with COM-based client applications by creating and using a TI Automation server to invoke a TP on a mainframe from a COM-based client application.

To learn TI and to design and plan your first TI system, complete the following tasks:

- **Learn the basics**

  Learn about each of the elements in a TI system and how they interoperate. You can use this understanding to determine whether you need to make any changes to your mainframe-based TP or to your COM-based client application. The TI Automation server (a TI component deployed in a COM+ application) is the software that forms the bridge between the mainframe transactions and the client application. For more information, see Learning the Basics.

- **Install TI**

  Install TI when you install Host Integration Server Server on the computers that you will use to create, deploy, and manage TI components.

- **Configure an SNA or TCP/IP connection**

  Configure an SNA connection from your computer to the mainframe by using Host Integration Server, or configure a TCP/IP connection. Even though Host Integration Server is not required to configure a TCP/IP connection, you must have Host Integration Server to install TI.

- **Create LUs and an APPC Mode for an SNA connection**

  Create local and remote logical units (LU) and an Advanced Program-to-Program Communications (APPC) Mode for all SNA connections.

Note
If you use .NET to access the remote server, the .NET Auto Web Proxy feature may cause a significant reduction in throughput. To disable this feature and achieve maximum throughput, add the following line to your WIP client code: System.Net.WebRequest.DefaultWebProxy = null;

To start using TI to connect COM-based applications with mainframe-based TPs, complete the following general steps:

To start using TI to connect COM-based applications with mainframe-based TPs

1. In TI Manager, create an appropriate Customer Information Control System (CICS) or Information Management Systems (IMS) remote environment (RE) and configure its properties.

   For help, see Creating a Remote Environment.

2. In Host Integration Server Designer, create a TI component for a specific RE.

   For help, see Creating TI Components.

3. Deploy the TI component by adding it to a COM+ application.

   This process creates the TI Automation server that any COM-based application can use to invoke the TP. For help, see How to Deploy a TI Component.

4. Test the new TI automation server by calling its methods from the Automation client application.

   This action will run the appropriate transactions in the TP on the mainframe. For help, see Testing a TI Automation Server.

5. Put the new, fully-tested TI Automation server into production; use TI Manager to reconfigure and manage the TI Automation server, its associated RE, and the TI run-time environment settings as needed.

Using Windows-Initiated Processing

Learning the Basics

Before you implement Transaction Integrator (TI), scan the topics in this section to gain a basic understanding of TI. This information is necessary to properly plan your TI implementation and make any necessary modifications.

TI System Elements

A TI system includes the following elements:

- A region on a mainframe computer and the COBOL transaction programs (TP) that run in that region. You do not need knowledge of COBOL, but you do need to understand what each of the component transactions in a mainframe-based TP does, as well as how TPs interact with each other and the total system. Each transaction in a Customer Information Control System (CICS) or Information Management Systems (IMS) TP on the mainframe can be invoked by a method defined in a TI component. Because after a mainframe transaction in a TP is invoked, it can call transactions in other TPs, it is important to know precisely what each transaction in the TP does. To be precise, each method in a TI Automation interface calls a single mainframe TP. It is the TP that determines which mainframe transaction to call. The mainframe TP makes this determination based on the information passed to it by the TI method.

- Component Object Model (COM) distributed COM (DCOM), and Component Services (COM+) in Windows 2000. For information about these elements, see Introduction to COM and COM+.

- CICS or IMS, remote and local independent logical units (LU), and APPC modes associated with the mainframe. See IBM documentation for information about these elements.

- Windows 2000 or later services, including the System Monitor and Event Viewer. Refer to the Windows Help for information about the Windows operating system.

- Host Integration Server server with which you connect your Windows computer to the mainframe. Review the Help file for this information.

- SNA or TCP/IP protocols. These are the IBM protocols that are supported by TI. See IBM documentation for this information.

- A remote environment (RE) associated with each TI component to define the mainframe environment that the TI component will use. To create and modify REs, use TI Manager.

- Transaction Integrator, which includes three tools: Host Integration Server Designer (HIS Designer), TI Manager, and the TI run-time environment. Both HIS Designer and TI Manager have context-sensitive Help that you can consult.

- A COM-based client application that calls the methods of a TI Automation server (a TI component deployed in a COM+ application) to interoperate with mainframe TPs.

- A TI component. This component wraps COM around the TP's data definition section. To create a new TI component or modify an existing one, use HIS Designer. To deploy a TI component in a COM+ application, use TI Manager.

- A COM+ application in which a TI component is deployed. After the TI component is deployed in a COM+ application, that COM+ application becomes a TI Automation server. The COM+ application provides the Automation interface for your TI Automation server. A client application can use the services of the new TI Automation server by way of the Automation interface.

- Microsoft Distributed Transaction Coordinator (DTC) included in and used internally by Component Services (COM+). You have to know that Microsoft DTC is the actual transaction manager, but you do not have to understand how it works.

Additional Information Sources

In addition to exploring the TI documentation, you can obtain other useful information, such as the Win32 Platform SDK documentation, from these Microsoft Web sites:

- The MSDN Online Library at http://go.microsoft.com/fwlink/?LinkId=12768 provides the Platform SDK, other SDK documentation, DDK documentation, Windows resource kits, technical programming information, sample code, technical articles, backgrounders, specifications, and reference guides.

- The MSDN Online home page at http://go.microsoft.com/fwlink/?LinkId=12768.

- The MSDN Online Web Workshop at http://go.microsoft.com/fwlink/?LinkId=12768 provides the latest information about Internet technologies, including reference material and in-depth articles on all aspects of Web site design and development.

- The Microsoft COM site at http://go.microsoft.com/fwlink/?LinkId=12800 gives you the latest information about Microsoft Component Object Model (COM), distributed COM (DCOM), and other COM-based technologies. You will find white papers, presentations, case studies, files to download, samples, the COM and DCOM specifications, a list of training courses, a list of other helpful sites, and a list of useful books. The covered technologies include COM, DCOM, COM+, and ActiveX.

Where to Begin

How to Create a Remote Environment

A remote environment (RE) holds the information about a particular mainframe region that the Transaction Integrator (TI) run-time environment needs to interact effectively with the mainframe environment. Use TI Manager to create the remote environments that you need.

The following are the RE types that you can create in TI Manager:

- Customer Information Control System (CICS) and Information Management System (IMS) using TCP/IP
- CICS LINK, using LU 6.2
- CICS (non-LINK), using LU 6.2
- Diagnostic Capture
- Diagnostic Playback
- IMS using LU 6.2
- IMS using IMS Connect or OTMA over TCP/IP

Note that there is no support for 3270-oriented transaction programs (TP).

You must associate every TI component that you create in Host Integration Server Designer (HIS Designer) with an RE of one of the following types (classes):

- CICS and IMS using TCP/IP
- CICS LINK using LU 6.2
- CICS (non-LINK) using LU 6.2
- IMS using LU 6.2
- IMS using IMS Connect or OTMA for TCP/IP

Once you create an instance of the RE, you can associate one or more TI components with that RE.

After you create the RE in TI Manager and create the TI component in HIS Designer, you are ready to deploy the TI component in a COM+ application by dragging the file from Windows Explorer and dropping it into a COM+ application in TI Manager. When you deploy a TI component, TI Manager automatically assigns that TI component to the default RE for the RE type specified in the TI component. If there is no default RE, TI Manager places the component in the Unassigned Components folder. For more information see How to Deploy a TI Component.

Before creating a new RE, you will need some information from the network administrator.

- To create a Diagnostic Capture RE or a Diagnostic Playback RE, you need to know which of the following RE types your TI component is designed to use:
    - CICS and IMS using TCP/IP
    - CICS LINK using LU 6.2
    - CICS (non-LINK) using LU 6.2
    - IMS using LU 6.2

- IMS using IMS Connect or OTMA for TCP/IP

- In the case of the Diagnostic Playback RE, you also need to know the name and location of the .rcd file that contains the recording.

- To create any of the TCP/IP-based REs, you need to know the IP address and the TCP ports list number of the IBM Listener for the CICS or IMS region in which the transaction program is deployed.

- To create any of the SNA (APPC/LU 6.2)-based REs, you need to know the local LU alias, the remote LU alias, and the APPC mode name.

To create a new RE for a TI component built in HIS Designer

1. Start TI Manager.
2. Expand the **Transaction Integrator** folder.
3. Right-click the **Remote Environments** folder, point to **New**, and then click **Remote Environment**.
4. Click one of the following RE types, and then click **Next**.
    a. CICS and IMS using TCP/IP

    b. CICS LINK using LU 6.2

    c. CICS (non-LINK) using LU 6.2

    d. IMS using LU 6.2

    e. IMS using IMS Connect or OTMA for TCP/IP

5. Enter the requested information in the pages that follow, and then click **Finish**.

Creating TI Components

Although you can create and test a Transaction Integrator (TI) component even before you have a connection to the mainframe, it is preferable to create and test your TI component after you have established a connection.

Use Host Integration Server Designer (HIS Designer) to build the TI component. While you are building the component, you are asked to associate it with an appropriate remote environment (RE). The wizards in HIS Designer guide you through the process, step-by-step. In the Object Creation Wizard, you are asked to select whether the component you are creating is Windows initiated or host initiated. As shown in the following graphic, select Windows Initiated.

Use HIS Designer to define a TI component to use a specific kind of environment for each TI component that you create.

Supported Programming Models

HIS Designer supports the following TCP/IP and SNA (APPC/LU 6.2) mainframe programming models:

- CICS Concurrent Server (TCP/IP)
- CICS MS Link (TCP/IP)
- IMS Implicit (TCP/IP)
- IMS Explicit (TCP/IP)
- IMS using IMS Connect or OTMA (TCP/IP)
- CICS LINK (APPC/LU 6.2)
- CICS non-LINK (APPC/LU 6.2)
- IMS (APPC/LU 6.2)

In HIS Designer, you can create TI components (type library .tlb files) that use each of these environments. The first four types listed are all associated with a CICS and IMS using TCP/IP RE that you created in TI Manager. The more detailed definition is needed in HIS Designer so that the data buffer can be laid out properly, and so that various checks that HIS Designer makes can be completed successfully.

In addition, in HIS Designer, you can specify whether or not a CICS LINK RE should allow 32 KB in each direction (in and out). If you do not specify each direction, 32 KB is the maximum for the sum of both directions (in and out); for example, you could have 16 KB in and 16 KB out, or 1 KB in and 31 KB out. This applies only when you are creating a component; you do not need to specify this when you are defining an RE in TI Manager. It matters for the TI component definition for two reasons:

- It affects how the data is laid out in the buffer.
- It affects how much data you can have in the method.

By configuring a TI component to use one of the eight supported environments, you can choose to communicate directly over TCP/IP or use LU 6.2, an SNA protocol. TI supports two-phase commit (2PC) for ACID (atomic, consistent, isolated, and durable) distributed transaction processing only over SNA LU 6.2networks. On the mainframe, 2PC is done with Sync Level 2 support. IBM does not yet support 2PC over the TCP/IP protocol, except for CORBA using the IIOP protocol. Therefore, for those TPs where you need to maintain distributed transactional integrity, use the APPC/LU 6.2 protocol.

How to Deploy a TI Component

To deploy a Transaction Integrator (TI) component, add it to a COM+ application. A TI component consists of a type library (.tlb file) that is created with Host Integration Server Designer (HIS Designer). Typically, you will deploy all TI components that you need for your Automation server application in a single COM+ application. You do not have to deploy other files, such as associated DLLs, together with a TI component library. When you add the TI component library in a COM+ application, that COM+ application becomes an Automation server that is automatically associated with the generic TI run-time environment code (tagen.dll).

After you deploy a TI component, you can view the component's interfaces and methods. To check the deployed component's property settings to verify that it is associated with the correct remote environment, right-click the component name, and then click **Properties**.

Use any of the following three methods to deploy a TI component. To use these procedures, you must have administrator privileges.

To deploy a TI component from HIS Designer

1. In HIS Designer, click the interface for the component you want to deploy.
2. On the **Tools** menu, click **Add To Package or Application**.
3. Click the appropriate package or application.
4. Click the appropriate remote environment for the TI component that is being deployed, and then click **OK**.

To deploy a TI component from TI Manager

1. Start TI Manager.
2. In the console tree, double-click the **Component Services** (or Microsoft Transaction Server) folder, double-click the **Computers** folder, double-click the folder for the computer in which you want to deploy the component, and then double-click that computer's **COM+ Applications** folder.
3. In the console tree, double-click the specific COM+ application in which you want to deploy the TI component.

   If you have not yet created a COM+ application for the component, right-click the **COM+ Applications** folder in the console tree, point to **New**, and then click **Application** to start the wizard. Follow the instructions to create the new COM+ application.
4. In the console tree, click the **Components** folder under the folder for the target COM+ application.
5. On the **Action** menu, point to **New**, and then click **Component** to start the wizard.

   (If you are using Windows 2000, the wizard asks you if you want to install a component, import a component that is already registered, or install a new event class; click the button next to **Install new component(s)**. You cannot import a TI component; you must install it (that is, deploy it). Finish deploying your TI component (.tlb file) by specifying its path and file name.)

To deploy a TI component by dragging it from Windows Explorer

1. Start TI Manager.
2. In the console tree, double-click the **Component Services** (or Microsoft Transaction Server) folder, double-click the **Computers** folder, double-click the folder for the computer where you want to deploy the component, and then double-click that computer's **COM+ Applications** folder.
3. In the console tree, double-click the COM+ application in which you want to deploy the TI component.

   If you have not yet created a COM+ application for the component, click the **COM+ Applications** folder in the console tree. Then right-click that folder, point to **New**, and click **Application** to start the wizard. Follow the instructions to create the new COM+ application.
4. In the console tree, click the **Components** folder for the target COM+ application.

   At this point, you will see the contents of the folder (if any) displayed in the details pane.
5. Resize or reposition the TI Manager window so that you have room on the desktop to open and use Windows Explorer.

6. Open Windows Explorer and locate the folder that contains the TI component (.tlb file) that you want to deploy.
7. Drag the .tlb file from Windows Explorer, and drop it into the details pane of TI Manager.

Creating a Remote Environment

Remote environment (RE) definitions are created and managed from the Remote Environments folder. When the WIP (Windows-initiated processing) Console is first started, the remote environment folder is empty.

A remote environment defines the network, hardware, and software characteristics of the non-Windows host that will be receiving requests from the Windows operating system. For example, a CICS host that uses the TCP/IP protocol to receive requests from Windows is identified to WIP through an RE that contains the IP address of the Host, the Port Number being listened on, and the code page that the host uses to represent its data.

Other Resources

Using Windows-Initiated Processing

Windows-Initiated Processing Console

The Windows-initiated processing (WIP) console supports the COM, .NET Framework, TCP/IP, and SNA environments, with COM objects and .NET Framework assemblies having similar capabilities and functioning.

There are two primary configuration elements for the WIP environment:

- **Remote environments.** The remote environments folder contains the definitions, called remote environments or REs, for the non-Windows host computers that receive requests from the WIP components.

- **Objects.** The objects folder contains the metadata definitions for the client proxy objects that were created through the Host Integration Server Designer (HIS Designer).

The Component Services node is used to configure COM+ packages for WIP COM objects. The Internet Information Services node is used to configure the virtual directories used by WIP .NET Framework objects.

In This Section

Remote Environments

Objects

Relationships

See Also

Concepts

Creating a Remote Environment

Creating and Managing Remote Environments Using TI Manager

Remote Environments

The Remote Environments folder contains definitions for the non-Windows host computers that will receive requests from the Windows-initiated processing (WIP) components. These host definitions are referred to as remote environments or REs.

The RE is used by the WIP Runtime for the following primary purposes:

- Define the code page used by the host.
- Define the data conversion object that will be used by the WIP Runtime.

Properties on each RE define the characteristics of the host that will be receiving requests.

REs Supported by WIP

WIP supports multiple types of REs (for backward compatibility reasons, there are not just two, as in host-initiated processing).

The following is a minimum set of REs that is supported:

- CICS and IMS using TCP/IP
- CICS LINK using LU6.2
- CICS using LU6.2
- IMS Connect
- IMS using LU6.2

Each of the previous RE types has a (possibly) unique collection of properties, some of which are in conjunction with the Host Security functionality.

TCP/IP RE Properties

The basic TCP/IP RE properties contain the following:

- IP Address or Host Name
- Port List
- Receive timeout value
- Locale and Code Page
- Windows Security Context to be used (User or Package)

SNA RE Properties

The basic SNA RE properties contain the following:

- Local and Remote LU Aliases, Mode Name
- Receive timeout value
- Support for Sync Level 2
- Locale and Code Page
- Windows Security Context to be used (User or Package)

How to View All Remote Environments

Concepts

Windows-Initiated Processing Console

Creating a Remote Environment

Objects

The Objects folder contains the metadata definitions for the Client Proxy objects that were created through the Application Integrator Designer. These metadata definitions contain the following:

- The COM ProgID of the callable COM object (in the form of a type library).
- The .NET Framework qualified namespace of the callable .NET Framework class (in the form of a .NET Framework assembly containing a type library)
- Conversion annotations used by the Windows-initiated processing (WIP) Runtime to interoperate with the host application program environment.
- A representation of the callable COM or .NET Framework object

The metadata definition files are Transaction Integrator metadata files (*.tlb or *.dll) generated by the Application Integrator Designer. The folder contains information about finding these metadata files and their relationships with remote environments and COM+ Packages (COM) or IIS Virtual Directories (.NET).

See Also
Concepts
Windows-Initiated Processing Console

Relationships

A configured Windows-initiated processing (WIP) environment is established by defining a set of WIP elements and then relating them in a manner that enables the client/client program, COM+ / .NET Framework remoting and the WIP Runtime to do the following:

- Write a program against a COM (type library) or .NET proxy (assembly).
- Locate the Proxy (in a COM+ Package or IIS Virtual Directory).
- Make a client call.
- Transform the incoming parameters from COM or .NET formats to wire format data streams.
- Select the correct Transport protocols and destination for the call.
- Transfer data to and from the host application
- Transform the data stream to a COM or .NET reply (parameters, return values, in the format expected, for example, **RecordSets** vs. **DataTables**)
- Return to the calling application.

The Object is the entity that the client "sees" as executed. Methods on the object are executed on a particular host based on any Selection Hint given or their associated remote environment (RE). There is a one-to-many relationship between an RE and an Object that allows for multiple Objects to be executed via the same Host definitions given by an RE.

The WIP Microsoft Management Console (MMC) Administrative Console enables these relationships to be established by using wizards or through manual configuration. After these relationships are established, client calls that result in host processing can be initiated.

Concepts
Windows-Initiated Processing Console

Starting the New Remote Environment Wizard

You can use the **New Remote Environment Wizard** to define the characteristics of the environment that receives request from the Windows system.

The remote environment definition includes:

- Remote Environment Name
- Network Transport type
- Host identification
- Host Software Environment
- Code Page

Concepts
Windows-Initiated Processing Console

How to View All Remote Environments

Follow these steps to view all remote environments (RE):

To view the names and properties of the remote environments

1. In the left pane, click the **Remote environments** folder, and then click an RE name.
2. In the right pane, view the name and properties of each application running on the computer.
    - **Remote Environment**
    - **Type**

To view the operations available on a remote environment

1. In the left pane, click the remote environment name.
2. In the right pane, click the desired action:
    - **New**
    - **View** displays a list of menu items:

      Add/Remove Columns enables you to choose which properties are displayed in the list view. All properties of the remote environment are viewable as a column.

      Large Icons displays larger icons for items in the right pane.

      Small Icons displays smaller icons for items in the right pane.

      List displays only the smaller icons and the names of the applications in the right pane.

      Detail displays the smaller icons and the properties of the applications in the right pane.

      Customize enables you to change the options to show or hide items displayed in the right pane.
    - **Delete** deletes the remote environment from the computer. The deleted item is removed from the specific computer that it was defined on and from the administrative data store.
    - **Rename** renames the highlighted remote environment. The new name must be unique and is reflected across all elements of the host-initiated processing (HIP) console. The **Rename** operation does not affect the operation of Objects that have references to the remote environment. After the **Rename** operation is completed, any Objects that reference the remote environment continue to maintain their reference to the renamed remote environment.
    - **Refresh** redraws the screen to show any updates.
    - **Export List** enables you to save the list of remote environments as a separate file.
    - **Properties** enables you to view and change the properties of a remote environment.
    - **Help** displays an online Help topic explaining the items that appear in the Transaction Integrator (TI) Manager console and the actions you can take.

Creating and Managing Remote Environments Using TI Manager

Use Transaction Integrator (TI) Manager to create and manage remote environments (RE) for each mainframe region.

In This Section

How to Start TI Manager

You can start TI (Transaction Integrator) Manager many different ways:

- Use the **Start** menu
- Start Microsoft Management Console (MMC), and then add the appropriate snap-in consoles
- Double-click a saved MMC configuration file (.msc file)
- Enter a command line at a command prompt
- Use the **Run** command on the **Start** menu

You can also start TI Manager from MMC. Then you can save your MMC configuration as an .msc file, so that later you can just double-click the .msc file to start it. This technique can be useful when you are adding other snap-ins to MMC in addition to the TI Manager snap-ins.

To start TI Manager from the Start menu

- Click **Start**, point to **Programs**, point to **Host Integration Server**, point to **Application Integration**, and then click **TI Manager**.

To start TI Manager from MMC

1. Start MMC by doing one of the following:
    a. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
    b. Type **mmc** at a command prompt, and then press ENTER.
2. On the **Console** menu, click **Add/Remove Snap-in**.
3. In the **Add/Remove Snap-in** dialog box, click **Add**.
4. In the **Add Standalone Snap-in** dialog box, double-click **TI Manager**.
5. In the **Specify machine to administer** dialog box, click **Local computer**.
6. Click **Finish**.
7. In the **Add Standalone Snap-in** dialog box, double-click **Component Services** (or **Microsoft Transaction Server**).
8. In the **Add Standalone Snap-in** dialog box, click **Close**.
9. In the **Add/Remove Snap-in** dialog box, click **OK**.

    If you save the configuration as, for example, MyCOMTI.msc, you can run it again later by double-clicking the file name.

To start TI Manager from the command

1. Click **Start**, and then click **Run**.
2. Type the following:

    MMC "c:\Program Files\Host Integration Server\System\ComtiComPlus.msc"
3. Click **OK**.

    Make sure that you include the quotation marks because the path contains spaces.

Starting TI Manager from the Command Line

You can also start TI Manager from a command line. Include the path and file name of the .msc file when you use the **Run** command or from a command prompt. Microsoft has included two .msc files (ComtiComPlus.msc and ComtiMTS.msc) for you

in the Host Integration Server\System folder. The following procedure is an example.

If you previously added TI Manager to a remote computer, you can use the command line to start TI Manager for the remote computer if you know the name of that computer. However, you must have enabled the following option at the time that you added the console for the remote computer: Allow the selected computer to be changed when launching from the command line. For example, if you created a file named MyOtherCOMTI.msc on another computer in a Windows 2000 network, you can run it on your local computer by using the following procedure.

To start a remote TI Manager from the command line

1. Click **Start**, and then click **Run**.
2. Type the following:

   MMC "C:\Program Files\Host Integration Server\System\MyOtherCOMTI.msc" /computer=computername
3. Click **OK**.

   Adding the **/computer=computername** option lets you configure and otherwise manage all your TI environments from a single computer.

How to Define an SNA CICS or SNA IMS Remote Environment

An SNA CICS or SNA IMS remote environment (RE) is an RE of the CICS Using LU 6.2, CICS LINK Using LU 6.2, or IMS Using LU 6.2 RE type.

To define an SNA CICS or SNA IMS RE

1. Start TI Manager.
2. Double-click **Transaction Integrator** in the console tree.
3. Right-click **Remote Environments**, point to **New**, and then click **Remote Environment**.
4. In the **Add Remote Environment** dialog box, click an RE type (CICS Using LU 6.2, CICS LINK Using LU 6.2, or IMS Using LU 6.2), and then click **OK**.
5. Specify the SNA attributes for the RE, and then click **Next**.
6. Enter a name for the new RE instance, or accept the default.

   The name can be a maximum of 255 characters.
7. Enter an optional comment to describe any distinguishing characteristics of this RE.
8. Click **Next**, and then click **Finish**.

How to Define a Transactional SNA CICS or SNA IMS Remote Environment

A transactional SNA CICS or SNA IMS remote environment (RE) is one that supports Sync Level 2 to enable two-phase commit (2PC). Note that none of the TCP/IP REs support 2PC because TCP/IP does not support Sync Level 2 or any other 2PC mechanism.

Note that IMS version 6.0 and IBM Resource Recovery Service (RRS) are required on the mainframe system for IMS sync level 2 support.

To define a transactional SNA CICS or SNA IMS RE

1. Start TI Manager.
2. Create a new CICS Using LU 6.2, CICS LINK Using LU 6.2, or IMS Using LU 6.2 RE, or click an existing SNA RE in the console tree.

   To create a new RE, double-click **Transaction Integrator** in the console tree, right-click **Remote Environments**, point to **New**, and then click **Remote Environment**.
3. Right-click **CICS Using LU 6.2**, **CICS LINK Using LU 6.2**, or **IMS Using LU 6.2 RE**, and then click **Properties**.
4. Click the **LU 6.2** tab.
5. Select the **Supports Sync Level 2 Protocols** check box.

Specifying SNA Attributes for Remote Environments

To determine the attributes that are required by Transaction Integrator (TI) when you are creating a new remote environment, see your Host Integration Server configuration. To obtain the required attribute values, open Host Integration Server SNA Manager or contact your Host Integration Server system administrator.

Note

To use two-phase commit, each local and remote logical unit (LU) must have SyncPoint support enabled in the SNA server n ode in which it is defined and should point to the computer that is running Resync services. For more information, see Providing a Fail-Safe Environment for ACID Transactions.

Local LU Alias

Enter the LU alias for the local APPC LU defined for the TI remote environment. From Host Integration Server SNA Manager, select the Host Integration Server computer that provides the required host connectivity. Then open the Local APPC LUs folder to obtain a list of configured local APPC LU aliases. Use a name from the list to specify this attribute.

Remote LU Alias

Enter the LU alias for the remote APPC LU defined for the TI remote environment. From Host Integration Server SNA Manager, select the computer running Host Integration Server that provides the required host connectivity. Then open the Remote APPC LUs folder to obtain a list of configured remote APPC LU aliases. Use a name from the list to specify this attribute.

Mode Name

Enter the APPC mode used for the connection. From Host Integration Server SNA Manager, open the APPC Modes folder to obtain a list of configured modes. Use a name from the list to specify this attribute.

To use two-phase commit, the APPC mode must be Sync Level 2 capable.

Creating and Managing Remote Environments Using TI Manager

How to Assign a TI Component to a Remote Environment

Each TI component is associated with a remote environment (RE) type. As you add multiple REs of the same type, verify that each component is assigned to an RE of the type for which it is configured.

To assign a component to a specific RE of the appropriate type, you can use one of the following methods:

- Set a default RE for the Transaction Integrator (TI) components you create. When you deploy the TI component in a COM+ application , the component is automatically associated with the default RE of the appropriate type. Unless you specifically set the default RE, the default RE is the first RE of that type (or class) that you defined.

- Manually move components from one specific instance of an RE type to another specific instance of the same type. This action applies to TI components that you have already deployed in a COM+ application. You can use TI Manager to move components from one RE to another.

- Deploy the TI component by using HIS Designer. In HIS Designer, you are asked to associate the TI component with a specific RE. For more information about this option, see How to Deploy a TI Component.

See Also

Concepts

Creating and Managing Remote Environments Using TI Manager
Creating and Managing TI Components
Getting Started with TI

Working with Unassigned Components

Before a Transaction Integrator (TI) component appears in the console tree of TI Manager, it must be deployed in a COM+ application. Before you can successfully run an application that calls the component, you must associate the component with a remote environment (RE) that describes the region on the mainframe where the host transaction program resides. Any TI component that is not associated with an RE appears in the **Unassigned Components** folder of TI Manager. Such components are valid COM+ components. However, they cannot be used by your application until they are assigned to the proper RE.

A TI component appears in the **Unassigned Components** folder if you do not set the default registration RE. This can happen for either of the following reasons:

- You created the TI component and added it to a COM+ application, but you have not yet created an instance of an RE of the RE type required by the TI component.

- The default registration RE is set to <none> on the **Registrar** tab of the Transaction Integrator properties. This setting is useful, for example, if you do not want to assign components to an RE until the mainframe is fully configured, or until you are ready to test or deploy your TI application.

See Also
Concepts
Creating and Managing Remote Environments Using TI Manager
Creating and Managing TI Components
Getting Started with TI

How to Set a Default Remote Environment

Each Transaction Integrator (TI) component must be associated with a remote environment (RE) type. When you register a TI component by adding it to a COM+ application , the component is associated with the first instance of the same type that you defined using TI Manager. For example, if you create an instance of a CICS using LU 6.2 RE with the default name of CICS1, any component created for use with a CICS using LU 6.2 RE will be associated with CICS1. If you define more REs of the same type (for example, CICS2 and CICS3), you can specify the default RE for associated components that you later deploy.

If you want to associate a component with an RE at a later time, you can specify a default RE of none. Registered components with no RE specified are shown in the **Unassigned Components** folder in TI Manager.

To set a default RE

1. Start TI Manager.
2. Right-click **Transaction Integrator** in the console tree, and then click Properties.
3. Click the **Registrar** tab.
4. Click an RE type, and then click **Change**.
5. In the list, click the name of the RE that you want to be the default RE instance for that RE type.
6. Click **OK**.

Creating and Managing TI Components
Getting Started with TI

How to Move a TI Component to Another Remote Environment

Each Transaction Integrator (TI) component is associated with a specific remote environment (RE), such as CICS Using LU 6.2, when you create the component in HIS Designer. Windows automatically registers a TI component with its appropriate RE when you add the TI component to a COM+ application to create a TI Automation server.

You can move a component to another RE when, for example, you want to move the component to a different region of a mainframe as your application goes through the cycle of development, testing, and deployment. TI components are designed for a certain type of RE, so you can only move a TI component to another RE of that identical type. However, you can move any component into the Unassigned Components folder to save it. Later, you can associate a component in the Unassigned Components folder with an appropriate RE. Use TI Manager to move TI components from one RE to another or to the Unassigned Components folder.

Note
You cannot move components across computer boundaries. For example, if you have two TI Manager consoles open on your computer, one for your computer and the other for a remote computer where TI is also installed, you cannot move a component from a RE on one console into a RE on the other console.

To move a TI component in TI Manager

1. Start TI Manager.
2. Under **Transaction Integrator** in the console tree, find the component that you want to move in either its current RE folder or in the Unassigned Components folder.
3. Click the component name, and on the **Action** menu, click **Move**.
4. In the **Move Component** dialog box, click a new RE instance name in the list. (The list only displays those currently defined REs that the selected component can be moved into.)
5. Click **OK**.

Getting Started with TI

How to Locate a TI Component

The more remote environments (RE) that you have configured, the more difficult it can be to locate a specific Transaction Integrator (TI) component in TI Manager's console tree. You can, however, easily locate a specific component without expanding all the REs in the console tree.

To locate a specific TI component

1. Start TI Manager, right-click **Transaction Integrator** in the console tree, and click **Find Component**.
2. In the list, click the name of the component that you want to locate, and then click **OK**.

   The console tree shows the remote environment with which the component is associated.

How to Activate or Deactivate a Remote Environment

When a region on a mainframe fails or is taken offline for administrative maintenance, any method invocation for components associated with the remote environment (RE) that describes that region will fail. Therefore, when a mainframe region is unavailable, you should deactivate the RE that is supported by that region. You can then temporarily move the affected Transaction Integrator (TI) components to another RE (for example, a back-up region for the offline one) so that your TI applications can continue to run. When the mainframe region is restored, you can once again activate the RE for that region. Deactivating an RE for an offline region on a mainframe also reduces the number of error messages that are sent to the Windows Event Log.

You can check the status of REs by clicking the Remote Environments folder in the TI Manager console tree. The details pane shows icons for all the remote environments contained in the folder. These icons indicate whether a remote environment is active or inactive.

Note
If a transaction is in progress at the time that the region on the mainframe is taken offline, the transaction finishes. However, subsequent method invocations will fail.

To activate or deactivate a Remote Environment

Use one of the following methods to activate or deactivate an RE:

- Start TI Manager, right-click the remote environment (RE) for the mainframe region that you want to activate or deactivate, and click **Activate** or **Deactivate**.

  -or-

- Start TI Manager, click the remote environment (RE) for the mainframe region that you want to activate or deactivate, and then click the green arrow on the tool bar to activate an inactive RE, or click the red arrow to deactivate an active RE.

If you click the Remote Environments folder in the console tree, the details pane lists all of the REs and indicates the current state of each RE.

How to Delete a TI Component from a Remote Environment

Deleting a Transaction Integrator (TI) component from a remote environment (RE) deletes that component from the COM+ application. You can delete only one component at a time.

To delete a TI component from an RE

1. Start TI Manager.
2. In the console tree, double-click **Transaction Integrator** for the appropriate computer, double-click **Remote Environments**, and then double-click the RE that contains the component to be deleted.
3. Right-click the component to be deleted, and click **Delete**.
4. Click **Yes** to delete the selected component.

   To reinstate the component, add it back into the COM+ application.

How to Delete a Remote Environment

You can delete a remote environment (RE) when, for example, you need to move a mainframe transaction program (TP) from one region of the mainframe to another. When you delete an RE, all Transaction Integrator (TI) components assigned to that RE are placed in the Unassigned Components folder in TI Manager.

To delete a remote environment

1. Start TI Manager, and right-click the RE that you want to delete.
2. Click **Delete**.
3. Click **Yes** to confirm the deletion.

How to Set or View Remote Environment Properties

Basic information about a remote environment (RE) is displayed on an item's property sheet. Property sheets are available for the following items:

- The Transaction Integrator (TI) folder
- An RE of any type
- Any component associated with an RE
- Any component present in the Unassigned Components folder

In addition, Context-sensitive Help is available for all properties.

Note
By default, no time-out value is specified when you create REs that use LU 6.2 or TCP/IP protocols. The TI run-time environment waits indefinitely for the mainframe transaction program to return output parameters. While waiting, the TI run-time environment also blocks the calling client application until a response is received. This behavior is typical for APPC applications. To avoid indefinite blocking, you can set a time-out value (in seconds) for REs using LU 6.2 or TCP/IP protocols. You set the value on the LU 6.2 or TCP/IP tab of the RE's properties page.

To view or set an item's properties

1. In TI Manager, right-click the item whose properties you want to view or set.
2. Click **Properties**.
3. If the property sheet has more than one tab, click the tab that contains the properties you want to set or view.

Supporting Two-Phase Commit in a Remote Environment

Only the SNA protocols support two-phase commit (2PC). The TCP/IP protocol does not support 2PC. For an SNA remote environment (RE) to support 2PC, it must be set to support ACID (atomic, consistent, isolated, durable) transactions. To accomplish this, you must set the RE to support the Sync Level 2 protocol.

Transaction Integrator (TI) supports Sync Level 2 for CICS Using LU 6.2, for CICS LINK Using LU 6.2, and for IMS Using LU 6.2 REs. Sync level 2 is the default for all CICS REs but not for IMS REs where IMS version 6.0 and IBM's Resource Recovery Services (RRS) are required for Sync Level 2 support.

To activate Sync Level 2 support, follow the procedure in
How to Define a Transactional SNA CICS or SNA IMS Remote Environment.

Note
The Host Integration Server LU 6.2 Resync TP Service only compares logs with CICS and IMS regions when the RE has been s et to support Sync Level 2.

Managing Transaction Integrator with TI Manager

Use TI (Transaction Integrator) Manager to create and manage remote environments (RE) for each mainframe region.

In This Section

How to Add or Remove TI Manager for a Remote Computer

You can use TI (Transaction Integrator) Manager to administer remote environments (RE) on your local client computer if you installed Host Integration Server Server on that computer. However, TI cannot reside on a computer that has Host Integration Server Administrator Client or Host Integration Server End-User Client installed instead of Host Integration Server Server.

Once you install Host Integration Server Server on the computer, you can use TI Manager to deploy TI components in COM+ applications on the local computer.

You can display a TI Manager on your local computer for your local computer and for up to nine remote computers that are currently running TI. This means that, from a single computer, you can administer the remote environment configurations on a maximum of 10 computers.

To add TI Manager consoles for remote computers to your local computer

1. Open Microsoft Management Console (MMC) by doing one of the following:
    a. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
    b. Type **mmc** at a command prompt, and then press ENTER.
2. On the **Console** menu, click **Add/Remove Snap-in**.
3. In the **Add/Remove Snap-in** dialog box, click **Add**.
4. In the **Add Standalone Snap-in** dialog box, double-click **TI Manager**.
5. In the **Specify computer to administer** dialog box, click **Another Computer** and type the name of that computer (for example, mycomputer2).
6. If needed, select the **Allow the selected computer** check box so that in the future, you can specify a different computer when you start TI Manager from the command line. To learn how to do this, see How to Start TI Manager.
7. Click **Finish**.
8. Repeat steps 4–7 for each remote computer that you want to administer from your local computer. You can add a maximum of nine.
9. In the **Add Standalone Snap-in** dialog box, click **Close**.
10. In the **Add/Remove Snap-in** dialog box, click **OK**.

To remove a TI Manager console

1. On the TI Manager master menu, click **Console**.
2. Click **Add/Remove Snap-in**.
3. Click the TI console that you want to remove, click **Remove**, and then click **OK**.

How to Create Multiple Views of a Single TI Manager Console

Each instance of a TI (Transaction Integrator) Manager console shows the remote environments configured for a single computer. You cannot load more than one TI Manager console for a single computer. However, you can create multiple views of a single TI Manager console, and then display each view in a separate window. Typically, you can use this feature to display the different details for different selected items in the console tree. To save space on the screen, you can hide the console tree on each window.

When you add a new window, that window is superimposed on the original window. To make them all visible, cascade or tile the windows. You can then resize or reposition the windows.

To create multiple views of a TI console

1. Start TI Manager for the computer.
2. On the **Action** menu, click **New Window from Here**.
3. Repeat step 2 for the number of windows that you want to add.
4. On the **Window** menu, click either **Cascade** or **Tile Horizontally**, depending on how you want to configure the windows.
5. For each window, select the item in the console tree that you want to display.

To hide the console tree for a window

- On the window's **View** menu, click **Customize**.
- Clear the **Console tree** check box, and select the **Description bar** check box, and then click **OK**.

  The description bar describes the content of the remaining pane, so you no longer need the console tree.

Refreshing the TI Manager Display

The contents of TI (Transaction Integrator) Manager are automatically refreshed as new TI-related entries are written to the Windows Registry. For example, TI Manager refreshes if you add a TI component to, or delete one from, a COM+ application. An automatic refresh, however, does not sort the updates that it makes to the display. For example, if you create a new remote environment (RE), the new remote environment is added to the bottom of the RE tree, rather than inserted alphabetically within the tree. You can manually refresh the display to resort its contents. Manually refreshing the display is also the best way to ensure that TI Manager shows current data from the Windows Registry.

You can refresh the TI Manager display in either of two ways:

- On the **Action** menu, click **Refresh**.

-or-

- On the MDI toolbar, click **Refresh**.

Managing Transaction Integrator with TI Manager

Creating and Managing TI Components

The topics in this section give you the information you need for creating and managing Transaction Integrator (TI) components.

In This Section

Reserved Words

When Host Integration Server Designer (HIS Designer) asks you to supply a name (for example, a method or parameter name), do not use any of the following reserved words. Words on this list are not case sensitive; for example, Byte, byte, and BYTE are all reserved words.

- Boolean
- BSTR
- Byte
- Currency
- CurrentRE
- Date
- Decimal
- Double
- enum
- Float
- IDispatch
- Int
- Integer
- Interface
- LastSM
- Long
- LPSTR
- LPWSTR
- module
- NewRecordset
- Password
- RECollection
- REStatus
- SelectionHint
- ServerPID

- Short
- Single
- String
- Struct
- typedef
- UserID
- VARIANT
- Void

How to Create a New TI Component

Use Host Integration Server Designer (HIS Designer) to create a new Transaction Integrator (TI) component and populate it with methods.

To create a new TI component

1. Start HIS Designer.
2. On the **File** menu, click **New**.
3. Type a library name for the new TI component library.
4. Type a name for the TI component library's interface.
5. Type a version number for the component library.

   The number to the left of the decimal point is the major version number. The number to the right of the decimal point is the minor version number.
6. Click the type of remote environment (RE) that your component will use.
7. Click the component library's Transaction support property.

   In this case, you are deciding whether the component will support ACID (atomic, consistent, isolated, durable) transactions that each support two-phase commit (2PC). If you click **Does not support transactions**, your TI component will still support mainframe transactions in mainframe transaction programs (TP).
8. If you are providing Help for your application, type the context ID for the first topic in the **Starting Help Context ID** box.
9. Click **OK**.

   You will now see folders and icons for **Interface**, **Methods**, **Recordsets**, and **User-Defined Types**.

   To add a method to the interface

   - In the console tree of HIS Designer, right-click **Methods**, point to **Insert Method**, and then click a data type that represents the return value.

   To add a parameter to a method

   - In the console tree of HIS Designer, right-click the name of the method, point to **Insert Parameter**, and then click a data type.

   To add a recordset to the interface

   - In the console tree of HIS Designer, right-click **Recordsets**, and then click **Insert Recordset**.

   To add a member to the recordset

   - In the console tree of HIS Designer, right-click the name of the recordset, point to **Insert Recordset Member**, and then click a data type.

   To add a user-defined type to the interface

   - In the console tree of HIS Designer, right-click **User-Defined Types**, and then click **Insert User-Defined Type**.

   To add a member to the user-defined type

   - In the console tree of HIS Designer, right-click the name of the User-Defined Type, point to **Insert User-Defined Type Member**, and then click a data type.

How to Import a TI Component

You can import the methods, recordsets, and user-defined types from an existing component library to another component library. This is useful, for example, if you want to build a new component library based on an existing one.

Imported methods, recordsets and user-defined types are added to those of the library into which they are imported. If duplicate method names exist between the two libraries, you are asked to supply a new name for a method before it is imported. Duplicate recordset names are allowed unless columns within the recordsets do not match, or Automation data types and associated COBOL data types within a column do not match. In this case, you are asked to supply a new name for a recordset before it is imported.

To Import a TI Component

1. In the console tree of HIS Designer, right-click the icon for your component library's interface.
2. Point to **Import**, and then click **Component Library**.
3. In the **Insert Component Library** dialog box, locate and click the TI component library (the .tlb file) that you want to import.
4. Click **Open**.

Transaction Integrator User's Guide

How to Import COBOL into a TI Component

You can import COBOL source code to define the Automation interface of a new Transaction Integrator (TI) component library. To do so, use the TI COBOL wizard to create one method at a time. The COBOL wizard initially imports an entire source file for a mainframe transaction program (TP). As you step through the wizard, you extract the data declarations that describe input sent to, and output received from, the mainframe TP. These data declarations are used to define your TI component library. All other content in the source file is ignored.

As you develop your TI application, you can continue to use the COBOL wizard to make adjustments to a component definition. For example, you can add a parameter to a method to incorporate updates that have been made to the COBOL source code on the mainframe. To adjust a component definition, you can re-run the COBOL wizard to replace a method or a recordset in your component definition. Before replacing an existing method or recordset, you must unlock the method or recordset. Component definitions are locked by default to protect against unintended changes.

To import COBOL into a TI component

1. In the console tree of Host Integration Server Designer (HIS Designer), right-click the icon for your component library's interface.
2. Point to **Import**, and click **COBOL Wizard**.
3. Follow the instructions on the screen.

   The COBOL wizard steps you through the process of importing the COBOL source code that you want.

To unlock a method or record set

1. Start HIS Designer, and right-click the method or recordset.
2. Click **Unlock**.

Concepts

Creating and Managing TI Components

Transaction Integrator User's Guide

How to Export COBOL from a TI Component

You can use a component definition to generate COBOL syntax for the data declarations that describe input sent to, and output received from, the mainframe transaction program (TP). The generated COBOL syntax is saved in a text file. The file's contents are not an actual program, but data declarations. The file contains data only, not logic, and is intended to serve as a guideline, for example, for code that can be incorporated into a mainframe TP.

To export COBOL from a TI Component

1. In the console tree of HIS Designer, right-click the icon for your component library's interface.
2. Point to **Export**, and then click **Generate COBOL Declarations**.

   If you are exporting from a new (unsaved) component library, you are prompted to save the library.
3. Click **OK**.

   The **Save File As** dialog box appears.
4. Fill in the dialog box and then click **Save**.

   Transaction Integrator (TI) displays the text file in Notepad for you to view.

Transaction Integrator User's Guide

Adding TI Components to COM+ Applications

To deploy a Transaction Integrator (TI) component, add it to a COM+ application.

A TI component consists of a type library (.tlb file) that is created by using Host Integration Server Designer (HIS Designer). Typically, you deploy all components that are required for your Automation server application in a single COM+ application. There are no other files (such as associated DLLs) that you must have to deploy together with a TI component library. When you add the TI component library in a COM+ application , that COM+ application becomes an Automation server that is automatically associated with the generic TI run-time environment code (tagen.dll).

You can deploy a TI component using one of these methods:

- Using HIS Designer.
- Using TI Manager.
- Just dragging and dropping the component.

To use any of these methods, you must have administrative privileges.

After you deploy a TI component, you can view the component's interfaces and methods. Check the deployed component's property settings to verify that it is associated with the correct remote environment. To do this, right-click the component's name in the console tree, and then click **Properties**.

Concepts
Creating and Managing TI Components

How to Remove a TI Component from a COM+ Application

To remove a TI component from a COM+ application

1. Start TI Manager.
2. In the console tree, double-click **Component Services** (or **Microsoft Transaction Server**).
3. Double-click **Computers**, and then double-click the computer where the component you want to remove is located.
4. Double-click **COM+ applications**, double-click the COM+ application that contains the component, and then double-click its **Components** folder.
5. Right-click the component that you want to remove, and then click **Delete**.
6. Click **Yes** to confirm that you want to delete the selected component.

   When you remove a TI component from a COM+ application , you also remove the entry for the component from the Windows Registry. In addition, the representation of the component is removed from TI Manager. You can no longer use that component.

Concepts
Creating and Managing TI Components
Transaction Integrator User's Guide

How to Set or View Component Properties

A property sheet displays basic information about a Transaction Integrator (TI) component. Property sheets are available in Host Integration Server Designer (HIS Designer) for the following:

- Interface.
- Each method in an interface.
- Each parameter of a method.
- Each recordset in an interface.
- Each column of a recordset.
- Each user-defined type in an interface.
- Each member of a user-defined type.

To view or set an item's properties

1. In HIS Designer, right-click the item, and then click **Properties**.

Note
After you deploy a TI-created component in a COM+ application, that component acquires additional properties. For a complete view of a component's properties, use TI Manager to view the properties for the component and the properties for the COM+ application where the component is located.

Some properties are informational only, so you cannot change them. However, there are many properties that you can change. When you are viewing properties in HIS Designer, you can protect against inadvertently changing a component definition by locking the definition. Doing so makes property settings read-only until you unlock them.

To lock or unlock a component definition in HIS Designer

1. Start HIS Designer, and open a TI component.
2. In the console tree, right-click the component's interface, and then click **Lock** or **Unlock**.

   Context-sensitive Help is available for all properties.

Concepts

Creating and Managing TI Components

Transaction Integrator User's Guide

How to Set a TI Component's Transaction Property

Set a Transaction Integrator (TI) component's Transaction support property to tell COM+ whether that TI component supports COM-based ACID (atomic, consistent, isolated, durable) transaction processing. When an instance of a TI component is created, COM+ always checks the component's transaction property to determine whether the instance should run in a COM-based ACID transaction.

Note
The term *transaction* can be confusing because it can mean different things depending on the context. A mainframe transacti on program can contain one or more mainframe transactions. However, a mainframe transaction is not necessarily an ACID t ransaction.

Not all components are designed to support COM-based ACID transaction processing. If your component is not designed to participate in an existing COM+ transaction or start a new COM+ transaction, be sure to set the component's Transaction support property to **Does not support transactions** in Host Integration Server Designer (HIS Designer) or to **Not supported** in TI Manager. This does not mean that the TI component does not support mainframe transactions; it means that the component does not support COM-based ACID transaction processing.

The application developer initially sets a component's transaction property in HIS Designer. After a TI component is deployed in a COM+ application , an administrator can change a TI component's transaction property to accommodate changing needs by using TI Manager or HIS Designer.

In HIS Designer, you can set the Transaction support property to one of the following values:

- **Requires a transaction** This TI component is to be used in an application that executes within a COM+ ACID transaction. This TI component's methods are called by client applications that must automate mainframe transaction programs (TP) that support sync level 2 requests (also known as two-phase commit). If a transaction is in progress, the application is enlisted in the transaction. Otherwise, COM+ starts a new transaction. None of the TCP/IP-based remote environments (RE) support this property because TCP/IP does not support two-phase commit. For an IMS Using LU 6.2 RE to support this property, you must be using IMS version 6.0 or later. The CICS LINK Using LU 6.2 RE type supports this property. The CICS Using LU 6.2 RE type requires mainframe ACID transaction processing support.

- **Requires a new transaction** This TI component is to be used in an application that executes within a COM+ ACID transaction. This TI component's methods are called by client applications that must automate mainframe transaction programs (TPs) that support sync level 2 requests (also known as two-phase commit). By setting this property, you are telling COM+ to always start a new ACID transaction, regardless of whether or not an existing ACID transaction is already in progress. None of the TCP/IP-based remote environments (RE) support this property because TCP/IP does not support two-phase commit. For an IMS Using LU 6.2 RE type to support this property, you must be using IMS version 6.0 or later. The CICS LINK Using LU 6.2 RE type supports this property. The CICS Using LU 6.2 RE type requires mainframe ACID transaction processing support.

- **Supports transactions** This TI component is to be used in an application that may or may not execute within a COM+ ACID transaction. This TI component's methods are called by client applications that must automate mainframe transaction programs (TPs) that support both sync level 0 (nontransactional) mainframe transactions and sync level 2 (transactional two-phase commit) mainframe transactions. For a sync level 2 transaction, if a transaction is in progress, the client application is enlisted in the transaction. Otherwise, COM+ starts a new transaction. None of the TCP/IP-based remote environments (REs) support sync level 2 because TCP/IP does not support two-phase commit. For an IMS Using LU 6.2 RE to support sync level 2, you must be using IMS version 6.0 or later. The CICS LINK Using LU 6.2 RE type supports this property. For the CICS Using LU 6.2 RE type to support sync level 2, the mainframe must support ACID transaction processing.

- **Does not support transactions** This TI component is to be used in an application that does not execute within a COM+ transaction. This component's methods are called by applications used with mainframe TPs that support sync level 0 mainframe transactions. All of the TCP/IP and SNA remote environment (RE) types support this property.

In TI Manager, in addition to these four possible transaction properties, you can disable transaction support for a TI component. The five values for the Transaction support property in TI Manager are as follows:

- **Disabled** Click this to eliminate ACID transaction-related overhead for objects that will never need access to a resource manager. This attribute simulates the transactional behavior of an undeployed component (a COM component that has not been installed in a COM+ application).

- **Not Supported** Click this to prevent an object from participating in an ACID transaction, regardless of the transactional status of its caller. Declaring this value guarantees that an object will not vote in its caller's ACID transaction or begin an ACID transaction of its own. This is the default value for all components. This is equivalent to the **Does not support transactions** setting in HIS Designer.

- **Supported** Click this to allow an object to participate in an ACID transaction if one exists. Declaring this value causes an object to share in its caller's ACID transaction but prevents it from initiating an ACID transaction of its own. This is equivalent to the **Supports transactions** setting in HIS Designer.

- **Required** Click this to specify that all objects created from the component will be transactional (that is, all must meet the ACID test). This is the preferred setting for a object that performs resource activities because it guarantees transaction protection for those activities. This is equivalent to the **Requires a transaction** setting in HIS Designer.

- **Requires New** Click this to require that an object be the root of a new transaction, regardless of the transactional status of the caller. COM+ automatically initiates a new transaction, which is distinct from the caller's transaction. This is equivalent to the **Requires a new transaction** setting in HIS Designer.

Use the following procedures to set or change the transaction property for a TI component.

- To set the transaction property for a new TI component

- To change an undeployed TI component's transaction property in HIS Designer

- To change a deployed TI component's transaction property in TI Manager

To set the transaction property for a new TI component

1. Start HIS Designer.
2. On the **File** menu, click **New**.
3. Click the transaction property value that you want under **Transaction Support in the New Component Library** dialog box.

To change an undeployed TI component's transaction property in HIS Designer

1. Open the TI component in HIS Designer.
2. In the console tree, right-click the TI component's interface, and then click **Properties**.
3. Under **Transaction support**, click the value you want to assign to the component, and then click **OK**.

To change a deployed TI component's transaction property in TI Manager

1. Start TI Manager.
2. In the console tree, under the **Component Services** (or **Microsoft Transaction Server**) folder, browse to the COM+ application where the TI component is located.
3. Right-click the name of the TI component, and the click **Properties**.
4. Click the **Transactions** tab, click one of the five options under **Transaction support**, and then click **OK**.

Transaction Integrator User's Guide

Managing TI Calls Using Status and Timeout Properties

A client application can manage its calls to a Transaction Integrator (TI) Automation server by checking the TI component's remote environment (RE) **Status** property and the **Timeout** property.

Status Property

TI provides a read-only RE **Status** property in each component library created by Host Integration Server Designer (HIS Designer). A client application can use this property to inquire about the current state of the RE with which a TI component is associated. It returns whether the RE is enabled, disabled, or blocked by a communications difficulty.

Timeout Property

All RE types supported by TI include a **Timeout** property. Set the **Timeout** property value on the **LU 6.2** or **TCP/IP** tab of the remote environment's properties page in TI Manager.

By default, an RE has no initial **Timeout** property value. Therefore, unless you use TI Manager to set a **Timeout** value, the TI run-time environment waits indefinitely for the mainframe transaction program (TP) to return output parameters. Meanwhile, the TI run-time environment blocks the calling client application until this response is received. This blocking behavior is typical for APPC applications.

For example, with LU 6.2, if an IMS program is disabled, request messages continue to be placed successfully on the IMS message queue without network errors being reported. This occurs even when these messages are not being processed.

Set the **Timeout** value to free a blocked client application after the time-out interval expires. After the time-out period expires, the client application is notified that a time-out error occurred when attempting to execute the IMS program. However, because the requests are successfully stored in the IMS message queue, the requests can still be processed later if the IMS program is enabled without first emptying the IMS queue.

Use TI Manager to specify a **Timeout** value, in seconds, for a given remote environment. Right-click the RE, and then click **Properties**.

Handling Time-out Errors

When sending messages to the CICS or IMS region described by a specific RE, the TI run-time environment measures the amount of elapsed time that occurs from when a request is sent to when a response is received. If the time-out interval elapses before receiving a response, the TI Automation server object is terminated, and the associated COM+ transaction stops the transaction and reports the error to the client application. A message describing this error is also written to the Windows Event Log.

To handle a time-out error, the TI run-time environment unbinds the LU 6.2 session established with the CICS or IMS region. This means that the TI run-time environment must reestablish a new LU 6.2 session before another message can be sent to this region. If the time-out error occurs over a TCP/IP connection, TI shuts down the TCP/IP connection.

Time-out errors can adversely affect the performance of TI. Therefore, you should set time-out values high enough to signal a significant failure in the remote CICS or IMS region.

Note
For TCP/IP, the time-out value set on an RE's properties page is significant only to the sending and receiving of data. In contr ast, the time-out value for establishing the connection itself is defined by the implementation of the underlying TCP transport .

How to Print a Component Description

Use the **Print** command in Host Integration Server Designer (HIS Designer) to print a description of the current component. This printed description includes the following:

- A description of the component's interface properties.
- A description of each method, its parameters, and its properties.
- A description of each recordset, its columns, and its properties.

To use the Print command

- In HIS Designer, click **Print** on the **File** menu.

How to Run TI Over TCP/IP

You can install and run Transaction Integrator (TI) over TCP/IP without installing or using any of the SNA services of Host Integration Server.

Use the following procedure to run a TI application over TCP/IP.

To run a TI application over TCP/IP

1. Configure the mainframe (CICS or IMS) for TCP/IP, and establish a connection with your Windows-based Host Integration Server Server computer.

   For more information, see the following:

   - Configuring CICS for TCP/IP
   - Configuring IMS for TCP/IP.
   - Configure Host Environment and Programming Model Wizard Page in the New Remote Environment Wizard
   - Enhanced Listener CICS Administration

2. Install the COBOL programs within the CICS or IMS region that receives TI-initiated calls.
3. Define an appropriate TCP/IP remote environment for the CICS or IMS region that receives TI-initiated calls.
4. Build the TI component with a method for each transaction in the transaction program (TP).
5. Deploy the TI component in a COM+ application to create a TI Automation server.
6. Run the client application that calls the new TI Automation server to automate the TP.

CICS version 3.3 or later

Connections to CICS using TCP/IP

CICS uses the IBM-supplied Concurrent Listener (program EZACIC02, transaction ID CSKL) to establish an interaction with TCP/IP. The Listener is a transaction that automatically starts when CICS TCP/IP is started and enabled. When the Listener starts, it obtains a socket on which it can "listen" for connection requests from TCP/IP. The Listener binds the socket to a specified port, and then waits for a client request on that port. TCP/IP maintains a relationship of a port number to a CICS job. When a client makes a request on a port associated with CICS, TCP/IP forwards the connection request to the Listener in that CICS job.

For additional details about the CICS MS LINK communication model, see CICS MS LINK (TCP/IP).

TCP/IP-to-CICS Configuration

A TCP/IP port number is associated with a CICS region in the TCP/IP profile data set (hlq.PROFILE.TCPIP). The port statement is used to define this relationship. For example, the following is a port statement that associates port 3000 with CICS region CICSRG:

```
3000 TCP CICSRG
```

CICS-to-TCP/IP Configuration

The following sample host definition shows configuration parameters for CICS-to-TCP using the EZAC transaction:

```
EZAC,DEFINE
ENTER ONE OF THE FOLLOWING
CICS         ===> yes                 Enter Yes|No
LISTENER     ===>                     Enter Yes|No
EZAC,DEFINE,CICS
ENTER ALL FIELDS
APPLID       ===> CICSRG              APPLID of CICS System
EZAC,DEFINE,CICS
OVERTYPE TO ENTER
APPLID       ===> CICSRG              APPLID of CICS System
TCPADDR      ===> TCPIP               Name of TCP Address Space
NTASKS       ===> 020                 Number of Reusable Tasks
DPRTY        ===> 000                 DPRTY value for ATTACH
CACHMIN      ===> 015                 Minimum Refresh Time for Cache
CACHMAX      ===> 030                 Maximum Refresh Time for Cache
CACHRES      ===> 010                 Maximum number of Resolvers
ERRORTD      ===> CSMT                TD Queue for Error Messages
```

The following sample host definition shows configuration parameters for the CICS Concurrent Listener using the EZAC transaction:

```
EZAC,DEFINE
ENTER ONE OF THE FOLLOWING
CICS         ===>                     Enter Yes|No
LISTENER     ===> yes                 Enter Yes|No
EZAC,DEFINE,LISTENER
ENTER ALL FIELDS
APPLID       ===> CICSRG              APPLID of CICS System
NAME         ===> CSKL                TRANSACTION NAME OF LISTENER
EZAC,DEFINE,LISTENER
OVERTYPE TO ENTER
APPLID       ===> CICSRG              APPLID of CICS System
```

```
TRANID       ===> CSKL                Transaction Name of Listener
PORT         ===> 03000               Port Number of Listener
IMMEDIATE    ===> YES                 Immediate Startup   Yes|No
BACKLOG      ===> 010                 Backlog Value for Listener
NUMSOCK      ===> 050                 Number of Sockets in Listener
MINMSGL      ===> 004                 Minimum Message Length
ACCTIME      ===> 060                 Timeout Value for ACCEPT
GIVTIME      ===> 030                 Timeout Value for GIVESOCKET
REATIME      ===> 000                 Timeout Value for READ
FASTRD       ===> YES                 Read Immediately    Yes|No
TRANTRN      ===> YES                 Translate TRNID     Yes|No
TRANUSR      ===> YES                 Translate User Data Yes|No
SECEXIT      ===>                     Name of Security Exit
```

Before you attempt to use the TCP/IP connection, do the following:

- Verify that you have a TCP address space running on the host. (You should be able to PING the host at its IP address or DNS name.) Record the IP address; you will need to know it later when you use Transaction Integrator (TI) Manager to define a TCP/IP remote environment for the CICS region.

- Check that the CICS region supports TCP/IP, and that the IBM-supplied Listener (program EZACIC02, transaction ID CSKL) is defined. These procedures are described in chapter 5 of *TCP/IP V3R2 for MVS: CICS TCP/IP Socket Interface Guide* (IBM Document #SC31-7131). Note that this is a CICS TS version 1.2 document, but the configuration is also supported in CICS version 4.1.

- Determine the IP port number of the Listener (EZAC DISPLAY LISTENER); you will need to know it when you use TI Manager to define a TCP/IP remote environment for the CICS region.

- Start the IBM-supplied Listener (EZAO START) and check the CICS view of the Listener status (execute the CEMT INQUIRE TASK command, and verify that CSKL is running).

How to Run TI Over TCP/IP

Configuring IMS for TCP/IP

This section describes the necessary steps in configuring IMS for TCP/IP. It may also be necessary to set up and configure the Host Web Service. See your IBM documentation for information on this.

IMS TCP/IP Platform Requirements

- TCP/IP version 3R2
- IMS version 4 or later

Connections to IMS using TCP/IP

IMS uses a Listener (program EZAIMSLN) to establish an interaction with TCP/IP. The Listener in an IMS Batch Message Processing (BMP) helps facilitate the connection process. When the Listener starts, it obtains a socket on which it can "listen" for connection requests from TCP/IP. The Listener binds the socket to a specified port, and then waits for a client request on that port.

TCP/IP maintains a relationship of a port number to an IMS Listener BMP. When a client makes a request on a port associated with IMS, TCP/IP forwards the connection request to the Listener in that BMP.

Implicit mode

Implicit mode uses the IMS Assist Module to translate conventional IMS communication into corresponding socket calls. The Implicit mode is dependent on the IBM-supplied default Listener (EZAIMSLN) that runs in a BMP region.

The host server application model processes input data using the IMS message queue. The Listener puts the TRANID and the input data into the queue. The IMS control region schedules the transaction in a Message Processing Region. The Transaction Program reads the request from the queue using GU and GN commands. All response data is delivered to the client by way of the ISRT command. The IBM-supplied Assist Module delivers the data directly to the client through socket API calls.

The Assist Module uses the DBLADLI API for Implicit mode. Host applications are written using CBLADLI or CBLTDLI APIs. If you want existing IMS applications to use Implicit Mode TCP/IP, you must change to the CBLADLI API and recompile the program.

Explicit mode

The IMS Explicit (TCP/IP) model requires the installation, within IMS, of the IBM-supplied default Listener (EZAIMSLN) that runs in a BMP region. This host server application model processes data without using the IMS message queue. The Listener places only a single segment (the Transaction Initiation Message) into the message queue. The IMS control region schedules the execution of the transaction into a Message Processing Region. The transaction then communicates directly with the client through socket API calls.

All IMS host server programs must be administered by IMS as no-response transactions.

For additional details about the IMS communication models, see IMS Implicit and IMS Explicit.

TCP/IP-to-IMS Configuration

A TCP/IP port number is associated with an IMS Batch Processing Region (BPR) in the TCP/IP profile data set (hlq.PROFILE.TCPIP). The port statement is used to define this relationship. For example, the following is a port statement associating port 3000 with an IMS batch region with a job name of WNWIBR1:

```
3000 TCP WNWIBPR1
```

IMS-to-TCP/IP Configuration

You can start an IMS Message Processing Program by specifying the program name of the IBM-supplied Listener program (EZAIMSLN). The Listener reads a configuration file identified by the DD statement **LSTNCFG**. This configuration data set contains one or more of the following startup parameter statements (one set for each transaction defined for at least one Command Region):

- **TCPIP** statement. Identifies the job name for the TCP/IP address space that manages the connection for the Listener
- **LISTENER** statement. Specifies the port number that the Listener will use. This statement also specifies other port-related

parameters, such as backlog, time-out values, and so on.

- **TRANSACTION** statement. Defines a list of transactions that the Listener can start. It also defines whether the Implicit or Explicit connection mode is used.

The Listener uses the three previously listed parameter statements to inform TCP/IP which port to use and which transactions can be accessed through TCP/IP.

The following is a sample of an IMS-to-TCP/IP host definition:

```
TCPIP ADDRSPC=WNWTCP31
LISTENER PORT=4000 BACKLOG=50
TRANSACTION NAME=TRANIMPL TYPE=IMPLICIT
TRANSACTION NAME=TRANEXPL TYPE=EXPLICIT
```

How to Run TI Over TCP/IP

Defining a TCP/IP Remote Environment

The following table shows how you can define a TCP/IP remote environment (RE) to fit each of the five mainframe-based programming models even though there are only two Transaction Integrator (TI) RE types.

TI Remote Environment Type	Mainframe Programming Model
CICS and IMS using TCP/IP	CICS Concurrent Server (TCP/IP)
CICS and IMS using TCP/IP	CICS MS Link (TCP/IP)
CICS and IMS using TCP/IP	IMS Implicit (TCP/IP)
CICS and IMS using TCP/IP	IMS Explicit (TCP/IP)
IMS Connect or OTMA	IMS Connect or OTMA (TCP/IP)

Use TI Manager to define either TCP/IP RE.

How to Run TI over SNA (APPC/LU 6.2)

If you have a distributed network, use Transaction Integrator (TI) over an SNA (APPC/LU 6.2) network connection to take advantage of its support for two-phase commit (2PC) in ACID (atomic, consistent, isolated, and durable) transaction processing. To support ACID transactions, your COBOL transaction program (TP) must support Sync Level 2. The TCP/IP protocol has no default support for 2PC, so TCP/IP is not appropriate in a distributed network.

To run a TI application over an SNA network

1. Configure the mainframe (CICS or IMS) for SNA, and establish a connection with your Windows-based Host Integration Server computer.
2. Install the COBOL transaction programs within the CICS or IMS region that receives TI-initiated calls.
3. Define an appropriate SNA remote environment for the CICS or IMS region that receives TI-initiated calls.
4. Build the TI component with a method for each transaction in the TP.
5. Deploy the TI component in a COM+ application to create a TI Automation server.

Run the client application that calls the new TI Automation server to automate the TP.

Using Windows-Initiated Processing

Determining Who Initiated a Transaction

You can easily determine who initiated a specific transaction. This is helpful, for example, when you need to track down the history of a transaction failure. You can also use this technique to implement resource or transaction-level, per user, security.

When you select either user-level or package-level security on the **Security** tab of the Transaction Integrator (TI) Remote Environment (RE) properties page, TI sends security information in the session request to the host. You can deploy the Host Account Mapping database known as the Host Account Cache (HAC), and set up a mapping between each Windows user and the corresponding host user ID, and that is what TI will send. Or you can use the **Allow application to override security** option on the **Security** tab, and have the application return any host user ID (and password).

Whether the host will do anything with the different user IDs depends mostly on the ATTACHSEC setting for the CICS connection; this corresponds to the APPC LU that TI uses. The default ATTACHSEC setting is **local**, meaning that CICS does not validate the user ID in the session, and CICS runs the transaction in a default host credential. But if you set the ATTACHSEC setting, CICS uses Resource Access Control Facility (RACF) to validate the user ID in the session, and CICS then attaches that user ID to the trusted computing base (TCB) for the transaction as it runs through the Mirror transaction into the target mainframe transaction program.

Concepts
Meeting Specific Real-World Needs

Providing a Fail-Safe Environment for ACID Transactions

ACID (atomic, consistent, isolated, and durable) transaction processing using two-phase commit (2PC) generally requires a fail-safe environment. This is an environment that ensures continuation despite hardware failures. This is often called *2PC failover* or *hot backup*.

Host Integration Server includes enhancements to the SNA LU 6.2 Resync transaction program (TP) generally referred to as the *Resync service* together with enhancements to the configuration and APPC DLL to make 2PC failover work through two or more redundantly configured Host Integration Server SNA servers (computers). In the event of a failure of one of the servers (computers), a separate Host Integration Server computer running either Transaction Integrator (TI) or the DB2 Provider can continue to initiate transactions through an alternate server (computer).

Configuring 2PC Failover

To configure 2PC failover to work with Host Integration Server, complete the following tasks:

- Configure two Host Integration Server servers to support the same SyncPoint-enabled local APPC LU alias but with different LU names. Have these local APPC LUs point to the same computer name where Microsoft Distributed Transaction Coordinator (DTC) service and the Resync service are running (that is, a separate Host Integration Server computer that supports TI or an application that uses the DB2 Provider). Also, have both servers support the same remote APPC LU alias and name.

- In the applicable TI remote environment (RE), configure the local and remote LU aliases, and select transactional support. If the application is using the DB2 Provider, configure the Universal Data Link with the local and remote APPC LU aliases, and set the Units of Work property to **DUW**.

When the Resync service starts, it searches all SyncPoint-enabled local APPC LUs that specify the computer name where the Resync service is running. Resync then initiates an Exchange Log Names request over every found local APPC LU with all SyncPoint-enabled remote APPC LUs.

When a TI Automation server (application) or the DB2 Provider invokes a transaction program (TP) on the mainframe and initiates a conversation, the APPC DLL locates any available Host Integration Server server (computer) that supports the LU/LU pair. In this way, a TI Automation server (application) or the DB2 Provider gains fault tolerance by getting a conversation through any Host Integration Server server (computer) that supports the LU/LU pair. The Resync service then coordinates the DTC transaction log reconciliation when a Host Integration Server SNA server (computer) comes back online, if a server (computer) failure occurs during a transaction. Note that this configuration does not provide fault tolerance for the Host Integration Server server (computer) that is running only TI or the DB2 Provider, not the SNA service.

Note that clustering the servers (computers) that are running the SNA service is not recommended. Instead of using Windows Clustering, use the configuration recommendations described in this topic. In addition, 2PC works only when you are using the SNA (APPC/LU 6.2) protocol to communicate with the host system. Neither TI nor the DB2 Provider support 2PC over the TCP/IP transport, so there is no 2PC failover solution for TCP/IP-based systems.

Concepts
Meeting Specific Real-World Needs

Using TI in a Non-DPL Environment

A non-linked environment (that is, a non-DPL environment) is one that does not use IBM Distributed Program Link (DPL). You can use Transaction Integrator (TI) to invoke a mainframe transaction program (TP) that uses the **EXEC CICS RECEIVE INTO** and **EXEC CICS SEND FROM** COBOL commands. These two COBOL commands are useful when you want a CICS TP to take on SNA (APPC/LU 6.2) conversation responsibilities and therefore bypass the Mirror TP. In other words, the **EXEC CICS RECEIVE INTO** and **EXEC CICS SEND FROM** COBOL commands are most often used in a non-linked environment to transfer data to and from a logical unit (LU) of type 6.2 (APPC).

TI supports the LU 6.2 model for both linked and nonlinked environments. You can create the following remote environment (RE) types to support each model:

- **CICS Link using LU 6.2** Use this in an IBM DPL environment that uses the Mirror TP.
- **CICS using LU 6.2** Use this in a non-DPL environment that bypasses the Mirror TP.

Separating Business Logic from Presentation Logic

Many customers use TI in a non-DPL environment. The only concern is whether terminal logic is embedded with the business logic. When a COBOL TP supports IBM DPL, the presentation logic has already been separated from the business logic, so you probably will not need to modify the COBOL. However, if the TP was written to communicate with a terminal, it is likely that you will need to modify the COBOL code to separate the business logic from the presentation logic.

For example, the following sample COBOL code shows how to handle unbound recordsets by using the **EXEC CICS RECEIVE INTO** and **EXEC CICS SEND FROM** COBOL commands:

```
*****************************************************
* Example showing how to send unbounded recordsets
* to a client application.

Meeting Specific Real-World Needs

Using Host-Initiated Processing

The topics in this section explain how to use host-initiated processing.

In This Section

Creating a Local Environment

A local environment (LE) is a set of end points that the host-initiated processing (HIP) runtime uses to listen for incoming requests from the host. If communication with the host uses the TCP/IP network protocol, the endpoints are either port numbers or service names. If communication with the host uses the SNA network protocol, the endpoint is the local logical unit (LU) alias.

Use the **New Local Environment Wizard** to create a new local environment.

See Also

Other Resources

Using Host-Initiated Processing

Creating a Host Environment

A host environment (HE) defines the network and hardware characteristics of the non-Windows host that will initiate requests to the Windows operating system. For example, a host that uses the TCP/IP protocol to initiate requests to Windows is identified to host-initiated processing (HIP) through an HE that contains the IP address of the host and the code page that the host uses to represent its data.

You can use the **New Host Environment Wizard** to create a new host environment.

See Also

Other Resources

Using Host-Initiated Processing

Creating a Security Policy

You can create and manage security policy definitions in the **Security Policies** node in the HIP (host-initiated processing) Console.

When the HIP Console is first started, the **Security Policies** node is empty. The **Security Policies** node contains definitions for how Windows security credentials are established before the execution of the server object. The source of the security credentials can be the following:

- Based on User IDs and Passwords delivered to HIP by the client application program.
- Based on User IDs and Passwords delivered to HIP by well-defined host protocol standards (SNA attach header: FMH5).
- Default host-based User ID and Password.
- Windows credentials that the HIP application runs under

When host-based credentials are used, the Windows credentials are obtained by using the Single Sign-On (SSO) feature. This feature translates host-based User ID, Password and SSO Affiliated Application ID to a security identification number (SID) that is representative of the Window credentials. The server object is then executed with the translated security credentials.

You can create a new security policy by using the **Security Policy Wizard**.

Other Resources

Using Host-Initiated Processing

Defining New Objects

Objects in the host-initiated processing (HIP) environment represent the Windows Server that will be started after a request is received from a host. The object is defined by a Transaction Integrator Metadata (TIM) file that is generated by the development-time tool in Microsoft Visual Studio.

See Also

Other Resources

Using Host-Initiated Processing

Creating an Object View

Object views in host-initiated processing (HIP) provide different ways to view and manage Windows Server objects in the HIP environment. During the definition of an object view, all methods or a subset of the Objects methods can be defined in the view. This helps provide a level of security by limiting the number of methods available for execution.

When a host environment (HE) is associated with an object view, the level of security is elevated. With the HE association, only certain hosts can execute specific methods of an Object.

When the object view is finally associated with a local environment, the security is enhanced further by restricting the execution of a method on an object to a request from a specific host that made a request to a specific transport endpoint on the Windows operating system.

You can create new object views by using the **New Object View Wizard**. This wizard helps you construct the following administrative entities:

- A view of an object.
- One or more methods in the object to be defined on the view.
- A local environment association.
- Host environment association.
- Method resolution information.

See Also
Other Resources
Using Host-Initiated Processing

How to Modify Objects

After an object has been created and assigned to an application within the host-initiated processing environment, you must be careful when making changes to the object or its Transaction Integrator metadata (TIM) file.

To safely modify a TIM file for an existing object

1. In the TI Manager console tree, right click the object to be changed, and then click **Delete**.
2. Exit TI Manager.
3. Modify the TIM file and save it.
4. Start TI Manager.
5. In the TI Manager console tree, right-click **Objects**, point to **New**, and then click **Object**.
6. Follow the instructions in the **Object Wizard** to re-create the object.
7. In the TI Manager console tree, right-click the re-created object, point to **New**, and then click **View**.
8. Follow the instructions in the **New Object View Wizard** to re-create the object views.

Creating a New Application

Host-initiated processing (HIP) applications represent the execution environment for Windows Server objects that are initiated or driven from host requests. The HIP application execution environment is hosted in and synonymous with a Windows service.

A HIP application can host more than one server object. A HIP application can also have more than one listening endpoint associated with it.

Application definitions are created and managed in the **Computers** node on a specific computer. When the HIP Console is first started, the **Computers** node has only a single computer defined. That single computer is the computer where the HIP administrative console is running. When the Console is first started, no applications are defined on that computer.

You can add a new application to the Transaction Integrator (TI) Manager without specifying the local environment, host environment, objects, and object views used by the application.

Using Host-Initiated Processing

Transaction Integrator Performance Guide

To ensure excellent performance out of the box, Microsoft has run performance tests on Transaction Integrator (TI) to determine its performance and scalability in various deployment situations. This section discusses what was learned about TI.

Many factors can affect performance:

- Security.
- Whether you are using two-phase commit.
- Sharing the server with other Microsoft BackOffice applications.
- Sizing the server initially.
- Planning for future growth.

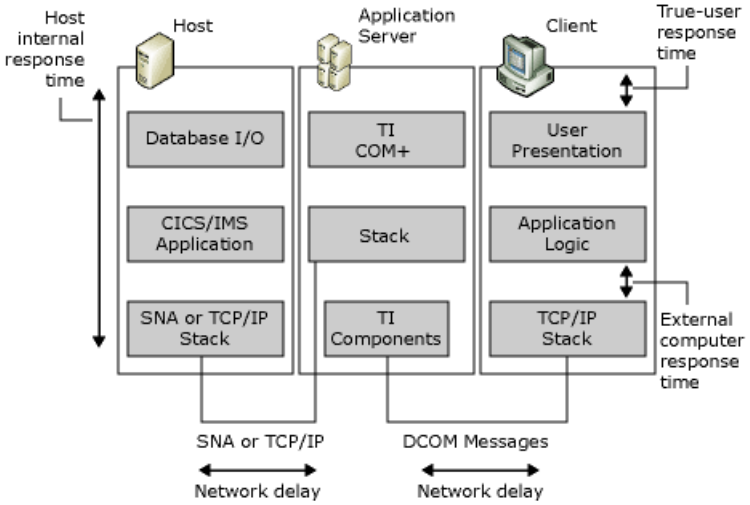
This section will help you handle various load conditions and help you tune your system to give the best possible TI performance while avoiding performance pitfalls, especially with transactions that run for a long time.

In This Section

Major Elements Affecting Overall Performance

Several factors contribute to the total user response time, often called the *response time budget*. To analyze the total system response time more easily, divide the response time into the parts of the system that play a major role in the total response time budget. The following figure shows the main divisions.

Three main divisions -- host, application server, and client --showing how response time is affected by at least three levels within each division and by the network response time between divisions



When you are benchmarking the interactive performance of computers executing a transaction program (TP) on the host, several response time and resource figures are of primary value. These include the host internal response time, external computer response time, network delays, and the true user response time, CPU use, and transaction rates.

In This Section

Host Internal Response Time

External Computer Response Time

Network Delay

True User Response Time

Transaction Integrator Performance Guide

Host Internal Response Time

The host internal response time is the time that the transactions spend inside the host system processing the transaction requests from Transaction Integrator (TI). These include components such as processing the business logic, disk and database I/O, and handling the two-phase commit (2PC) processing.

One way to get an indication of the host internal transaction processing performance is to run the transactions under load without the TI and computer components. A typical goal for an interactive transaction is to keep the response time at 500 ms and less than one second for most part of the daily load conditions. This is a tough goal, and many systems under ordinary operational loads have hard times maintaining this. There is a section dedicated to analyzing the effects on the application server in case the response times get longer.

See Also

Other Resources

Major Elements Affecting Overall Performance

External Computer Response Time

External computer response time is sometimes referred to as end-user response time or end-to-end response time. It is the actual response time that the client application that is running on the computer sees.

When you are using the "FAT-client" architecture, it includes all processing and network delays incurred to the transaction from the time DCOM call was sent to the TI server until the time the reply for the transaction comes back. For "thin client" application architecture, additional delays are incurred because Internet Information Services (IIS) converts the ASP requests to DCOM calls, and delivers the DCOM replies back to the ASP pages for the client on the intranet or Internet.

Other Resources

Major Elements Affecting Overall Performance

Network Delay

Network delay is the difference between what the host measures as the internal transaction response time and what the client computer sees as external response time, excluding the processing time on the application server. On a high-speed local area network (LAN) deployment, the contribution from the network delay can be very small, but when wide area networks (WAN), satellite hops, or modems are involved, they can be major contributors to poor end-user response times.

Major Elements Affecting Overall Performance

True User Response Time

The true user response time is the time that the whole transaction takes to process. This is measured on the user-interface level. The difference in the true user response time and the external computer response time for Transaction Integrator (TI) transactions depends on how much of the processing is done on the client itself. For the FAT client approach, the opportunities to have "business logic" on the client side are greater than that of the thin client. The thin client processing typically involves just screen presentation processing delays.

The response time for FAT client transactions through TI, when the host processing time is virtually zero, is at maximum approximately 50 milliseconds for a small transaction (481 KB in/out). This is measured by the VCperform client application, and represents very closely the true end-user response time, missing only the screen presentation processing time. The amount of data conversion, heavy or light, and also using selection hints and UDTs did not affect the response time.

This response time includes the LAN delays for both TI processing and the backend host simulation processing; it is as close as possible to the optimum possible performance.

Response Time Contributors

On a properly tuned system, TI processing generally contributes less than 50 ms to the overall user response time. Two-phase commit (2PC) adds approximately 100 ms to this as a result of the disk I/O for the Microsoft Distributed Transaction Coordinator (DTC) logging.

The most significant contributor to the overall response time is naturally the host, where most of the work is done (business logic and database access). So the area to focus first in optimizing the performance is the host. To get a better idea of the response time and transaction volumes, use the TI performance counters.

Major Elements Affecting Overall Performance

Performance Monitoring Counters

Transaction Integrator (TI) has 24 basic performance monitoring counters that you can add to the Windows System Monitor to analyze performance and find out where the bottlenecks are in your system. You can select any of the counters, and then click **Explain** to get information about that counter.

The 24 TI performance monitoring counters are as follows:

- **Active Clients**

  Displays the total number of active clients, which are those clients that have created an instance of a TI object but have not yet released that instance.

- **Average method call time**

  Measures the average number of seconds of elapsed time that TI uses to process method calls made by the client application. The time begins when TI receives the request from the client application (the **Invoke** call). The time ends when TI returns control to the client application. This counter includes the host response time, and it is not specific to any TI programming model. Consider the following two facts when you are using this counter:

  - Special TI properties, such as **GetNewRecordsSet**, have been omitted from the calculation.
  - Two-phase commit (2PC) response time is not considered and is omitted from the calculation.

Note
Host response times for CICS, CICS Non-LINK, and IMS can be subtracted from the average method call time to calculate the amount of time TI spends processing methods. For example, assume a transaction takes one minute to complete. The host response time is 48 seconds and the average method call time is 60 seconds. Subtracting the host response time from the average method call time leaves 12 seconds that TI uses to process the methods. The host uses most of the transaction time.

- **Bytes recv'd from a TCP host / sec**

  Displays the number of bytes per second received from the mainframe by TI over the TCP/IP protocol. This counter is not specific to any TI TCP/IP programming model. For the CICS MSLink model, the number reported will be slightly more than the amount of user data due to the Link model protocol header data. Bytes received from the host represent all data traffic, including user data.

- **Bytes recv'd from an SNA host / sec**

  Displays the number of bytes per second received from the mainframe by TI over the SNA protocol (APPC/LU 6.2). This counter is not specific to any TI SNA (APPC/LU 6.2) programming model. For the CICS Link model, the number reported will be slightly more than the amount of user data due to Link model protocol header data. Bytes received from the host represents all data traffic, including user data and two-phase commit (2PC) flows.

- **Bytes sent to a TCP host / sec**

  Displays the number of bytes per second sent from TI to the mainframe over the TCP/IP protocol. This counter is not specific to any TI TCP programming model. For the CICS MS Link model, the number reported will be slightly more than the amount of user data due to Link model protocol header data. Bytes sent to the host represent all data traffic over TCP/IP, including user data.

Note

To determine the TI load on the Host Integration Server computer, you can compare the average number of bytes sent and received by TI with the corresponding performance counters for Host Integration Server. For example, if the averag e number of bytes sent to the host from TI is 20 and the average number of bytes sent to the host by Host Integration S erver is 100, Host Integration Server traffic is responsible for most of the load. Consequently, the amount of informatio n coming back from the host could be less than that going to the host. That is why two counters are available, one for t he number of bytes sent and one for the number of bytes received.

- **Bytes sent to an SNA host / sec**

  Displays the number of bytes per second sent from TI to the mainframe over the SNA (APPC/LU 6.2) protocol. This counter is not specific to any TI SNA (APPC/LU 6.2) programming model. For the CICS Link model, the number reported will be slightly more than the amount of user data due to Link model protocol header data. This number is represented in terms of bytes per second.

- **Calls currently executing**

  Displays the number of method calls that are currently being executed.

- **Cumulative calls**

  Displays the total number of method calls that have occurred since the COM+ application was started.

- **Host resp time CICS Link**

  Measures the average time the host spends processing the transaction program's unit of work when the CICS Link model is in use. In other words, this counter measures how long the host takes to respond to a request. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time. Consider the following two facts when you are using this counter:

  - Two-phase commit (2PC) response time is not considered and is omitted from the calculation.
  - Multiple receives might be contained in the first response buffer sent to TI. Therefore, the response time ends when TI has obtained all receives to the first response buffer.

- **Host resp time CICS Non-link or IMS**

  Measures the average time the host spends processing the transaction program's unit of work when either the CICS Non-LINK or IMS models is in use. In other words, this counter measures how long the host takes to respond to a request. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time. Consider the following two facts when you are using this counter:

  - Two-phase commit (2PC) response time is not considered and is omitted from the calculation.
  - Multiple receives might be contained in the first response buffer sent to TI. Therefore, the response time ends when TI has obtained all receives to the first response buffer.

- **Host resp time TCP Concurrent Server**

  Measures the average time the host spends processing the transaction programs unit of work when the TCP/IP CICS Concurrent Server model is being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time.

- **Host resp time TCP Explicit**

Measures the average time the host spends processing the transaction programs unit of work when the TCP/IP IMS Explicit model is being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time.

- **Host resp time TCP Implicit**

  Measures the average time the host spends processing the transaction programs unit of work when the TCP/IP IMS Implicit model is being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time.

- **Host resp time TCP MS Link**

  Measures the average time the host spends processing the transaction programs unit of work when the TCP/IP CICS MSLink model is being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time.

- **Host resp time TCP IMS Connect or OTMA**

  Measures the average time the host spends processing the transaction programs unit of work when the TCP/IP IMS Explicit model is being used. This average time counter measures the time the host takes to respond to a request sent to it. The time starts after TI sends the final data buffer and ends when the first response buffer is received by TI. This counter is represented in terms of seconds of elapsed time. IMS Connect or OTMA enables customers to connect to existing IMS transactions without linking listeners to the transaction programs (TP), so you do not have to recompile your IMS TP.

- **Link calls / sec**

  Displays the number of method calls that use the CICS LINK programming model. This number represents of calls per second.

- **Non-link calls / sec**

  Displays the number of method calls that use the CICS Non-LINK or IMS programming model. This number represents calls per second.

- **TCP Concurrent Server calls / sec**

  Displays the number of method calls that use the TCP/IP CICS Concurrent Server programming model. This number represents calls per second.

- **TCP Explicit calls / sec**

  Displays the number of method calls that use the TCP/IP IMS Explicit programming model. This number represents calls per second.

- **TCP Implicit calls / sec**

  Displays the number of method calls that use the TCP/IP IMS Implicit programming model. This number represents calls per second.

- **TCP MSLink calls / sec**

  Displays the number of method calls per second that use the TCP/IP CICS MS Link programming model.

- **TCP OTMA calls / sec**

Displays the number of method calls that use the TCP/IP OTMA programming model. This number represents calls per second.

- **Total calls / sec**

  Displays the total number of method calls per second that TI has processed. This counter is not specific to any TI programming model.

- **Total errors / sec**

  Displays the total number of method calls per second that have returned a non-zero HRESULT to the client application. This counter is not specific to any TI programming model.

Note
Comparing method call errors with CICS LINK calls and CICS Non-LINK calls shows the severity of a given situation. For example, if the Method call errors counter reports two errors per second and LINK calls or CICS Non-LINK calls are reporting 50 method calls per second, it may indicate that one client application has trouble with a specific host application. Consequently, if the Method call errors counter reports 50 errors per second and CICS LINK calls or CICS Non-LINK calls are reporting 50 method calls per second, this indicates that a connection to the host might have been terminated.

How to Add TI Performance Counters to Windows 2000 System Monitor

Follow these steps to add Transaction Integrator (TI) performance counters to Windows 2000 System Monitor.

To add TI performance counters to Windows 2000 System Monitor

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Performance**.
2. Click **+** at the top of the details pane.
3. In the **Add Counters** dialog box, move to the top of the **Performance object** box, and then click **COM Transaction Integrator**.
4. Select all the TI performance counters that you want from **Select counters from list**, and then click **Add**.
5. Click **Close** to close the **Add Counters** dialog box.

Performance Monitoring Counters

Method Calls per Second

The counter reports the method call volume going through the Transaction Integrator (TI) server. There are actually three counters implemented:

- Method calls using the CICS LINK mode.
- Method calls using the CICS non-LINK or calls to IMS.
- Total method calls.

Assuming that the system is in somewhat stable condition, that is, the calls are returning at the same rate that they are made, these counters represent the transactions per second throughput number for TI.

See Also

Other Resources

Performance Monitoring Counters

Average Method Call Time

The average method call time performance counter represents the response time the transaction has from the time Transaction Integrator (TI) receives the method call, until the time it sends the reply back to the client. This does not include the LAN/WAN delays between the client and TI server.

See Also

Other Resources

Performance Monitoring Counters

Errors Per Second

The errors per second performance counter indicates whether the method calls are failing on errors. Under normal operation, this value should remain at zero or very close to zero.

Performance Monitoring Counters

Host Response Time

The host response time indicates the response time observed by the Transaction Integrator (TI) transport component, measuring the time from the call to the server computer, or TCP/IP stack, until the reply from the host. This includes some networking overhead. In a typical well-tuned high bandwidth LAN environment, this response time should be very close to the actual host processing time.

You should consider some important tuning issues, especially with SNA Link, in order to declare this to be the representative figure for the host. For more information, see SNA Link Tuning. For the host response time, TI again separates the CICS LINK mode, and the CICS non-LINK or IMS mode into two separate counters.

Performance Monitoring Counters

Bytes Sent Per Second

The bytes sent per second performance counter reports the total data flow in bytes from the Transaction Integrator (TI) server to the host per second. This becomes a useful counter when TI transactions become large, and communication links can become the bottleneck in the system. This is particularly important when WANs are used.

See Also

Other Resources

Performance Monitoring Counters

Bytes Received Per Second

The bytes received per second counter reports the total bytes received from the host per second. The bytes received together with the bytes sent represent the total data transfer on the communications links between the Transaction Integrator (TI) server and the host computer.

Adjusting Application Priority

Under ordinary loads, there is no need to adjust the Windows tasking priorities. However, you can increase server task performance out of the system to cover peak loads by adjusting the balance between background and foreground applications. An even balance between the two gives background applications a better response time, but still gives more processor time to the foreground application.

To adjust the balance between background and foreground applications in Windows 2000

1. Open **System** in **Control Panel**.
2. Click the **Advanced** tab.
3. Click **Performance Options**, click **Background services** under **Optimize performance for**, and then click **OK**.

Windows Server Tuning

Reducing Context Switching

Context switching reduces server performance on any operating system: Windows 2000 is no exception. If a system is doing 50,000+ context switches per second (unlikely, but possible), it does not have time to do actual work. Instead, it is spending all its time switching various code and data pages in and out of its memory to L2 cache, RAM, or even to the disk drive; in other words, the system is *thrashing*.

Adjusting Thread Count

You can reduce the amount of context switching by reducing the total number of active threads. The topics in the Transaction Programs that Run for a Long Time section describe two registry entries that can increase the thread counts for a COM+ application and Transaction Integrator (TI) two-phase commit (2PC) transactions. Be sure to adjust the thread counts to gain optimum performance. Always track the context switching per second when making adjustments to these two registry entries.

In addition to adjusting the COM+ and TI threading, you can also adjust the Host Integration Server asynchronous I/O threading model. These threads serve the Host Integration Server client traffic only, and are designed to handle the full 30,000 sessions hitting Host Integration Server with over 1,000 transactions per second (TPS). Performance testing in the Microsoft lab environment has shown no reason for adjusting these values, but if you need to minimize the thread count in your system, you can make adjustments because TI represents only one client to Host Integration Server.

Use the following information to calculate the thread count:

- The Host Integration Server I/O thread count is equal to the base thread count plus the additional threads per CPU multiplied by the number of CPUs.
- The base thread count is five.
- By default, there are an additional four threads per CPU.

To adjust the thread count, specify the number of additional threads per CPU by adding a DWORD value *NumberofIOthreads* to the \parameter registry location. You can have up to 64 I/O threads per system.

Windows Server Tuning

Streamlining Authentication

Transaction Integrator (TI) users are typically authenticated for both the Windows domain and the host domain on a transaction-by-transaction basis. Host Integration Server provides the necessary security integration between these systems.

You can set the *Already verified* parameter to streamline the authentication on the host side. Both TI and the Host Integration Server node maintain a cache of verified domain/user IDs in a secured location. To guarantee fast access to the Windows authentication, install the primary or backup Windows 2000 domain controllers, TI, and Host Integration Server all in the same LAN segment. Installing these helps to eliminate delays caused by bridging or routing.

How to Optimize Network Throughput in Windows

For Windows 2000 and Windows Server 2003, you can adjust networking priority to guarantee the best possible networking throughput.

To optimize network throughput in Windows

1. Click **Start**, point to **Settings**, and then click **Network and Dial-up Connections**.
2. Right-click a connection, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **Components checked are used by this connection**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
   - If this is a dial-up, VPN, or incoming connection, on the **Networking** tab, in **Components checked are used by this connection**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
4. Click **Maximize data throughput for network applications**.

Transaction Integrator Performance Guide

LU 6.2 Contention Winner Limit

Transaction Integrator (TI) uses only LU 6.2 contention winner sessions. The number of sessions negotiated with the host system determines the number of sessions available for concurrent TI client requests. The parallel session limit and contention winner limit should be set to the same value within the Host Integration Server APPC mode definition used by TI.

Note
Other APPC applications can share the same Local APPC LU, Remote APPC LU, and Mode used by TI. If they do, you must define sufficient sessions to handle the needs of all applications.

In addition, the Request/Response Unit (RU) size should be sufficiently large to hold the standard message size sent between TI and the host application. For example, if the host response is expected to exceed 2 KB, set the Max Send and Receive RU size to 4096 within the Host Integration Server APPC mode definition. The session level pacing values will not likely affect transaction performance because a transaction may only involve a single request and single (under 4 KB) response. In this case, an APPC mode send and receive window of two or more should be sufficient. However, if a large host response is expected, it is recommended to use a larger RU size to reduce SNA-level message acknowledgements.

Troubleshooting Suggestions

Before starting a connection, enable Host Integration Server data link control (DLC) and LU 6.2 message traces of the connection startup and initial TI component use. Provide the traces to an SNA support engineer. This engineer can decode the DLC trace to determine the parallel session limit and contention winner limits negotiated in the Change Number of Sessions (CNOS) exchange for the LU/LU/mode used by TI.

Other Resources

SNA Communication Tuning

Transaction Integrator Performance Guide

Pre-Activation of the LU 6.2 Sessions

Activating LU 6.2 sessions in advance will automatically prevent a short delay in establishing new LU 6.2 sessions as Transaction Integrator (TI) conversation allocation requests are made. In addition, pre-activating sessions keeps idle sessions active during the SESTIMEOUT period (approximately 20 seconds).

Host Integration Server honors its APPC mode automatic activation limit setting for any APPC LU/LU partnership defined within the APPC mode when the connection is initially activated. Partnerships are defined in the **APPC-mode Partners** tab.

For more information about the *SesTimeout* registry parameter, search the Host Integration Server online Help.

Other Resources

SNA Communication Tuning

SNA Link Tuning

If you are using token-ring, Ethernet, or FDDI to communicate with your host system, investigate data link control (DLC) tuning. The following 802.2 connection default settings should be sufficient:

- Unacknowledged Send limit is 8 by default.

- Receive ACK threshold is 2 by default. However, some hosts are set to a Send Window of 1, so they require an ACK from Host Integration Server for every frame they send; whereas with the default of 2, the host can stop sending until the ACK has been received. The DLC will then go through the time-out and recovery, but the performance will be decreased significantly. It is important that you set each node's send window to be larger than its partner's receive window.

- Maximum BTU length: 1929 for token-ring, 1493 for Ethernet. If a 16-Mbps token-ring is being used, and the TI request or host response will exceed this BTU length, increase the maximum BTU length to 4105 (or 8192 for the maximum possible) within the Host Integration Server connection.

Troubleshooting Suggestions

Capture a Network Monitor or Sniffer trace of Host Integration Server computer-to-host traffic, and provide it to an SNA support engineer. The engineer can use this trace to observe the Send Window and Receive ACK threshold being used by both ends by looking at the LLC traffic.

Other Resources

SNA Communication Tuning

Host (VTAM, CICS or IMS) Response Time

The host response time, also called the unit of work (UOW) or host processing time, for each transaction affects the number of transactions that can be performed given the number of LU 6.2 sessions that are used.

If CICS is used, investigate the CICS region definitions for parallel session limit and contention winner limit. These values are configured in the Maximum parameter in the CICS region SESSION PROPERTIES:

SESSION PROPERTIES Maximum==>100, 000

The first value is the parallel session limit and the second value is the CICS contention winner limit. For Transaction Integrator (TI) use, Host Integration Server should be configured as the contention winner for all sessions, so you should set the CICS contention winner limit to zero (0). Also, verify that the CICS region maximum tasks value is sufficient to handle the concurrent client requests.

If you are using IMS, verify that IMS has sufficient message processing regions to handle the expected load.

Troubleshooting Suggestions

Capture a Host Integration Server data link control (DLC) message trace of the throughput test and analyze the host response time observed on the LU 6.2 sessions.

Within a Host Integration Server DLC message trace, a unique LU 6.2 session is distinguished by a unique Originating Address Field (OAF), Destination Address Field (DAF), and OAF/DAF Assignor Indicator (ODAI) values. The OAF and DAF specified in a Host Integration Server session request will alternate on the host response.

Note
Either end can deallocate the conversation, although this is often done by TI. However, it is possible for the host data respons e to contain the Conditional End Bracket (CEB).

SNA Communication Tuning

SNA vs. TCP/IP

TCP/IP is not as scalable as SNA with Transaction Integrator (TI), but TCP/IP is more effective in other areas such as file transfer and data access (about 10-15% better on OLEDB tests). In addition, the IBM endorsement of TCP/IP simplifies the corporate networking infrastructure and enables easier interoperability to the Internet.

To study the performance differences for TI with TCP/IP as the up-stream link protocol versus SNA, Microsoft performed a stress test where the only change to the setup was the up-link protocol. The SNA test was set to use the **SelectionHint** property setting because this is the same process performed by the TCP/IP up-link. For more information about the effects of the **SelectionHint** property, see Remote Environment Selection Using the SelectionHint Property.

Analyzing the average response time as a function of transactions performed, Microsoft found that TCP/IP is as fast as SNA. In fact, TCP/IP is faster than SNA when the load is below 100 transactions per second (tps). For some deployments, that is the typical operating range. As the load increases, the connectionless TCP/IP up-link starts to slow down the response time and clips the top performance at 500 tps. The SNA up-link enables stable response times throughout the load range, and therefore achieves higher scalability.

To analyze the superior scalability of SNA compared to TCP/IP, Microsoft charted the frames per second over the backbone LAN. Whereas SNA maintains its sessions from transaction to transaction, TCP/IP must establish and destroy the TCP/IP connection for each transaction. This results in more frames transmitted over the up-link compared to SNA. In our tests, the 100baseT Ethernet LAN did not become a bottleneck, but this can become the critical issue if the link speed between the TI server and the host is slower. In any case, the TCP/IP connections and disconnections generate some additional interrupts for both ends.

Additional analysis shows an advantage that the TCP/IP up-link has over the SNA up-link that might become the deciding factor in a real-world deployment. When you are using the SNA up-link, the TI Automation server must endure almost twice the amount of context switching compared to the TCP/IP up-link case. This is because with SNA, the messages are passed from TI first to the SNA server node and then to the SNA link service. These are separate processes, so there is process-to-process communication and context switching. With TCP/IP this does not occur; TI passes the messages directly to the NDIS driver. On a server where additional processing of business logic is occurring, so much context switching may occur that throughput and scalability are affected.

Transaction Integrator Performance Guide

LAN Throughput

The **100baseT** alternative to connect the Transaction Integrator (TI)/Host Integration Server computer to your host system is the most popular and currently the most available. This topic explains the bandwidth offered by **100baseT**, and the amount of that bandwidth that you can actually start using productively.

Calculating the Maximum for 100baseT

You can calculate the theoretical maximum in the following way for the **100baseT** Ethernet:

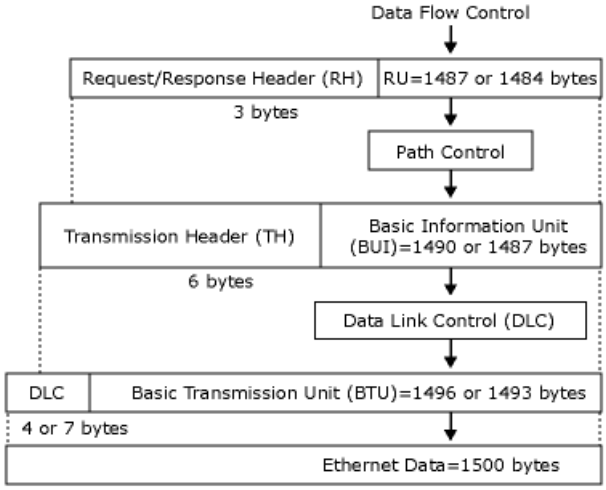
100BASE-T is clocked at 100 MHz, with a 25-MHz crystal multiplied by 4. The coding is 8/10, meaning one byte is packaged into 10 bits. Therefore, you can at most transfer 100/10=10 million bytes per second. To convert this number to megabytes per second (MBps), divide it in the following way:

*10,000,000/(1024*1024)=9.5 MBps*

Then there is the question of efficiency. Ethernet provides up to 90-95% efficiency (CSMA-CD). There is a maximum payload of about 1500 bytes per frame, and some minimum inter-frame spacing. Also, if you use half-duplex cabling, the ACK packets must take the bus sooner or later, making it almost impossible to reach the maximum.

The frame format for 802.2 over Ethernet is at maximum 1487 bytes, or 1484 depending on the Ethernet standard used IEEE, or DIX. The following figure shows the maximum RU and BTU sizes over an Ethernet.

Data flow control showing maximum sizes over an Ethernet: 1487/1484 bytes for RU, 1490/1487 bytes for BIU, 1496/1493 for BTU, and 1500 bytes for Ethernet data



The format for TCP/IP over Ethernet is 14-byte Ethernet layer+20 IP+20 TCP+12 (TCP-timestamp)+1448 data. For each packet, the header overhead is 54/66 bytes. Of course, there are the ACK packets, one every two packets in TCP/IP. Therefore, the header overhead is three headers for two data packets, which is around 7-8%.

For 802.2 data link control (DLC) traffic, the acknowledged frequency is controlled by each end negotiating with its partner. For more information, see SNA Communication Tuning.

For the 90–95% efficiency referred to previously, the throughput is affected by various other factors, such as the size of the broadcast domain, whether the LAN is on a switch or a hub, the number of servers sharing the segment causing possible collisions, and whether your network has other protocols such as IPX, whose broadcasts can consume some of the available bandwidth.

Looking at the LAN usage levels in lab tests on an isolated switched 100baseT, with only a few servers on the segment, we should be getting close to the theoretical maximum minus the known overhead. Can TI push the LAN to the maximum performance?

The test results show that when sending 32000 bytes, and receiving 32,001 bytes back, TI can drive the 100baseT close to its maximum performance if there is only minimal data conversion and no other "business logic" or processing competing with TI on the server. This is, of course, with an isolated optimized network. The backbone network in the real world must endure a lot more overhead without becoming the bottleneck for the system. To be on the safe side, a prudent design criterion for 100baseT LAN would be to keep the planned load as follows:

- Less than 4 MBps for systems that mainly move data.
- Less then 3 MBps for systems with short interactive transaction messages.

The reason for designing the interactive LAN load to a lower limit is due to the higher number of frames per MBps. Observing these criteria will set the peak LAN load to a safe 50% of the LAN's capacity.

Other Resources

System Sizing

Escon Channel Throughput

Although the 100baseT LAN can operate with 3–5 MBps throughput range on a heavily loaded system, the Escon channel specified at 17 MBps can reach very close to its maximum specified throughput. Tests done with Host Integration Server on a channel-attached quad PP200 were able to reach 12 MBps against a large mainframe using LU 6.2 doing straight memory-to-memory transfer. This rate is not typically reached except during system backup procedures or database distribution.

To place this result in the right context for a large online transaction processing (OLTP) system doing 500 TPS with transactions typically consisting of 200-byte input and 1900-byte reply, the Escon overall data rate would be 1 MBps plus some overhead. The Escon channel rarely becomes the system bottleneck because one adapter can support multiple 17-MBps channels using the Escon Multiple Image Facility (EMIF).

System Sizing

Normal Load

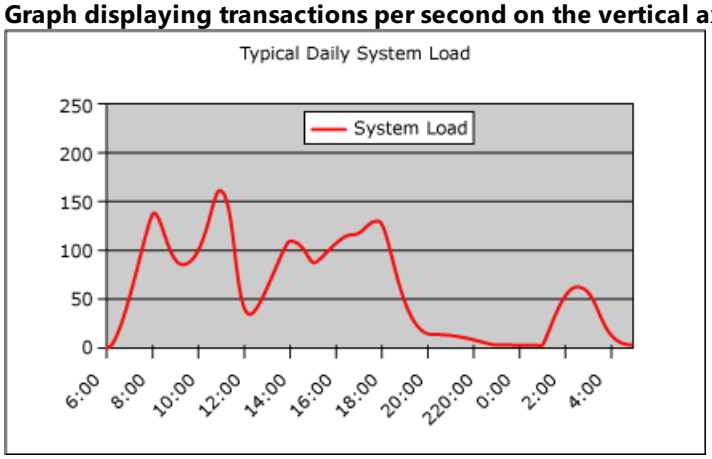
To size the Windows 2000 applications server, you must review system behavior over the course of a day, and also over the course of a longer period of time (typically matching the accounting period to capture the month-end processing).

Analyzing Load Patterns

Analyzing these load patterns gives a more accurate view of the requirements for the system sizing. The following chart illustrates a hypothetical business system load on a typical business day. If you make the effort to capture the daily load spread, Mondays or Fridays typically give the most information about the daily swings on the load. The chart shows an average workload of 60 TPS over 24 hours, and 100 TPS over 12 hours—a business day. If you used the daily averages for the system sizing, (peak loads at 8:00 AM, right before lunch, and close of business at 5:00 PM), the result is system overload and poor performance. This poor performance would irritate users daily and cause them to change their work patterns, yielding less efficient operations.

The following figure shows a typical system load.

Graph displaying transactions per second on the vertical axis and hour of the day on the horizontal axis



Additionally, at less frequently occurring high peaks, such as month-end processing, the required peak load handling is increased if the processing overlaps with the daily peak loads. If the extra processing can be scheduled during low load time periods, for example, 10:00 PM to 1:00 AM, no extra capacity is needed.

Preparing for Running in Degrade Mode

Because Transaction Integrator (TI) is a combination of application server and transactional gateway between COM applications and CICS and IMS applications, some level of fault tolerance is required. On large OLTP systems, for example, serving a company's order entry, shipping, and inventory management, system uptime is an essential requirement for success. Levels of fault tolerance can be achieved as described in Load Balancing and Hot Backup.

When sizing the system to match the throughput requirements, you must provide enough processing power on the remaining servers if one server in the cluster fails. For load balancing two servers under ordinary conditions, each server should be able to handle the daily peak loads alone—not necessarily at 60% CPU load, but not exceeding the 90% limit either. For three server systems, any two should be able to handle the daily peaks at 60-90% CPU levels. If you size close to 90% CPU on a degraded operation, a slight response time impact can be expected. This is acceptable, if the recovery from the failure does not last more than a day or two. This usually means that a spare server is available locally and that it can be easily configured for service.

You should also study the excess load caused by the recovery process, its duration, and impact on the system responsiveness during that time.

Considering System Growth

Estimating system growth can be difficult. Careful study of the functional requirements, business plans, market growth, and user community might not provide the exact answers, but it can provide a rough estimate of the growth potential for the system. For a successful company, this growth rate can be as high as 25% per year, and usually during the first year from the deployment even as high as 50% per year. If our projection for the system growth follows these lines, we must deploy with 50% extra capacity at hand, either as larger servers, or as additional servers available for load balancing. Looking at a 5-year growth path, the plan can include changing to more powerful servers, adding more SMP CPUs to the servers, or adding more servers into the cluster.

The following tables show an example where a typical system with daily peaks of 160 TPS first grow at 50%, with 25% growth after that. The first table shows the server rating at various CPU% based on the applications used and tested.

Server	**TPS at 60%**	**TPS at 90%**
Dual Xeon 400	110	160
Quad Xeon 400	220	320

The following table shows the growth projections.

	First year	**Second year**	**Third year**	**Fourth year**	**Fifth year**	**Sixth year**
Growth %	50%	25%	25%	25%	25%	
Daily peak TPS	160	240	300	375	468	585
Deployment	Two dual 400s in a cluster.	Three dual 400s in a cluster.	No upgrade	One dual two quad 400s in a cluster.	No upgrade.	Three quad 400s in a cluster.
Action		Add a dual server to the cluster.		Add two CPUs to two servers.		Add two CPUs to one server.
Reason		Dual 400 maxes out at 160 TPS.		Two dual 400s max out at 320 TPS.		A dual and a quad max out at 480.TPS
Best practice	Two quad 400s in a cluster.	No upgrade.	No upgrade.	Three quad 400s in a cluster.	No upgrade.	No upgrade.

Creating a Plan for Growth

Creating a plan for future growth can be a time-consuming and difficult task. You can spend a lot of time testing and creating load scenarios for the future. Also, the continuing development of the hardware and software will affect your planning. Future computer systems are likely to outperform the currently available models with many 100% increase in dollars/throughput, thus causing the plan to be less accurate and outdated. To avoid this, a few rules of thumb can be helpful:

- Plan at least two growth scenarios with the hardware available today, with easily available performance data. Plan one scenario for aggressive growth, and one for minimal growth.
- For the initial purchase of the hardware/software, consider such factors as architecture, hardware availability, networking options.
- Revisit your plan annually, updating your projections and growth plans.

- Consider your growth plan in light of the future roles of the other computing systems in the enterprise: How is inventory control going to evolve? How are customer orders handled and which system is handling them? Are customer orders going to migrate from one system to another?

Estimating the System Load

The following table can help you collect the transactional load information you need for appropriate system sizing.

Element	Sample	Comments
Transaction name	MD481	
Input buffer size	481	Data that user/client application sends to CICS/IMS.
Data Conversion; L/M/H	m	Light= mostly char, Medium= 1/3 Char, 1/3 Float, 1/3 Packed Decimal.
Structured data; NO/UDT/ADO RS	no	UDT=user-defined data types, ADO RS= disconnected recordsets
Reply buffer size	481	Reply buffer size from CICS/IMS.
Data conversion; L/M/H	m	Heavy= No char data, mix of floats, date-times, packed dec.
Structured data; NO/UDT/ADO RS	no	
Transactional; YES/NO	no	YES= two-phase commits are used with CICS/IMS and other forks.
Security; NO/User/Pkg	no	Type of integrated security in use.
Client type; ASP/DCOM	asp	ASP= Web-based client, DCOM= client using DCOM to invoke pkg.
Package: Lib/Svr	svr	Library= inprocess COM pkg, Server=COMTI pkg is on its own process.
Number of users	3000	
Total average daily load; TPS	30	
Total daily peak load; TPS	70	
Minimum Host Unit of Work time in ms	350	Milliseconds spent from processing input to sending user reply.
Minimum Host prepare time in ms		Two-phase commit only.
Minimum Host commit time in ms		Two-phase commit only.
Expected user response time	800	
Maximum allowed response time	1600	Maximum acceptable response time.

Creating a System Load Spreadsheet

This table provides all the detailed information you need including the type of transactions, the load levels, and the acceptable response times. In your spreadsheet, create a "Sample" column to represent each type of transaction. For example, you might have five columns, one for each of the following transactions:

- Order header entry
- Order line item
- Inventory move
- Shipping header
- Shipment line

As you can see, on a large-scale system, with many different transactions, the number of columns can become unmanageable. In that case, you might want to flip the spreadsheet clockwise 90 degrees so that you can list the elements in the columns of the first row, and then place each transaction in a row.

Adding the columns to illustrate the amount of server, LAN, and host resources will complete the estimation. These will remain the real challenge, because each transaction and implementation is different, and cannot be standardized. Thus, all the test cases illustrated in this table are without any business logic processing included. They remain a task for the system designer to estimate.

Load Balancing and Hot Backup

Load balancing and hot backup allow for scalable applications and increased performance on enterprise systems. Deploying multiple servers increases application throughput by distributing the load based on rules that are defined by the load balancing engine. Load balancing services also increase availability by detecting connection failures and providing redundant resources for client applications.

Transaction Integrator (TI) can be deployed taking advantage of several load balancing and hot backup solutions. The topics in this section describe the various load balancing and hot backup methods that TI supports today.

In This Section

Host Integration Server Load Balancing

Transaction Integrator (TI) can use Host Integration Server load balancing and hot backup capability by deploying multiple Host Integration Server End-User Client and Host Integration Server Server computers in a single subdomain. Redundant APPC session pairs can be configured across multiple Host Integration Server computers to provide load balancing and hot backup. When a communication failure occurs, hot backup reroutes sessions to other host connections. For information about how to set up a hot backup system for two-phase commit and TI, see Providing a Fail-Safe Environment for ACID Transactions.

Autoactivating Sessions

For sessions to be spread across several servers, you must configure the mode definition to autoactivate sessions. When an APPC application (such as TI) requests a conversation, the APPC library sends a non-forced open LU 6.2 request to every node (SNA Server), which has the required Local logical unit (LU) (or a Local LU in the default pool if no LU name is specified). The node returns an error that indicates the best connection to use. The APPC library then chooses the response that has the lowest error number and issues a forced open LU 6.2 request.

LU 6.2 Errors

The errors for LU 6.2 are as follows:

0804 = Connection is disabled.

0604 = Session limits reached for LU/LU/mode.

0404 = Dependent LU - Connection active, but no LU-SSCP session active.

0204 = Dependent LU - LU-SSCP active, and PLU-SLU session already in-use.

0008 = Connection is pending.

0004 = Connection is inactive, no LU-SSCP session active.

0003 = If dependent LU, no LU-SSCP or PLU-SLU session active. If independent LU, CNOS not done yet for this LU/LU/mode.

0002 = Independent LU - CNOS done but no sessions currently active.

If the connection has an active session available (in other words, it is a bound session without a conversation established), the non-forced open LU 6.2 is processed by the node and returns a positive response to the APPC library (assuming it was successful in its request to the host).

For load balancing to work correctly, all connections must have active sessions available. If this is not the case, the first connection to establish a conversation is always chosen by the APPC library because it will return a lower error than the other connections. You can configure connections to autoactivate sessions by setting the autoactivation limit and LU partnering in the mode definition.

Configuring TI and Host Integration Server for Load Balancing

TI must also be installed on its own server independent of the two Host Integration Servers that have connections to the host. If TI is installed on either of the two servers that have connections to the host, load balancing will not function.

The Host Integration Server client process (the SnaBase service on Windows 2000) opens a sponsor connection to the SnaBase service on a Host Integration Server computer in the subdomain. This sponsor connection remains active while the Host Integration Server client process is running. When the Host Integration Server client process first starts, the client receives a list of all Host Integration Server computers in the subdomain. After that, only server changes are sent.

Host Integration Server

To configure Host Integration Server for APPC Load Balancing, define redundant local LU and remote LU aliases across Host Integration Server computers by using SNA Manager. For example:

Server 1

- Local APPC LU alias=COMTI
- Local APPC LU network name=APPN and LU name=SERVER1
- Select the **Member of default outgoing Local APPC LU pool** check box
- Remote APPC LU alias=CICS

- Remote APPC LU network name=APPN and LU name=CICS

Server

- Local APPC LU alias=COMTI
- Local APPC LU network name=APPN and LU name=SERVER2
- Select the **Member of default outgoing Local APPC LU pool** check box
- Remote APPC LU alias=CICS
- Remote APPC LU network name=APPN and LU name=CICS

Server

- Local APPC LU alias=COMTI
- Local APPC LU network name=APPN and LU name=SERVER3
- Select the **Member of default outgoing Local APPC LU pool** check box
- Remote APPC LU alias=CICS
- Remote APPC LU network name=APPN and LU name=CICS

Required Parameters

The following table references the required Host Integration Server, VTAM, and CICS parameters.

Host Integration Server	VTAM	CICS
Local Node ID—First 3 Digits	IDBLK in PU definition	Not applicable
Local Node ID—Last 5 Digits	IDNUM in PU definition	Not applicable
Control Point Name	CPNAME in PU definition	Not applicable
Max BTU Length	MAXDATA in the PU	Not applicable
Local APPC LU Name	Name in LU definition	Sessions
APPC Mode	DLOGMOD in the LU definition	Mode name
Remote APPC LU Name	Not applicable	APPLID

Transaction Integrator

To configure TI to use the Host Integration Server load balancing capability, you must do the following:

- Configure the "CICS Link using LU 6.2," "CICS using LU 6.2," or "IMS using LU 6.2" remote environments for the same local LU alias and remote LU alias defined on the Host Integration Server computer.
- Create a unique Local Node ID on each Host Integration Server computer, configured for hot backup to occur across Host Integration Server computers to a single host. (LOCADDR in the VTAM definition must be set to 0 to support independent LU 6.2.)

- Define the following registry entry on the Host Integration Server End-user client:

  KEY_LOCAL_MACHINE\System\CurrentControlSet\Services\SnaBase\Parameters\Client\ ResLocFlags: REG_DWORD: 0x8001

- In mode definition, set the autoactivation limit and LU partnering limits. This configures your connections to autoactivate sessions.

Load Balancing and Hot Backup

Web-to-Host Load Balancing

Internet Information Services (IIS) can use Windows 2000 Network Load Balancing (NLB) to provide load balancing and fail-over support for incoming HTTP requests. NLB is a TCP/IP-based load balancing solution that load balances incoming TCP/IP packets to all nodes in a cluster or to a single node in a cluster. NLB distributes the load across identical servers.

The Host Integration Server clients and Web browsers go through IIS to gain access to the Active Server Pages (ASP) that invoke the Transaction Integrator (TI) methods that call the CICS or IMS transaction program (TP).

NLB provides high availability on enterprise systems. It detects connection failures and automatically redirects requests to other nodes in the server farm. NLB also improves performance when all incoming packets are load balanced between various nodes in the server farm based on server load.

You can configure NLB to balance the load on multiple servers that use single affinity, no affinity, or Class C. No affinity distributes all incoming TCP/IP requests across any node in the NLB server farm, which can increase the number of requests that need to be redirected because there is no concept of a session state. We recommend that you use IIS to distribute HTTP requests configured for single affinity. When the server is configured for single affinity, all incoming packets using the NLB virtual IP address are locked to a specific node in the server farm. Every packet that is sent from the client using the cluster IP address will connect to that node.

Note
NLB cannot detect whether the TI Automation server fails to respond. It can only detect if the server fails, for example if TCP/IP does not respond.

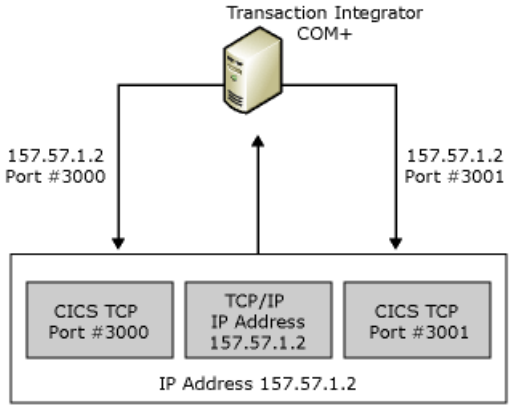
Load Balancing and Hot Backup

TI TCP/IP Load Balancing

Transaction Integrator (TI) can load balance TCP/IP ports when you have configured TI for CICS and IMS TCP/IP remote environments. To enable load balancing, supply multiple TCP port numbers when you create the remote environment; this enables connections to redundant CICS or IMS regions on a single host system. The following figure shows the TI TCP port load balancing solution.

Transaction Integrator receiving a TCP/IP address and sending it to CICS ports 3000 and 3001



The first TCP port is used by the first transaction and will take turns going through all the configured ports for each transaction that is invoked.

Additional host configuration details for CICS and IMS are included in the following sections.

CICS TCP/IP Platform Requirements

The version dependencies for CICS include the following:

- TCP/IP version 3R2
- CICS version 3.3 or later

Connections to CICS Using TCP/IP

CICS uses the IBM-supplied Concurrent Listener (program EZACIC02, transaction ID CSKL) to establish an interaction with TCP/IP. The Listener runs as a CICS task to help facilitate the connection process. The Listener transaction starts automatically when CICS TCP/IP is started and enabled. When the Listener starts, it obtains a socket on which it can listen for connection requests from TCP/IP. The Listener binds this socket to a specified port, and then it waits for a client request on that port. TCP/IP maintains a relationship of a port number to a CICS job. When a client makes a request on a port associated with CICS, TCP/IP forwards the connection request to the Listener in that CICS job.

TCP/IP-to-CICS Configuration

A TCP/IP port number is associated with a CICS region in the TCP/IP profile data set (hlq.PROFILE.TCPIP). The port statement is used to define this relationship. An example of a port statement that associates port 3000 with CICS job CICSRG follows:

```
3000 TCP CICSRG
```

CICS to TCP/IP Configuration

The following sample host definition shows configuration parameters for CICS-to-TCP using the EZAC transaction. The items in bold type are CICS transactions.

```

FASTRD        ===> YES                   Read Immediately    Yes|No
TRANTRN      ===> YES                  Translate TRNID     Yes|No
TRANUSR      ===> YES                  Translate User Data Yes|No
SECEXIT       ===>                          Name of Security Exit
```

IMS TCP/IP Platform Requirements

The version dependencies for IMS include the following:

- TCP/IP version 3R2
- IMS version 4 or later

Connections to IMS using TCP/IP

IMS uses a Listener to establish an interaction with TCP/IP. A Listener in an IMS Batch Message Processing (BMP) helps facilitate the connection process. When the Listener starts, it obtains a socket on which it can listen for connection requests from TCP/IP. The Listener binds this socket to a specified port, and then waits for a client request on that port.

TCP/IP maintains a relationship of a port number to an IMS Listener BMP. When a client makes a request on a port associated with IMS, TCP/IP forwards the connection request to the Listener in that BMP.

Implicit Mode

Implicit mode uses the IMS Assist Module to translate conventional IMS communication into corresponding socket calls. It is dependent on the IBM-supplied default Listener (EZAIMSLN) that runs in a BMP region.

This host server application model processes input data using the IMS message queue. The Listener places the TRANID and the input data into queue. The IMS control region schedules the transaction in a Message Processing Region. The transaction program reads the request from the queue using GU and GN commands. All response data is delivered to the client by way of the ISRT command. The IBM-supplied Assist Module delivers the data directly to the client through socket API calls.

Host applications are written using CBLADLI or CBLTDLI APIs. The Assist Module uses DBLADLI API for Implicit mode. If you want an existing IMS transaction programs (TPs) to use Implicit Mode TCP/IP, you must change to the CBLADLI API and recompile the TP.

Explicit Mode

The IMS explicit (TCP/IP) model requires installation, within IMS, of the IBM-supplied default Listener (EZAIMSLN) that runs in a BMP region. This host server application model processes data without using the IMS message queue. The Listener places only a single segment (the Transaction Initiation Message) into the message queue. The IMS control region schedules the execution of the transaction into a Message Processing Region. The transaction then communicates directly with the client through socket API calls.

All IMS host server programs must be administered to IMS as no-response transactions.

TCP/IP to IMS Configuration

A TCP/IP port number is associated with an IMS Batch Processing Region (BPR) in the TCP/IP profile data set (hlq.PROFILE.TCPIP). The port statement is used to define this relationship. An example of a port statement that associates port 3000 with IMS batch region with a job name of WNWIBPR1 is:

3000 TCP WNWIBPR1

IMS to TCP/IP Configuration

An IMS MPP is started specifying the program name IMS IBM supplied Listener program (EZAIMSLN). This Listener reads a configuration file identified by the DD statement **LSTNCFG**. This configuration data set contains one or more the following startup parameter sets (one set for each transaction defined for least one CR):

- **TCPIP** statement
- **LISTENER** statement
- **TRANSACTION** statement

The **TCPIP** statement is used to identify the job name for the TCP/IP address space that will manage connection for this listener.

The **LISTENER** statement is used to specify the port number that this Listener will be using. This statement also specifies other port-related parameters such as backlog, time out values, and so on.

The **TRANSACTION** statement defines a list of transaction that this Listener can start. In addition, this statement defines whether the implicit or explicit connection mode is used.

The Listener uses these three parameter statements to inform the Listener which TCP/IP port to use and which transactions can be accessed through TCP/IP.

Here is a sample of an IMS-to-TCP/IP host definition:

```
TCPIP       ADDRSPC=WNWTCP31
LISTENER    PORT=4000 BACKLOG=50
TRANSACTION    NAME=TRANIMPL TYPE=IMPLICIT
TRANSACTION    NAME=TRANEXPL TYPE=EXPLICIT
```

Load Balancing and Hot Backup

Security Implications

Transaction Integrator (TI) can provide user ID and password credentials for authentication on the mainframe. They are provided in compliance with existing IBM standards, and mainframe authentication is completed by standard IBM procedures such as Resource Access Control Facility (RACF), Top Secret, and so on. All mainframe authentication is completed in a manner transparent to the developer.

When LU 6.2 is used for connectivity, credentials are transmitted to the mainframe in an SNA LU 6.2 Function Management Header Type 5 (FMH-5) ATTACH message. For more information, refer to the IBM manual, *Systems Network Architecture Formats, Document Number GA27-3136-16, Section 11.1.5 FM Header 5: Attach (LU 6.2*).

When TCP/IP is used for connectivity, credentials are transmitted in the Transaction Request Message (TRM) sent from TI to the Listener. There are some additional coding requirements on the mainframe for TCP/IP to provide user exits for authentication. For information about CICS, refer to *IBM TCP/IP for MVS CICS TCP/IP Socket Interface Guide and Reference, Document Number SC31-7131-03, Section 6.6.3 Writing Your Own Security Link Module for the Listener*. For information about IMS, refer to *IBM TCP/IP for MVS IMS TCP/IP Application Development Guide and Reference, Document Number SC31-7186-03, Section 3.4.4 The IMS Listener Security Exit*. Prior to TCP/IP version 3R2, the CICS exit module required the name, EZACICSE. However, you can choose any name when you are using TCP/IP version 3R2. For IMS, the exit module must be named IMSLSECX.

There are three alternative sources of mainframe credentials.

- The identity of the COM+ application that contains the TI component.
- The identity of the Windows user of the TI application.
- The optional explicit security override feature of TI.

Use of the explicit override feature dissociates mainframe security from Windows 2000 security; therefore, its use is not recommended over the first two alternatives. Using either of the first two alternatives integrates mainframe security with Windows 2000 security by using Host Integration Server Host Security Integration (HSI), or Single Sign-On functionality. (You do not need to install software on the mainframe for HSI unless you also want Host Password Synchronization.)

By default, passing credentials to the mainframe for authentication is not enabled. You must activate the TI remote environment (RE) security properties by selecting the **Set security on** check box. You must click either **Authenticate with package credentials** or **Authenticate with user credentials** even if you plan to use the explicit security override feature.

To select the explicit security override, select the **Allow application override** check box. This option is the least recommended of the three. If **Allow application override** is selected but not implemented by the application, the security mechanism reverts to whichever of the other two security options you selected.

Note
Explicit security override is not the preferred method of specifying credentials for a client. If possible, you should use the Client Context USERID and PASSWORD override keywords. For more information, see the COMTIContext Keywords.

In This Section

How to Use Optional Explicit-Level Override Authentication

Level of Security

Using Host Security Integration

How to Use Already Verified Authentication

Mainframe Authentication for CICS LINREs

How to Use Optional Explicit-Level Override Authentication

Clicking the **Allow application override** check box enables applications to supply credentials at run time through a callback mechanism supplied by Transaction Integrator (TI). Using application override does not require the installation and use of Host Integration Server Host Security Integration (HSI). Instead, the client application supplies TI with a pointer to a callback object that can be used to request credentials when they are needed at run time. A utility component is provided so that customers can add their callback pointer to the context, and create new COM+ objects that inherit from the modified context. The security callback component is automatically installed.

Note
Explicit-Level Override Authentication is not the preferred method of specifying credentials for a client. If possible, you shoul d use the Client Context USERID and PASSWORD override keywords. For more information, see the COMTIContext Keywords.

To use explicit security, the client application must follow these steps:

To use explicit security

1. Create an instance of an object that implements **IHostSecurityCallback**.

   This object is created in the client application and is implemented by the developer.

2. Create an instance of the TI utility object **COMTI.HostSecurityContext**.

3. Call **SetCallbackObject** on the utility object, and pass it the **IHostSecurityCallback** pointer on the callback object.

4. Create instances of its TI component by using the **CreateInstance** method on the security utility object.

When the TI component instance created in step 4 establishes a conversation with the host, it calls the **ReturnSecurityInfo** method on the callback object. TI passes this method the name of the remote environment being contacted. The output parameters provide the logon and password as clear text.

As an additional aid to developers, TI provides the type information for the **IHostSecurityCallback** interface inside the component library for the TI security component. This enables Visual Basic developers to set a reference to this component and then use the **Implements** keyword to implement the callback class.

Security Implications

Level of Security

Application-level (or package-level) security and user-level security are the two preferred means of authentication because they integrate security on the mainframe with Windows 2000 security. The Transaction Integrator (TI) run-time environment obtains credentials from either the Windows identity of the COM+ application or from the identity of the client application that invoked the TI Automation server that contains the TI component.

In both cases, the facilities of Host Integration Server Host Security Integration (HSI) are required. The Windows 2000 credentials are *replicated*, *unchanged*, or *mapped* to another set of credentials specific to the mainframe. The credentials are then sent to the mainframe for authentication.

Internally, the mechanism functions as follows. For COM+ application identity credentials, TI sets the user ID and password fields in the MC_ALLOCATE verb to MS$SAME, and sets the security field to AP_PGM. This informs HSI to derive host credentials for the owner of the currently executing process.

For user credentials, TI sets the security field in the MC_ALLOCATE verb to AP_PGM OR'd with AP_PROXY, and fills in the domain and account name fields in the verb ctl block with the values it obtained from **LookupAccountSid** (in the Win32 API). This informs HSI to derive host credentials corresponding to that Windows account, regardless of the running process. In other words, the run process acts as a proxy for the real user and passes the real user's credentials.

Security Implications

Using Host Security Integration

When you create a Host Integration Server Host Security Domain (HSD), two Windows 2000 local user groups are created. For example, if you name the HSD **OURHOST**, the two user groups created are named **OURHOST** and **OURHOST_PROXY**. There is also a Host Account Cache that is used to maintain user credential mappings. These mappings are used by Host Integration Server Host Security Integration (HSI) to map (or replicate) the original Windows 2000 credentials to host credentials.

Host Integration Server Credential Settings

The following table shows the Host Integration Server credential settings that you must specify in a given Windows 2000 user group and in the Host Account Cache when using one of the authentication options.

TI Authentication Option	OURHOST	OURHOST_PROXY	Host Account Cache
User Credentials	User	COM+ Application*	User
COM+ Application Credentials	COM+ Application		COM+ Application
Application Override	Not applicable	Not applicable	Not applicable

*The reason that you must add the COM+ application identity in the PROXY user group is because you are allowing a process (your TI component) to run under an identity other than the identity that Windows 2000 has authenticated. This group assignment specifies that you are allowing the COM+ application to run host transaction programs on your behalf.

Note

If **Application Override** is not implemented correctly by the client application, the mechanism for supplying credentials to t he mainframe falls back to one of the other two methods.

COM+ application identity defines the Component Services computer process that is running. The process can run either as an Interactive User or as a specified Windows user account. It is typical for server processes to run as Interactive User during development; however, in production, a Windows user account is usually used.

Host Account Cache

Host Integration Server maintains the Host Account Cache. For any Windows 2000 domain user, the Host Account configuration specifies whether Windows credentials are replicated to the mainframe or mapped to other credentials to be sent to the mainframe.

Security Implications

How to Use Already Verified Authentication

You can set the **Use Already Verified or Persistent Verification authentication** option on the remote environment (RE) Security property page in Transaction Integrator (TI) Manager.

To view or modify the Security properties for an RE

1. Start TI Manager.
2. Right-click the RE, and then click **Properties**.
3. Click the **Security** tab, and then select the **Set security on** check box.

When you select the **Use Already Verified or Persistent Verification authentication** check box, only a user ID is sent to the mainframe; that is, no password is sent, provided the mainframe partner allows it. The mainframe relies on the assumption that this user ID has already been authenticated and does not require a password. The SNA mode on the mainframe must specify this type of authentication. For CICS applications, the mode setting is determined by the ATTACHSEC=IDENTIFY parameter of the Sessions definition used for the connection.

Security Implications

Mainframe Authentication for CICS LINREs

If you use a CICS LINK LU 6.2 remote environment (RE), you must use resource-level authentication.

Because of a restriction imposed by the IBM Distributed Program Link (DPL) protocol, a user ID and password transmitted from the workstation by Transaction Integrator (TI) are ignored and not used for transaction-level authentication. The target CICS region expects, under the circumstances, that authentication was completed by the TI application that initiates the IBM DPL call. (Traditionally, the application that initiates an IBM DPL call is a program in another CICS region.) Instead of using credentials from the FMH-5 ATTACH, for transaction-level authentication, the target CICS region associates the default user ID for the region with the transaction ID of the CICS task (the mirror transaction).

As a result of this behavior, any attempt to secure the mirror transaction can cause an application malfunction because of a failure to authenticate.

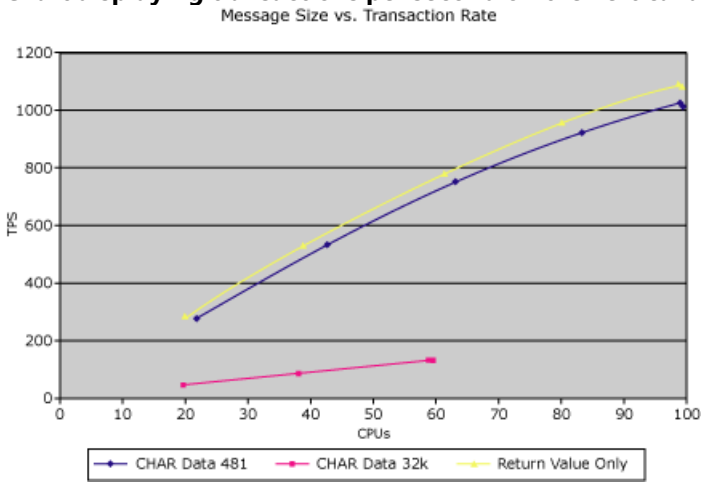
Security Implications

Transaction Size vs. Transaction Throughput

When looking at the transactions per second (TPS) rates that the server might be capable of sustaining, you must consider the amount of data moved and processed for each transaction. It is generally understood that the more data that you transfer for each transaction, the fewer TPS you can push through. For Transaction Integrator (TI), this also holds true. The following figure shows the rate at which the TPS decrease as transaction sizes increase on the Quad Xeon 400 test server.

Chart displaying transactions per second on the vertical axis and percent CPU on the horizontal axis



The best TPS rate is produced by the test transaction, which returns only 1 byte of data. This return value only sets the high bar to 1093 TPS. The Char481 (simple application screen) can maintain close to the maximum possible rate. The data transfer test of 32k, which moves 64000 bytes of data per transaction, cannot maintain the same TPS rate as the others. In this case, the latencies on the LAN, memory allocations, and copies begin to really show.

Transaction Integrator Performance Guide

Transaction Size vs. Data Throughput

As a result of the transaction throughput test shown in Transaction Size vs. Transaction Throughput, the question of what the best message size for these transactions arises. We captured the actual user data transferred with these transactions and looked at the MB/sec throughput versus message size. The following figure shows that if the data throughput is the objective of optimization, the larger the message size, the higher the throughput. Additional considerations can influence the selections of the message size, such as the maximum frame size on the LAN or WAN. For example, Ethernet 802.2 frames can fit 1484 bytes of user data per frame; token-ring can go up to 8186 bytes.

Transaction Integrator Performance Guide

Scalability and Long-Running TPs

When the transaction processing times (unit of work and commit times) become longer because of the nature of the transactions or an excessive load on the host, the behavior of the middle-tier software might change the throughput and end-user response time. This occurs because the number of active concurrent transactions increases and the middle-tier server is doing some level of transaction caching. For example, in a system that processes 200 TPS (transactions per second) at an average transaction response time of one second, the concurrent active transaction count at any give time is around 200. If the response time grows to five seconds, the concurrently active transactions grow to approximately 1000.

Transaction Caching

When sizing the middle-tier server, you must consider queries and batch jobs that run from seconds to hours. You can allow more transaction requests in COM+ waiting for the host responses, but excessive transaction caching might not be a good idea because it increases thread count, context switching, and memory usage. This burdens the middle-tier server and can cause performance degradation. Therefore, use COM+ or Transaction Integrator (TI) pooling capabilities cautiously; pooling does not help in the actual transaction processing, and it does not improve the response times or throughput.

In some cases, this shows real advantages. However, when transactions run against multiple host systems and databases (multi-forked transactions), the transaction caching in the middle-tier enables each transaction in the fork to start processing immediately, with the slowest fork determining the overall response time. If the transaction is not cached, all the work is blocked, until the prior transactions are completed, thus yielding lower performance. The two thread pools that are transferred when the number of active transactions grows on the middle-tier server are the COM+ user thread pool and the TI 2PC thread pool.

Processing Two-Phase Commit Transactions

This topic discusses what happens with the two-phase commit (2PC) transaction while it is being processed by Microsoft Distributed Transaction Coordinator (DTC) in COM+, Transaction Integrator (TI), and CICS.

The process begins when the client application invokes a method on the TI Automation server (the COM+ application that contains the TI component). COM+ then allocates a thread for the transaction from its user thread pool, begins the transaction, and passes the method's input parameters to the TI run-time environment. This thread is blocked for the transaction until the response comes back from the CICS host. This is the unit of work time, which consists mostly of time it takes the CICS application to process the transactions business logic and gain access to the database as needed (assuming that the transmission speeds keep up with the LAN speed). When the method's output parameters are sent back to COM+ from the host, the commit message is sent to DTC. The output data is stored waiting for the commit complete message from DTC. If the unit of work time grows longer, more transactions are kept active by COM+, with each transaction occupying a thread from the COM+ user thread pool.

DTC activates the prepare phase for the transactions, causing TI to allocate a thread from its 2PC thread pool and keep it blocked until the request commit message arrives from the host. After all the forks of the transactions are prepared, DTC sends a commit complete message to COM+, and COM+ then sends the method's output parameters and return values back to the calling client application and releases the thread.

This completes the transaction for the user, but the transaction monitors (DTC and CICS) still must complete the second phase of the commit, and again, a thread from the TI 2PC thread pool is allocated for each transaction doing the second phase of the commit.

Transaction Integrator Performance Guide

Component Services User Thread Pool

A thread from the Component Services user thread pool is allocated to a transaction as long as the host is processing the transaction (unit of work time). This occurs for both transactional (two-phase commit transactions), and nontransactional processing. If you have slow host or communication lines, or your transactions take a long time to process, you might have to adjust a registry entry to enable more threads for this pool. The default is 100 threads per COM+ application.

Transaction Programs that Run for a Long Time

Transaction Integrator Performance Guide

TI 2PC Thread Pool

The Transaction Integrator (TI) two-phase commit (2PC) thread pool is different from the COM+ user thread pool. The TI 2PC thread pool is used only for 2PC transactions. The threads are precreated, and a single process interacts with Microsoft Distributed Transaction Coordinator (DTC) to handle *prepare* and *commit* transactions. This improves the performance by eliminating thread creation and destruction for every 2PC transaction.

Default Maximum Thread Settings

You do not have to worry about overburdening this pool unless large numbers of 2PC transactions are processed. Only when *prepare* or *commit* times for the transactions become very long can queuing to interact with DTC occur.

- Default maximum threads for each CPU is 20.
- Default maximum active threads for each CPU is 19.
- Default maximum total threads for each system is 80.

You can adjust the default amounts by adding a TEXT string value to the registry location:

HKLM\Software\Microsoft\Cedar\Defaults\Threads

- IOPortPoolFactor=20
- IOPortActive=19
- ThreadPoolMax=80

Rules for Specifying Values

The following rules apply for specifying values:

- All values must be greater than zero.
- IOPortPoolFactor must be >= IOPortActive + 1.
- ThreadPoolMax must be >= IOPortPoolFactor.

Caution
Allocating too many threads can cause Windows to run out of resources, and that can cause unpredictable behavior in COM + and in Windows.

SNA Parallel Sessions

Each active transaction allocates one parallel session to interact with the host when SNA is used instead of TCP/IP. This session is activated when the transaction sends the attach message (allocate conversation) and released after the forget message (TpEnded). When you configure too few parallel sessions for the SNA connection, the transactions that are waiting for the active ones to release can start queuing up. To avoid this queuing problem, configure enough sessions for the worst-case scenario.

Note
SNA Server 4.0 SP3 required the use of a contention winner session, but Host Integration Server does not. Host Integration Server can use any session as it becomes available.

Host Integration Server can handle large numbers of parallel sessions. The maximum is 30,000 parallel sessions for each LU-LU pair, after which another LU-LU pair must be configured. The CICS system is a bit more sensitive to the amount of parallel sessions configured. Contact your CICS systems experts for the appropriate session count.

Two-Phase Commit Performance Considerations

When a Transaction Integrator (TI) component executes within a transaction, the TI run-time environment sends a message to Microsoft Distributed Transaction Coordinator (DTC) in the COM+ environment, enlisting itself on the transaction as a special type of LU 6.2 resource manager. After TI sends its data buffer to the host and receives the reply, it calls the **SetComplete** method and returns control to COM+. At this point, the client application, or other component driving TI, can perform other work also included in the same transaction. When all resource managers have made their updates and issued **SetComplete**, the transaction's creator (which can be COM+ itself for an Auto-Transaction) sends the **Commit** method to DTC. DTC sends the first-phase (**Prepare**) message to all the resource managers, including the TI run-time environment. TI generates the **Prepare PS Header** defined in the SNA Formats, and sends it to the host. It receives a **RequestCommit** in reply, which indicates that the host updates are valid and can be committed, and passes this information back to DTC. DTC collects the votes from all the resource managers, and if all prepared okay, it force-writes a Commit record to the log and sends the **Committed** message. Again, TI translates this into an **SNA PS Header**, receives the reply, and translates this back to DTC. If everything works as planned, DTC rolls back the transaction and the APPC/LU 6.2 conversation is deallocated.

Note

Neither TI nor the AP need be concerned about an APPC or CPI/C SYNCPT verb. The decision to "take a SyncPoint" is made b y the transaction creator, is expressed in the semantics of OLE transactions, and involves all participants in the transaction, no t just the TI LU 6.2 branches. The role of TI is at a lower level; TI acts as a resource manager to DTC. It translates between the COM interfaces used by DTC, and the SNA protocols understood by the host, to perform the two phases of the protocol and enable DTC to make the Commit decision between phase one and phase two.

From a performance standpoint, guaranteeing the atomicity of the host updates adds significant, unavoidable overhead. There are two additional round-trip message flows to the host for the two-phase commit (2PC), plus the Windows message flows to enlist, and the transaction logging (forced disk writes) by DTC and on the host. Transactions that do not require a great deal of business logic processing can take twice as long or more to complete when you compare it to the same transaction without 2PC.

The only time you should configure a TI component to support ACID transactions is when the associated host transaction program (TP) modifies a mission critical resource that must be kept consistent with resources on the Windows 2000 operating system. If the TP will not modify any resource for which consistency must be guaranteed, configure the TI component as **Does Not Support Transactions**, so that 2PC is not attempted. Then you are also free to use the TCP/IP protocol. The TCP/IP protocol does not support 2PC.

TI components should never be configured as **Requires a New Transaction**. This means that you are managing the transaction remotely for the host, and it would incur the overhead of creating a new transaction, enlisting on it, and performing the 2PC exchanges with the host, but the TI method would be a transaction unto itself. It is more efficient to enable CICS and IMS to manage their own transactions. Any updates on the Windows operating system would not be part of that transaction, so they would commit or roll back independently.

Note

Additional business logic processing on the same server lowers the throughput limits, stealing some of the CPU. However, th e cost can be relatively small in the scope of the overall response time budget.

Transaction Integrator Performance Guide

Data Conversion Cost

The following list provides advice on selecting the data types that convert most efficiently between Automation and COBOL.

- If the source and destination data types are not strictly dictated, you can decrease the amount of CPU resource consumed by Transaction Integrator (TI) by appropriately selecting the data conversions that are performed (that is, selecting the source and destination data types wisely).

- The most efficient way to pass data is to select an Automation type of **VT_BYTE** and a COBOL data type of **PIC X** untranslated. There is no conversion performed and the data is copied as is.

- The Automation type **VT_BSTR** (a UNICODE character string) converts efficiently to COBOL **PIC X**. Be aware that a **BSTR** is not the same as a C character data type; it is a Visual Basic **String**.

- The most efficient numeric data type conversions are **VT_I2** (Visual Basic **Integer** or C **short**) to COBOL **PIC S9(4) COMP**, and **VT_I4** to **PIC S9(8) COMP**.

- If the data type you want is a COBOL packed decimal, the best choice for data conversion performance is one of the Automation integer data types. If fractional parts are required (that is, a COBOL picture like **PIC S9(5)V99 COMP-3**), the best choice for the Automation type is **VT_DECIMAL** (Decimal) or **VT_CY** (Currency).

- When the COBOL data type is zoned decimal (that is, a COBOL picture similar to **PIC S9(7)V99 DISPLAY**), the same considerations as for packed decimal apply. It is slightly more work to convert Automation data types to and from zoned decimal than it is to perform the conversions to packed decimal. If the data is used in calculations on the mainframe system, it is more efficient to use packed decimal instead of zoned decimal.

- Converting floating point data types (Automation types **VT_R4** and **VT_R8**) is, in most cases, the most expensive. Converting **VT_R4** to a COBOL **COMP-1**, or **VT_R8** to a COBOL **COMP-2** (a COBOL floating point number) data type is the most efficient conversion involving floating-point numbers.

Transaction Integrator Performance Guide

ADO Recordsets vs. User-Defined Types in Structured Data Tests

Tests on structured data transfer show that user-defined types outperformed ADO recordsets in CPU usage, transactions per second, and response time.

Tests were conducted using six Pentium 300 MHz clients, one quad-processor Xeon p2-400 system as a gateway, and four SNA host server computers to emulate the CICS region of a mainframe. When transferring user-defined types, the clients were under less stress, and there was much better throughput overall. User-defined types were also much less stressful to the server.

The overall response times for the user-defined types are also much less because of the metadata that recordsets contain. The metadata inside the recordsets increases the size of the data marshaled back and forth across the DCOM connection. In addition to the increased size, the metadata increases processing overhead.

Remote Environment Selection Using the SelectionHint Property

Developers can use the **SelectionHint** property to specify a remote environment (RE) programmatically.

By setting the **SelectionHint** property, applications can specify which CICS or IMS RE should be used when servicing Transaction Integrator (TI) requests. The algorithm used by an application in selecting an RE is determined by the application code. For example, a business enterprise can use separate CICS or IMS regions when handling requests from different branches. In this case, the application chooses the RE that identifies the region suitable for the current branch.

To specify an RE in an application, set the **SelectionHint** property to the name of the RE you want to use. TI Designer automatically adds the write-only **SelectionHint** property to each TI component.

Before you can use the **SelectionHint** property to specify a remote environment (RE) programmatically, the following must be in place:

- Host Integration Server must be installed on all computers running the TI run-time environment or TI Designer.
- The TI component must be assigned to an RE even though RE selection is in use. The RE assigned to the component is used when an application that has a TI component does not explicitly set the **SelectionHint** property.

To assign a TI component to an RE, use TI Manager and follow the instructions provided in the TI online Help.

In This Section

Guidelines for Using Remote Environment Selection

Consider these guidelines when you are using the **SelectionHint** property to specify a remote environment (RE) programmatically:

- Avoid hard-coding RE names into applications. Instead, load RE names from a file or database.
- Ensure that applications are structured to handle failures when they are attempting to set the **SelectionHint** property.
- Ensure that procedures for adding and configuring REs include a mechanism to update REs referenced in the application code.
- Confirm that administrative and operational tasks do not interfere with application code that uses the RE selection. Specifically, review when and how REs are deactivated and deleted.

See Also

Other Resources

Remote Environment Selection Using the SelectionHint Property

Writing Code that Specifies a Remote Environment

Applications can set the **SelectionHint** property to specify a remote environment (RE) programmatically. By specifying the RE, the application identifies the CICS or IMS region where transaction programs are carried out when the Transaction Integrator (TI) run-time environment handles calls to the TI component's methods.

The following Visual Basic code demonstrates how to set the **SelectionHint** property:

```
Dim objExample As Object
Dim Store As String
Set objExample = CreateObject("MyComponent.MyInterface")
Open "My REList.txt" for Input as #1
Line Input #1, strRE
Close #1

objExample.SelectionHint = strRE
RtrnVal = objExample.method1(parm1,  , parmN) 'Use RE named "MyRemEnvName"
```

This example shows how the application can explicitly instruct the TI run-time environment to use the RE named **MyRemEnvName** when handling the call to **method1**. In this example, **MyRemEnvName** is the first string in the file MyREList.txt. Any method calls made after **method1** that follow the **SelectionHint** assignment are handled using the original RE that was assigned to the component, not the new one. In other words, the programmatic override of the default RE does not continue past a single method call.

If an application attempts to set the **SelectionHint** property to a string that does not correspond to the name of an RE, an error is reported, and the original RE is used.

The **SelectionHint** property can be set to a deactivated RE. However, the next method call to the object will fail because a deactivated RE was selected.

The **SelectionHint** property is optional. If the **SelectionHint** property does not specify an RE, the TI run-time environment uses the original RE.

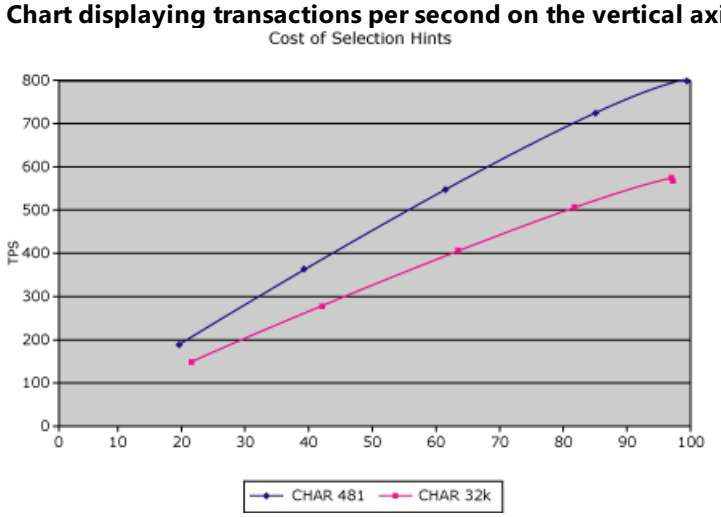
Remote Environment Selection Using the SelectionHint Property

Cost of Remote Environment Selection

The following figure shows the transaction throughput against the CPU load on the middle tier (the business-logic tier). Each data point represents the number of stress clients, and the total amount of time that it takes for the clients to finish their transactions. (For example, eight clients simultaneously perform transactions at a collective rate of approximately 200 TPS.) Both requests and responses consist of 481 bytes of mixed data (text and numeric).

Chart displaying transactions per second on the vertical axis and percent CPU on the horizontal axis



The arrow in the graph shows the last level of CPU use at which transactions using **SelectionHint** and transactions not using **SelectionHint** ran at a similar number of TPS. Pushing the load beyond this level causes a drop in throughput. Up to the 85% CPU load level, you will see the same response time for both types of transactions. Using the **SelectionHint** property provides additional flexibility with only a very small cost in maximum throughput level (15%). On the other hand, when pushing 680 TPS through the server, not using **SelectionHint** drops the CPU from above 80% to a comfortable 60% level. These CPU cycles can be used to process the business logic on the middle tier.

Remote Environment Selection Using the SelectionHint Property

Performance Improvements in Host Integration Server

The Windows-initiated processing (WIP) feature of Host Integration Server, when installed on Windows Server 2003, shows the following performance improvements when compared to Host Integration Server 2000 SP1 installed on Windows 2000 Server:

- CICS over SNA performance is higher by up to 12%.
- CICS and IMS over TCP performance is higher by up to 30%.
- Performance for methods that contain **RecordSets** is higher by up to 77%.
- Enhanced Listener Message (ELM) performance is higher by up to 5% than Transaction Request Message (TRM) performance.
- Performance for persistent connection calls is higher than for the non-persistent calls by up to 56%.
- WIP .NET performance is generally about 17% of WIP COM; numbers for the .NET Framework methods that contain **DataTables** are within 30% of the COM methods that contain **RecordSets**
- The TCP ELM Link Persistent model delivers the best performance, with 1900 calls/sec for the light conversion methods.

The performance tests were conducted on a Fujitsu 4-processor server running Windows Server 2003, with all computers on a private 100-megabit network. The performance monitor was running on a separate computer.

- UI Help
- Administrators Reference

Glossary

3270

The information display system for IBM hosts (mainframes). The system includes terminals, printers, and controllers that enable a user to access host functions.

5250

The information display system for IBM AS/400 computers.

802.2

The logical link control protocol used for communication over a Token Ring or Ethernet network. The 802.2 protocol is an IEEE standard.

1-byte unsigned Integer

An integer data type that has a positive value ranging from 0 to 255.

2-byte signed Integer

An automation integer data type that can be either positive or negative. The most significant bit is the sign bit, which is 1 for negative values and 0 for positive values. The storage size of the integer is 2 bytes. A 2-byte signed integer can have a range from -32,768 to 32,767.

2PC

See **two-phase commit (2PC)**.

4-byte Real

Also referred to as a single-precision floating-point or Single. Single variables are stored as IEEE 32-bit (4-byte) floating-point numbers, ranging in value from –3.402823E38 to –1.401298E-45 for negative values and from 1.401298E-45 to 3.402823E38 for positive values. The type-declaration character for Single is an exclamation point (!).

4-byte signed Integer

An Automation integer data type that can be either positive or negative. The most significant bit is the sign bit, which is 1 for negative values and 0 for positive values. The storage size of the integer is 4 bytes. A 4-byte signed integer can have a range from -2,147,483,648 to 2,147,483,647.

8-byte Real

Also referred to as a double-precision floating-point or Double. Double data type variables are stored as 64-bit (8-byte) numbers. A Double variable is stored as a 64-bit (8-byte) number ranging in value from 1.79769313486232E308 to –4.94065645841247E-45 for negative values, from 4.94065645841247E-324 to 1.79769313486232E308 for positive values, and 0. The type-declaration character is a number sign (#).

3270 emulator

Software that enables a microcomputer to act as a 3270 terminal, displaying information from a host system (mainframe). Emulator software can also enable a desktop computer to send print jobs from a host system to a printer connected to the microcomputer.

3270 terminal emulation

The use of software that enables a microcomputer to act as a 3270 terminal, displaying information from a host system (mainframe). Emulation software can also enable a microcomputer to send print jobs from a host system to a printer connected to the microcomputer.

5250 emulator

Software that enables a microcomputer to act as a 5250 terminal interacting with an AS/400 system.

5250 terminal emulation

The use of software that enables a microcomputer to act as a 5250 terminal interacting with an AS/400 system.

A3270

The server transaction program for the APPC 3270 Terminal Emulator facility.

abend

Short for abnormal end. The premature ending of a program because of program error or system failure.

ACID

See **atomic, consistent, isolated, and durable (ACID)**.

acknowledgment required (ACKRQD)

A field in the header of a Status-Control message. If a Status-Control request has ACKRQD set in the message header, the recipient must supply a Status-Control response before the sender sends further messages or further Status-Control requests.

ACKRQD

See **acknowledgment required (ACKRQD)**.

ActiveX® Data Objects (ADO)

A data access interface that communicates with OLE DB-compliant data sources to connect to, retrieve, manipulate, and update data.

ACTLU

SNA command sent by the system services control point (SSCP) to a logical unit (LU) to activate a session and establish session parameters.

ACTPU

SNA command sent by the system services control point (SSCP) to activate a physical unit (PU), so that any logical units (LUs) controlled by this PU are available to the SNA network.

adapter

Refers to a circuit board, network card, and similar expansion devices with a specialized function, such as controlling a video display monitor or accessing a communications line. Not the same as a driver.

administration access

The level of access available to a user. The user may be granted or denied the right to use the interfaces (Host Integration Server Setup, SNA Manager, or the **snacfg** command) to read and change the configuration file, to start and stop services and connections, or to reset LUs.

ADO

See **ActiveX® Data Objects (ADO)**.

Advanced Peer-To-Peer Networking (APPN)

An extension to SNA that features (a) greater distributed network control that avoids critical hierarchical dependencies, thereby isolating the effects of single points of failure; (b) dynamic exchange of network topology information to foster ease of connection, reconfiguration, and adaptive route selection; (c) dynamic definition of network resources; and (d) automated resource registration and directory lookup. APPN extends the LU 6.2 peer orientation for end-user services to network control and supports multiple LU types, including LU 2, LU 3, and LU 6.2.

Advanced Program-to-Program Communications (APPC)

A means of enabling programs to communicate directly with each other, across a network or within a single system. APPC uses a type of logical unit called LU 6.2, and enables transaction programs (TPs) to engage in peer-to-peer communications in an SNA environment.

(1) The general term that characterizes the LU 6.2 architecture and its various implementations in products. (2) Refers to the LU 6.2 architecture and its product implementations as a whole or to an LU 6.2 product feature in particular, such as an APPC application programming interface. (3) A method for enabling programs to communicate directly with each other across a network or within a single system. APPC uses a type of LU called LU 6.2, and enables TPs to engage in peer-to-peer communications in an SNA environment.

AFTP

See **APPC File Transfer Protocol (AFTP)**.

AFTPD

The server transaction program for the APPC File Transfer Protocol facility.

aggregation

A composition technique for implementing component objects whereby a new object can be built using one or more existing objects that support some or all of the required interfaces of the new object.

alert

A message that indicates an abnormal event or a failure.

allocate

(1) The process that an operating system uses to respond to a request from a program to reserve memory for use by the program. (2) In Advanced Program-to-Program Communications (APPC), a verb that assigns a session to a conversation. *Contrast with***deallocate**.

American Standard Code for Information Interchange (ASCII)

A coding scheme that assigns numeric values to letters, numbers, punctuation marks, and certain other characters.

API

See **application programming interface (API)**.

APING

(1) The APPC Connectivity Tester facility. (2) The client transaction program for the APPC Connectivity Tester facility.

APINGD

The server transaction program for the APPC Connectivity Tester facility.

APPC

See **Advanced Program-to-Program Communications (APPC)**.

APPC File Transfer Protocol (AFTP)

(1) The client transaction program for the APPC File Transfer Protocol facility. (2) An interactive full-screen environment with a specific set of commands used to manage and transfer files between a client and server computer. (3) An API that provides APPC file transfer capabilities.

APPC mode

A collection of session properties used by LU 6.2-type logical units (LUs) as they carry on a session. A mode can be used by many LU pairs at the same time.

APPC mode name

The name used to represent a set of characteristics to be used in an APPC LU-LU session.

APPC verb

The mechanism by which a program accesses APPC. Each verb supplies parameters to APPC. *See also***Advanced Program-to-Program Communications (APPC)**.

application programming interface (API)

The set of programming language constructs or statements that can be coded in an application program to invoke the specific functions and services provided by an underlying operating system or service program.

application requester (AR)

(1) The source of a request to a remote relational database management system (DBMS). (2)The ODBC driver to DB2 connector that enables C and C++ applications to issue dynamic SQL queries and call DB2 stored procedures.

application TP

An application program that uses Advanced Program-to-Program Communications (APPC) to accomplish tasks for end-users and exchange data with other transaction programs (TPs) in an SNA environment.

APPN

See **Advanced Peer-To-Peer Networking (APPN)**.

See **Advanced Peer-To-Peer Networking (APPN)**.

AR

See **application requester (AR)**.

array

A set of sequentially indexed elements which have the same intrinsic data type. Each element of an array has a unique identifying index number. A changes made to one element of an array does not affect the other elements.

ASCII

See **American Standard Code for Information Interchange (ASCII)**.

assembly

A collection of functionality built, versioned, and deployed as a single implementation unit (one or multiple files). An assembly is the primary building block of a .NET Framework application. All managed types and resources are marked either as accessible only within their implementation unit or as exported for use by code outside that unit. In the common language runtime, the assembly establishes the name scope for resolving requests and the visibility boundaries are enforced. The runtime can determine and locate the assembly for any running object because every type is loaded in the context of an assembly.

assembly cache

A machine-wide code cache used for side-by-side storage of assemblies. There are two parts to the cache. First, the global assembly cache contains assemblies that are explicitly installed to be shared among many applications on the computer. Second, the download cache stores code downloaded from Internet or intranet sites, isolated to the application that triggered the download so that code downloaded on behalf of one application or page does not impact other applications. *See also***global assembly cache (GAC)**.

asynchronous verb completion

Processing of an SNA verb where the initial API call returns immediately, so that the normal operation of the program is not blocked while processing completes. When the verb completes, the application is notified through a Microsoft® Windows® message or event. *Contrast with***synchronous verb completion**.

atomic, consistent, isolated, and durable (ACID)

An acronym that describes the four key properties required of any Windows-based transaction:

- **Atomic.** Each transaction must execute completely or not at all.
- **Consistent.** The structural integrity of the transaction database must be maintained.
- **Isolated.** A transaction cannot access data that is already involved in a transaction.
- **Durable.** The TP data must be stored securely to enable recovery of the transaction results.

Note
A mainframe-based transaction program (TP) differs from a Windows-based transaction. A mainframe-based TP is a COBOL program that exists in the CICS or IMS environment and contains one or more mainframe transactions. A mainframe transaction might or might not meet the ACID properties.

atomicity

A feature of a transaction that indicates that either all actions of the transaction happen or none happens.

auditing

Tracking the activities of administrators and users by recording selected types of events (for example, the changing of the configuration file) in the security log of a computer running Host Integration Server.

authentication

The process of determining the identity of a user attempting to access a system. For example, passwords are commonly used to authenticate users.

automatic partnering

A setting for APPC LUs and modes that enables LU-LU pairs (with assigned modes) to be generated automatically by Host Integration Server. Each time a new APPC LU or mode is created with automatic partnering enabled, Host Integration Server searches for existing LUs and modes that also have automatic partnering enabled. Host Integration Server then uses all available automatic partners to create as many unique LU-LU pairs as possible, each pair containing a remote LU, local LU, and assigned mode. Disabling an automatic partner setting after an LU or mode has been created does not remove that LU or mode from LU-LU pairs already generated.

automatic transaction

A transaction that is created by the COM+ run-time environment for an object based on the transaction attribute of a component.

Automation

Automation is COM-based technology that enables dynamic binding to COM objects at run time.

Automation client

Also called an Automation controller. An application that manipulates the objects, methods, and properties of another application (the Automation server) through Automation.

Automation object

An object that is exposed to other applications or programming tools through Automation interfaces.

Automation server

An application that enables its objects, methods, and properties to be controlled by other applications through Automation.

-B-

backup configuration file

An extra copy of the configuration file, saved by using the **File** menu **BackupConfiguration** command in SNA Manager. The default extension for backup configuration file names is .SNA.

backup server

A computer running Host Integration Server, and designated as a backup server, on which the configuration file is replicated by Host Integration Server. Host Integration Server loads the copy of the configuration file located on a backup server if the primary server goes down. One or more computers running Host Integration Server can operate as backup servers.

Base

A part of each Host Integration Server component that provides the operating environment for the core functions of that component. The Base passes messages between components and provides functions common to all components, such as diagnostic tracing.

base client

A client that runs outside the COM+ run-time environment, but that instantiates COM+ objects.

base process

An application process in which a base client executes. A base client runs outside the COM+ run-time environment and instantiates COM+ application objects.

basic conversation

In APPC, a conversation type generally used by applications that provide services to other local applications. Basic conversations provide a greater degree of control over the transmission and handling of data than mapped conversations. *See also***mapped conversation**.

basic transmission unit (BTU)

A standard unit of information transmitted over an SNA network. A BTU consists of the transmission header (TH), the request/response header (RH), and the request/response unit (RU). The maximum size of the BTU is controlled in VTAM by the MAXDATA= parameter and in Host Integration Server by the Max BTU Length parameter.

batch job

A predefined sequence of programs that can be run through the Job Entry Subsystem or through an automated scheduling

system. Each program that runs as part of the sequence is considered a batch step. Typically data is passed from one step to the next through temporary or permanent files on the file system.

batch step

An application program that is executed as part of a larger batch job. Typically, data is read from and written to temporary or permanent files on the files systems.

BBI

See **begin bracket indicator (BBI)**.

BBIUI

See **begin basic information unit indicator (BBIUI)**.

BCI

See **begin chain indicator (BCI)**.

begin basic information unit indicator (BBIUI)

Bit 5 of Flag 2 of a Status-Control message. BBIUI is set on a Status-Control message corresponding to an outbound SNA request with BBIU (begin basic information unit). It is supplied solely for the use of SNA server components. Your application should not attempt to use it.

begin bracket indicator (BBI)

Bit 4 of Flag 1 of a Status-Control message. BBI is set if the chain carries BB (begin bracket). Note that this does not necessarily indicate that the bracket has been initiated.

begin chain indicator (BCI)

Bit 1 of Flag 1 of a Status-Control message. BCI is set if the message starts a chain.

blocking

A method of operation in which a program that issues a call does not regain control until the call completes. *See also***synchronous verb completion**.

Boolean expression

An expression that can be evaluated either true (nonzero) or false (0). You can use the keywords True and False to supply the values of -1 and 0, respectively. The field data type Yes/No is Boolean and has the value of -1 for Yes and 0 for No.

bounded

Refers to recordsets or arrays. The last input parameter or the last output parameter in a method can be bounded. This means its actual size can vary from zero to the maximum number of elements (in an array) or rows (in a recordset) specified at design time.

bracket

A chained set of RUs and their responses, which together make up a transaction between two LUs. One bracket must be finished before another can be started.

BTU

See **basic transmission unit (BTU)**.

business rule

The combination of validation edits, logon verifications, database lookups, policies, and algorithmic transformations that constitute an enterprise's way of doing business. Also known as business logic.

byte

A unit of information consisting of eight bits. A byte, or binary term, is the smallest collection of bits that can be accessed directly. The integer value of a byte can range from 0 to 255.

-C-

caller

A client that invokes a method of an object. The caller of an object is not necessarily the creator of an object. For example, client A could create object X and pass this reference to client B, and then client B could use that reference to call a method of

object X. In this case, client A is the creator, and client B is the caller. *See also***creator**.

catalog

In Windows 2000 and later, the catalog is the COM+ application data store that maintains configuration information for components, COM+ applications, and roles. You can administer the catalog by using TI Manager.

CDI

See **change direction indicator (CDI)**.

CEI

See **chain ending indicator (CEI)**.

chain

A series of related messages or data packets that are transmitted consecutively and are treated as a single entity forming a complete message.

change direction indicator (CDI)

Bit 6 of Flag 1 of a Status-Control message. CDI is set if chain carries change direction (CD).

Channel

A channel-attached connection to a host system.

characteristics

A set of internal values maintained by CPI-C for each conversation. They can affect the operation of the entire conversation or of specific calls.

CICS

See **Customer Information Control System (CICS)**.

class

A type that defines the interface of a particular type of object. A class defines the properties of the object and the methods used to control the behavior of an object.

class factory

An object that implements the **IClassFactory** interface, which enables it to create objects of a specific class.

class ID (CLSID)

A universally unique identifier (UUID) that identifies a COM component. Each COM component has its CLSID in the Windows registry so that it can be loaded by other applications.

client

A computer or a software component using services available through Host Integration Server. To run applications such as a 3270 emulator, the client uses the Host Integration Server computer to gain access host or peer systems on the SNA or TCP/IP network.

client/server

A distributed application model in which client applications request services from a server application. A server can have many clients at the same time, and a client can request data from multiple servers. An application can be both a client and a server.

CLSID

See **class ID (CLSID)**.

coaxial cable

A cable that consists of a conductor within another conductor, with insulation between the two conductors. The inner conductor is usually a small copper tube or wire, and the outer conductor is usually copper tubing or copper braid. It is the common medium used to connect LANs and 3270 devices. The maximum distance that a coaxial cable can be run between a 3270-type cluster controller and peripheral devices is 5,000 feet (1,500 meters).

code page

A table that associates specific ASCII or EBCDIC values with specific characters.

COM

See **Component Object Model (COM)**.

COM+

See **Component Services (COM+) component**; **Component Services (COM+) object**.

COMMAREA

An area of memory in the mainframe used for communications and accessible to various programs. It is similar to a data structure that contains both input parameters and return data.

Common Programming Interface for Communications (CPI-C)

A set of C-language routines that applications distributed across an SNA network can use to work together. Through CPI-C, distributed applications on computers communicating as peers can exchange data to accomplish a processing task, such as querying a remote database or copying a remote file.

An evolving application programming interface (API), embracing functions to meet the growing demands from different application environments and to achieve openness as an industry standard for communications programming. CPI-C provides access to interprogram services such as (a) sending and receiving data, (b) synchronizing processing between programs, and (c) notifying a partner of errors in the communication.

Common Service Verb (CSV)

An application programming interface (API) that provides ways of tracing, translating characters, and sending network management information to a host. Each verb supplies parameters to CSV.

communications controller

A device that directs the transmission of data over a network (for example, the IBM 3725 front-end processor).

COMP-1

Specified for internal floating-point items (single precision). The items are four bytes long. The sign is contained in the first bit of the leftmost byte, and the exponent is contained in the remaining seven bits of that byte. The last three bytes contain the mantissa.

COMP-2

Specified for internal floating-point items (double precision). The items are eight bytes long. The sign is contained in the first bit of the leftmost byte, and the remaining seven bits of that byte contain the exponent. The remaining seven bytes contain the mantissa.

COMP-3

Specified for internal decimal items. In storage, these items appear in packed decimal format. There are two digits for each character position (byte), except for the trailing character position (byte), which is occupied by the low-order digit and sign. The item can contain only the digits 0 through 9, plus a sign (in the last position), representing a value not exceeding 29 decimal digits (15 bytes).

component

A discrete unit of code built on ActiveX® controls that deliver a well-specified set of services through well-specified interfaces. Components provide the objects that clients request at run time.

Component Object Model (COM)

An open architecture for cross-platform development of client/server applications based on object-oriented technology. Clients have access to an object through the interfaces implemented on the object. COM is language-neutral, so any language that produces COM components can also produce COM applications.

Component Services (COM+) component

A Component Object Model (COM) component that executes in the COM+ run-time environment. A COM+ component is commonly known as a COM+ application. A COM+ component must be a dynamic-link library (.dll) file that implements a class factory to create objects and that describes all of the interfaces of the component in a type library to facilitate standard marshaling.

Component Services (COM+) object

A Component Object Model (COM) object that executes in the COM+ run-time environment.

concurrency

The appearance of simultaneous execution of processes or transactions by interleaving the execution of multiple pieces of work.

configuration file

A file containing setup and configuration information for Host Integration Server. It defines servers, connections, LUs, users, and other items. The configuration file that is loaded when SNA Manager starts is called COM.CFG.

connection

The data communication path between a workstation or server and other computers on the SNA network. Host Integration Server offers a variety of connection types:

- 802.2 (Token Ring or Ethernet)
- Synchronous Data Link Control (SDLC)
- X.25
- Distributed function terminal (DFT)
- Channel
- Twinax

connection object

In AFTP, a connection (not necessarily active) to a partner computer.

connectivity

(1) The capability of a system or device to be attached to other systems or devices without modification. (2) The capability to attach a variety of functional units without modifying them.

connectivity option

A type of connection hardware and software through which one computer communicates with other computers.

consistency

A state in which durable data matches the state expected by the business rules that modified the data.

constructor

In C, a special initialization function that is called automatically whenever an instance of a class is declared. This function prevents errors that result from the use of uninitialized objects. The constructor has the same name as the class itself and cannot return a value.

contention loser

In an APPC LU-LU session, the LU that cannot start a conversation with its partner LU (the contention winner) without first requesting permission of the partner LU. *See also***contention winner**.

contention winner

In an APPC LU-LU session, the LU that can start a conversation with its partner LU (the contention loser). If parallel sessions between the two LUs are being used, each LU may be the contention winner for some sessions and the contention loser for other sessions. *See also***contention loser**.

context

The state that is implicitly associated with a given COM+ object. The context contains information about the execution environment of an object, such as the identity of the creator of an object and, optionally, the transaction encompassing the work of the object. The context of an object is similar in concept to the process context that an operating system maintains for an executing program. The COM+ run-time environment manages a context for each object.

control point

A node or other SNA component that controls network resources and coordinates the activation of sessions.

controller

A device that directs the transmission of data over a network (for example, the IBM 3725 front-end processor).

conversation

The process used by network-based applications to communicate with each other and to exchange data to accomplish processing tasks. (1) A logical connection between two transaction programs using an LU 6.2 session. Conversations are delimited by brackets to gain exclusive use of a session. (2) The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously. *See also* **basic conversation**; **mapped conversation**.

conversation characteristics

Internal API values that define the overall operation for a conversation or for a specific call. *See also***application programming interface (API)**; **conversation**.

conversation ID

A unique identifier for a conversation between two transaction programs (TPs).

CPI-C

See **Common Programming Interface for Communications (CPI-C)**.

creator

A client that creates an object provided by a component (using **CreateObject**, **CoCreateInstance**, or the **CreateInstance** method). When a client creates an object, it is given an object reference that can be used to call the methods of that object. *See also***caller**.

CSV

See **Common Service Verb (CSV)**.

Currency

An 8-byte, fixed-point data type that is useful for calculations involving money or for fixed-point calculations in which accuracy is extremely important. This data type is used to store numbers with up to 15 digits to the left of the decimal point and 4 digits to the right. The type-declaration character in Microsoft® Visual Basic® is an at sign (@). Currency can range from –922,337,203,685,477.5808 to 922,337,203,685,477.5807.

current directory

The first directory in which the operating system looks for programs and data files and stores files for output.

Customer Information Control System (CICS)

An IBM transaction processing program that provides an environment on IBM mainframes in which applications can communicate with terminals or other applications.

-D-

DACTLU

An SNA command that is sent to deactivate the session between the system services control point (SSCP) and a logical unit (LU).

DACTPU

An SNA command that is sent to deactivate the session between the system services control point (SSCP) and a physical unit (PU).

data link control (DLC)

In SNA, the protocol stack layer that transmits messages across links and manages link-level flow and error recovery.

data set members

Members of partitioned data sets that are individually named elements of a larger file that can be retrieved by name.

data source name (DSN)

The name that applications use to request a connection to an ODBC data source. DSN also means Data Set Name on the mainframe.

database

(1) A collection of data with a given structure for accepting, storing, and providing on demand data for multiple users. (2) A collection of interrelated data organized according to a database schema to serve one or more applications. (3) A collection of data fundamental to a system. (4) A collection of data fundamental to an enterprise.

Date

An 8-byte, real data type used to store dates and times as a real number. Variables are stored as 64-bit numbers. The value to the left of the decimal represents a date, and the value to the right of the decimal represents a time. The Date data type can range from January 1, 1000 to December 31, 9999.

DCOM

See **distributed COM (DCOM)**.

DDM

See **distributed data management (DDM)**.

deallocate

(1) The process an operating system uses to free memory that has been previously allocated by a program. (2) In Advanced Program-to-Program Communications (APPC), a verb that ends a conversation. *Contrast with***allocate**.

Decimal

A data type that stores a signed, exact numeric value described as the number of digits appearing before and after the decimal point, with a maximum of 29 total digits. All possible digits cannot be represented if you are using the maximum number of digits.

default

The value that is automatically used if nothing is specified.

dependent local APPC LU

A local logical unit (LU) that enables Advanced Program-to-Program Communications (APPC) with a peer system, but only through a host (mainframe) system. The type of LU used in dependent APPC is LU 6.2.

DFT

See **distributed function terminal** (**DFT)**.

digit

In COBOL, any of the numerals from 0 through 9 not used in reference to any other symbol.

direct caller

The identity of the process (base client or server process) calling into the current server process.

direct creator

The identity of the process (base client or server process) that directly created the current object.

directory

(1) A list of files that are stored on a disk or diskette. A directory also contains information about the files such as size and date of last change. (2) A named grouping of files in a file system.

display emulation

A feature that enables a personal computer to emulate an IBM 3278 or 3279 terminal. *See also***emulation**.

display model

One of several different sizes of display:

- Model 2 is 24 lines by 80 characters
- Model 3 is 32 lines by 80 characters

- Model 4 is 43 lines by 80 characters
- Model 5 is 27 lines by 132 characters

display session

A 3270 emulation session between a networked personal computer and a host. The session is used to emulate a 3278 or 3279 display. Also called a host display session.

DISPLAY verb

An APPC verb that returns configuration information and current operating values for a computer running Host Integration Server.

distributed COM (DCOM)

An object protocol that enables COM components to communicate directly with each other across a network. Because DCOM is language-neutral, any language that uses COM components can also produce DCOM applications.

distributed data management (DDM)

A function of the operating system that enables an application program or user on one system to use database files stored on remote systems. A communications network must connect the systems, and the remote systems must also be using DDM.

distributed function terminal(**DFT)**

A type of intelligent terminal supported by IBM 3270 control units, in which some of the terminal's functions are controlled by the terminal and some by the control unit. Enables multiple sessions, and connects to host systems or to peer systems through host systems. DFT terminals are often connected using coaxial cable.

distributed processing

A form of information processing in which the work is performed by separate computers that are linked through a local or wide area network, using data-transfer mechanisms that enable different programs to use and share data.

distributed program call (DPC)

An AS/400 remote communication model.

Distributed Query Processor (DQP)

Enables queries to access multiple data sources on multiple servers, even SQL and DB2, and combine views, create data warehouses, and so on. DQP supports an extended version of the SQL language that permits users to qualify table names with the databases in which they exist. This gives users the capability to formulate queries that span multiple distributed databases.

Distributed Relational Data Architecture (DRDA)

A connection protocol for distributed relational database processing that is used by IBM relational database products. The DRDA protocol comprises protocols for communication between an application and a remote database, and communication between databases. The DRDA protocol provides the connections for remote and distributed processing. The DRDA protocol is built on the Distributed Data Management Architecture.

Distributed Transaction Coordinator (DTC)

A transaction manager that coordinates transactions spanning multiple resource managers. Work can be committed as an atomic transaction even if it spans multiple resource managers, even on separate computers.

distributed unit of work (DUW)

In DB2 UDB for AS/400, this is a method of accessing distributed relational data in which a user or application can, within a single unit of work, read and update data on multiple database management systems (DBMSs). The user or application directs each SQL statement to a particular DBMS for execution at the DBMS. Each SQL statement may access only one DBMS.

DL-BASE

The type of Base used by Host Integration Server 3270 emulation programs. It supports a single Host Integration Server component or a single user application and has entry points for initialization, sending messages, receiving messages, and termination. *See also***Base**.

DLC

See **data link control (DLC)**.

DLL

See **dynamic-link library (DLL)**.

DMOD

See **Dynamic Access Module (DMOD)**.

document type definition (DTD)

Can accompany a document, essentially defining the rules of the document, such as which elements are present and the structural relationship between the elements. It defines what tags can go in your document, what tags can contain other tags, the number and sequence of the tags, the attributes your tags can have, and optionally, the values those attributes can have.

DTDs help to validate the data when the receiving application does not have a built-in description of the incoming data. The DTD is declared within the document type declaration production of the XML file. With XML, however, DTDs are optional.

downstream connection

A connection that enables a computer running Host Integration Server to support communication between hosts and clients. Even though such clients do not use the Host Integration Server client/server interface, with a downstream connection they can access host connections available through a computer running Host Integration Server.

Host Integration Server offers several types of downstream connection:

- 802.2 (Token Ring or Ethernet)
- SDLC
- X.25

downstream LU

A logical unit (LU) used by clients to access a host connection through a computer running Host Integration Server. Such clients do not use the Host Integration Server client/server interface, but by using a downstream LU, can receive access to connections on a computer running Host Integration Server. A downstream LU uses a downstream connection, and passes information between the client and the host.

downstream system

A client such as an IBM Communications Manager/2 system that can access host connections available on a computer running Host Integration Server. Even though such clients do not use the Host Integration Server client/server interface, they can use a downstream connection and a downstream LU to communicate with the host through Host Integration Server. Host Integration Server passes the information between the downstream system and the host. With Host Integration Server, downstream systems appear to the host as logical units, not physical units.

DPC

See **distributed program call (DPC)**.

DPL-enabled

Compatible with the IBM Distributed Program Link (DPL) protocol.

DQP

See **Distributed Query Processor (DQP)**.

DRDA

See **Distributed Relational Data Architecture (DRDA)**.

DSN

See **data source name (DSN)**.

DTC

See **Distributed Transaction Coordinator (DTC)**.

DTD

See **document type definition (DTD)**.

duplex

Capable of simultaneously transmitting and receiving data. Also called **full-duplex** or **4-wire**. *Contrast with***half-duplex**.

durability

A state that survives failures.

DUW

See **distributed unit of work (DUW)**.

Dynamic Access Module (DMOD)

An SNA component that provides the communications facilities needed to pass messages between the Bases.

dynamic-link library (DLL)

A binary file that contains one or more functions that are compiled, linked, and stored separately from the processes that use them. The operating system maps a DLL to the address space of the calling process when the process starts or while it is running. It uses the .dll file extension.

-E-

EBCDIC

See **Extended Binary Coded Decimal Interchange Code (EBCDIC)**.

EBI

See **end bracket indicator (EBI)**.

EBIUI

See **end basic information unit indicator (EBIUI)**.

ECI

See **end chain indicator (ECI)**.

ELM

See **enhanced listener message (ELM)**.

emulation

A process whereby one device imitates another; for example, a personal computer can emulate a 3278 terminal. *See also***display emulation**.

end bracket indicator (EBI)

Bit 5 of Flag 1 of a Status-Control message. Set if chain carries end bracket (EB). Note that this does not indicate that the bracket has terminated.

end chain indicator (ECI)

Bit 2 of Flag 1 of a Status-Control message. Set if this message ends a chain.

enhanced listener message (ELM)

A streamlined, application-level protocol exchange sequence that sends to and receives from the host application a single data stream composed of a header followed by the application data.

ERI

See **exception response indicator (ERI)**.

Ethernet

An IEEE 802.3 standard for contention networks. Ethernet uses a bus or star topology and relies on the form of access known as Carrier Sense Multiple Access with Collision Detection (CSMA/CD) to regulate communication line traffic. Network nodes

are linked by coaxial cable, by fiber-optic cable, or by twisted-pair wiring. Data is transmitted in variable-length frames containing delivery and control information and up to 1,500 bytes of data. The Ethernet standard provides for baseband transmission at 10 megabits per second.

event log

Host Integration Server records events involving communications hardware (for example, communications adapters) or software in the Windows Event Log. Events can include attempts to establish communication, successful establishment of sessions, failures of system components, attempts to use files that are damaged or missing, configuration problems, and responses from remote systems.

exception

An abnormal condition or error that occurs during the execution of a program and that requires the execution of software outside the normal flow of control.

exception request (EXR)

A request in which an intermediate component has detected an error and modified the request so the final destination is also aware of the error.

exception response indicator (ERI)

A specified response for a request. The response should be issued only if the request cannot be processed or if an error was encountered during processing.

exchange identification (XID)

An identifier that is exchanged between nodes on an SNA network, and that enables the nodes to recognize each other and to establish link and node characteristics for communicating. With Host Integration Server, there are two possible kinds of XIDs that can be exchanged: Format 0 XIDs (containing only basic information such as Node ID) and Format 3 XIDs (containing more detailed information such as Network Name and Control Point Name). *See also***Format 0 XID**; **Format 3 XID**.

EXR

See **exception request (EXR)**.

Extended Binary Coded Decimal Interchange Code (EBCDIC)

A coding scheme developed by IBM for use with its mainframe and AS400 computers as a standard method of assigning binary (numeric) values to alphabetic, numeric, punctuation, and transmission-control characters.

Extensible Markup Language (XML)

A specification developed by the World Wide Web Consortium (W3C) that enables designers to create customized tags beyond the capabilities of standard Hypertext Markup Language (HTML). While HTML uses only predefined tags to describe elements within the page, XML enables tags to be defined by the developer of the page. Tags for virtually any data item, such as a product or an amount due, can be used for specific applications. This enables Web pages to function as database records.

Extensible Stylesheet Language (XSL)

A style sheet format for Extensible Markup Language (XML) documents. XSL is used to define the display of XML in the same way that cascading style sheets (CSS) are used to define the display of Hypertext Markup Language (HTML).

-F-

fault isolation

Containing the effects of a fault within a component, rather than propagating the fault to other components in the system.

fault tolerance

The ability of a system to recover from an error, a failure, or a change in environmental conditions (such as loss of power). True fault tolerance provides for fully automatic recovery without disruption of user tasks or files, in contrast to manual means of recovery such as restoring data loss with backup files.

file transfer

The process of sending and receiving data files to and from computers.

fill type

A value that indicates whether programs will receive data in the form of logical records or as a specified length of data.

flow

A verb flows from one LU to another.

FMHI

See **function management header indicator (FMHI)**.

FMI

See **function management interface (FMI)**.

Format 0 XID

A type of XID that supplies minimal information about the node. Format 0 XIDs have a fixed length. They can be used for 3270 and LUA communication, and cannot be used for Advanced Program-to-Program Communications (APPC). *See also***exchange identification (XID)**, **Format 3 XID**.

Format 3 XID

A type of XID that supplies more detailed information about the node than a Format 0 XID. Format 3 XIDs have a variable length. They can be used for 3270 and LUA communication, and are the only type of XID that can be used for Advanced Program-to-Program Communications (APPC). *See also***exchange identification (XID)**; **Format 0 XID**.

full-duplex

Capable of simultaneously transmitting and receiving data. Also called **duplex** or **4-wire**. *Contrast with***half-duplex**.

full-duplex transmission

Two-way electronic communication that takes place in both directions simultaneously. Also called **duplex transmission** or **4-wire transmission**. *Contrast with***half-duplex transmission**.

fully qualified LU name

The two-part network address (network.lu) that uniquely identifies a destination (typically a user) in the network.

function management header indicator (FMHI)

Headers inserted into requests containing end-user data to convey control information.

function management interface (FMI)

An interface that provides applications with direct access to SNA data flow and information about SNA control flows by means of status messages. It is particularly suited to the requirements of 3270 emulation applications.

-G-

GAC

See **global assembly cache (GAC)**.

global assembly cache (GAC)

A machine-wide code cache that stores assemblies specifically installed to be shared by many applications on the computer. Applications deployed in the global assembly cache must have a strong name.

group

A set of one or more Windows 2000 or later user accounts.

-H-

half-duplex

Capable of only one direction of communication at a time, either receiving data or transmitting data, but not doing both at the same time. Also called **2-wire**. *Contrast with***full-duplex**.

half-duplex transmission

Two-way electronic communication that takes place in only one direction at a time. Also called **2-wire transmission**. *Contrast with***full-duplex transmission**.

HCD

See **host column description (HCD)**.

HE

See **host environment (HE)**.

high-level language application programming interface (HLLAPI)

An API that enables you to develop and run programmer-operator applications on IBM personal computers (or compatibles) that communicate with IBM mainframes using 3270 emulation.

HIP

See **host-initiated processing (HIP)**.

HLLAPI

See **high-level language application programming interface (HLLAPI)**.

host column description (HCD)

Maps AS/400 flat file data types to OLE DB data types. The HCD is an external file stored on the computer that enables administrators to describe the host record format. At run time, the OLE DB Provider for AS/400 and VSAM transparently converts the host data to computer data using the local HCD information.

host environment (HE)

An object that defines the network and hardware characteristics of the non-Windows software platform that initiates requests to the Windows platform. The host environment consists of the host environment name, host identification, network transport type, data conversion information, default method resolution criteria, and security credential mapping.

Host Integration Server

A Microsoft® software program that enables a personal computer to communicate with remote computers such as IBM mainframes, AS/400s, or other personal computers on a TCP/IP or SNA network.

host response time

The amount of time that a host computer takes to reply to a message sent to it by a client computer. Host response time is measured from the moment that the personal computer sends the message until one of the following events: the client computer receives data back from the host, the host unlocks the client computer's keyboard, or the host enables the client computer to send more data.

host system

A computer system (usually a mainframe) that controls interactions between it and the computers connected to it. A host system makes operating systems and applications available by way of Host Integration Server to computers running software for terminal emulation or for APPC.

In SNA terminology, a host is capable of sending an ACTPU command to Host Integration Server and sets up a PU-SSCP session with Host Integration Server.

host-addressable printer

A printer that is defined as a device associated with a logical unit (LU) configured as LU type 1 or 3 and that can support host printing as well as local printing.

host-initiated processing (HIP)

A non-Microsoft software platform (usually a mainframe or mid-range computer such as the AS/400) that can access and integrate its programs with the programs on a Windows server platform.

hot backup

(1) The ability to take systems online and offline without disrupting service. (2) A configuration in which one resource (such as a server running Host Integration Server software) can automatically handle sessions if another cannot. Such servers can provide hot backup for 3270, LUA, or downstream sessions through pools containing LUs from multiple servers. Servers running Host Integration Server software can provide hot backup for 5250 terminal emulation through the use of LU names that are the same on multiple servers.

-I-

I-frame

See **Information frame (I-frame)**.

identity

A COM+ application property page that specifies the user accounts authorized to use that application. You can set it to **Interactive user** (to authorize the current logged on user), to a specific user account, or to a group of users within a Windows domain.

IEEE

See **Institute of Electrical and Electronics Engineers (IEEE)**.

implicit incoming mode

A mode that defines the properties to use when Host Integration Server receives a request to start a session, and the mode named in the request is not recognized by Host Integration Server. An implicit incoming mode enables greater flexibility in starting sessions with remote systems.

For a session to be established, the incoming local LU name must be recognized by Host Integration Server. Then, the incoming remote LU must either be recognized explicitly or handled implicitly (if an implicit incoming remote LU has been configured). If the remote LU is recognized explicitly, but the mode is not recognized (as part of an LU-LU pair), Host Integration Server internally creates a new mode definition with the correct name, using the properties of the implicit incoming mode. Alternatively, if the remote LU is handled implicitly, Host Integration Server also handles the mode implicitly, by internally creating a mode, as described.

Note that an implicit incoming mode must be configured for any remote LU that will be used as an implicit incoming remote LU. An implicit incoming mode can be (but does not have to be) configured for remote LUs that will only be used explicitly.

implicit incoming remote LU

A remote APPC LU that defines the properties to use when Host Integration Server receives a request to start a session with a local LU, and the remote LU named in the request is not recognized by Host Integration Server. An implicit incoming remote LU that enables greater flexibility in starting sessions with remote systems.

Note that for a session to be established, the local LU name must be recognized by Host Integration Server. If the local LU name is recognized, but the remote LU name is not recognized as a partner for the local LU, Host Integration Server internally creates a new remote LU definition with the correct name, using the properties of the implicit incoming remote LU.

In SNA Manager, before a remote APPC LU can be used as an implicit incoming remote LU, an implicit incoming mode must be configured for it.

IMS

See **Information Management Systems (IMS)**.

independent local APPC LU

A local logical unit (LU) that enables Advanced Program-to-Program Communications (APPC) with a peer system without involving a host (mainframe) system. The type of LU used in independent APPC is LU 6.2. An independent LU does not require a host system, but can work through one.

IND$FILE

IBM file transfer program that enables files to be transferred from a personal computer to the host and from the host to the personal computer. It operates in three host environments: CICS, VM/CMS, and MVS/TSO.

Information frame (I-frame)

A standard unit of information transmitted over an SNA network. For 802.2 or SDLC communication, an I-frame is equivalent to a BTU. *See also***basic transmission unit (BTU)**.

Information Management Systems (IMS)

A transaction processing monitor created and sold by IBM Corporation.

in-process component

A component that runs in a client's process space. This is typically a dynamic-link library (DLL).

instance

An object of a particular component class. Each instance has its own private data elements or member variables. A component instance is synonymous with object.

Institute of Electrical and Electronics Engineers (IEEE)

An organization that maintains the standards for the 802.x protocols used in communications on local area networks.

Integer

A fundamental Automation data type that holds integer numbers. An integer variable is stored as a 16-bit (2-byte) number ranging in value from –32,768 to 32,767. The type-declaration character is a percent sign (%) (ANSI character 37). In Microsoft® Visual Basic®, you can use integers to store Boolean (**True**/**False**) values.

interface

A group of logically related operations or methods that provides access to a component object.

Internet Packet Exchange/Sequenced Packet Exchange (IPX/SPX)

A set of protocols used by Novell NetWare networking software for communication across a network.

Internet Protocol (IP) routed network

A TCP/IP wide area network in which IP packets are propagated across the network through devices called IP routers.

invokable

Indicates the capability of a program to be started by another program. For example, an invokable APPC transaction program (TP) can be started in response to a request from another TP (the invoking TP).

invoked program

A program that has been activated by a call or verb. *See also***invoking program**.

invoked TP

A host transaction program (TP) started by:

- Another (the invoking) TP.
- A Transaction Integrator Automation server working in conjunction with the TI run-time environment and Microsoft Distributed Transaction Server (DTS) included in COM+.

invoking program

A program that uses a call or verb to activate another program. Also known as the calling program or the client. *See also***invoked program**.

invoking TP

A TP that initiates a conversation with another TP. The invoking TP starts the other TP by instructing the remote node to load the invokable TP.

IP routed network

See **Internet Protocol (IP) routed network**.

IPX/SPX

See **Internet Packet Exchange/Sequenced Packet Exchange (IPX/SPX)**.

isolation

A characteristic whereby two transactions running in parallel produce the illusion that there is no concurrency. It appears that the system is running one transaction at a time.

-J-

No terms.

-K-

No terms.

-L-

LAN

See **local area network (LAN)**.

LE

See **local environment (LE)**.

leased SDLC line

A dedicated telecommunications line using SDLC. *See also***Synchronous Data Link Control (SDLC)**.

link service

The software component of Host Integration Server that communicates with the device driver for a particular communication adapter (802.2, SDLC, X.25, DFT, Channel, or Twinax).

listener

A local environment associated with an application, where the local environment monitors the TCP/IP or SNA network for requests to the application.

load balancing

Distribution of the processing load among several servers carrying out network tasks to increase overall network performance.

local account

An account provided in a local domain for a user whose regular account is not in a trusted domain. Local accounts cannot be used to log on interactively. Local accounts created in one domain cannot be used in trusted domains.

local area network (LAN)

A high-speed communication system consisting of hardware (computers and peripherals) and software (programs and data files) that are interconnected by cable in a way that enables these resources to be shared. The connected devices are located within a limited geographic area such as a building or campus.

local environment (LE)

An object that defines the endpoint on a Windows computer that accepts incoming requests from a non-Windows software platform. The local environment consists of the local environment name, network transport type, network transport class, and endpoint identification.

local LU

In an APPC or CPI-C conversation, the logical unit (LU) on the local end. *Contrast with***partner LU** and **remote LU**.

local LU alias

The name by which a local logical unit (LU) is known to the local transaction program (TP).

local node

The software component of Host Integration Server that interacts with clients and other nodes on the SNA network.

local printer

A printer that is attached directly to a personal computer.

local program

In CPI-C, the program on the local end of the conversation. *Contrast with* partner program.

local TP

In an Advanced Program-to-Program Communications (APPC) or Common Programming Interface for Communications (CPI-C) conversation, the transaction program (TP) on the local end. *Contrast with***partner TPs** and **remote transaction program**. *See also***local LU**.

locality

A base and the components within it; that is, a Host Integration Server executable program.

locality, partner, index (LPI)

An LPI address that is used to identify each end of a connection. It has three components: locality (L), partner (P), and index (I).

logical unit (LU)

(1) A type of network-accessible unit that enables users to gain access to network resources and communicate with each other. (2) A preset unit containing all of the configuration information needed for a user, program, or downstream system to establish a session with a host or peer computer. *See also***LU alias**; **LU name**; **LU pool**.

logical unit application (LUA)

A conventional LU application, or the interface that these applications use. LUA enables workstations to communicate with host applications using LU 0, 1, 2, or 3 protocols.

LPI

See **locality, partner, index (LPI)**.

LPI address

Used to identify each end of a connection between two partners. It can have three components: L identifies the locality, P identifies the partner within the locality, and I identifies a logical entity within the partner. *See also***locality**; **partner**.

LU

See **logical unit (LU)**.

LU alias

A string that identifies an APPC or CPI-C logical unit (LU) to transaction programs (TPs) in the same organizational unit (OU). An LU alias is used only locally by Host Integration Server, but it also can be used by any program in the OU of the host mainframe system. *See also***LU name**.

LU name

For 3270 or LUA communication, a name that identifies a logical unit (LU). For independent APPC or CPI-C, a name that (when used with the network name) identifies an LU to other components on an SNA network. For dependent APPC or CPI-C, a name that identifies an LU to local software, such as the Windows Event Viewer. *See also***LU alias**.

LU pool

A number of logical units (LUs) of the same type that are made available as a group. A user or LU application addressing the pool will connect to the next available LU in the pool for that session only. *See also***logical unit (LU)**.

LU type

Logical unit type. A subset of the SNA protocol that characterizes the communication between two LUs.

LU type 0

A logical-unit protocol with minimal constraints, on which special applications can be built for SNA.

LU type 1

A logical-unit protocol used by a host application communicating with a printer, sending data that conforms to the 3270 SNA Character String (SCS) definition.

LU type 2

A logical-unit protocol used by a host application communicating with a 3270-type display terminal, using the SNA 3270 data stream.

LU type 3

A logical-unit protocol used by a host application communicating with a printer, sending data that is 3270 data stream compatible (DSC).

LU type 6.2

A logical-unit protocol used by two applications or transaction programs (TPs) communicating as peers in an SNA environment. LU 6.2 works in combination with node type 2.1 to provide Advanced Program-to-Program Communications (APPC) using independent LUs. LU 6.2 also works with node type 2.0 to provide APPC with dependent LUs.

LU-LU session

A logical, two-way exchange between two logical units (LUs) over a specific connection for a specific amount of time.

LUA

See **logical unit application (LUA)**.

-M-

MAC address

A 12-byte hexadecimal address used by the media access control (MAC) layer of an 802.2 connection. It corresponds to the VTAM MACADDR= parameter and to the Remote Network Address parameter for an 802.2 connection with Host Integration Server.

management object

A TI component that manages or provides access to administration information. Typically, management objects are visible only when errors or messages are reported or placed in the Windows Event Log.

mapped conversation

A conversation in which the sending program sends one logical record at a time and the receiving program receives one record at a time. *See also* **conversation**.

marshaling

The process of packaging and sending interface method parameters across thread or process boundaries.

member server

A server that does not contain a configuration file. One or more servers can operate as member servers. The other types of servers are the primary server and backup servers.

method

A procedure (function) that acts on an object.

Microsoft .NET

Microsoft® .NET is a set of software technologies for connecting information, people, systems, and devices. This new generation of technology is based on Web services—small building-block applications that can connect to each other as well as to other, larger applications over the Internet.

mode

A collection of session properties used by LU 6.2-type logical units (LUs) as they carry on a session. A mode can be used by many LU pairs at the same time.

mode name

The name used by the initiator of a session to designate the characteristics desired for the session, such as traffic pacing values, message-length limits, Sync Point and cryptography options, and the class of service within the transport network.

model

One of several different sizes of display:

- Model 2 is 24 lines by 80 characters
- Model 3 is 32 lines by 80 characters
- Model 4 is 43 lines by 80 characters
- Model 5 is 27 lines by 132 characters

Messaging-oriented middleware

Messaging-oriented middleware (MOM) is a set of products that connects applications running on different systems by sending and receiving application data as messages. Examples are RPC, CPI-C, and message queuing.

multidrop

A connection in which one primary node communicates with multiple secondary nodes concurrently over the same physical transmission medium.

multiple sessions

In CPI-C, two or more concurrent sessions with different partner LUs. *Seealso***LU-LU session**.

Multiple Virtual Storage (MVS)

An operating system for large IBM mainframe computers. Implies MVS/370, the MVS/XA product, and the MVS/ESA product.

MVS

See **Multiple Virtual Storage (MVS)**.

-N-

NAU

See **network addressable unit (NAU)**.

NC

See **network control (NC)**.

NCP

See **Network Control Program (NCP)**.

.NET Framework

An integral Microsoft® Windows® component for building and running the next generation of applications and XML Web services.

NetView

A reporting system that runs on an IBM host (mainframe), forwarding alerts and other information back and forth between the host and personal computers, and other network addressable units that connect to the host.

NetView alert

A message sent to the NetView reporting system, indicating an abnormal event or a failure.

NetView user alert

A message sent by a 3270 user to a host system operator through NetView, requesting an action such as mounting a tape or changing forms on a printer. Also called user alert.

NetWare

A collection of networking software products from Novell, Inc.

network

Computer systems, controllers, terminals, and software connected in a way that enables them to communicate with each other.

network addressable unit (NAU)

The basic functional entities in an SNA environment that are the source or destination of all information flowing within the SNA network. The NAU can be a logical unit (LU), a physical unit (PU), or a system services control point (SSCP).

network control (NC)

A set of SNA-defined requests and responses used to control explicit and virtual routing.

Network Control Program (NCP)

An IBM program that supports communication controllers in single-domain, multiple-domain, and interconnected networks.

Network Management Vector Transport (NMVT)

SNA message containing network or system management information.

network name

A name identifying an SNA network. The network name is used in combination with other identifiers, either a control point name (to identify a control point or node) or an LU name (to identify an APPC LU, particularly an independent local APPC LU). The combination of a network name with a control point name is sometimes called a network qualified control point name. The combination of a network name with an LU name is sometimes called a fully qualified network name.

NMVT

See **Network Management Vector Transport (NMVT)**.

node

(1) A server, controller, workstation, printer, or other processor that implements SNA functions. SNA defines three kinds of nodes: the host subarea node, which functions to control and manage a network; the communication controller subarea node, which routes and controls data flow through the network; and peripheral nodes, which include printers, workstations, cluster controllers, and distributed processors.

(2) A branch on a navigation tree.

node type 2.1

An SNA component, such as an intelligent terminal or a personal computer, that works together with LU type 6.2 to support peer-to-peer communications, allowing the logical units (LUs) to function independently from the host.

null

A value that indicates missing or unknown data.

-O-

object

A run-time instance of a Component Object Model (COM) component. An object is created by a component's class factory. Object is synonymous with instance.

object variable

A variable that contains a reference to an object.

OCCURS DEPENDING ON

Code syntax that specifies variable-length tables. This is the COBOL version of an array that contains a variable number of elements.

OCCURS *fixed times*

Code syntax that specifies fixed-length tables. This is the COBOL version of an array.

ODBC

See **open database connectivity (ODBC)**.

ODBC resource dispenser

A resource dispenser that manages pools of database connections for COM+ components that use the standard open database connectivity (ODBC) programming interfaces.

open database connectivity (ODBC)

A set of standards that enables universal access to relational data, including Microsoft relational databases and mainframe databases.

open transaction management architecture (OTMA)

A high-performance, connectionless protocol used by IMS to communicate efficiently with Multiple Virtual Storage (MVS) applications without using the SNA protocol.

operator-loaded TP

An invokable transaction program (TP) that is manually loaded and started by an operator.

original caller

The identity of the base client that initiates an activity.

original creator

The identity of the base client that created the current object. The original caller and original creator are different only if the original creator passed the object to a different base client. *See also***original caller**.

OS/390

The IBM operating system for the IBM S/390 family of enterprise servers and that includes and integrates functions previously provided by other IBM software products such as the MVS operating system.

OS/400

The IBM operating system for the IBM AS/400.

OTMA

See **open transaction management architecture (OTMA)**.

out-of-process component

A component that runs in a separate process space from its client.

-P-

pacing receive count

The maximum number of frames for the local logical unit (LU) to receive from the partner LU before the local LU sends a response.

pacing send count

The maximum number of frames for the local logical unit (LU) to send without receiving an SNA pacing response from the partner LU.

packet

A transmission unit of fixed maximum size, used as the basic unit on a packet-switching network. A packet contains both a header and data.

In data communication, a sequence of binary digits, including data and control signals, that is transmitted and switched as a composite whole. The data, control signals, and possibly error control information are arranged in a specific format.

packet switching

A message-delivery technique in which small units of information (packets) are relayed through stations in a computer network along the best route currently available between the source and the destination. Packet-switching networks are considered to be fast and efficient. The protocol used on packet-switching networks is X.25. *See also* **X.25**.

parallel sessions

Multiple concurrent sessions between a pair of LU 6.2-type logical units (LUs), allowing multiple operations to be performed simultaneously.

parameter

A variable used as input to a program, operating system, or API to govern how systems, programs, or functions perform.

partitioned data set (PDS)

A data set in direct access storage that is divided into partitions, called members, each of which can contain a program, part of a program, or data.

partner

An addressable component of a locality; that is, code to which messages can be sent. *See also***locality**.

partner LU

In an APPC or CPI-C conversation, the LU on the far end. The partner LU serves the partner Transaction Processor. *Contrast with***local LU**; *see also***remote LU**.

partner LU alias

A name that identifies a partner logical unit (LU) to partner transaction programs (TPs).

partner LU name

A name that identifies a partner logical unit (LU) to other LUs on the LU 6.2 session.

partner program

For CPI-C, the program receiving the CPI-C call.

partner TPs

Two transaction programs (TPs), residing on the same or separate nodes that are configured to communicate with each other. Partner TPs use partner LUs.

password

A string of characters that a user, a program, or a computer operator must specify to meet security requirements before gaining access to a system and to the information stored within it.

path

(1) In SNA, the series of nodes and communications links over which data must travel from one LU to another. (2) A sequence of folders that identify the location of a file. (3) A path exists between two localities when the DMODs in the localities can successfully pass messages between them. A path must exist between two localities before a connection can exist between partners in these localities. *See also***Dynamic Access Module (DMOD)**; **locality**.

pattern-matching character

A special character such as an asterisk (*) or a question mark (?) that can be used to represent one or more characters. Any character or set of characters can replace a pattern-matching character. *Synonymous with* wildcard character.

PC Support

A set of IBM programs that helps personal computer users access, share, and store information on an AS/400.

PDS

See **partitioned data set (PDS)**.

peer system

A mainframe, midrange, or personal computer that communicates with another computer as an equal partner, with both computers sharing control over the communication.

peer-to-peer

A type of communication in which two systems communicate as equal partners sharing the processing and control of the exchange, as opposed to host-terminal communication in which the host does most of the processing and controls the exchange.

permanent virtual circuit (PVC)

A type of circuit used by an X.25 connection, in which the circuit is constantly active, and the destination address is preset.

permissions

Settings that grant or deny a particular kind of access to a particular file, folder, or other object. For example, granting read permission but denying write permission for File1.ext for Domain Admins means that the members of Admins group can read but not change File1.ext.

physical unit (PU)

A network-addressable unit that provides the services needed to use and manage a particular device, such as a communications link device. A PU is implemented with a combination of hardware, software, and microcode.

PIC S9(4) COMP Integer

A 16-bit COBOL data type that represents signed arithmetic operations occupying 2 bytes of storage. This is normally analogous to an Integer data type in Microsoft® Visual Basic® and a Short Integer in C when referring to 32-bit. It can take on values from –9999 to +9999 or –32768 to +32767. It is similar to a Short in C.

PIC S9(9) COMP Integer

A 32-bit COBOL assignment statement to represent signed arithmetic operations that occupy 4 bytes of storage. It can take on values from –999999999 to +999999999 or –2147483648 to +2147483647 depending on compiler options. It is similar to a Long Integer in C.

PIC X

Specifies a single COBOL EBCDIC character.

PIC X No Translation

A character string handled like binary data. There is no translation from EBCDIC to Unicode or from Unicode to EBCDIC.

PICTURE clause

Specifies the general characteristics and editing requirements of an elementary item. The PICTURE character string is made up of COBOL characters used as symbols and can contain a maximum of 30 characters.

pipe

A portion of memory that can be used by one process to pass information along to another.

PLU

See **primary logical unit (PLU)**.

pool

See LU pool.

pooling

A performance optimization based on using collections of pre-allocated resources, such as objects or database connections. Pooling results in more efficient resource allocation.

primary logical unit (PLU)

On an SNA session, the LU on the node that sent the session activation request.

primary server

The server designated to contain the primary configuration file. There can be only one primary server active in a subdomain. *See also***backup server**.

printer emulation

The ability of a personal computer-type printer to emulate a 3287 or 4224 printer to print host data.

printer session

A 3270 emulation session between a host and a local area network printer connected to a personal computer. The printer emulates the type of printer normally used by a host system.

private assembly

An assembly that is available only to clients in the same directory structure as the assembly. *See also***assembly**.

ProgID

See **programmatic identifier (ProgID)**.

programmatic identifier (ProgID)

A name that identifies a COM component. For example, a ProgID could be Bank.MoveMoney.

programmatic security

Procedural logic provided by a component to determine if a client is authorized to perform the requested operation. *See also***declarative security**.

protocol

(1) A set of semantic and syntactic rules that determine the behavior of functional units in achieving communication. (2) In Open Systems Interconnection architecture, a set of semantic and syntactic rules that determine the behavior of entities in the same layer in performing communication functions. (3) In SNA, the meanings of, and the sequencing rules for, requests and responses used for managing the network, transferring data, and synchronizing the states of network components.

proxy

An interface-specific object that provides the parameter marshaling and communication required for a client to call an application object that is running in a different execution environment, such as on a different thread or in another process. The proxy is located with the client and communicates with a corresponding stub that is located with the application object that is being called. In the case of TI, the TI run-time environment serves as the proxy to the mainframe transaction program (TP).

PU

See **physical unit (PU)**.

PU 2.0

In an SNA network, the component that defines controller and terminal-type resources similar to an IBM 3274 Control Unit.

PU 2.1

In an SNA network, a component such as an intelligent terminal or a personal computer that works together with logical unit (LU) type 6.2 to support peer-to-peer communications, allowing the LUs to function independently from the host.

PVC

See **permanent virtual circuit (PVC)**.

-Q-

QLLC

See **qualified logical link control (QLLC)**.

qualified logical link control (QLLC)

A protocol that permits SNA sessions to occur over X.25 networks.

queued TP

An invokable transaction program (TP) that can be started by only one incoming allocate command at a time. Incoming allocate commands that arrive while the queued TP is running do not start the program again, but are queued until the program issues another **RECEIVE_ALLOCATE** or until it finishes execution.

-R-

race condition

A condition in which a feedback circuit interacts with the internal circuit processes in a way that produces chaotic output behavior.

RE

See **remote environment (RE)**.

Record Level Input/Output (RLIO)

A protocol of IBM Distributed Data Management architecture.

remote component

Components used by a client on a different computer.

remote environment (RE)

A collection of properties that describes a region on the mainframe, or in the case of diagnostic tools such as Capture and Playback, a simulated region. You can view and change these properties by using TI Manager.

remote LU

In an APPC or CPI-C conversation, the logical unit (LU) on the remote end. *Contrast with***local LU**. *See also***remote transaction program**.

remote network address

For an 802.2 connection, a 12-digit hexadecimal address that identifies a remote host, peer, or downstream system. The Remote Network Address in Host Integration Server corresponds to the VTAM MACADDR= parameter in the PORT definition.

remote node

(1) The node at the other end of a connection. (2) The node that contains the logical unit (LU) at the other end of a session. (3) The node that contains the transaction program (TP) at the other end of a conversation.

remote node ID

One of the types of identifiers that can be used to identify a remote node. The remote node ID is an 8-digit hexadecimal number. The first three digits are called the block number, and correspond to the VTAM parameter IDBLK. The last five digits are called the node number, and correspond to the VTAM parameter IDNUM.

remote procedure call (RPC)

A standard that enables one process to make calls to functions that are executed in another process. The processes can be on the same computer or on different computers in the network.

remote transaction program

In an Advanced Program-to-Program Communications (APPC) or Common Programming Interface for Communications

(CPI-C) conversation, the transaction program (TP) on the remote end. *Contrast with***local TP**. *See also***remote LU**.

remote unit of work (RUW)

(1) The form of SQL distributed processing in which the application is on a system different from the relational database, and a single application server services all remote unit-of-work requests within a single logical unit of work. (2) A unit of work that allows for the remote preparation and execution of SQL statements.

Report Program Generator (RPG)

A column-oriented programming language designed for writing application programs for business data processing. RPG requires that certain information, such as control codes and field names, must be placed into specific columns of the program statements.

Request Unit Interface (RUI)

A basic interface that enables programs to acquire and release control of conventional LUs. The RUI also reads and writes request/response headers (RHs), transmission headers (THs), and request/response unit (RU) data. *Contrast with***Session Level Interface (SLI)**.

request/response unit (RU)

Under SNA, a message that controls the session, data flow, and function management aspects of the SNA protocol.

resource dispenser

A service that synchronizes and manages nondurable resources within a process. This service provides for efficient sharing by COM+ objects. For example, the ODBC resource dispenser manages pools of database connections.

Resource Dispenser Manager

A dynamic-link library (.dll) file that coordinates work among a collection of resource dispensers.

resource manager

A system service that manages durable data. Server applications use resource managers to maintain the durable state of the application, such as the record of inventory on hand, pending orders, and accounts receivable. The resource managers work in cooperation with the transaction manager to provide the application with a guarantee of atomicity and isolation (using the two-phase commit protocol). Microsoft® SQL Server™ is an example of a resource manager.

Response Time Monitor (RTM)

A 3270 and NetView facility that monitors the amount of time it takes for a host to respond during 3270 display sessions.

RLIO

See **Record Level Input/Output (RLIO)**.

role

A symbolic name that defines a class of users for a set of components. Each role defines which users are allowed to invoke interfaces on a component.

root

The topmost node in a directory structure.

root directory

The first directory on a drive in which all other files and subdirectories exist.

RPC

See **remote procedure call (RPC)**.

RPG

See **Report Program Generator (RPG)**.

RTM

See **Response Time Monitor (RTM)**.

RU

See **request/response unit (RU)**.

RUW

See **remote unit of work (RUW)**.

-S-

SAA

See **Systems Application Architecture (SAA)**.

safe reference

A reference to the current object that is safe to pass outside the context of the current object.

SAP address

See **service access point (SAP) address**.

SC

See **session control (SC)**.

schema

The definition of the structure of an XML file. A schema contains property information as it pertains to the records and fields within the structure. *See also***document type definition (DTD)**.

SDLC

See **Synchronous Data Link Control (SDLC)**.

security ID (SID)

A unique name that identifies a logged-on user to the security system. SIDs can identify one user or a group of users.

security key

An identifier used by two APPC logical units (LUs) to validate security when a session is activated. The security key performs a function similar to that of a password, but at the LU-LU session level rather than at the TP-conversation level.

security log

The location in which events related to security are recorded when auditing is set up for such events. For example, auditing can be set up to create a security log entry every time the configuration file is changed on a server. *See also***event log**.

security password

The password that is required, along with the security user ID, to gain access to an invoked program when using conversation security.

security user ID

The user ID (also known as user name) that is required, along with the security password, to gain access to an invoked program when using conversation security.

semaphore

A flag variable that is used to govern access to shared system resources.

server

(1) A functional unit that provides shared services to workstations over a network; for example, a file server, a print server, or a mail server. (2) In a network, a data station that provides facilities to other stations; for example, a file server, a print server, or a mail server.

server process

A process that hosts COM+ application components in Windows 2000 or later. For example, to use TI, you can drop a TI component (type library) into a COM+ application to create an Automation server that a client application can call. When a client application calls a method on the TI Automation server, the Windows 2000 or later run-time environment loads the TI Automation server along with the TI run-time environment into a surrogate server process that automates the mainframe transaction and passes the results back to the client application.

service access point (SAP) address

A value that codes for access to certain services on an 802.2 connection within an SNA network. The Remote SAP Address

parameter is used for 802.2 connections in Host Integration Server, and corresponds to the VTAM parameter called SAPADDR= in the PU definition.

service TP

A transaction program (TP) that uses APPC to perform services related to SNA functionality. *See also***application TP**; **transaction program (TP)**.

session

(1) A period of time when a connection is active and communication can take place. (2) A set of resources that when activated allow communication to take place. (3) In network architecture, for the purpose of data communication between functional units, all the activities that take place during the establishment, maintenance, and release of the connection. (4) A logical connection between two network-accessible units (NAUs) that can be activated, tailored to provide various protocols, and deactivated as requested. Each session is uniquely identified in a transmission header (TH) accompanying any transmissions exchanged during the session. *See also***LU-LU session**.

session control (SC)

A subcomponent of a transmission control component of a half-session, responsible for activating and deactivating the session and data flow and for receiving the data flow following an error.

Session Level Interface (SLI)

A higher-level interface that facilitates the opening and closing of SNA sessions with host LU 0, LU 1, LU 2, and LU 3 application programs. The SLI permits application programs to control the data traffic at a logical message level. *Contrast with***Request Unit Interface (RUI)**.

session limit

The maximum number of parallel sessions that can be active between two APPC LUs. When an LU-LU session is established, the session limit is negotiated between the two LUs.

severity level

A number that indicates the severity of an audit or error message. Audit messages provide information and have severity 6, 8, or 10. Error messages have severity 12 or 16, indicating a problem that needs to be corrected.

shared assembly

An assembly that can be referenced by more than one application. An assembly must be explicitly built to be shared by giving it a cryptographically strong name. *See also***assembly**; **private assembly**.

SID

See **security ID (SID)**.

side information table

In CPI-C, a table that stores the initialization information required for two programs to communicate. The table resides in the operating systems memory and the system administrator maintains it by accessing a symbolic destination name. The table is derived from the configuration file for Host Integration Server.

single session

A limit of one session between a pair of Advanced Program-to-Program Communications (APPC) logical units (LUs), which limits the associated transaction programs (TPs) to one operation at a time.

SLI

See **Session Level Interface (SLI)**.

SNA

See **Systems Network Architecture (SNA)**

SNA service TP

A transaction program (TP) that uses APPC to perform services related to SNA functionality.

SNA subdomain

With SNA Server version 2.11 and SNA Server version 3.0 or later, you can have several SNA subdomains in a Windows 2000 Server or later domain.

A Windows 2000 Server or later domain:

- Can contain several SNA subdomains.
- Can contain several primary servers, provided that each one is set up in its own subdomain.

With regard to Host Integration Server, each subdomain:

- Contains one primary server.
- Can contain up to 14 backup servers.
- Cannot contain computers running Host Integration Server from other Windows 2000 Server or later domains.

Host Integration Server Setup requires you to specify the name of the subdomain to which the server will belong. One of the SNA subdomains can have the same name as that of the Windows 2000 Server or later domain in which all the servers operate.

Because each subdomain can have only one primary server, it is not advisable to implement an SNA subdomain across slow bridges or routers. Multiple servers in a single subdomain can produce unwanted traffic on the wide-area network.

SnaBase

The SNA Workstation Process. It is present at all times on personal computers whose users want to participate in the SNA network and on personal computers where dynamic loading is to be performed.

SNALink

Link support software that integrates hardware components into a Host Integration Server system. An SNALink is defined when a Host Integration Server system is installed. An SNALink can support only one physical connection from the server.

source TP Name

The host system attempts to identify the source of a request for monitoring, reporting, and so on. The source must be a TP name. MSTX is the default, because it is usually an MS Transaction Server process.

SSCP

See **system services control point (SSCP)**.

string expression

Any expression that evaluates to a sequence of contiguous characters.

stub

An interface-specific object that provides the parameter marshaling and communication required for an application object to receive calls from a client that is running in a different execution environment, such as on a different thread or in another process. The stub is located with the application object and communicates with a corresponding proxy that is located with the client that calls it. In the case of TI, the TI run-time environment serves as the proxy.

subdirectory

A directory contained within another directory in a file system hierarchy.

subdomain

A collection of computers running Host Integration Server that share a single configuration. A subdomain contains one primary server and can also contain one or more backup servers. All servers in a subdomain must belong to the same Windows domain. *See also***backup server**; **primary server**.

SVC

See **switched virtual circuit (SVC)**.

switched SDLC line

A standard telephone line used for SDLC connections on an SNA network. The line is dialed in one of three ways: manually, by a modem that stores the phone number, or by a modem that accepts a phone number string from the software.

switched virtual circuit (SVC)

A type of circuit used by an X.25 connection, in which the circuit is not constantly active, but is called and cleared dynamically. The destination address is supplied when the circuit is called.

Synchronous Data Link Control (SDLC)

A type of link service used for managing synchronous data transfer over standard telephone lines (switched lines) or leased lines.

synchronous transmission

Transmission in which the data characters and bits are transmitted at a fixed rate, with the transmitter and receiver being synchronized. This eliminates the need for individual start and stop bits surrounding each byte. Both SDLC and X.25 use synchronous transmission.

synchronous verb completion

Processing of an SNA verb where the operation of the program is blocked until processing completes. *Contrast with***asynchronous verb completion**.

system administrator

A person who configures, maintains the configuration of, helps users diagnose problems with, and manages a computer system. With Host Integration Server, this person can also be the LAN administrator or a TI developer.

system services control point (SSCP)

(1) A host system network component that provides network services for dependent nodes. (2) An SNA network component that helps control and maintain communication flow between PUs and LUs on the network. Multiple SSCPs can work together to coordinate communications.

Systems Application Architecture (SAA)

Guidelines created by IBM to help developers standardize applications so they function in different operating environments with minimal program modification and retraining of users.

Systems Network Architecture (SNA)

The description of the logical structure, formats, protocols, and operational sequences for transmitting information units through, and controlling the configuration and operation of, networks

-T-

TCP/IP

See **Transmission Control Protocol/Internet Protocol (TCP/IP)**.

terminal

A device that can send or receive data over a data communications channel. Host Integration Server includes emulation of 3278 and 3279 terminals.

TH

See **transmission header (TH)**.

thread

The basic entity to which the operating system allocates CPU time. A thread can execute any part of the application's code, including a part currently being executed by another thread. All threads of a process share the virtual address space, global variables, and operating system resources of the process.

TI

See **Transaction Integrator (TI)**.

Token Ring

A type of LAN using the 802.2 protocol, in which a token is passed in a ring around the network, permitting a computer on the network to transmit data only when that computer has the token.

TP

See **transaction program (TP)**.

trace file

A file containing records of internal activities on the SNA network, including calls made to APIs, the activities of APIs, and the activities of communication links and internal flows.

trace message

A message that includes the current status of various COM+ activities, such as startup and shutdown.

tracing

The action of tracking the activities of an application programming interface (API), communication links, and internal flows, including the calls made to APIs. Tracing stores a history of activity in trace files.

transaction

Data entered into a system (such as a customer deposit to a bank account) triggering a certain action (such as updating an account balance).

An atomic unit of work in COM-based systems that either succeeds or fails as a whole or a section of a mainframe COBOL transaction program (TP). A mainframe-based transaction is a section of COBOL code within a transaction program (TP) that completes a certain task or set of tasks.

A mainframe transaction may or may not be an ACID (atomic, consistent, isolated, and durable) transaction. A mainframe-based TP is the actual COBOL program file that contains one or more transactions (sections of COBOL code). A Windows-based transaction is always an ACID transaction that is coordinated by the Microsoft Distributed Transaction Coordinator (DTC).

Data entered into a system (such as a customer deposit to a bank account) triggers a certain action or set of actions (such as updating an account balance) that must all occur or that must all not occur; that is, they act as a unit. That unit is called a transaction in Windows-based terminology.

Each method in a TI component invokes a single mainframe transaction in a mainframe TP. After being invoked, a mainframe transaction can call other transactions in the same or in a different TP.

transaction context

An object used to allow a client to dynamically include one or more objects in one transaction.

transaction ID

The identifier used to invoke a particular CICS or IMS application (transaction program); in CICS, it is the name of the transaction. A transaction ID (TRANID) can be up to four characters in length. The acceptable characters are A-Z, a-z, 0-9, dollar sign ($), at sign (@), period (.), slash mark (/), hyphen (-), underscore (_), percent sign (%), ampersand (&), question mark (?), exclamation point (!), colon (:), vertical bar (|), quotation mark ("), equal sign (=), caret (^), comma (,), semicolon (;), less than sign (<), and greater than sign (>).

Transaction Integrator (TI)

A Windows server-based program that enables you to integrate mainframe or midrange computer transaction programs with component-based and .NET Framework applications.

transaction manager

The transaction manager creates transaction objects and manages their atomicity and durability. Applications request the creation of a transaction object by calling the transaction manager's **BeginTransaction** method.

transaction program (TP)

A COBOL-based mainframe transaction program file. An application program that uses Advanced Program-to-Program Communications (APPC) to exchange data with another TP on a peer-to-peer basis. Within the context of TI, a TP is the mainframe-based CICS or IMS program file that a TI Automation server automates. A TP can contain one or more transactions that are managed on the mainframe side. Each method in a single TI Automation server invokes a single TP. That TP then uses the information passed into it by the TI Automation server to determine which mainframe transaction to run within the TP. Each mainframe transaction within a TP can call other transactions. It is dependent upon how the mainframe COBOL application developer has designed the system.

(1) An application program that uses APPC or CPI-C to exchange data with another TP on a peer-to-peer basis. (2) A program that processes transactions in an SNA network. There are two kinds of transaction programs: application transaction programs and service transaction programs. *See also* **conversation**.

Transmission Control Protocol/Internet Protocol (TCP/IP)

The transport protocol in use by many academic, military, scientific, and commercial organizations to provide communication across wide area networks (WANs). TCP/IP provides communication across interconnected networks that include a variety of different operating systems (such as VMS, UNIX, and Windows 2000 or later).

transmission header (TH)

A header prefix to a message unit flowing within the Path Control Network (PCN), and containing PCN-specific data about routing, sequencing, blocking, and route pacing.

Twinax

A twinaxial connection to a peer system.

twisted-pair cable

Two paired wires, with each wire twisted two or more times per inch to help cancel out noise.

two-phase commit (2PC)

A protocol that ensures that transactions that apply to more than one server are completed on all the servers or none at all. Two-phase commit is coordinated by the transaction manager and supported by resource managers.

type library

A file (or component within another file) that contains Automation descriptions of exposed objects, properties, and methods. Object library (.olb) files contain type libraries. Type libraries that are shipped as stand-alone files use the file extension .tlb. A TI component is an example of a type library (.tlb file).

-U-

UDA

See **universal data access (UDA)**.

UDT

See **user-defined type (UDT)**.

unbounded

Refers to recordsets or arrays. In TI, the rows in a recordset or the elements in an array are transmitted one at a time. Therefore, the mainframe application program must issue multiple receives or sends until all data is transmitted.

This type of parameter or return value can be defined as unbounded for the **CICS Using LU 6.2** and **IMS Using LU 6.2** models only. The number of rows in a recordset or the number of elements in an array is not determined (that is, bounded) before run time. Unbounded parameters or return values can occur anywhere in the Automation method. However, a parameter or return value of this type is always transmitted to and from the mainframe after all other data. TI supports, at most, a single unbounded input parameter and a single unbounded output parameter or a single unbounded in/out parameter.

universal data access (UDA)

A Microsoft data access method which supplies access to information across the enterprise. Universal data access provides high-performance access to a variety of information sources, including relational and non-relational, and an easy to use programming interface that is tool and language independent.

user alert

A message sent by a 3270 user to a host system operator by way of NetView, requesting an action such as mounting a tape or changing forms on a printer.

user identifier

A string of characters that uniquely identifies a user to a system.

user name

The name (also known as user ID) that identifies a Windows user account.

user-defined type (UDT)

A data type that is defined in a program. User-defined data types generally contain many different data types that are defined by the programming language being used. In COBOL, UDTs are called RECORDS (that is, any declaration containing lower-level numbers).

-V-

variable-length string

A fundamental data type that holds character information. A String variable can contain approximately 65,535 bytes (64 KB), and it is either fixed-length or variable-length. Strings usually have one character per byte; however, TI supports Unicode BSTR strings that occupy 16 bits per character. Fixed-length strings are declared to be a specific length, and variable-length strings can be any length up to 64 KB, less a small amount of storage overhead.

VCB

See **verb control block (VCB)**.

verb

Command from one LU to another to exchange data and perform tasks. *See also***APPC verb**.

verb control block (VCB)

A structure made up of variables, which identifies the verb to be executed, supplies information to be used by the verb, and contains information returned by the verb when execution is complete.

VINES

See **VIrtual NEtworking System (VINES)**.

VIrtual NEtworking System (VINES)

A collection of networking software products from Banyan Systems, Inc. VINES includes an addressing system called StreetTalk.

Virtual Telecommunications Access Method (VTAM)

A set of IBM mainframe programs that control communications between mainframe applications and the terminals and computers that connect to the mainframe.

VTAM

See **Virtual Telecommunications Access Method (VTAM)**.

-W-

WAN

See **wide area network (WAN)**.

wide area network (WAN)

A high-speed communication system, consisting of hardware (computers and peripherals) and software (programs and files), that provides communications services and enables resources to be shared over a larger geographic area than that served by a LAN. *Contrast with***local area network (LAN)**.

wildcard character

Synonym for pattern-matching character.

Windows-initiated processing (WIP)

A Windows server platform can access and integrate its programs with the programs on a non-Microsoft server platform (usually a mainframe or mid-range computer such as the AS/400).

WIP

See **Windows-initiated processing (WIP)**.

-X-

X.25

The CCITT standard used for communication over a packet-switching network. X.25 uses the protocol called qualified logical link control (QLLC).

XID

See **exchange identification (XID)**.

XML

See **Extensible Markup Language (XML)**.

XML Schema Definition (XSD)

A language proposed by the W3C XML Schema Working Group for use in defining schemas. Schemas are useful for enforcing structure and constraining the types of data that can be used validly within other XML documents. Unlike DTD, which requires its own language and syntax, XSD uses XML syntax for its language. XSD closely resembles and extends the capabilities of XDR. The W3C now recommends the use of XSD as a standard for defining XML schemas.

XSD

See **XML Schema Definition (XSD)**.

XSL

See **Extensible Stylesheet Language (XSL)**.

-Y-

No terms.

-Z-

No terms.

UI Help

This section contains the user interface (UI) Help that appears when you press the F1 key or click **Help** in the Host Integration Server or Microsoft Visual Studio UI.

In This Section

Installation Help

Use the topics in this section to navigate through the setup user interface.

In This Section

Welcome Screen

Be sure to read the **Welcome** screen because it contains important information.

Setup cannot install system files or update shared files if the files are in use. Before continuing, close all open applications.

Important
Stopping existing SNA Server or Microsoft Host Integration Server services will immediately disconnect users from the Host computer and terminates all sessions.

Viewing the Welcome Screen

1. Click **Cancel** if you would like to quit Setup.

   -or-

   Click **Next** to continue setup.

Note
You can click **Cancel** at any screen to quit the Setup program. If you need to make changes to information you have entered in a previous screen, you can click **Back**.

License Agreement Screen

Read the End-User License Agreement to become familiar with the terms of the Host Integration Server license.

Note
You must accept the License Agreement to complete the server installation.

To accept the End-User License Agreement

1. Select **I accept the License Agreement**.
2. Click **Next**.

User Information Screen

Enter the Full Name and Organization information.

The Full Name is mandatory and the Organization is optional.

To enter the user information

1. Enter the **Full Name** and **Organization** information.
2. Click **Next**.

Select Features Screen

From the **Select Features** dialog box, you can select from several options.

- **Browse** allows you to select the location where Host Integration Server will be installed.
- **Disk Cost** displays the disk space requirements for installed components.
- **Reset** sets all features back to the default setting of all components getting installed.
- **Make Features Unavailable** removes features from your current installation option.

To accept features

1. Either accept all of the Host Integration Server features or make options that you do not want to install unavailable.
2. Click **Next** to continue.

Folder Installation Location

For new installations, Setup displays the current location where Host Integration Server software will be installed. The default location is **C:\Program Files\Host Integration Server**.

For upgrades, the existing folder where the Host Integration Server or a previous version of SNA Server is installed will be displayed.

Current folder location

1. To change the current folder location where Host Integration Server will be installed, click **Browse**.
2. You will be prompted to enter the new folder name. Click **OK**.

Checking Disk Cost

To view the disk cost for installed components, click **Disk Cost** on the **Select Features** dialog box.

This dialog box shows the current disk volumes with the disk size, amount of available space, the amount of space required for selected components, and the difference available.

To check disk cost

1. View the Disk Cost information.
2. Click **OK** to close the **Disk Cost** dialog box.

Resetting Installation Features

You can reset the selected features back to the original settings by clicking **Reset** on the Select Features dialog box.

To reset the install features

1. Click **Reset** to verify that you want Setup to reset all features to be installed.

All features that were marked as unavailable will now be available to Setup.

Make Features Unavailable

To make a Host Integration Server feature unavailable, click the feature icon. One of the two menu options will appear, depending on the item you are selecting. If you make all of the features under **SNA Application Support** unavailable to Setup, the basic SNA Service (SNABASE.EXE) will still be installed. If you make the parent item, SNA Service unavailable, all services under SNA Service will be unavailable to Setup.

The choices for Setup include:

- Will be installed on local hard disk
- Entire feature will be installed on local hard disk

- Entire feature will be unavailable

Note
You will see a red "X" when a feature is marked unavailable.

To make a feature unavailable

1. Click the Host Integration Server feature that you want to make unavailable.
2. Select the **Install** option.

Services Account Screen

Setup installs a number of services that must be able to log on to the Windows 2000 domain. This requires Setup to create a domain user account and to assign the account the privileges that the services require to operate properly.

You must provide a domain and user name (domain/user) along with the password for the account. If the account does not exist, Setup will create it.

Services Account Configuration screen

1. Type the domain and user name (domain/user).
2. Type and confirm the password.
3. Click **Next**.

Begin Installation Screen

All required information for the installation process to start has been entered.

Setup will copy all required files and make all configurations to your system.

Note
If you need to make any changes to information you have entered, click Back and make the appropriate changes.

To start the installation and configuration process

1. Click **Next** to start the Setup process.
2. Setup will now copy all required files to your hard disk.

Finish Installation Screen

To finish the installation and configuration process

1. If you installed components that require SNA support, the Configuration Wizard will start when you click **Finish**.
2. After Setup is completed, click **Finish** to complete the installation process.

Configuration Wizard Help

Use these topics to navigate through the Configuration Wizard.

This section contains:

Common Settings Page

Enable the Common Settings for this HIS Group

Select to configure the settings in the **Security Group** field.

Security Group

Click **Edit** to edit the **HIS Runtime Users** and **HIS Administrators** groups.

Enable Support for 3270, APPC and LUA Applications

Select to configure the settings in the **Resource Location** field.

(Only displayed when the SNA Gateway is not installed.)

Resource Location

Select **Sponsor Server Support** and enter the **Sponsor Server** name, or select **Active Directory Support** and enter the **Organizational** name.

(Only displayed when the SNA Gateway is not installed.)

Advanced

Click to configure advanced settings.

(Only displayed when the SNA Gateway is not installed.)

Windows Service

View or change the current Windows Service accounts.

(Only displayed when the SNA Gateway is not installed.)

Advanced Client Page

Configure the following settings as desired:

- Terminate Sponsor
- Timeout
- Update Random Sponsor list Dynamically
- Select Random Sponsors
- Accept Backup Sponsors
- Run resource location component as an application
- Allow per user settings
- Use the Credentials of
- Logged on User
- This account

Advanced Client Configuration Page

Configure the following settings as desired:

- Terminate Sponsor
- Timeout
- Update Random Sponsor list Dynamically
- Select Random Sponsors
- Accept Backup Sponsors
- Run resource location component as an application
- Allow per user settings
- Use the Credentials of
- Logged on User
- This account

Network Integration Page

Use this page to configure Network Integration.

Enable the Network Integration for this HIS Group

You must select this to make any changes on this page.

Subdomain

If you select the role of **Primary Configuration Server**, enter the **Subdomain Name**.

If you select the role of **Secondary Configuration Server**, enter the **Primary Server Name** and also the **Subdomain Name**.

Services

Select the services you want to have configured.

Advanced

Click to configure Client Protocol Support and Active Directory Support.

Windows Service

View or change the current Windows Service accounts.

Network Integration Advanced Page

Client Protocol Support

Select **TCP/IP**, **Microsoft Networking (Named Pipes)**, or both.

Active Directory Support

Select **Support Active Directory Clients** to make changes in this field. Then enter a valid **Active Directory Name** and **Organizational Unit**.

Data Integration Page

Select **Enable Data Integration Feature** to make configuration changes on this page.

Enable DB2 Distributed Transactions

Select to configure DB2 Distributed Transactions properties, or accept the defaults.

Enable Host Files component (DDM) as a service

Select as desired.

Windows Service

View or change the current Windows Service accounts.

Transaction Integrator Page

Enable Host Initiated Processing

Select this option to make changes on this page.

Then specify a **Server Name** and **Database Name** for the **Database Store**.

Session Integrator Page

Select **Enable Session Integrator Feature**, and then view or change the current **Windows Service** accounts as desired.

MSMQ-MQSeries Bridge Page

Use this page to configure the MSMQ-MQSeries Bridge.

Start Page

Choose either **Basic** or **Custom** configuration.

Basic Configuration

Recommended for first-time users. This configures your system with default settings.

In the **Service Credential** field, enter a **Username** and **Password**.

In the **Network Integration** field, select either **Primary** or **Secondary Configuration Server**.

In the **Database** field, enter the **Database Server Name**.

In the **Data Integration** field, enter the **Partner DB2 Resource Managers** (optional).

Click **Configure** to begin the configuration process.

Custom Configuration

Recommended only for advanced users. This allows you to enable and disable features, and to customize the values for each database and service account.

In the **Service Credential** field, enter a **Username** and **Password**.

In the **Network Integration** field, select either **Primary** or **Secondary Configuration Server**.

In the **Database** field, enter the **Database Server Name**.

In the **Data Integration** field, enter the **Partner DB2 Resource Managers** (optional).

Click **Configure** to begin the configuration process.

Overview Page

The **Overview** page displays the features you have selected to configure, and the status of each.

Click a feature on the left side of the pane to begin configuration.

Service Accounts Page

Use this page to edit the selected service account.

User Name

Type the user name for this service account.

Password

Type the password for this account.

Database Accounts Page

Use this page to edit the server name and database name for the selected feature.

Database server name

Type the name of the database server that will host this feature.

Database name

Type the name of the database for this feature.

Service Accounts View

Use this page to view a list of features and the accounts used to run the services used in your configuration.

Edit

Edit the service account name of the selected features.

You can select multiple features to edit by pressing CTRL and clicking the mouse.

Database View Page

Use the **Consolidated Databases View** page to view a list of features, servers, databases, and data stores used in your configuration.

Edit

Edit the database server name and database name of the selected features.

You can select multiple features to edit by pressing CTRL and clicking the mouse.

Summary Page

Before beginning the configuration process, you can review the selections you have made. Click **Back** to make any changes.

Progress Page

Displays the progress of your configuration.

Finish Page

Review your errors or log file if necessary, and then click **Finish**.

Unconfigure Page

Select the features you want to unconfigure on this computer, and then click **OK**.

SNA Manager Help

Use these topics to navigate through the SNA Manager user interface.

In This Section

Active TN5250 Sessions

AS/400 Definition Properties

APPC Modes Folder

CPI-C Symbolic Names Folder

Link Service Adapter

Link service allows Host Integration Server to communicate with host, peer, or downstream computers over token ring and Ethernet Local Area Networks.

Configure a DLC 802.2 Link Service

A DLC 802.2 link service allows Host Integration Server to communicate with host, peer, or downstream computers over token ring and Ethernet Local Area Networks.

Title

The default title is DLC 802.2 Link Service #1. To change the default title, delete the title and enter a new title for this link service. You can use up to 40 characters for the title.

Adapter

Select the adapter card you are using for this service.

Local Service Access Point (SAP)

Enter the local SAP. This number must be a multiple of 4, ranging from 4 through 252. In most cases, the SAP for Host Integration Server is 4.

Select **Use Fixed SAP** to use a fixed SAP address.

Select **Allow Link Service to be Distributed** to allow this service to be distributed.

Demo SDLC Link Service

Configure a demonstration SDLC link service. This service uses a script file to simulate an SDLC link service.

Title
The default title is Demo SDLC Link Service #1. To change the default title, delete the title and enter a new title for this link service. You can use up to 40 characters for the title.

Script File
Select a demonstration script file from the drop-down list.

Select Allow Link Service to be Distributed to allow this service to be distributed.

Distributed Link Service Properties

Service Title

The default title is Distributed Link Service #1. To change the default title, delete the title and enter a new title for this link service. You can use up to 40 characters for the title.

Link Type

Select the type of link service represented by this Distributed Link Service from the drop-down list.

Primary Remote Link Services

Enter the name of the remote link service used by this service.

Alternate Remote Link Services

Enter the name of an alternate remote link service used by this service.

Select **Compression used** if data compression is to be used on this link service.

APPC Mode Properties

The following tabs are available on the APPC Mode Properties Sheet:

APPC Mode Properties: General

Mode Name

Enter a Mode Name.

Comment

Optionally, type a comment of not more than 25 characters.

APPC Mode Properties: Limits

Parallel Session Limit

Specify the maximum number of sessions allowed with this mode. To allow only a single session, specify 1. To allow parallel sessions, specify a value greater than 1. If the local APPC LU to be used with this mode is dependent, specify 1; dependent local APPC LUs cannot have parallel sessions. One of the key mode properties is the **Parallel Session Limit**. This limit determines whether an LU-LU pair can carry on only one interaction at a time (a parallel session limit of 1), or multiple concurrent interactions (a parallel session limit greater than 1). If parallel sessions are to be allowed with an LU-LU pair, the local LU must be independent, and the remote LU in the pair must support parallel sessions.

If the LU-LU pair can carry on multiple parallel sessions, other mode properties, such as minimum contention winner limit, determine to what extent each LU can initiate interactions.

Minimum Contention Winner Limit

Specify the Minimum Contention Winner Limit. The sum of the Minimum Contention Winner Limit and the Partner Min Contention Winner Limit must be less than or equal to the Parallel Session Limit.

Partner Min Contention Winner Limit

Specify the Partner Min Contention Winner Limit. The sum of the Partner Min Contention Winner Limit and the Minimum Contention Winner Limit must be less than or equal to the Parallel Session Limit.

Automatic Activation Limit

Specify the number of contention winner sessions to be activated for the local LU whenever the connection for this mode is started. In a local contention winner session, the local LU can initiate conversations without permission from the partner LU.

This does not apply for single-system APPC (communication between two local LUs on the same system).

APPC Mode Properties: Characteristics

Pacing Send Count

Specify the maximum number of frames for the local LU to send without an SNA pacing response from the partner LU. If you specify 0, the local LU can send an unlimited number of frames without receiving a response; in this case, the partner LU can negotiate and set a limit on the count.

Pacing Receive Count

Specify the maximum number of frames for the local LU to receive from the partner LU before the local LU sends an SNA pacing response. If you specify 0, the local LU can receive an unlimited number of frames without sending a response.

Max Send RU Size

Specify the maximum size for RUs sent by the TP(s) on the local system.

It is not necessary to set a minimum send RU size, which is 256 on Host Integration Server.

Max Receive RU Size

Specify the maximum size for RUs received from the TP(s) on the remote system.

It is not necessary to set a minimum receive RU size, which is 256 on Host Integration Server.

High-Priority Mode

Select to give preference to communication with this mode over communication with a low-priority mode.

APPC Mode Properties: Partners

This tab allows you to **Add** or **Remove** APPC LU partnerships from the Host Integration Server configuration file. The mode name appears in the title. The list box shows the **Server**, **Local LU Alias**, **Remote LU Alias**, **Connection**, and which LUs are partnered with the APPC mode in the title.

Remove

Click **Remove** to delete APPC LU partnerships from the Host Integration Server configuration file.

Add

1. Click **Add** to add APPC LU partnerships from the Host Integration Server configuration file. The **Add Partnerships** dialog box appears.
2. Select a **Server name** from the subdomain by clicking the DOWN arrow in the drop down list.
3. After the server is selected, a list box showing **Local LU**s and a list box showing **Partner LU** and **Connection** are filled. Make selections from each list to establish partnerships.
4. Click **Apply** to add pairs to the **APPC Mode Properties: Partners** page while keeping the **Add Partnerships** dialog active.
5. When you finish selecting partnerships, click **OK** on the **Add Partnerships** dialog to return to the **APPC Mode Properties: Partners** page.
6. Click **OK** on the **APPC Mode Properties: Partners** page to commit the changes to the Host Integration Server configuration file.

Note
You can select multiple modes for partnerships using the same LUs. Press the SHIFT key and the CTRL key and click to select non-contiguous modes.

Note
The Host Integration Server configuration file is updated dynamically. There is no need to stop and restart SNA service.

APPC Mode Properties: Compression

Maximum Send Compression

Select the maximum compression desired from the drop down list. The valid values are: **None**, **Run Length Encoding (RLE)**, and **LZ9**. These options offer progressively better compression, but at a progressively higher CPU usage.

Maximum Receive Compression

Select the maximum compression desired from the drop down list. The valid values are: **None**, **Run Length Encoding (RLE)**, and **LZ9**. As with Maximum Send Compression, these options offer progressively better compression, but at a progressively higher CPU usage cost.

Allow LZ and RLE Compression

If LZ9 is used, this option controls whether data is compressed using RLE before being further compressed using LZ9.

Endpoint Only Compression

This option controls whether intermediate nodes may use compression if one of the endpoints does not support or otherwise does not use compression.

3270 LU Properties: General

LU Number
Enter the LU Number for LUs on 802.2, SDLC, or X.25.

Enter an appropriate LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed from this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Use Compression

Select this option to enable 3270 LU data stream compression. This option must also be set in the host VTAM configuration for the LU.

User Workstation Secured

Select this option to enable a higher level of security. When the option is selected the user can only acquire an LU if:

- the user's User Record is assigned to this LU, and
- the user's workstation has been defined with a Workstation Definition.

3270 Display LU Properties: Associated Printer LU
Display LU

Shows the display LU name if you have already created a display LU; otherwise, this will be filled in when you complete the configuration of this display LU.

Associated Printer LU

Click the DOWN arrow to display the list of available printer LUs on this connection. Choose a printer LU to associate with this display LU. If you have not created any printer LUs on this connection, you must do so before they will appear in the list.

3270 LU Properties: LUA

The following tabs are available on the 3270 LUA Properties Sheet:

3270 LU Properties: LUA General Tab

LU Number

Enter the LU Number for LUs on 802.2, SDLC, or X.25.

Enter an appropriate LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed from this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Use Compression

Select this option to enable 3270 LU data stream compression. This option must also be set in the host VTAM configuration for the LU.

User Workstation Secured

Select this option to enable a higher level of security. When the option is selected the user can only acquire an LU if:

the user's User Record is assigned to this LU, and

the user's workstation has been defined with a Workstation Definition.

High Priority Mode

Select this option to increase the priority for this LU.

Note
Two additional property pages appear when the LU is assigned to a TN3270. These are the TN3270 property page and the IP Address List page.

3270 LU Properties: TN3270 Tab

Type

Select from the list the display or printer type.

Generic Display

This is the default pool type. The display LU or pool will be assigned to a client computer that either does not specify a particular LU or Pool, or that requests this LU or Pool by name.

Specific Display

The LU or pool configured as specific will only be assigned to client systems that request this LU or pool, and not to clients making generic requests.

Generic Printer

The printer LU or pool will be assigned to a client computer that either does not specify a particular LU or pool, or that requests this LU or pool by name. When this option is checked, the **terminal name** will default to IBM-3287-1.

Specific Printer

The printer LU or pool configured as specific will only be assigned to client computers that request this LU or pool, and not to client computers making generic requests. When this option is checked, the **terminal name** will default to IBM-3287-1.

Associated Printer

Printer LUs can be marked as associated instead of generic or specific. To associate a printer LU with a terminal LU, select this option and choose the **Associated LU** from the drop-down list box. When this option is checked, the **terminal name** will default to IBM-3287-1.

Sessions

This is the number of TN3270 sessions allowed for the selected LU or pool. The number of TN3270 sessions must not exceed the number of LUs listed under Host Integration Server Resource Information.

If you reduce the TN3270 Sessions limit to 0 (zero) TN3270 service will not assign the LU or pool.

Associated Printer

When the **Type** option **Associated Printer** is selected, choose an **Associated Printer** from the drop-down list. In this case, the printer LU is partnered with one terminal LU. A client computer accesses that printer LU by sending in an "associate" request and giving the name of the terminal LU with which the printer LU is partnered.

Terminal types

TN3270 service will default to IBM Terminal Model 2. To add a different terminal model to this LU, click the corresponding number (**2**, **3**, **4**, or **5**) to the left of the list of terminal names. After a Terminal Model is selected, Terminal Names are automatically assigned. You can remove selection of individual terminal names that do not apply to your network configuration by clearing the checkbox opposite the name, or you can clear all terminal names by clicking **Clear**.

Note
The terminal name strings selected must be compatible with the host logmode entry for the LU. For printer LUs, the **Terminal Name** will default to IBM-3287-1.

Port

Select **Default port** to use the port number configured with the service (on the Service Properties page), or select a port from the list. The list displays all of the defined TN3270 ports along with their Security setting (High, Medium, Low, None, or Unsecured).

Note
TN services listen on multiple ports simultaneously. You can set a default number for the TN service and override this number on a per session basis, allowing a single client computer to connect to multiple host computers.

Note
TN3270 client systems can only access LUs that are configured as generic terminal LUs. TN3270 client systems can access generic, specific, and associated LUs.

Note
Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. Users who were connected at the time the configuration changes were made will not be affected.

3270 LU Properties: IP Address List

You can associate this LUA to a specific IP address or server name.

Add Address

Click to specify the **IP Address** and **Subnet Mask** of the client workstation to which you are granting access.

IP Address

Click an entry in the **IP Address** column to edit the IP address for a client workstation.

Subnet Mask

Click an entry in the **Subnet Mask** column to edit the subnet mask for a client workstation.

Add Name

Click to add a workstation name to the **IP Address** list box. The workstation name identifies that a client workstation whose

Click to add a workstation name to the **IP Address** list box. The workstation name identifies that a client workstation whose address resolves to that name can connect to the service.

Remove

Click to remove an entry that is currently highlighted in the **IP Address** list box.

Clear All

Click to remove all entries in the **IP Address** list box. The service will then be configured to allow access from any client workstation.

Note
The IP address must be changed from the default value of 0.0.0.0 if you want to assign a specific IP address. If you try to add t he default IP address with the default subnet mask value, you will receive a message indicating an Invalid IP Address/Subnet Mask.

Note
The IP address of an incoming connection is compared to each of the available LUs or pools in turn. Each resource has an ass ociated list of IP address patterns and subnet masks. The IP address from the incoming connection is masked (by bit and by t he resource's subnet mask), then compared to the resource's IP address pattern masked by the resource's subnet mask. If th e result is equal, the connection is allocated to this resource.

3270 LU Properties: Down Stream

Enter the LU Number for LUs on 802.2, SDLC, or X.25.

Enter an appropriate LU Number.

LU Name

Type the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed from this dialog box.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Pool Properties: General

Pool Name

Enter a name for this pool.

Comment

Optionally, enter a comment of not more than 25 characters.

Pool contains Display LUs with Associated Printers

This option is intended for users whose host applications have a direct relationship between display LUs and printer LUs (i.e., this applies to display-type pools only). With this option selected, all display LUs in the pool will be treated as though they have associated printer LUs. Also configure the display and printer LUs with the LU numbers that the host application is expecting.

Pool Properties: Display Model

Display Model

If you select **Display** for the LU Type, you can select a Display Model.

When an LU is assigned to a pool, the display model setting for the pool overwrites the setting of the LU, and the setting displayed in the **3270 LU Properties** dialog box is dimmed.

Some emulators can only emulate certain display models. For more information, see your emulator documentation. If there is a conflict between the Display Model setting for the pool and the Display Model setting for an LU in the pool, a message box appears. You can configure the individual LU setting to change or exclude the LU from the pool.

Model can be overridden

Select this check box to allow the user to override the display model type by using a 3270 terminal emulation program.

User Properties

User Name

Provided for information only. This field cannot be changed here.

Domain

Provided for information only. This field cannot be changed here.

Comment

Optionally, type a comment of up to 25 characters.

Use Client/Server Encryption

Check this box to enable encryption between the client system and Host Integration Server.

Allow Access To Dynamically Created Remote APPC LUs

Check this box to let this user or group use dynamically created APPC LUs.

APPC Defaults

Local APPC LU

If this user will be using APPC programs (TPs, 5250 emulators, or APPC applications), you can choose a default local APPC LU to be used when the user starts such programs.

Avoid assigning a default local APPC LU to the group "Everyone". Instead, to make a local APPC LU available to any user, when configuring the local LU, select the check box labeled **Member of Default Outgoing Local APPC LU Pool** on the **Advanced** tab of **Local LU Properties**.

Remote APPC LU

If this user will be using APPC programs (TPs, 5250 emulators, or APPC applications), you can choose a default remote APPC LU to be used when the user starts such programs.

To accept the settings, click **OK**; to exit the dialog box without accepting the settings, click **Cancel**.

When you assign default APPC LUs to user and group accounts with overlapping memberships, some of these assignments override others.

TN3270 Properties: General

Name

Displays the name of the server running the TN3270 service. This field cannot be edited here.

Comment

Optionally, type a comment of up to 25 characters.

Use Name Resolution

Name Resolution should only be selected if you are running a domain name resolver. A domain name resolver catalogs IP addresses and corresponding network names of connected computers. The domain name resolver allows you to enter the name of a computer rather than the IP address when an IP address is required.

TN3270 Mode only

The TN3270 service also supports TN3270E, an enhancement to TN3270. When a client computer first connects to a computer running TN3270 service it negotiates which functions they both support. TN3270 emulators should be able to negotiate with TN3270 service, if only to state that they do not support TN3270. However, some TN3270 emulators are unable to negotiate properly with TN3270 service, causing the negotiation to fail. For this reason the TN3270 service has an option to default to TN3270 mode and not to use TN3270 features, so that these TN3270 negotiation problems do not occur.

Printer Flow Control

If a TN3270 service adheres strictly to the specification described in RFC 1647, there is no way of implementing flow control between a computer running TN3270 service and a TN3270 client. In practice this causes no problems for display emulators, but it does cause a problem for printer emulators, which can be overloaded with data and have no way of notifying the TN3270 service that they cannot process any more messages. If this option is turned on, the TN3270 service sends all messages to a TN3270 printer client as RESPONSE-REQUIRED, and does not send any messages until it has received a response for the previous message.

Close Listen Socket

By default the TN3270 service always has a socket open to listen for incoming requests. If this option is turned on, the TN3270 service stops listening on this socket after all of its defined LUs are in use. The purpose of this is to work with emulators that can try to connect to a number of computers running TN3270 service and that connect to whichever computer accepts their connection attempt. In this case it is useful if a computer with no LUs available is not listening.

Log Normal Audit Events

If this is set, audit messages are logged. These are messages that log successful client connection and successful client termination.

Use SNA Event Log

If this is selected, all TN3270 service event messages are written to the event log being used by the Host Integration Server system. If this is not set, all TN3270 service event messages are written to the Windows event log on the local machine.

TN3270 Properties: Port/Security

This property page contains two groups.

The **Defined ports** group displays information pertaining to the currently configured 3270 Server ports.

The **Configure ports** group consists of controls for adding, editing, and deleting port configurations.

Defined ports

Port

Lists all ports and corresponding Security settings. On a new installation, setup automatically defines Port 23 as the Default Port.

Security

Displays the level of encryption/authentication assigned to that port. Values are High (168), Medium (128), Low (40), and Unsecured (TLS/SSL not enabled). Default is **Unsecured**.

Client certificate

Displays status: Required or Not required. Default is **Not Required**.

Comment

Displays a comment.

Port configuration

Port

Enter a valid port number from 1-65535.

Security

Choose a setting from the list: High (168), Medium (128), Low (40), or Unsecured. Default is **Unsecured**.

Comment

This is optional. Maximum length allowed is 25 characters.

Verify client certificate

If selected, the client will have to provide a valid certificate to make the connection. Default is not selected. If Security level is set to Unsecured, this option is unavailable.

The client requires a valid Certificate with the following properties:

- Type X509
- Client Authentication
- Associated private key

These certificate settings may match some of those you would not choose to grant access to. It is therefore recommended that you check the list of default Trusted Root Certification Authorities in the TN3270 Service Store, and remove any you do not want to be there.

TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client computer to connect to multiple host computers.

You can also add the TN3270 port by using the SnaCfg tool, with the command and parameters shown below:

```
TN3PORT tn3270Server:PortNumber /ADD
   /COMMENT:"comment"
   /SECURITY:{ None | Low | Medium | High }
   /CLIENTSertVALAUTH:{ Yes | No }
```

The properties of the command are described in the following table:

Property or Method	Description	Validation
/COMMENT:Text	The comment field	0 – 25 characters
/SECURITY:Type	Security level	None, Low, Medium or High
/CLIENTCertVAL:YesNo	Indicates whether the client certificate verification is enabled	No – disabled Yes - enabled

Default Port

On a new installation, setup automatically defines Port 23 as Default Port. There can only be one default port at a time. After a port has been designated Default Port, it cannot be deleted until another Default Port has been selected. The default is **Not Selected**.

Adding Ports and Security

This property page allows increased security through support for Secure Sockets Layer (SSL) and TLS for all network transport-level services.

Although the Microsoft 3270 Client (emulator) does not support SSL or TLS, many third-party software vendors offer 3270 emulators that support this functionality, including Attachmate, IBM, NetManage, and WRQ.

To add a new port

1. On the **TN3270 Properties: Port/Security** page, click **New**.
2. Enter the port number and select a security level (default is Unsecured). You can also add a comment and make this the default TN3270 Server port.
3. For maximum security, check the Client Certificate checkbox.

To edit the properties of an existing port

1. On the **TN3270 Properties: Port/Security** page, highlight the port.
2. Click Edit.
3. When you are finished, click **Save**.

TN3270 Properties: Settings

Idle Timeout

Specify time limits. If the session is inactive for this length of time, then TN3270 service disconnects the client system.

Init Status Delay

Specify time limits. This is the delay between the time when TN3270 service connects to a host session and the time the TN3270 service starts updating the client screen. There are often a large number of startup messages when the TN3270 service first connects to a host session, and this option gives the user the opportunity not to receive them all.

Message Close Delay

Specify time limits. When TN3270 service forces a client computer to disconnect (for example, when the Host Integration Server session to the host has been lost), it sends the client computer an error message to be displayed on the screen. This value specifies the time between sending the message to the client computer and closing the socket with the client computer (which causes some client computers to clear the screen, and so erase the message).

Refresh Cycle Time

Specify time limits. This is the delay between updates of the status on the display.

Default RU Sizes - Inbound and Outbound

This controls the RU size (SNA message size) used by the TN3270 service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

Certificate CN

The common name of the certificate used if TLS/SSL is enabled.

Connection Properties: SDLC

The following tabs are available on the SDLC Connection Properties sheet:

Connection Properties: General

Name

Enter a Name.

Link Service

Select a link service from the drop down list. If the link service you want is not in the list, click **Cancel**.

Comment

Optionally, enter a comment of not more than 25 characters.

Remote End

Select the type of remote system for this connection:

- Host System
- Peer System
- Downstream
- PU Passthrough

If this connection will be used for 3270 or LUA LUs, then select Host System.

If you will be using dependent APPC, which relies on a host system for communications, then select Host System, not Peer System.

Allowed Directions

Select the allowed call direction(s), **Outgoing Calls** and/or **Incoming Calls**.

Selecting **Outgoing Calls** causes Host Integration Server to initiate the link-level connection to the remote system or host. If a remote system tries to initiate a connection, Host Integration Server will not accept the connection attempt.

Selecting **Incoming Calls** causes Host Integration Server to accept connection attempts from remote systems or hosts.

If both are selected, Host Integration Server will both initiate a connection and accept connection attempts by other systems.

When multiple SDLC connections all use the same link service, and the connections accept incoming calls, the encoding (**NRZ/NRZI**) settings for all the connections must match.

Activation

If **Outgoing Calls** are included in Allowed Directions, select an Activation setting:

On Server Startup. Select this option if you want the connection to be readily available whenever the server is started.

On Demand. Select this option if you want the connection to be started when needed, and stopped when not in use.

By Administrator. Select this option if you want the administrator to control the connection on a case-by-case basis.

Passthrough via Connection

Displays a list of available (unpaired) PU Passthrough Connections. Connections that have already been paired are not available. Choose a connection that will route you to your destination PU. If PU Passthrough is not selected in the Remote End field, this list is unavailable.

Supports Dynamic Remote APPC LU Definition

Automatically configures the APPC Remote LUs as users request them. This feature requires that an APPN End Node or Net Node be available on the connection. This feature is for convenience, and should not be used in situations of restricted access. If Host System or Peer System is not selected in the Remote End field, this option is unavailable.

With dynamic APPC configuration, if a user requests a session with a valid remote LU, the connection will be established even if the remote LU has not been configured in SNA Manager. If a connection is designated to support dynamic APPC configuration, Host Integration Server will automatically define a remote LU and partner it with a local LU when needed. However, to take advantage of session status and other features of Host Integration Server, it is recommended that administrators configure commonly used remote LUs.

Connection Properties: Address

Dial Data

If this connection uses a switched line and the phone number is not stored in the modem, enter the dial data. With a leased SDLC line, this field is unavailable.

For ways to supply a phone number to the modem, see Phone Number Storage and Modem Types below.

Poll Address

Type a two-digit hexadecimal number. Contact the administrator of the remote system to determine the appropriate value. If the remote system is a host, the local poll address should match the VTAM PU definition for the ADDR= parameter.

If the remote system is a peer, the poll address can be any value except the reserved values 00 and FF. When the connection is used, the link roles will be negotiable; the system that takes on the primary role uses the poll address of the other system, so that the poll addresses match during the session.

Note
Do not use 00 or FF. These values are reserved.

Encoding

Select the encoding scheme for your modem to use.

Your modem must use the same encoding scheme as the modem at the remote computer.

One of two encoding methods for modems:

- NRZ — Non-return to zero
- NRZI — Non-return to zero inverted

For connections to host systems, the encoding scheme must match the NRZI setting in the LINE/GROUP definition in VTAM. Obtain this setting from the host administrator. If VTAM does not specify an NRZI setting, it defaults to NRZI=YES.

When multiple SDLC connections all use the same link service, and the connections accept incoming calls, the encoding (**NRZ/NRZI**) settings for all the connections must match.

Phone Number Storage and Modem Types

Host Integration Server can store a phone number and then send the number (in ASCII) to a modem, which dials the number. This requires that the modem be attached to an SDLC adapter with a built-in serial (COM) port (for example, the SDLC adapters from MicroGate).

Several connection parameters must be set to work with your modem: Dial Data the duplex setting, half-duplex or full-duplex, and the encoding scheme.

Changing the Host Integration Server Dialing Method

To change the Host Integration Server dialing method for a modem, use the Host Integration Server Link Service Setup program to modify the link service. Restart SNA Manager and, from the **File** menu, choose **Save Configuration**.

Modem Requirements for Accepting a Phone Number from Host Integration Server

To accept a phone number from Host Integration Server, your modem must be set up so that it will do the following:

- Accept dial commands in ASCII (eight data bits, no parity bit, one stop bit).
- Not dial when the DTR signal is raised.
- Set Clear to Send (CTS) and Data Set Ready (DSR) to **On** when ready to accept dial commands.

- Set DSR to **Off** after accepting a dial command.
- Set DSR to **On** again when (and only when) the dialed connection is made.
- Change to **Synchronous** mode after the dial-up has completed.
- Change back to **Dial-command** mode if Data Terminal Ready (DTR) is dropped and raised again.

Host Integration Server Actions When Sending a Phone Number

When Host Integration Server is sending a phone number to a modem, it ignores modem responses and holds the modem interface signals Select Standby and DTR to **Off**.

The dialing attempt initiated by Host Integration Server is assumed to have failed if one of the following occurs:

- DSR stays on after the dial string has been sent.
- The connection time-out expires before DSR comes on to indicate that the call is connected.

When Host Integration Server creates a dial string to send to a modem, it uses the outgoing command string supplied in Setup as a base, and then appends the Dial Data (phone number) configured in SNA Manager, followed by a carriage-return line-feed sequence.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: System ID

Local Node Name

Network Name

If you are instructed by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Network Name of the remote system. Format 3 is the default XID type.

The Network Name works with the Control Point Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Control Point Name

If you are instructed to by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Control Point Name of the remote system. Format 3 is the default XID type.

The Control Point Name works with the Network Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Local Node ID

If this connection uses a switched SDLC line (standard telephone line) to connect to a host system, type the Local Node ID. Use the same Local Node ID for all connections and link services on a particular server.

If this connection uses a leased SDLC line, you can use the default for the Local Node ID.

Note
Do not use 000 or FFF for the first three digits; these values are reserved.

XID Type

Select the XID Type. Most systems use Format 3.

If you want to use independent APPC LUs on this connection, you must select Format 3.

When Host Integration Server is configured to use Format 0 over a host connection, the host treats it as a PU type 2.0, and so Host Integration Server exercises only its PU type 2.0 capabilities. When Host Integration Server establishes a host or peer connection using Format 3 and independent LUs, Host Integration Server exercises its PU type 2.1 capabilities.

For configuration changes to take effect, restart the server.

Remote Node Name

Network Name (Remote Node)

If you are instructed by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Network Name of the remote system. Format 3 is the default XID type.

The Network Name works with the Control Point Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Control Point Name (Remote Node)

If you are instructed to by the administrator of a remote host, peer, or downstream system, and if you are using Format 3 XIDs, type the Control Point Name of the remote system. Format 3 is the default XID type.

The Control Point Name works with the Network Name to identify a system. If either of these parameters is supplied, the other should also be supplied.

Remote Node ID

If instructed to by the administrator of a remote host, peer, or downstream system, type the Remote Node ID.

Note
Do not use 000 or FFF for the first three digits; these values are reserved.

Peer DLC Role

Select the DLC role for this connection. The options are:

- Primary
- Secondary
- Negotiable

Connection Properties: SDLC

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

Maximum Basic Transmission Unit length. The maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Data Rate

Select the Data Rate.

The data rate for transmissions between the Host Integration Server communications adapter and the modem:

- **Low** gives more reliable transmissions and prevents the transmission errors sometimes caused by poor-quality lines at the high rate. If a fall-back line speed setting is supported by your modem and communications adapter, and you want to enable it, select **Low**.
- **High** gives faster transmissions. If you select **High**, the CCITT line 111 on the V24 interface of your modem is set to on.

Check your adapter and modem manuals to find out if the data rate can or must be set for your equipment.

Duplex

Select the setting that matches your modem:

- For a half-duplex modem, select **Half**. If none of your adapters were installed with the Constant RTS option set, you can only choose half-duplex.

- For a full-duplex modem, select **Full**. If you want to use the full-duplex setting, one or more of your adapters must have the Constant RTS option set (at installation).

Most servers will use the default, **Half**.

Idle Timeout (for host or peer connections)

Specify the length of time, in tenths of a second, for the local system to wait for a response to a transmission before trying again. Too small of a timeout can cause connection problems. This parameter affects sessions in which the server has a link role of secondary; therefore, it affects all sessions with a host system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is **300** (30 seconds).

Idle Retry Limit (for host or peer connections)

Specify the number of times for the local system to try to send data to the remote system if there is no response. This parameter affects sessions in which the server has a link role of secondary; therefore, it affects all sessions with a host system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 through 255; the default is **10**.

Poll Rate

If the remote system is a peer or downstream system, specify the **Poll Rate** (in polls per second).

The range is from 1 through 50 polls per second; the default is **5**.

Poll Timeout (for peer or downstream connections)

Specify the length of time, in tenths of a second, for the local system to wait for a response to a poll before trying again. Too small of a timeout can cause connection problems. This parameter affects sessions in which the server has a link role of primary; therefore, it affects all sessions with a downstream system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 (one-tenth of a second) through 300 (30 seconds). The default is **10** (1 second).

Poll Retry Limit (for peer or downstream connections)

Specify the number of times for the local system to poll the remote system if there is no response. This parameter affects sessions in which the server has a link role of primary, therefore, it affects all sessions with a downstream system and some sessions with a peer system (where the link role is negotiable).

The range is from 1 through 255; the default is **10**.

Select Standby

If you want your modem's Standby line to be set to on, select this check box.

Check your adapter and modem manuals to find out if standby can be set for your equipment.

Multidrop Primary

If this is a leased SDLC line to downstream systems, and this server will be the primary station for a multidrop connection, then select this box.

This is a connection through which one primary computer simultaneously communicates with multiple secondary computers. Host Integration Server supports multidrop connections to peer or downstream systems on leased SDLC lines.

Contact Timeout

Specify the length of time, in tenths of a second, which the SDLC link service waits for an XID or SNRM response before resending the XID or SNRM.

This parameter is ignored for incoming calls.

The range is from 5 (five-tenths of a second) through 300 (30 seconds).

The default for a host connection is 300 (30 seconds). The default for a peer or downstream connection is 10 (1 second).

Contact Retry Limit

Specify the maximum number of times the link service will resend an XID or SNRM before declaring an outage to Host Integration Server.

This parameter is ignored for incoming calls.

The range is from 1 through 20; the default is **10**.

Connection Dialing Timeout

If this connection uses a switched SDLC line (standard telephone line), specify the number of seconds that will be allowed for the user or modem to dial and make a connection to the remote computer. If the dialing will be done manually, be sure to allow enough time for the user to dial, wait for an answer, and make the connection.

The range is from 10 through 500 seconds; the default is **300**.

This parameter is ignored by incoming calls.

To exit the dialog box without accepting the configuration settings, click **Cancel**. To accept the settings, click **OK**.

To put configuration changes into effect, restart the server.

Connection Retry Limits

Supply activation limits for the connection.

Maximum Retries

Select the number of attempts for Host Integration Server to make when trying to establish the connection. After making this number of attempts, Host Integration Server makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

Connection Properties: DLC 802.2

The following tabs are available on the DLC 802.2 Connection Properties sheet:

General Tab

The following information must be entered on the **General** tab for the 802.2 connection:

- Connection Name
- Link Service
- Comment (optional)
- Remote End
    - Host System
    - Peer System
    - Downstream
    - PU Passthrough
- Allowed Directions
    - Outgoing Calls
    - Incoming Calls
    - Both Directions
- Activation
    - On Server Startup
    - On Demand
    - By Administrator
- Passthrough via Connection
- Supports Dynamic Remote APPC LU Definition

Address Tab

The following information must be entered on the **Address** tab for the 802.2 connection:

- Remote Network Address
- Remote SAP Address
- Local SAP Address

System Identification Tab

The following information must be entered on the **System** tab for the 802.2 connection:

- Local Node Name
    - Network Name
    - Control Point Name
    - Local Node ID
- XID Type
- Remote Node Name
    - Network Name
    - Control Point Name
    - Remote Node ID
- Peer DLC Role
- Compression Type

DLC 802.2 Tab

The following information must be entered on the **DLC 802.2** tab for the 802.2 connection:

- Max BTU Length
- Receive ACK Threshold (frames)
- Unacknowledged Send Limit (frames)
- Retry Limit
- XID Retries
- 802.2 Timeouts
    - Response (t1)
    - Receive Ack (t2)
    - Inactivity (ti)
- Connection Retry Limits
    - Maximum Retries
    - Delay After Failure

Connection Properties: Address

Remote Network Address

A 12-digit hexadecimal network address. Contact the remote system's administrator or the network administrator for the

correct value.

The default is **400000000000**.

The value is determined as follows:

- For connections to a 3174 controller, use the value in the configuration response 900 of the controller's customization program.
- For connections to a 3720, 3725, or 3745 front-end processor, use the value in the MACADDR= parameter in the NCP configuration.
- For connections to an IBM 9370 host, use the value in the VTAM PORT definition for the MACADDR= parameter.
- For connections to another Host Integration Server system, the network address can be found through the **net config server** command. When this command is typed at the command prompt of the other Host Integration Server system, the resulting display shows the network address of that system, in the line labeled **Server is Active On**.

Remote Service Access Point (SAP) Address

A two-digit hexadecimal number that is a multiple of 04, between 04 and EC. See your token ring or Ethernet manual for more information.

The default is **04**.

You can also contact the remote system's administrator for information about the following:

- For connections to a 3174 controller, use the value in the configuration response 940 of the controller's customization program.
- For connections to an IBM 9370 host, use the value in the VTAM PU definition for the SAPADDR= parameter.

Local Service Access Point (SAP) Address

A two-digit hexadecimal number that is a multiple of 04, between 04 and EC. See your token ring or Ethernet manual for more information.

The Default is **04**.

You can also contact the remote system's administrator for information about the following:

- For connections to a 3174 controller, use the value in the configuration response 940 of the controller's customization program.
- For connections to an IBM 9370 host, use the value in the VTAM PU definition for the SAPADDR= parameter.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: DLC 802.2

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

This is the maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Receive ACK Threshold (frames)

Specify the maximum number of frames that the local system can receive from the remote system before sending a response. Set this to a value less than the **Unacknowledged Send Limit**, so that the local system acknowledges received transmissions more frequently than it expects responses to sent transmissions.

Unacknowledged Send Limit (frames)

Specify the maximum number of frames that the local system can send without receiving a response from the remote system. This parameter is sometimes called the Send Window Size.

Retry Limit

Specify the number of times that the local system should retransmit a frame if no response is received from the remote system.

The range is from 0 through 255; the default is **10**. A value of 0 means the system uses its internal default retry limit.

XID Retries

Specify the number of times that the local system should retransmit an XID (an identifying message) if no response is received from the remote system.

The range is from 0 through 30; the default is **3**.

Response (t1) Timeout

Select a value for the Response (t1) Timeout.

The amount of time that the local system should wait for the remote system to respond to a transmission before the local system tries again.

The values used for Default for the Response Timeout are 400 milliseconds for a local ring and 2 seconds for a remote ring.

If you do not select Default, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

Select a value greater than the total amount of time needed for the relaying of frames between the local system, the remote system, and the network.

Select **Default** to allow for two timeout values — one for a remote system on a local ring, one for a remote system on a remote ring. If you do not select **Default**, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

Receive ACK (t2) Timeout

Select a value for the Receive ACK (t2) Timeout.

The maximum amount of time that should be allowed before the local system sends an acknowledgment of a received transmission. An acknowledgment is sent at the end of the timeout, if some other process has not already triggered it.

Select a value less than the Response Timeout, so that the local system takes less time to acknowledge received transmissions than it takes to seek responses to sent transmissions.

Select **Default** to allow for two timeout values — one for a remote system on a local ring, one for a remote system on a remote ring. If you do not select **Default**, but instead select a specific value, the timer always waits the selected amount of time, regardless of whether the remote system is on a local or remote ring.

The values used for default for the Receive ACK Timeout are 80 milliseconds for a local ring and 800 milliseconds for a remote ring.

Inactivity (ti)

Select a value for the Inactivity (ti) Timeout.

The amount of time that the link can be inactive before the local system treats it as nonfunctioning and shuts it down.

Select **Default** to allow for two timeout values — one for a remote system on a local ring, one for a remote system on a remote ring. If you do not select **Default**, but instead select a specific value, the timer always waits the selected amount of

time, regardless of whether the remote system is on a local or remote ring.

The values used for default for the Inactivity Timeout are 5 seconds for a local ring and 25 seconds for a remote ring.

Connection Retry Limits

Supply activation limits for the connection.

Maximum Retries

Select the number of attempts for Host Integration Server to make when trying to establish the connection. After making this number of attempts, Host Integration Server makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

Connection Properties: X.25

The following tabs are available on the X.25 Connection Properties sheet:

Connection Properties: Address

Remote X.25 Address

Select the type of virtual circuit used by the connection.

Switched Virtual Circuit Address

Enter the Switched Virtual Circuit Address of the host.

Permanent Virtual Circuit Alias

Enter the Permanent Virtual Circuit Alias of the host. This is a number that identifies the channel: 1 for the first channel, 2 for the second, and so on. The default is **1**.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: X.25

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

This is the maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Facility Data

For an SVC channel, specify the codes for any Facility Data required by your network provider or by the administrator of the remote system. You can specify as many as 126 Hexadecimal characters (63 Hexadecimal bytes).

User Data

For an SVC channel, specify the codes for any User Data required by your network provider. Type an even number of hexadecimal characters of 32 characters or fewer.

Packet Size

For a PVC channel, select the maximum number of data bytes (not header bytes) to be sent in a frame. Obtain this value from your network provider.

Window Size

For a PVC channel, select the maximum number of frames that the local system can send without receiving a response from the remote system. Obtain this value from the administrator of the remote host or peer system.

Connection Retry Limits

Supply activation limits for the connection:

Maximum Retries

Select the number of attempts for Host Integration Server to make when trying to establish the connection. After making this number of attempts, Host Integration Server makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

Reference

X.25 Connection Parameters

Connection Properties: Channel

The following tabs are available on the Channel Connection Properties sheet:

Connection Properties: Address

Channel Address

Type a two-digit hexadecimal number identifying the channel. The range is from 00 through FF; the default is **FF**.

Control Unit Image Number

Type a value for the control unit image number. The range is 0 through F; the default is **0**.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

Connection Properties: Channel

Max BTU Length

Specify the Maximum Basic Transmission Unit (BTU) Length.

The range is from 265 through 16393; the default is **265**.

With an IBM SDLC adapter, set the Max BTU Length to 521 or less.

This is the maximum number of bytes that can be transmitted in a single data-link information frame. A BTU is sometimes called an I-frame.

For downstream connections, specify a Max BTU Length less than or equal to the maximum value supported by software on the downstream system.

For host connections, specify a Max BTU Length less than or equal to the VTAM PU definition for the MAXDATA= parameter.

Connection Retry Limits

Supply activation limits for the connection.

Maximum Retries

Select the number of attempts for Host Integration Server to make when trying to establish the connection. After making this number of attempts, Host Integration Server makes an entry in the event log and stops trying. The range is from 1 through No Limit; the default is **No Limit**.

Delay After Failure

Select the length of time for Host Integration Server to wait between attempts to establish the connection. The range is from 5 seconds through 255 seconds; the default is **10** seconds.

Local LU Properties: General

Local APPC LUs can be independent or dependent.

LU Alias

Enter the LU Alias.

Network Name

Type the Network Name. Obtain the correct name from the host or peer administrator if you will be connecting to a host system with VTAM,

The Network Name for an APPC LU that communicates with a host should match the NETID parameter in the VTAM Start command for the VTAM system.

If this server communicates with several different hosts over several connections, use the name of the subarea of the host with which the LU will communicate.

For independent LUs, the Network Name is required. For dependent LUs, the Network Name is recommended but not required, since it is used only by local software, such as the Windows event log software.

LU Name

Enter the LU Name. For independent APPC, the LU Name identifies the LU to other components on the SNA network, and therefore is required. For dependent APPC, the LU Name identifies the LU to local software, such as the Windows event log software, and is recommended but not required.

The LU Name and LU Alias for an APPC LU can be the same.

Comment

Optionally, enter a comment of no more than 25 characters.

Local LU Properties: Advanced

Member of Default Outgoing Local APPC LU Pool

If you want this LU to be available for use by a 5250 user or invoking TP not specifying a local LU, select this check box.

When a request comes from an invoking TP, and the request does not specify a local LU for the invoking TP to use, Host Integration Server first checks the user record of the user who started the TP, and tries to use the default local APPC LU assigned to that user or group. If this does not succeed, Host Integration Server tries to find a free LU in the pool of Default Outgoing Local APPC LUs. If this in turn does not succeed, the request is rejected.

Local LUs only support the number of sessions configured for the mode being used. The default for QPCSUPP is 64 sessions. If you need more than that number of sessions, then you need to configure multiple local LUs or increase the session limits in the mode definition for each mode used. To simplify user configuration, you can make all of these local APPC LUs part of the default pool by checking the **Member of Default Outgoing Local LU Pool.** This allows any user who does not specify a local APPC LU to get an available session from any local APPC LU in the default pool. This also enables load balancing among local APPC LUs. In addition, to ensure proper load balancing, do not specify a **Default Local LU Alias** for users or groups. However, if you want to have certain users or groups default to a certain local APPC LU, then you should specify that local APPC LU as the **Default Local LU Alias** in the user or group properties.

This default pool differs from, and should not be confused with, the 3270, LUA, and downstream LU pools.

Timeout for Starting Invokable TPs

If the **Invokable TP** is started manually by an operator, specify a value greater than 60 seconds to give the operator sufficient time.

Implicit Incoming Remote LU

To specify an Implicit incoming remote LU, choose an existing remote LU name from the list.

LU 6.2 Type

Select **Independent** or **Dependent**.

LU Number

For dependent LUs, enter the LU Number.

For independent LUs, this field is unavailable.

Connection

For **Dependent LU**s, choose the connection from the drop-down list.

For **Independent LU**s, this field is unavailable.

LU 6.2 Resync Service

Computer

Type the **IP Address** or the **Name** of the client computer. The client computer specifies a system that is dedicated in that the LU routes incoming connections to that client computer.

Check the **Enable** box if you have a very specialized transaction program (TP) that requires Resync Service. Resync Service or SyncPoint support is used by some database management systems (DBMS) for commit and rollback procedures. If you enable this service, the Local LU alias must be unique.

If you have multiple local and remote LUs using two-phase commit, you may want to explicitly partner the LUs. This will prevent the Resync Service from attempting to bind invalid LU pairs.

To explicitly partner LUs

1. In **SNA Manager**, click the **APPC Modes** folder.
2. Right-click **RSYNPRTN**, and then click **Properties**.
3. Select the **Partner** tab.
4. Click **Add**, and then follow the directions in the dialog box.

If you would like the Resync Service to use a different mode name, you can specify a new name with the following registry key:

HKLM\Software\Microsoft\Host Integration Server\UN2

REG_SZ: modename

Remote LU Properties: General

Connection

From the drop-down list, choose the connection that will be used to access this remote LU.

LU Alias

Enter an LU Alias

Network Name

Enter a Network Name. Obtain the correct name from the host or peer administrator. If you will be connecting to a host system with VTAM, the Network Name for an APPC LU that communicates with a host should match the NETID parameter in the VTAM Start command for the VTAM system.

LU Name

Enter the LU Name.

A name identifying an LU. The name can be from one through eight characters long and can contain alphanumeric characters and the special characters $, #, and @. Lowercase letters are converted to uppercase. The name cannot be the same as any other LU name or pool name (except for APPC LU names) on the server.

For communication with an AS/400, make the remote LU name the same as the name of the AS/400.

Uninterpreted LU Name

If this LU will be paired with a dependent local APPC LU, type the Uninterpreted LU Name.

Comment

Optionally, enter a comment of not more than 25 characters.

Remote LU Properties: Options

Supports Parallel Sessions

If this LU will be used with an independent local LU, and parallel sessions will be used, select this check box. If this LU will be used with a dependent local APPC LU, do not select this box.

If a remote LU supports parallel sessions, it can only be used with a mode that has a value greater than 1 for the parallel session limit.

Implicit Incoming Mode

To designate a mode as the Implicit Incoming Mode for this LU, select a mode from the list.

If this remote LU will be used as an Implicit Incoming Mode be sure to select a mode from the list.

No Session-Level Security

Select this option to turn off Session-Level Security.

Security Key in Hex

For a security key in hexadecimal, select this option, then type a 16-digit hexadecimal number.

Security Key in Characters

For a security key in characters, select this option, then type an eight-character string. The string can include uppercase and lowercase alphanumeric characters, and the special characters $, @, #, and the period (.).

Enable SyncPoint

If you enable **SyncPoint**, the Local LU alias must be unique.

Server Configuration Properties

Name

Displays the current server name. Click **Change** to change the server name.

Properties

The properties display the current configuration. These properties are display only. To change any of the following configuration items, click **Change**.

Subdomain

The **Subdomain** displays the current SNA subdomain.

Server Role

The server can be either a primary, backup, or member. The current role of the server is displayed.

Network Transports

Network Transports shows the transport currently in use.

Support Active Directory Clients

If selected, this server supports client computers using Active Directory and displays the current Active Directory Domain Name/Organization Unit.

Server Configuration

Subdomain Name
Displays the SNA subdomain that this server is a member of. To change the subdomain name, enter a new subdomain name and click **Save**.

Active Directory Client Support
If selected, this server is part of the Active Directory Organizational Unit (OU) as shown in the **Active Directory OU Name:** field. To change the OU, enter a new OU name and click **Save**.

Role
Select how this server will be configured, either as a **Primary Configuration Server** or a **Backup Configuration Server**.

Network Transports
Select all network transport protocols that this server will use on the network.

Services
The **Services** box shows the status of the **MngAgent** and **SnaBase** services. If these services are running, you must restart them before changes to the subdomain, server role, or network transports will take effect.

Restart
Click **Restart** to restart services required for changes to the subdomain, server role, or network transports to take effect. **Restart** is active only if you change the configuration of another server. If you want to change the configuration of the server on which you are currently working, **Restart** is unavailable. For changes to take effect on your server, close SNA Manager, open **Control Panel**, open **Services**, and then **Stop** and **StartSNA MngAgent** and **SnaBase**.

Save
Click **Save** to save your server configuration changes.

Important
Changing server configuration parameters can have serious consequences. Restarting the server will cause all connections a nd sessions to be disconnected. Notify all users prior to restarting.

Workstation Properties: General

Workstation ID

The **workstation ID** is usually the workstation name.

Workstation ID Type

Click the type of workstation ID:

Name is the workstation name.

Address is the IP address. An IP Address specifies one server for a network address (for example, IP, IPX, or Vines).

IP Subnet is the IP Subnet address. An IP Subnet address specifies several servers with the same network address. Subnetting enables host administrators to distribute the hostids for a given netid to several subnetworks. Without subnetting, an IP address is interpreted in two parts: netid + hostid (network + node). With subnetting, an IP address is interpreted in three parts: netid + subnetid + hostid (network + subnetwork + node). Subnetting is a mechanism for using some bits in the hostid as a subnetid.

IP Mask

If you select **IP Subnet**, you must specify the **IP Mask** as well. The IP Mask refers to the netid + subnetid. You must know the IP Mask. For example, an IP Mask might be: "255.255.248.0."

Comment

Optionally, enter a comment of no more than 25 characters.

Allow access to both workstation and user resources

Select this option to allow users logged on to this computer to see the LUs assigned both to the workstation and to that user.

Allow access to workstation resources only

Selecting this option provides a higher degree of security by restricting resources available on this computer to the LUs assigned to this workstation. Users will not be able to access LUs assigned to them unless the LU is also assigned to the workstation. This feature will be useful for secure workstations, such as those used to print checks.

Allow access to Dynamically Created Remote APPC LUs

Select this check box to allow users access to remote APPC LU as they are created.

TN5250 Properties

Name

Displays the name of the server running the TN5250 service. This field cannot be edited here.

Comment

Optionally, type a comment of up to 25 characters.

Use Default

Select **Use Default** to use the port number associated with telnet (as set in \\DRIVERS\ETC\SERVICES).

Use

You can override the default value for a given server by selecting **Use** and typing another port number. You can also override this port number for a given session. TN services listen on multiple ports simultaneously. You can set a default port number for the TN service (assign the port number to the server) and override this number on a per session basis (assign the port number to the LU session), allowing a single client computer to connect to multiple host computers.

Host Integration Server, VTAM, and NCP Parameters for X.25 Connections

The following table shows how Host Integration Server parameters for X.25 connections correspond to VTAM or NCP parameters. Asterisks (*) indicate required parameters.

Properties Tab	**SNA Parameter**	**VTAM or NCP Parameter**
System Identification	**Local Node ID**,* first three digits (block number)	**IDBLK=** parameter in the PU definition
System Identification	**Local Node ID**,* last five digits (node number)	**IDNUM=** parameter in the PU definition
System Identification	**Network Name (Remote Node)** Note: Network Name for local and remote nodes is generally the same	**NETID=** parameter in the VTAM Start command for the remote SSCP (VTAM system)
System Identification	**Control Point Name (Remote Node)**	**SSCPNAME=** parameter in the VTAM Start command for the remote SSCP (VTAM system)
Address	**Virtual Circuit Type or Remote X.25 Address**	**DIALNO=** parameter in the PORT definition
X.25	**Max BTU Length**	**MAXDATA=** parameter in the PU definition (set Max BTU Length less than or equal to MAXDATA)

- Required parameter in Host Integration Server.

Domain Properties

The following tabs are available for the SNA Subdomain Properties sheet:

Domain Properties: NetView

NetView sends alerts back and forth between a host system and the Host Integration Server and associated client computers.

Send NetView Management Data to this Connection

Select a connection to which NetView data should be sent. This can be any host connection.

Domain Properties: Display Verb

Default Connection for Display

Select a connection for use by Display Verbs. When the Display Verb is used but does not specify a connection, Host Integration Server uses the connection you specify in **Display Verb Properties**. If you do not specify a default Display connection, Host Integration Server randomly selects a connection for the verb to use.

Domain Properties: Server Broadcasts

Servers communicate with each other using server broadcasts.

Mean Time between Server Broadcasts

The interval at which server broadcasts are repeated. Broadcasts of state changes (such as the activation of a server) do not wait for this interval; instead, broadcasts are repeated at this interval to ensure reception (since broadcasts by definition are not guaranteed to be received).

Specifying a larger value causes less demand on the network (since broadcasts occur less often). However, a smaller value compensates better for loss of broadcast messages.

The range is from 45 through 65535 seconds; the default is **60** seconds.

Network Transport for server Broadcasts

Choose only the protocols you need, because sending unneeded broadcasts can significantly decrease network efficiency.

Domain Properties: Security

An administrator can adjust the subdomain security settings, including user permissions, configuration file ownership, and subdomain security events to audit.

LU Types

Select the **LU Types** (3270, LUA, or APPC) to which the security settings will apply. If security for an LU type is off, anyone who knows the LU name can use it. If security is on, only users to whom the LU is assigned can use it. The default setting is on for 3270, and off for LUA and APPC.

Configuration File

To view or change user permissions on the configuration file, click **Permissions**.

To view or change audited events, click **Auditing**.

To view or change configuration file ownership, click **Take Ownership**.

Domain Properties: Client Backup Configuration

Disable Sending Client Backup Information

The server sends no information to the client computer.

Backup Domain

The server updates the client computer with the backup SNA subdomain name specified in the box.

Backup Sponsor Servers

The server updates the client computer with all of the SNA Sponsor Server names (shown in the box). The maximum is 15.

Domain Properties: Error / Audit Logging

You can use information from the Windows 2000 event logs as you test a configuration or to diagnose a problem.

Centralized Event Log Server

Select the name of the server on which Windows 2000 event logs for this server installation should be stored.

Route All Popup Messages to

Select the name of the server to which pop-up error messages should be routed.

Default Audit Log Level

Select a level

Detailed problem analysis: To record all events that can be recorded, select this option.

General information messages: To record general activity but not all events, select this option.

Significant system events: To record only major events, select this option.

Audit logging disabled: To turn off audit logging, select this option.

Domain Properties: Response Time Monitor (RTM)

Response Time Monitor tracks the time it takes a host to respond to 3270 session requests. RTM is supported only by certain emulators. You should configure RTM only if the emulators you are using support RTM.

RTM Data Sent at

Select one or both of the following:

Counter Overflow:

To cause RTM data to be sent to the host when the number of host responses in a given time period overflows the size of the available counter, select this box.

End of Session:

To cause RTM data to be sent to the host at the end of each LU-to-LU session, select this box.

RTM Timers Run Until

Select the point at which RTM will register that a host has responded; this is when RTM stops the timers. (The timers are started when the local system sends data.)

First Data Reaches Screen:

To stop timing when data reaches the local screen, select this option.

Host Unlocks Keyboard:

To stop timing when the host unlocks the local keyboard, select this option.

Host Lets User Send:

To stop timing when the host lets the local computer send more data, select this option.

RTM Thresholds

Specify the cutoff times, in tenths of a second, at which RTM saves its count of host responses, and then restarts the count. For example, you could specify 5, 10, 20, and 50, to save the count of host responses during the intervals from 0.0 to 0.5 seconds, from 0.5 to 1.0 seconds, from 1.0 to 2.0 seconds, and from 2.0 to 5.0 seconds.

AS400 Definition Properties: General

AS/400 Remote LU Alias

Click the drop-down list box arrow and select an **AS/400 Remote LU Alias**, which contains addressing information for the AS/400.

Local LU Alias

Click the drop-down list box arrow and select a **Local LU Alias**. The **Local LU Alias** maps to the LU the client computer will use.

Mode

You must select the **QPCSUPP mode**.

AS/400 User Name

Enter your **AS/400 User Name**, which is required information.

AS/400 Password

Enter your **AS/400 Password**, which is required information.

Confirm Password

Enter your password again to confirm.

Comment

Optionally, enter a comment of not more than 25 characters long.

Active Users

This folder displays the users that are currently actively using this server.

LUA LU Properties: General

After assigning or viewing an LUA LU, in the **LUA LU Properties** box, supply information according to the following list.

LU Number (for LUs on 802.2, SDLC, or X.25)
Type the LU Number.

LU Name
Type the LU Name.

Connection
The connection for this LU is shown. The connection cannot be changed in this dialog box.

Pool
If the LU has already been assigned to a pool, the pool name appears here.

Comment
Optionally, type a comment of 25 characters or fewer.

CPI-C Symbolic Name: General

Name

Type the Symbolic Destination Name.

Comment

Optionally, enter a comment of not more than 25 characters.

Conversation Security

Select a Conversation Security option:

- **None** turns off conversation security.
- **Same** requires the same user ID and password as that of the Remote Partner LU.
- **Program** specifies the user ID and password, select Program, and then click **User ID**.

Mode Name

Select a mode name from the drop-down list.

CPI-C Symbolic Name: Partner Information

Partner TP Name

- **Application TP:** For an Application TP, select this option, and type the Application TP Name.
- **SNA service TP** (in hex)**:** For an SNA service TP select this option, and type the SNA service TP Number.Partner LU Name
- **Alias:** To identify the **Partner LU by** Alias, select this option, and type the alias.
- **Fully Qualified:** To identify the partner LU by a Fully Qualified name, select this option, and type the name.

To accept the settings, click **OK**; to exit the dialog box without accepting the settings, click **Cancel**.

CPI-C Symbolic Name: Security Settings

Specify a User ID and Password

User ID
The **User ID** can contain from 1 through 10 characters.

Password
The **Password** can contain from 1 through 10 characters.

Verify Password
Type the **password** again.

Host Integration Server 2009 Folder

Expand the Servers folder to show the Host Integration Server assigned to this SNA Domain.

SNA Service Folder

This folder contains the SNA service installed on this Host Integration Server computer. Each Host Integration Server computer can have a maximum of four SNA services installed and active at one time.

Select **SNA Service**, then right-click to perform various tasks, including:

- Save the current configuration.
- Stop the service.
- Pause the service.
- Start the service.
- Create a new service.
- Display additional service properties.

Link Services Folder

This folder contains the link services that are configured on this Host Integration Server.

To create a new link service, select the **Link Services** folder, right-click, point to **New** and then select **Link Service**.

Connections Folder

This folder contains the connections configured on this Host Integration Server.

To create a new connection, select the **Connections** folder, right-click, point to **New** and then select the type of connection you want to make.

Local APPC LUs Folder

This folder contains the Local APPC LUs configured for this server.

Remote APPC LUs Folder

This folder contains the Remote APPC LUs configured for this server.

Microsoft SNA Manager

Host Integration Server Microsoft Management Console application is also called the SNA Manager.

AS/400 Definitions

This folder displays the AS/400 definitions that are currently being used on this server.

Active TN5250 Sessions

This folder displays the active TN5250 sessions that are using this server.

AS/400 Definition Properties

The following tabs are available on the AS/400 Definition Properties:

AS/400 Definition Properties: General

AS/400 Remote LU Alias

Click the drop-down list box arrow and select an **AS/400 Remote LU Alias**, which contains addressing information for the AS/400.

Local LU Alias

Click the drop-down list box arrow and select a **Local LU Alias**. The **Local LU Alias** maps to the LU the client computer will use.

Mode

You must select the **QPCSUPP mode**.

System 36, AS/36

Select if connection to a System 36 or AS/36 computer system.

AS/400 User Name

Enter your **AS/400 User Name**, which is required information.

AS/400 Password

Enter your **AS/400 Password**, which is required information.

Confirm Password

Enter your password again to confirm.

Comment

Optionally, enter a comment of not more than 25 characters long.

AS/400 Definition Properties: Terminal Types

Terminal Names

Terminal names are displayed. You can remove selection of individual terminal names that do not apply to your network configuration by clearing the checkbox opposite the name

Port

Use Default

Select **Use Default** to use the port number configured with the service (on the Service Properties page).

Use

You can override the default value for a given session by selecting **Use** and typing another port number.

Note
TN services listen on multiple ports simultaneously. You can set a default number for the TN service and override this numbe r on a per session basis, allowing a single client computer to connect to multiple host computers.

Note
Configuration changes are apparent only to users who establish a connection after the configuration changes are saved. User s who were connected at the time the configuration changes were made will not be affected.

AS/400 Definition Properties: IP Address List

You can associate this LUA to a specific IP address or server name.

Add Address

Click to specify the **IP Address** and **Subnet Mask** of the client workstation to which you are granting access.

IP Address

Click an entry in the **IP Address** column to edit the IP address for a client workstation.

Subnet Mask

Click an entry in the **Subnet Mask** column to edit the subnet mask for a client workstation.

Add Name

Click to add a workstation name to the **IP Address** list box. The workstation name identifies that a client workstation whose address resolves to that name can connect to the service.

Remove

Click to remove an entry that is currently highlighted in the **IP Address** list box.

Clear All

Click to remove all entries in the **IP Address** list box. The service will then be configured to allow access from any client workstation.

Note

The IP address must be changed from the default value of 0.0.0.0 if you want to assign a specific IP address. If you try to add the default IP address with the default subnet mask value, you will receive a message indicating an Invalid IP Address/Subnet Mask.

Note

The IP address of an incoming connection is compared to each of the available LUs or pools in turn. Each resource has an associated list of IP address patterns and subnet masks. The IP address from the incoming connection is masked (by bit and by the resource's subnet mask), then compared to the resource's IP address pattern masked by the resource's subnet mask. If the result is equal, the connection is allocated to this resource.

APPC Modes Folder

This folder contains the APPC Modes configured for this server.

CPI-C Symbolic Names Folder

This folder contains the CPIC Symbolic Names configured for this server.

Visual Studio Help

Microsoft Visual Studio provides a graphical user interface for creating, viewing, and editing the objects used by the host-initiated processing (HIP) and Windows-initiated processing (WIP) environments in Transaction Integrator (TI). TI objects are created and edited within a TI Project, one of several project types supported by the Visual Studio design environment.

The user interface for a TI Project includes a tree view in the Solution Explorer window, wizards, dialog boxes, and properties displayed in the Properties window. The tree view presents a two-pane design tool. The left pane displays a hierarchical representation of the components of a type library or .NET assembly. The right pane displays a list of details about the properties associated with the contents of the library or assembly selected in the left pane. You can customize the details view to display other types of information, for example, a COBOL, RPG, or IDL source code. You can display Help topics about the individual user interface controls by highlighting a control or node and pressing the F1 key.

The TI wizards in a project have **Help** buttons on each wizard page. Clicking **Help** on the page takes you to the relevant Help topic in this section. You can display Help topics about the individual user interface controls by clicking **Help** on the Visual Studio wizard page or dialog box or by highlighting a control or node and pressing the F1 key. All of the TI Project Help topics are combined in this section for easy reference and review.

In This Section

COM Library Nodes

When you view a COM type library (.tlb for client and .tim for server) from within a TI Project, the Visual Studio design environment displays the objects in the library in a tree view in the left pane and a details view in the right pane. Double-click the node to expand the node and right-click the node to display a shortcut menu.

The topics in this section describe the functionality of each menu and each command in the navigation tree.

In This Section

- Library Name Node
- Interface Name Node (COM)
- Method Name Node (COM)
- Parameter Name Node (COM)
- Recordsets Node
- Recordset Name Node
- Recordset Column Name Node
- User-Defined Types Node
- User-Defined Type Name Node
- User-Defined Type Member Name Node

Library Name Node

Use the ***library name*** node to support Microsoft Visual Basic 6.0, transactions, and select the remote environment class.

Double-click the ***library name*** node to expand it. The right pane displays the following information about the node's children:

- **Name**.The object name.

Right-click the ***library name*** node to display the following nine options:

- **Import**. Displays a menu with two options:
    - **Host Definition**. Starts the Import COBOL Wizard or RPG Import Wizard to help you import COBOL or RPG to the interface definition.
    - **Library**. Starts the **Import Library** open file dialog box to help you to import an existing type library or assembly to the interface definition.
- **Export Host Definition**. Starts the **Export Host Definition** file save dialog box to help you generate a COBOL or RPG copy book equivalent to the current library.
- **Lock**. Marks the library as read-only. The library is automatically marked as locked if it is registered in a COM+ application or IIS virtual directory.
- **Rename**. Renames the library.
- **Properties**. Displays the **Properties** window.

Interface Name Node (COM)
Recordsets Node
User-Defined Types Node

Interface Name Node (COM)

Use the ***interface name*** node to set the name of the interface in a component.

Double-click the ***interface name*** node to expand it. The right pane displays the following information about the interface methods:

- **Method Name**. The method name.
- **Return Type**. The method return type.
- **Host Data Type**. The COBOL or RPG equivalent of the method's return type.
- **Array Size(s)**. If the return type is an array, this column will contain the number of dimensions and their sizes. For example, a single dimension of size 10 will be displayed as (10); a 3-dimensions array with sizes 2, 4, and 6 will be displayed as (2, 4, 6).
- **Rows**. The number of recordset rows if the return type of the method is a recordset.
- **Link-to-Program Name**. The name of an executable running under the host environment that will be linked to by this method and passed a COMMAREA. It is valid only for link models.
- **TP Name**. The name of the transaction program (TP) used by the method to locate a program to be executed. In the case of link models, it identifies the mirror transaction identifier which parses the distributed program link (DPL) header and identifies the link-to-program name.
- **Meta Data**. Indicates whether the host is sent no metadata, only the name of the method, or all metadata.

Right-click the ***interface name*** node to view the following seven options:

- **Add Method**. Adds a new method .
- **Paste**. Inserts a method into the current interface definition.
- **Rename**. Renames the interface.
- **Properties**. Displays the **Properties** window.

Method Name Node (COM)
Library Name Node

Method Name Node (COM)

Use the ***method name*** node to define the conditions for interacting with the host environment, including the value for the initial buffers, whether to include all information.

Double-click the ***method name*** node to expand it. The right pane displays the following information about the method parameters:

- **Parameter Name**. The name of the parameter.
- **Type**. The data type of the parameter.
- **Direction**. The direction of the parameter: in only, in and out, or out only.
- **Host Data Type**. The COBOL or RPG data type that best describes the parameter type.
- **Array Size(s)**. The size and number of the dimensions of the parameter, if it is an array.
- **Rows**. The number of recordset rows if the parameter type is a recordset.

Right-click the ***method name*** node to view the following seven options:

- **Add Parameter**. Adds a new In\Out integer parameter to the method.
- **Cut**. Copies the selected method to the Clipboard and deletes it.
- **Copy**. Copies the selected method to the Clipboard.
- **Paste**. Inserts a parameter from the Clipboard into the current method definition.
- **Delete**. Deletes the method.
- **Rename**. Renames the method.
- **Properties**. Displays the **Properties** window.

Remote Environment Wizard Page 1 (COM Client Wizard)

Use the **Remote Environment** wizard page to define the remote environment (RE). A remote environment identifies an application execution environment running on a remote host system. The remote environment can have a data communication protocol and a programming model associated with it.

Use this	To do this
Vendor	Select the name of the vendor supplying the remote environment.
Protocol	Select the data communication protocol to be used to connect to the remote environment. The available communication protocols are: • **TCP/IP** (default) • **LU 6.2**
Target environment	Select the application environment running on the remote host system. The available environments are: • **CICS** (default) • **IMS** • **OS400** (TCP/IP only)
Programming model	Select the programming model associated with the remote environment. The available models for the TCP/IP CICS target environment are: • **TRM User Data** (default) • **TRM Link** • **ELM User Data** • **ELM Link** The available models for the LU 6.2 CICS target environment are: • **CICS User Data** • **CICS Link** • The available models for the TCP/IP IMS target environment are: • **IMS Connect** • **Implicit** • **Explicit** • The only available model for the LU 6.2 IMS target environment is **IMS User Data**. • The only available model for the OS400 target environment is **Distributed Program Call**.

Allow 32 K in/out	Select this option if you want TI to treat the input DFHCOMMAREA independently from the output DFHCOMMAREA. TI typically combines the input DFHCOMMAREA and the output DFHCOMMAREA area. The combined areas cannot exceed 32 KB of data. When this option is selected, TI treats the input DFHCOMMAREA independently from the output DFHCOMMAREA. Each input and output area uses up to 32 KB of data.

Library Wizard Page (.NET Client Wizard)

Library Wizard Page (.NET Client Wizard)

Use the **Library** wizard page to identify the .NET client library you are creating.

Use this	To do this
Interface name	Type the full name for the class in the .NET assembly. The name of the interface, when combined with the major version number and the namespace name, cannot exceed 39 Unicode characters.
Version	Type the version information for the .NET assembly in the form *major.minor*. The major version number, when combined with the name of the interface and the namespace name, cannot exceed 39 Unicode characters.
Component class name	View the component class name to be associated with the managed class in the .NET assembly. The format is *Namespace.Interface.MajorVersion*. The namespace name, when combined with the major version number and the name of the interface, cannot exceed 39 Unicode characters.
Type Restrictions	Select the type appopriate to your library. As you continue to develop your project, appropriate restrictions will be applied based on this selection. This step will help prevent you from creating a library that contains types that are not supported by the applications that will be using them (for example, ASMX or BizTalk Server). Selecting **None** will result in no restrictions. Selecting **Web Service** will allow access to data sets, but restrict access to data tables and multi-dimensional arrays. Selecting **BizTalk Adapter for Host Applications** will allow access to arrays only, and restrict access to data tables, data sets, and multi-dimensional arrays.
Description	Type the description to be associated with the interface. The description can be a maximum of 256 Unicode characters.

Select Item Wizard Page

Select Item Wizard Page

Use the **Select Item** wizard page to create a new method or rewrite an existing method in your interface. Enter the identifying information for the method.

Use this	To do this
Method name	Select or type the name of the COM or .NET method. The name can be a maximum of 250 Unicode characters. If you are creating a new method, the name of the new method cannot be the same as the name of an existing method.
Program name	Select or type the name of the AS/400 Report Program Generator (RPG) program. The name can be a maximum of 10 Unicode characters.
Library name	Select or type the name of the library on the AS/400 computer from which the named RPG program will be retrieved for execution. The name can be a maximum of 10 Unicode characters.

Properties (TI Project)

In This Section

Library Properties

Use the **Library** properties page to set design and remote environment (RE) properties on the component library or .NET assembly.

Design Properties

Use this	To do this
Component Type	View the type of library component. Possible values are: • **COM Type Library** (default) • **.NET Assembly**
Description	Type a description of the component. The description can be a maximum of 250 Unicode characters.
Help Context ID	Type the Help context ID associated with this method. It is used to connect to the Help topic for this method, and returned when an exception occurs during invocation of this method.
Initiation Type	View the location of the transaction program (TP) making the request. Possible values are: • **Windows-initiated** (default) • **Host-initiated**
Name	Type the name of the component. The name can be a maximum of 250 Unicode characters. The name must be different from any other component name in the same project. The default is **Library(n)**.
Support Visual Basic 6.0 Decimal Type	Select this option to specify whether the component allows application programs written with Visual Basic 6.0 that reference decimal data types. The possible values are: • **True** • **False** (default)
Visual Basic 6.0 Compatible	Select this option to require that the Visual Basic server use the **Implements** keyword within the Visual Basic server script. The server script then creates the Visual Basic interface to the Transaction Integrator metadata (TIM) type library. The possible values are: • **True**. Use the **Implements** keyword. • **False** (default) Note This property is the same as the property **Visual Basic Implements Compatible** in Host Integration Server.
Version	Type the version information for the type library or the .NET assembly, expressed in the form of *major.minor*.

Remote Environment Properties

Use this	To do this

Allow 32K In/Out	Select this option if you want TI to treat the input DFHCOMMAREA independently from the output DFHCOMMAREA. TI typically combines the input DFHCOMMAREA and the output DFHCOMMAREA area. The combined areas cannot exceed 32 KB of data. When this option is selected, TI treats the input DFHCOMMAREA independently from the output DFHCOMMAREA. Each input and output area uses up to 32 KB of data. Changing this option affects the currently selected method. Possible values are: • **True** • **False** (default)
Remote Environment Class	Select the programming model associated with the remote environment. The available models for the TCP/IP CICS target environment are: • **TRM User Data** (default) • **TRM Link** • **ELM User Data** • **ELM Link** The available models for the LU 6.2 CICS target environment are: • **CICS User Data** • **CICS Link** • The available models for the TCP/IP IMS target environment are: • **IMS Connect** • **Implicit** • **Explicit** • The only available model for the LU 6.2 IMS target environment is **IMS User Data**. The only available model for the OS400 target environment is **Distributed Program Call**.

Transaction Support	The possible values are: • **Required**. The new TI component is used in applications that execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support Sync Level 2 requests. If a transaction is in progress, the application will enlist in the transaction. Otherwise, the application will start a new transaction. • **Required New**. The new TI component is used in applications that execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support Sync Level 2 requests. The application will always start a new transaction, regardless of whether an existing transaction is already in progress. • **Supported**. The new TI component is used in applications that might or might not execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support both Sync Level 0 (non-transactional) and Sync Level 2 (transactional) requests. In the case of a Sync Level 2 transaction, the calling application will enlist in the transaction if the transaction is already in progress. Otherwise, the application will start a new transaction. • **Not Supported**. The new TI component is used in applications that do not execute within COM+ transactions. The component's methods will be called by applications used with mainframe transaction programs that support only Sync Level 0 requests. IMS transaction programs prior to IMS 6.0 support only Sync Level 0. CICS and IMS 6.0 transaction programs support either Sync Level 0 or Sync Level 2 requests.

⚠Warning

The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Interface Name Node (.NET)

Method Properties

Use the **Method** properties page to set array, COBOL, design, host definition, and recordset properties on the method.

Array Properties

Use this	To do this
Array Dimensions	Select the array dimensions for the return value. The default is **(none)**.
Is Array	Select whether the return value is an array. The possible values are: • **True** • **False** (default)
Occurs Depending On	Select to indicate that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Equivalent to variable-length tables in COBOL. Use the drop-down list to select the numeric data item that specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. Arrays with multiple dimensions can only be used for the outermost loop (COBOL) or rightmost dimension (Microsoft® Visual C++® or Visual Basic). The default is **(none)**.

COBOL Properties

Use this	To do this
HostDataType	Select the host data type.
ErrorHandling	Select the return value error handling. The possible values are: • **Truncate**. Select this option to set TI to truncate the value when an error occurs. (default) • **Round**. Select this option to set TI to round the value when an error occurs. • **Error**. Select this option to set TI to return an error when an error occurs.

Filler	Type the return value filler. The default is **0**.
FromHost	Type the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side. The default is **0**.
ToHost	Type the number of bytes of FILLER that follows this data item in buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side. The default is **0**.
Scale	Type the return value scale.
SignAttribute	Select the return value sign attribute. The possible values are: • **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size	Type the return value size.
SOSI	Select this option to specifywhether a double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. The possible values are: • **True**. The SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. • **False** (default)

String Delimiting	Select the return value string delimiting. The possible values are: • **Space-padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. For more information, see Padding Mainframe Character Strings with Spaces. (default) • **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this
Allow 32K In/Out	Select this option if you want TI to treat the input DFHCOMMAREA independently from the output DFHCOMMAREA. TI typically combines the input DFHCOMMAREA and the output DFHCOMMAREA area. The combined areas cannot exceed 32 KB of data. When this option is selected, TI treats the input DFHCOMMAREA independently from the output DFHCOMMAREA. Each input and output area uses up to 32 KB of data. Changing this option affects the currently selected method. Possible values are: • **True** • **False** (default) Note You can use this property as an accessory to "Use Link Programming Model" in the Windows-initiated processing (WIP) CICS programming model and in any host-initiated processing (HIP) programming models. Note This property is available only if the **Is Link** property is set to **True**.
Description	Type a description of the method. The description can be a maximum of 250 Unicode characters.
Help Context ID	Type the Help context ID associated with this method. The ID is used to connect to Help for this method, and returned when an exception occurs during invocation of this method. The default is **0**.

Include Context Parameter	Select whether the client object method automatically includes context. The possible values are: • **True**. Visual Basic .NET automatically includes the context as an additional parameter in the argument. If you do not include **COMTIContext** parameter in your method call along with your other parameters, Visual Basic .NET returns the error message **An unhandled exception of type 'System.MissingMemberException' occurred in microsoft.visualbasic.dll** and informs you that the method cannot be called with the number of parameters you have written. If you receive this message, verify that the **Include Context Parameter** is included as a parameter within the list of parameters on the method. • **False**. Visual Basic .NET does not automatically include the context as an additional parameter in the argument. If you set this property to **False** and include **COMTIContext** parameter in your method call along with your other parameters, Visual Basic .NET returns the error message **An unhandled exception of type 'System.MissingMemberException' occurred in microsoft.visualbasic.dll** and informs you that the method cannot be called with the number of parameters you have written. If you receive this message, remove the **COMTIContext** parameter from the method parameter list. The default is **True**.
Initial Buffer Value	Type the initial buffer value. The default is null.
Is Link	Select whether the host object method uses the Link programming model. The possible values for Windows-initiated processing (WIP) are: • **True**. Use the link model. The link programming model can be used only with CICS link protocols. • **False**. Do not use the link model. The default is **False**. The possible values for host-initiated processing (HIP) are: • **Yes**. Use the link model. The link programming model can be used with all protocols. • **No**. Do not use the link model. • **Link using 32K In/Out**. Use the link model and set the From Host and To Host properties. The default is **No**.
Meta Data	Select how metadata is handled. The possible values are: • **(none)**. By default no special data is sent to or received from the host application. Select this option button if you only want to send and receive the data for the method. • **Include Method Information**. The name of this method to be sent to the host along with parameter data. The method name is sent as the first 32 bytes in the buffer. This option is useful if multiple method calls go to the same transaction and you want to differentiate the data from the different calls. • **Include All Information**. All metadata available to be sent and received with your method data. For details of the format of metadata, see description for "Optional Metadata".

Name	Type the name of the method. The name can be a maximum of 250 Unicode characters. The name must be different from any other method name in the same project. The default is **null**.
Position Return Value After	Type the Automation method return value that follows the selected data item when it is received from the host. This option does not affect the Automation side. Use this option when the data item that you want to specify as the Automation return value is not the first data item field in the data declaration that describes the data received from the host.
Preliminary Filler	View the number of bytes of FILLER received from or sent to the host.
From Host	Type the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
To Host	Type the number of bytes of FILLER that follows this data item in the buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Return Type	Select the return value type. The possible values are: • **Void** • **Boolean** • **Byte** • **Date** • **Currency** • **Decimal** • **Integer** • **Long** • **Double** • **Single** • **String** • **User-defined type** • **Recordset** • **(none)** (default)

Variable Sized Final Field	• Select this option when the last data item is a string to indicate that the size of the string varies. This option is also used to define a datatable or recordset as being either bounded or as including all rows as defined as **Maximum Occurrence** set on the parameter.
From Host	• **True** • **False** (default)
To Host	• **True** • **False** (default)

Host Definition Properties

Use this	To do this
Link-to-Program Name	Type the link-to-program name (CICS LINK/DPL).
Mirror Transaction ID	Type the mirror TRANID that this method uses, if you want to override the mirror TRANID for the remote environment (RE) that this component is associated with. Leaving this box blank causes the mirror TRANID in the remote environment description to be used. The TRANID can be up to four characters in length. Acceptable characters are A-Z a-z 0-9 $ @ # . / _ % & ? ! : | = , ; < >. Transaction names beginning with C are reserved for CICS and should not be used. The % and & characters may cause problems with Resource Access Control Facility (RACF) if transaction security is active.
TP Name	Type a source transaction program (TP) name when the CICS application program must access a DB2 database. The TP name is referenced in a CICS Resource Control Table (RCT) entry, which associates CICS transactions with DB2 plans. Specifies the name of the host transaction program (IMS or CICS) or the link-to program name (CICS LINK/DPL).

Recordset Properties

Use this	To do this
Include Actual Size	The host program will not include or expect any information that indicates the actual number of rows (recordsets) or elements (arrays) being sent or received. The possible values are: • **True** • **False** (default) This property is read-only and will always be set to **False** unless it was set to **True** at the time the type library was created with the first version of COM Transaction Integrator.

Maximum Occurrence	Maximum row occurrence. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item. The default is **1**.
Occurs Depending On	Equivalent to variable-length tables in COBOL. Indicates that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic). Return value recordset occurs depending on. The default is **(none)**.
Unbounded	Indicates the recordset is unbounded. Indicates that any number of rows can be sent to or received from the host. You would select this option when the rows being sent or received are from a database and the maximum number of rows is not known. The possible values are: • **True**. When the last data item is a string, this means that the size of the string varies. • **False**. When the last data item is an array, this means that the number of elements in the array varies. When the last data item is a recordset, this means that the number of rows in the recordset varies. (default)

⚠Caution

The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Parameter Properties

Use the **Parameter** properties page to set the array, host, COBOL design, and recordset properties on a parameter.

Array Properties

Use this	To do this
Array Dimensions	Use this control to indicate how many dimensions (Visual C++ or Visual Basic) or nested OCCURS clauses (COBOL) that the array or table contains.
Is Array	Select this option to indicate whether the parameter is an array. The possible values are: • **True**. Parameter is an array. • **False**. The item is a simple data type including RDA recordset objects. (default).
Occurs Depending On	Select this option to indicate that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic). The RPG language, unlike COBOL, does not directly support **Occurs Depending On**. TI provides a feature that replicates the Occurs Depending On action for the RPG language. A TI Project supports a single level of dimension applied as an Occurs Depending On associated with a array of records in RPG. An index parameter must be defined prior to defining the parameter associated with a datatable or structure for the parameter to show as an **Occurs Depending On** selectable choice.

Host Properties

Use this	To do this
Host Data Type	Specifies the parameter host data type.

ErrorHandling	Parameter error handling. The possible values are: • **Truncate**. If selected and an error occurs, TI will truncate the value. (default) • **Round**. If selected and an error occurs, TI will round the value. • **Error**. If selected and an error occurs, TI will return an error.
Filler	Indicates the number of bytes of FILLER that follow this data item in the buffers that are sent to or received from the host. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
FromHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
ToHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Scale	The parameter scale.
SignAttribute	Parameter sign attribute. The possible values are: • **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size	Specifies the length of the string.

SOSI	Specifies whether double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. When this check box is selected, the SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. The possible values are: • **True** • **False** (default)
StringDelimiting	Return value string delimiting. The possible values are: • **Space-Padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. (default) • **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this

Data Type	The possible values are: • **Void** • **Boolean** • **Byte** • **Date** • **Currency** • **Decimal** • **Integer** • **Long** • **Double** • **Single** • **String** • **User-defined type** • **Recordset** • **(none)** (default)
Name	Name of the parameter. The name can be a maximum of 250 Unicode characters.
Parameter Direction	The possible values are: • **In** • **Out** • **In / Out** (default)

Recordset Properties

Use this	**To do this**
Include Actual Size	Default option indicating that the host program will not include or expect any information that indicates the actual number of rows (recordsets) or elements (arrays) being sent or received. The possible values are: • **True** • **False** (default)

Maximum Occurrence	Maximum row occurrence. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item.
Occurs Depending On	Parameter recordset occurs depending on. Equivalent to variable-length tables in COBOL. Indicates that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic).
Unbounded	Indicates the recordset is unbounded. Indicates that any number of rows can be sent to or received from the host. You would select this option when the rows being sent or received are from a database and the maximum number of rows is not known. The possible values are: • **True** • **False** (default)

Caution

Parameter Name Node (.NET)

Recordset Properties

Use the **Recordset** properties page to set design and host definition properties on a recordset.

Design Properties

Use this	To do this
Name	Name of the recordset. The name can be a maximum of 250 Unicode characters.

Host Definition Properties

Use this	To do this
Column Filler	Recordset filler. Indicates for each row of data sent or received, the number of bytes of FILLER that precedes each row. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Variable Sized Rows	Recordset variable sized rows. Use this option to indicate that the last data item or group item returned from the host varies from zero to the maximum size specified for the data item. When the last data item is character data, it refers to the number of bytes (TI terminology is "variably sized"). When the last data item is an array, it refers to the number of elements. When the last data item is a recordset, it refers to the number of rows. The last two are called "bounded" in TI terminology. The possible values are: • **(none)** (default) • **Half-word binary (16 bits)**. Indicates that the length specifier for the actual size of a variably sized row will be a half-word binary (16-bit) value. This is the default. • **Full-word binary (32 bits)**. Indicates that the length specifier for the actual size of a variably sized row will be a full word binary (32-bit) value. • **Half Word (16 bits) Inclusive**. If the value of the actual size of variably sized rows will include the length specifier (the actual size of the row plus 2 or 4 bytes), select this check box. Verify that this check box is cleared if the value should only specify the actual size of a row itself. • Full Word (32 bits) Inclusive.

⚠**Caution**
The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Recordset Name Node

Recordset Column Properties

Use the **Recordset Column** properties page to set COBOL and design properties on a recordset column.

COBOL Properties

Use this	To do this
HostDataType	Specifies the recordset column host data type.
ErrorHandling	Recordset column error handling. The possible values are: • **Truncate**. If selected and an error occurs, TI will truncate the value. (default) • **Round**. If selected and an error occurs, TI will round the value. • **Error**. If selected and an error occurs, TI will return an error.
Filler	Recordset column filler. The default is **0**.
FromHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER ca uses an untranslated gap in the buffer. FILLER is not visible on the Automation side.
ToHost	Indicates the number of bytes of FILLER that follows this data item in buffers that are sent to the server. FILLER causes an un translated gap in the buffer. FILLER is not visible on the Automation side.
Scale	Recordset column scale.

SignAttribute	Recordset column sign attribute. The possible values are: • **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). • **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. • **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). • **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size/Precision	Recordset column size.
SOSI	Specifies whether double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. When this check box is selected, the SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. The possible values are: • **True** • **False** (default)

StringDelimiting	Recordset column string delimiting. The possible values are: • **Space-padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. For more information, see Padding Mainframe Character Strings with Spaces. • **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this
Data Type	The data type of the currently displayed column. Recordset column data type. The possible values are: • **Void** • **Boolean** • **Byte** • **Date** • **Currency** • **Decimal** • **Integer** • **Long** • **Double** • **Single** • **String**
Name	Name of the recordset column. The name can be a maximum of 250 Unicode characters.

Caution

The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Recordset Column Name Node

User-Defined Type Properties

Use the **User-Defined Type** properties page to set design and host definition properties on user-defined types (UDTs).

Design properties

Use this	To do this
Name	Name of the user-defined type (UDT). The name can be a maximum of 250 Unicode characters.

Host Definition properties

Use this	To do this
Independent UDT	Independent user-defined type. An independent user-defined type (UDT) is a UDT that is not referenced by a method (directly or indirectly). When you use TCP/IP, the client sends the host a transaction request message (TRM) or enhanced listener message (ELM) containing the Transaction Program ID, User ID, Password, and other administrative data to be used by the host. The client sends a TRM or ELM reply containing additional administrative data. The data in the TRM or ELM is independent from the actual program data to be exchanged with the Transaction Program on the host. You can use the independent UDT options and the naming convention of TRMIN, TRMOUT, ELMIN, or ELMOUT to control the data content and format in the TRM or ELM request and TRM or ELM reply. For TRMs or ELMs destined for the host, the name of the UDT must begin with the characters TRMIN or ELMIN. For TRM or ELM replies from the host, the name of the UDT must begin with the characters TRMOUT or ELMOUT. Examples of valid TRM names are: TRMINMyVeryOwn, ELMINStandard, TRMOUTMyVeryOwn, and ELMOUTStandard. When you begin the UDT with the character TRMIN, TRMOUT, ELMIN, or ELMOUT, Visual Studio automatically formats the first member as an Int or Long and the last members as a String or Array. After an independent UDT has been defined, it can be referenced by the client application and passed to and from the TI runtime (by using the COMTIContext object) as an optional parameter. The possible values are: • **(none)** (default) • **Length Inclusive** • **Length Exclusive**
Member Filler	User-defined type member filler. Type the number of bytes of FILLER that precedes each row of data sent or received. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side. This option is not available if the length specifier option to include or exclude itself is selected.

⚠Caution
The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

User-Defined Types Node

User-Defined Type Name Node

User-Defined Type Member Properties

Use the **User-Defined Type Member** properties page to set array, COBOL, host, design, and recordset properties on user-defined type members.

Array Properties

Use this	To do this
Array Dimensions	User-defined type member array dimensions. The default is **(none)**.
Is Array	User-defined type member is an array. The possible values are: • **True** • **False** (default)
Occurs Depending On	User-defined type member array occurs depending on.

Host Properties

Use this	To do this
HostDataType	User-defined type member host data type.
ErrorHandling	User-defined type member error handling. The possible values are: • **Truncate**. If selected and an error occurs, TI will truncate the value. (default) • **Round**. If selected and an error occurs, TI will round the value. • **Error**. If selected and an error occurs, TI will return an error.
Filler	User-defined type member filler.
FromHost	Indicates the number of bytes of FILLER that follows this data item in the buffers that are received from the server. FILLER ca uses an untranslated gap in the buffer. FILLER is not visible on the Automation side.

ToHost	Indicates the number of bytes of FILLER that follows this data item in buffers that are sent to the server. FILLER causes an untranslated gap in the buffer. FILLER is not visible on the Automation side.
Scale	User-defined type member scale.
SignAttribute	User-defined type member sign attribute. The possible values are: • **Trailing**. For signed DISPLAY data type, indicates that the sign is trailing (default). This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). • **Trailing Separate**. For signed DISPLAY data type, indicates that the sign is separate. • **Leading**. For signed DISPLAY data type, indicates that the sign is leading. This option indicates to the TI run-time environment how a signed DISPLAY data type is formatted and affects how data from the host is converted to and from the Automation data type. For signed DISPLAY data type, indicates that the sign is not separate (default). • **Leading Separate**. For signed DISPLAY data type, indicates that the sign is separate.
Size	User-defined type member size.
SOSI	Specifies whether double-byte character set data is expected to begin with a shift-out (SO) and end with a shift-in (SI) character. When this check box is selected, the SO and SI characters are removed from the data when it is received from the host application, and the SO and SI characters are added to the data when it is sent to the host application. In the length of the PIC G, it is not necessary to include the two bytes for the SO and SI characters because the TI run-time environment applies them. The possible values are: • **True** • **False** (default)

StringDelimiting	User-defined type member string delimiting. The possible values are: • **Space-padded**. Tells the TI run-time environment that the mainframe representation of the string is delimited by padding the string definition with space characters. For example, if the mainframe's COBOL definition is PIC X(10) but only three characters are in the string, the mainframe expects seven trailing spaces. Therefore, selecting this option tells the TI run-time environment to convert strings being sent to the mainframe to change the string's NULL termination character to the appropriate number of trailing spaces before sending it to the mainframe. For example, if the string is defined on the mainframe as PIC X(10), TI will send a string of *ABC* followed by seven trailing spaces. Selecting this option also tells the TI run-time environment to convert the output string being returned from the mainframe to the TI Automation server by converting the string's trailing spaces to a single null termination character. For more information, see Padding Mainframe Character Strings with Spaces. • **Null-terminated**. Tells the TI run-time environment that the mainframe representation of the string is delimited by a null character (EBCDIC 0x00). Selecting this option tells the TI run-time environment to add a single null character to the end of a string if there is room for the byte before sending a string to the mainframe, and it tells the TI run-time environment to stop at the first null character encountered when receiving a string from the mainframe. Therefore, by selecting this option, you are telling TI to retain trailing spaces in output strings coming from the mainframe because TI will not convert the trailing spaces to a single NULL terminator. For more information, see Padding Mainframe Character Strings with Spaces.

Design Properties

Use this	To do this
Data Type	User-defined type member data type. The data type of the currently displayed user-defined type member. The possible values are: • **Void** • **Boolean** • **Byte** • **Date** • **Currency** • **Decimal** • **Integer** • **Long** • **Double** • **Single** • **String** • **User-defined type** • **Recordset**

Name	Name of the user-defined type member. The name can be a maximum of 250 Unicode characters. The name must be unique from any other user-defined type member name in the same project. The default is **null**.

Recordset Properties

Use this	To do this
Include Actual Size	Default option indicating that the host program will not include or expect any information that indicates the actual number of rows (recordsets) or elements (arrays) being sent or received. The possible values are: • **True** • **False** (default)
Maximum Occurrence	Maximum row occurrence. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item.
Occurs Depending On	User-defined type member recordset occurs depending on. Indicates the maximum number of rows to be sent to or received from the host. Equivalent to the OCCURS n TIMES keyword on a COBOL group item. Equivalent to variable-length tables in COBOL. Indicates that a numeric data item preceding the table (recordset or array in Automation) indicates the actual number of rows or elements being sent or received. Use the drop-down list to select which numeric data item specifies this value. For CICS Link, the recordset or array and the associated length specifier must be in/out. The data in the buffer that follows a variable length table immediately follows the last data item in the table regardless of the maximum size specified for the table. For arrays with multiple dimensions, it can only be used for the outermost loop (COBOL) or rightmost dimension (Visual C++ or Visual Basic).
Unbounded	Indicates that any number of rows can be sent to or received from the host. Set to **true** when the rows being sent or received are from a database and the maximum number of rows is not known. The possible values are: • **True** • **False** (default)

⚠Caution

The properties of a component are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the component to function incorrectly.

Map Remote Environment Class Dialog Box

Use the **Map Remote Environment Class** dialog box to update the definition of a remote environment (RE) class that is no longer supported or does not conform to Transaction Integrator (TI) requirements.

Use this	To do this
Remote environment class	Type or select the COM type library or .NET assembly class of the remote environment.
Vendor	Select the name of the vendor supplying the remote environment.
Protocol	Select the data communication protocol to be used to connect to the remote environment. The available communication protocols are: • **TCP/IP** (default) • **LU 6.2**
Target environment	Select the application environment running on the remote host system. The available environments are: • **CICS** (default) • **IMS** • **OS400** (TCP only)
Programming model	Select the programming model associated with the remote environment. The available models for the TCP/IP CICS target environment are: • **TRM User Data** (default) • **TRM Link** • **ELM User Data** • **ELM Link** The available models for the LU 6.2 CICS target environment are: • **CICS User Data** • **CICS Link** • The available models for the TCP/IP IMS target environment are: • **IMS Connect** • **Implicit** • **Explicit** • The only available model for the LU 6.2 IMS target environment is **IMS User Data**. The only available model for the OS400 target environment is **Distributed Program Call**.

Select Convert Prim Dialog Box

Use the **Select Convert Prim** dialog box to provide a Convert PrimEx class that is missing from your server library.

Use this	To do this
Convert prim class	Select the conversion class to use with the host environment (HE). The available classes are: • **Transaction Integrator - ConvertPrim for OS390** (default) • **Transaction Integrator - ConvertPrim for AS400**

Host Integration Server Designer UI

Host Integration Server Designer (HIS Designer) is a graphical user interface for creating Transaction Integrator (TI) components, which are annotated type libraries or assemblies. You can use HIS Designer to export or import the COBOL data declarations used in mainframe CICS and IMS programs. HIS Designer is a standalone program that does not need to have connectivity to the mainframe.

HIS Designer is hosted within the Visual Studio environment. You can use it to generate both Windows-initiated processing (WIP) and host-initiated processing (HIP) objects. It also supports COM type libraries and Microsoft .NET Framework assemblies.

Getting Started with TI

Solution Explorer

Visual Studio Solution Explorer provides an organized view of projects and their files, in addition to access to available commands and toolbars. The following files are supported by the project:

- COM Client-Initiated libraries, which are annotated COM type libraries (.tlb).
- .NET Client-Initiated libraries, which are Microsoft .NET Framework assemblies with embedded annotated COM type library.
- Host-Initiated libraries, which are annotated COM type libraries (.tim).

To open Solution Explorer

- On the **View** menu, click **Solution Explorer**.

Host Integration Server Designer UI

Add New Item Dialog Box (Visual Studio)

The Add New Item dialog box enables you to add an item to the currently selected project. There are two panes in the dialog box:

- The **Categories** pane lists the project item hierarchy.
- The **Templates** pane lists the related project item types.

When you select an item from the **Categories** list, the appropriate files and references are added to your project. The type of project selected determines the item choices that are displayed. The project items created for Transaction Integrator include the following:

- COM Server Library, which is an annotated COM type library that you must implement separately, and the implemented object, which can be invoked from an IBM host.
- COM Client Library, which is a COMTI classic type library that can call host applications.
- .NET Server Library, which is an assembly with an embedded COM Server library. It is a managed version of the COM Server library.
- .NET Client Library, which is an assembly with an embedded COM Client library. It is a managed version of the COM client library.

To add a new item

1. On the **Project** menu, click the type of library (COM client, COM Server, .NET Client, or .NET Server) you want to add.
2. On the **Add New Item** dialog box, confirm that the correct template is highlighted.
3. Next to **Name**, type the name that you want to use for the library.
4. Click **Add**, and follow the directions for the relevant Wizard.

Host Integration Server Designer UI

New COM Client Library Wizard

The **New COM Client Library Wizard** is a two-page wizard. The first page of the wizard collects library information, and the second page collects remote environment information. There is a **Welcome** page and a **Finish** page that displays summary information.

The generated client component is either an annotated COM type library (.tlb) or a Microsoft .NET Framework assembly with the annotated type library embedded in it as resources; it depends on the platform that you select in the Add New Item Dialog Box (Visual Studio).

When the file is created, it is added to the project and displayed in Solution Explorer.

Concepts

Host Integration Server Designer UI

New COM or .NET Server Library Wizard

Like the **New COM or .NET Client Library Wizard**, this wizard is a two-page wizard. The first page collects library information, and the second page collects host environment information. In addition, there is a **Welcome** page, and a **Finish** page that displays summary information.

The generated client component is either an annotated COM type library (.tlb) or a Microsoft .NET Framework assembly with the annotated type library embedded in it as resources; it depends on the platform that you selected in the Add New Item Dialog Box (Visual Studio). When the file is created, it is added to the project and displayed in Solution Explorer.

Host Integration Server Designer UI

Import Library Wizard

The **Import Library Wizard** enables you to import an existing library, whether it is annotated or not, to the existing component. The methods, recordsets, user-defined types, and unions from the imported library are inserted under the library in the Host Integration Server (HIS) designer.

You can start this wizard by selecting **Import Library** on the **Library** top-level menu. This wizard does not have welcome and finish page because it only selects a file to import. It is a single page dialog box, which is the standard Open File dialog box.

See Also

Concepts

Host Integration Server Designer UI

Welcome to the Import COBOL Wizard

The **Import COBOL Wizard** enables you to select a COBOL copy book and use it for designing the component in the designer. You can start this wizard by selecting **Import COBOL** on the **Library** top-level menu.

This is a rather complex wizard because there are multiple options and paths to follow. It is a multiple-page wizard that contains **Welcome** and **Finish** pages.

See Also
Concepts
Host Integration Server Designer UI

Export Wizard

The **Export Wizard** is used in exporting an equivalent COBOL definition for the current component. It is not really a wizard because it does not contain any pages, such as a welcome or finish page. You can start this wizard by selecting **Export** on the **Library** top-level menu. When you select the menu item, a text window opens under Visual Studio .NET, and the COBOL is displayed in it. You can then save it, discard it, or add it to the project.

Host Integration Server Designer UI

HIS Designer Options

You can select the initial view to display when the Host Integration Server Designer (HIS Designer) starts. You can modify this option through the standard **Options** dialog box in Visual Studio, which is extended to support the functionality of the HIS Designer. You can open this dialog box by clicking **Options** on the **Tools** menu in Visual Studio.

Host Integration Server Designer UI

HIS Designer Views

The Host Integration Server Designer (HIS Designer) development tool uses a two-pane user interface. The left pane displays a tree view, and the right pane displays a list view, or **Details** view. The tree view displays a hierarchical representation of the contents of the library. The list view displays a compact subset of the selected type library component's properties that are displayed in the property browser. You might find it useful to customize the details view by using something other than a list. For example, a COBOL, RPG, or IDL view might be more useful.

Tree View

The tree view displays a hierarchical view of the components in a type library or Microsoft .NET Framework assembly.

The tree view contains the following elements:

Type Library

- Methods
    - Method1
    - Parameter1
    - Parameter2
    - ...
    - Parameter(n)
    - Method2
    - ...
    - Method(n)
- Recordsets (Data tables for .NET Framework libraries)
    - Recordset1
    - Recordset Member1
    - Recordset Member2
    - ...
    - Recordset Member(n)
    - Recordset2
    - ...
    - Recordset(n)
- User-Defined types (Structures for .NET Framework libraries)
    - UDT1
    - UDT Member1

        - UDT Member2
        - ...
        - UDT Member(n)
        - UDT2
        - ...
        - UDT(n)
- Unions
        - Union1
        - Union Member1
        - Union Member2.
        - ...
        - Member(n)
        - Union2
        - ...
        - Union(n)

Details View

The details view displays context-sensitive information about the item that is selected in the tree view. The details view displays a subset of the properties of that type library component. These properties are displayed in columns labeled in a context-sensitive manner.

The detail views include the following:

- Interface view
- Method view
- Parameter view
- Recordsets view
- Recordset view
- Recordset column view
- User-defined types view
- User-defined type view
- User-defined type member view

- Unions view
- Union view
- Union member view

Host Integration Server Designer UI

HIS Designer Main Menu

The main menu in Host Integration Server Designer (HIS Designer) presents two tabs, **Edit** and **Library**, which contain individual commands.

Edit Tab

The following commands appear on the **Edit** tab of the main menu:

Undo: Undo the last operation.

Redo: Redo the last undo operation.

Cut: Cut the selected item.

Copy: Copy the selected item.

Paste: Paste the copied item to the selected one.

Rename: Rename the selected item.

Delete: Delete the selected item.

Select All: Select all items.

Find and Replace: Find and replace the specified text.

Move Up: Move a parameter up in the list.

Move Down: Move a parameter down in the list.

Library Tab

The following commands appear on the **Library** tab of the main menu:

Add Method: Add a new method with an integer return type.

Add Parameter: Add a new In\Out integer parameter to the selected method. This command is only visible if the current selection in the tree view or the details view is a method.

Add Recordset: Add a new recordset with an integer column.

Add Recordset Column: Add a new integer recordset column to the selected recordset. This command is only visible if the current selection in the tree view or the details view is a recordset.

Add User-Defined Type: Add a new user-defined type with an integer member.

Add Union: Add a new union with two integer members.

Add Union Member: Add a new integer union member.

Add User-Defined Type Member: Add a new integer user-defined member to the selected user-defined type. This command is only visible if the current selection in the tree view or the details view is a user-defined type.

Import Host Definition: Invoke the Import COBOL Wizard, which enables you to import COBOL to the interface (Class) definition.

Import Library: Invoke the Library Import Wizard, which enables you to import an existing type library or assembly to the interface (Class) definition.

Export Host Definition: Invoke the Export Wizard, which enables you to generate a COBOL copy book equivalent to the current library.

Definition: Display the definition of the current library in a new Visual Studio default editor window. With COM libraries, you can display the IDL definition, and with .NET Framework assemblies, you can display the Cdefinition. When the definition is available in Visual Studio, all standard file operations can be applied to it (for example, **Save**, **Save As**, and so on).

Host Data Definition:

HIS Designer Menus

HIS Designer Shortcut Menus

Host Integration Server Designer (HIS Designer) has two types of context-sensitive, or shortcut menus. The first type is context-sensitive to the HIS Designer files in Visual Studio Solution Explorer. The second type is context-sensitive in the HIS Designer itself.

Shortcut menus do not have context-sensitive Help available when you use them. Therefore, the topics in this section describe the functionality of each menu and each command.

In This Section

Solution Explorer Shortcut Menu

When you select a Transaction Integrator-compatible file in Solution Explorer, the appropriate context-sensitive, or shortcut menu commands are displayed.

Add: Adds a new item to the project.

Method: Adds a new method with an integer return type.

Parameter:

Recordset: Adds a new recordset with an integer column.

Recordset Member:

User-defined Type: Adds a new user-defined type with an integer member.

User-defined Type Member:

Import: Imports an existing item into the project.

COBOL: Starts the **Import COBOL Wizard** to help you import COBOL to the interface (Class) definition.

Library: Starts the **Library Import Wizard** to help you import an existing type library or assembly to the interface (Class) definition.

Export: Starts the **Export Wizard** to help you generate a COBOL copy book equivalent to the current type library.

Generate Definition: Displays the definition of the current library. For COM libraries, it displays the IDL definition; for .NET Framework assemblies, it displays the C# definition.

Library Shortcut Menu

When you select the **Library** node in the tree view of HIS Designer, the following shortcut menu commands appear.

Import: Displays the following commands:

Host Definition: Starts the **Import COBOL Wizard** to help you import COBOL to the interface (Class) definition.

HCD: Imports a Host Column descriptor. Usable only with a Host File Project.

Library: Starts the Library Import Wizard to help you import an existing type library or assembly to the interface (Class) definition.

Export: Starts the **Export Wizard** to help you generate a COBOL copy book equivalent to the current library.

Lock: Marks the library as read-only. The library is automatically marked as locked if it is registered in a COM+ application, IIS Virtual Directory, or is being used by a host-initiated processing (HIP) application.

Deploy: Deploys the library.

Undeploy: Undeploys the library.

Cut: Copies the content of the library to the clipboard and marks it as deleted.

Copy: Copies the content of the library to the clipboard.

Paste: Inserts the contents of the clipboard into the current library definition.

Delete: Deletes the current library.

Rename: Renames the library.

Properties: Displays the property browser (if it is not already visible) and displays the library properties.

HIS Designer Shortcut Menus

Importing RPG

The Report Program Generator (RPG) is oriented to programs written for use by distributed program call (DPC). The expectation is that the RPG source contains an ***ENTRY PLIST** operation statement. This statement leads the importer down the path of explicitly understanding the exact parameter names. This eliminates the picking and choosing of data areas found in the **Import COBOL Wizard**.

This implies that the RPG Importer is simple to use. It also implies that the RPG Importer is not designed to be used for raw TCP and raw SNA programming models. The assumptions are as follows:

- RPG DPC is the most likely programming model that will be used.
- For those situations where raw TCP or SNA is required, you can still create RPG definitions through basic HIS Designer functionality (not the Import Wizard)

Discriminant Value Table Dialog Box

Use the **Discriminant Value Table** dialog box to create the logic for determining which union member returns information to the calling procedure. You can open the **Discriminant Value Table** dialog box by viewing the properties of an instanced union member, clicking **DVT**, and then clicking the ellipsis (**...**) button.

Use this	To do this
Discriminant Variable	List the name of the selected union.
Discriminant type	List the data type that the union will use to create the logic.
Discriminant Value Table	Create the Discriminant Value Table. The **Union Member** column lists the union members that will be checked, in order. The **Condition** column describes what to check for in order to use that member.
Move Up	Move a union member and associated condition up in priority.
Move Down	Move a union member and associated condition down in priority.
Delete	Delete a union member and associated condition from the DVT. It does not delete the member from the union. You may add the union member back into the DVT at any time.
OK	Save the additions you make to the DVT, and close the dialog box.
Cancel	Close the dialog box without saving the changes you made to the DVT.

Host Integration Server Designer UI

Host File Designer UI

Host File Designer is a graphical user interface for creating Host File components, which are annotated type libraries or assemblies. As with Host Integration Server (HIS) Designer, you can use Host File Designer export or import the COBOL data declarations used in mainframe CICS and IMS programs. Host File Designer is a standalone program that does not need to have connectivity to the mainframe.

Host File Designer is hosted within the Visual Studio environment. You can use it to generate both Windows-initiated processing (WIP) and host-initiated processing (HIP) objects.

Add New Item Dialog Box (Host File Designer)

The Add New Item dialog box enables you to add a host file object the currently selected project. There are two panes in the dialog box:

- The **Categories** pane lists the project item hierarchy.

  For Host File Designer, the only item in this pane is **Host Integration Project Items**.

- The **Templates** pane lists the related project item types.

  For Host File Designer, the only usable item in this pane is **Host Files Library**. A host files library is a .NET assembly that describes the host file system to your application.

To add a new item

1. On the **Project** menu, click **Add Host File Library** or **Add New Item...**.

   For the purposes of a Host File Designer project, you can add only a Host File Library.

2. On the **Add New Item** dialog box, confirm that **Host File Library** is highlighted.

3. Next to **Name**, type the name that you want to use for the library.

4. Click **Add**, and follow the directions for the relevant Wizard.

Host File Designer UI

Host File Designer Views

The Host File Designer development tool uses a two-pane user interface. The left pane displays a tree view, and the right pane displays a list view, or **Details** view. The tree view displays a hierarchical representation of the contents of the library. The list view displays a compact subset of the selected type library component's properties that are displayed in the property browser. You might find it useful to customize the details view by using something other than a list. For example, a COBOL, RPG, or IDL view might be more useful.

Tree View

The tree view displays a hierarchical view of the components in a type library, also known as a metadata assembly.

The tree view contains the following elements:

Library

- Tables
    - Table1
    - Table Member1
    - Table Member2
    - ...
    - Table Member(n)
    - Table2
    - ...
    - Table(n)
- Schemas
    - Schema1
    - Schema Member1
    - Schema Member2
    - ...
    - Schema Member(n)
    - Schema2
    - ...
    - Schema(n)
- Unions
    - Union1
    - Union Member1

- Union Member2.
- ...
- Member(n)
- Union2
- ...
- Union(n)

Details View

The details view displays information about the item that is selected in the tree view. The Details view consists of three tabs, each describing the information in the Tree view in a different fashion.

List Tab

The List tab displays a subset of the properties of the selected type library component.

The detail views include the following:

- Tables view
- Table Member view
- Schemas view
- Schema view
- Unions view
- Union view
- Union member view

Definition Tab

The Definition tab displays the type library as a .NET interface.

HCD Tab

The HCD tab displays the host column description associated with the type library.

Solution Explorer Shortcut Menu (Host File Designer)

When you select a Transaction Integrator-compatible file in Solution Explorer, the appropriate context-sensitive, or shortcut menu commands are displayed.

Add: Adds a new item to the project.

Add Host File Library: Brings up the Add New Item dialog.

New Item...:Adds a new item to the project.

Existing Item...: Adds an existing item to the project.

Cut: Cuts the current object to the clipboard and marks the object for deletion.

Paste: Pastes the object currently in the clipboard to the current location.

Open: Opens the selected object using Visual Studio

Open With: Opens the selected object with the specified application.

Remove: Removes the selected object from the Solution.

Rename: Renames the selected object.

Properties: Displays the property browser (if it is not already visible) and displays the selected object properties.

Library Shortcut Menu (Host File Designer)

When you select the **Library** node in the tree view of Host File Designer, the following shortcut menu commands appear.

Import: Displays the following commands:

Host Definition: Starts the **Import COBOL Wizard** to help you import COBOL to the interface (Class) definition.

HCD: Imports a Host Column descriptor.

Library: Starts the Library Import Wizard to help you import an existing type library or assembly to the interface (Class) definition.

Export HCD: Starts the **Export Wizard** to help you generate a COBOL copy book equivalent to the current library.

Cut: Visible but not available.

Copy: Visible but not available.

Paste: Visible but not available.

Delete: Deletes the current library.

Rename: Renames the library.

Properties: Displays the property browser (if it is not already visible) and displays the library properties.

Transaction Integrator Manager Help

Transaction Integrator (TI) Manager provides a graphical user interface for creating, viewing, and managing the host-initiated processing (HIP) and Windows-initiated processing (WIP) environments. The user interface is accessible through the TI Manager management console and appears in tree view, property pages, and wizards. You can display Help topics on the individual user interface controls by clicking **Help** on the TI Manager wizard page or dialog box or by selecting a control or node and pressing the **F1** key. These individual Help topics are included in this section for easier reference and review.

In This Section

- TI Manager Nodes
- TI Manager Wizards and Dialog Boxes
- TI Manager Properties

TI Manager Nodes

The Transaction Integrator (TI) Manager console provides a tree view of the primary configuration elements used in host-initiated processing (HIP) and Windows-initiated processing (WIP). HIP enables an IBM mainframe program in CICS, IMS, or MVS to call a COM or .NET object. WIP enables a Windows client application to access an IBM mainframe transaction program in CICS, IMS, or MVS.

Each major element of the process is represented by a node on the tree in the left pane of the management console. Double-clicking the node expands it; right-clicking the node displays a shortcut menu.

In This Section

Transaction Integrator (mode) Node

Use the **Transaction Integrator** (TI) node to view the basic grouping of elements within the host-initiated processing (HIP) environment and the Windows-initiated processing (WIP) environment. You can also use the **Transaction Integrator** (TI) node to control the operating mode of the TI Manager console.

All computers that have TI installed are able to share the same physical SQL Server configuration database, and TI Manager allows you to edit the configuration of any computer registered in that database from any TI-enabled computer. In HIP, an administrator could edit database entries such as the host environments, objects, or views that are shared among computers. In WIP, an administrator can only edit local WIP settings.

Although multiple system administrators using the TI Manager console can concurrently view, start, or stop any application and listener on any TI-enabled computer registered in the configuration database, only one authorized administrator at a time can create or edit the configuration of the TI database.

As long as the TI Manager is not locked, the administrator can create or edit the following items on any TI-enabled computer:

- Applications
- Listeners on an application
- Local environments
- Host environments
- Security policies
- HIP objects
- Object views

The administrator can also create or edit remote environments and WIP objects on the local computer, and can start, stop, or refresh applications and listeners.

Host-Initiated Processing Node

Use the **Host-Initiated Processing** node to view the major elements used in host-initiated processing (HIP) environment. The major HIP elements are:

- Computers that have the HIP run-time environment installed. The run-time environment is responsible for accepting incoming requests, instantiating a Microsoft Windows® server object, and returning a reply to the host program that initiated the request.
- Local environments (LEs) that a HIP runtime uses to listen for incoming requests. The LE definitions contain network-transport specific endpoint identification.
- Host environments (HEs) that represent the non-Windows host computers or host environments that deliver requests to a HIP run-time environment. The HE is used by the HIP runtime to define the code page and the data conversion object to be used by the HIP runtime when communicating with the host system identified by the HE.
- Security policies that define how Windows security credentials are established before the server object is invoked.
- Objects that represent the metadata for the server objects that were created through Microsoft Visual Studio®.
- Views define the resolution criteria used by TI when directing the call made from a host environment to a server object. Views restrict access to object methods based on the host environment calling the object and the local environment receiving the call.

Double-click the **Host-Initiated Processing** node to expand the node. The right pane displays the following information about the node:

- **Name**. The name of the major HIP elements.

Right-click the **Host-Initiated Processing** node to display the following five options:

- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of elements as a separate text or Unicode text file.
- **Properties**. Displays the **Host-Initiated Processing Properties** dialog box and one tabbed property page:
    - **Database**. Displays the name of the database.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you

can take.

Host Environments Node
Security Policies Node
Objects Node (HIP)

Computers Node

Use the **Computers** node to view all the computers that have Transaction Integrator (TI) installed on them and are referenced in the same TI Manager configuration database (MSHIS60_HIP).

Note
If the computer you are looking for does not appear in this list, the computer might be registered in a different configuration database. After you have installed TI, run the **Microsoft Host Integration Server Configuration Wizard** and configure the new computer to use the same Transaction Integrator configuration database as the other computers. You can select the sam e configuration database by changing the **Server** and **Database** settings on the **Database Configurations** wizard page.

Double-click the **Computers** node to expand the node. The right pane displays the following information about the node:

- **Computer**. Displays the name of the HIP-enabled computer.

Right-click the **Computers** node to display the following four options:

- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of computers as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Computer Node

Computer Node

Use the **Computer** node to view and manage the applications running on the computer that is selected in the left pane. An application represents the execution environment for Windows server objects that are initiated by, or driven from, requests from the host computer.

Double-click the **Computer** node to expand the **Computer** node. The right pane displays the following information about the application:

- **Application**. Displays the name of the application.
- **PID**. Displays the process ID of the HIPService. **0** indicates that HIPService is not running.
- **Thread Count**. Displays the minimum number of worker threads the runtime always has active.
- **Maximum Queue Depth**. Displays the maximum number of requests that are stored in the queue waiting to be processed before new requests are rejected.
- **Comment**. Displays additional information about the application.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

   The columns should now be in their original order.

Right-click the **Computer** node to display the following five options:

- **New**.Displays the following menu items:
  - **Empty Application**. Launches the **New Application** dialog box, which allows you to define an application that does not have executable objects associated with it.
  - **Configured Application**. Launches the **New Application Deployment Wizard**, which walks you through the steps of creating the application, local environment, host environment, and objects.
- **View**. Displays the following menu items:
  - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
  - **Large Icons**. Displays large icons for items in the right pane.
  - **Small Icons**. Displays small icons for items in the right pane.

- **List**. Displays only the small icons and the names of the nodes in the right pane.
- **Detail**. Displays the small icons and the properties of the nodes in the right pane.
- **Customize**. Allows you to change the options to show or hide items displayed in the right pane.

- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of applications as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Application

Application

Use the ***application*** **[*status*]** node to start or stop an application or to manage the listeners for an application. An application represents the execution environment for Windows server objects that are initiated by, or driven from, requests from the host computer. An application can host more than one server object and can have more than one listening endpoint associated with it.

The term shown in brackets at the end of the node indicates status of the application:

- **Stopped**. The execution environment and Windows Server 2003 service for the application and its objects are inactive.
- **Incomplete**. The application is missing one or more objects and, therefore, is not available.
- **Starting**. TI Manager is starting the execution environment and Windows Server 2003 service for the application and its objects.
- **Active**. The execution environment for the application is running and the listeners and local environments are active.

Double-click the ***applications*** **[*status*]** node to expand the node. The right pane displays the following information about the listeners:

- **Listener**.The name of the listener.
- **Type**. The type of network (either TCP/IP or SNA).
- **Listening Address**. For a TCP/IP network, the local host. For an SNA network, the local LU defined in the local environment.
- **Endpoints**. The endpoints used to communicate with the host.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** c ommand on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manag er. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column hea dings are in the their default order.

Note
If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the **Application** node to view the following 12 options:

- **Tracing**. Launches the ***application*** **Trace Options** dialog box. You can select one or more of the following categories for tracing and select one or more options within a category:

    - **General**. Provides high-level information about the end-to-end application processing.
    - **Transport**. Provides detailed connection information about the activities on the SNA or TCP network.
    - **Convert**. Provides detailed information about the data conversion between COM and .NET data on the servers and COBOL or Report Program Generator (RPG) data on the host.
    - **Read Lib**. Provides information about the contents of the type library; used to augment the information in the **Convert** trace.
    - **Flow Control Proxy**. Provides detailed information about object instantiation, state transitions, and method invocation.
- **Reload Definitions**. Performs a dynamic refresh of the application listener's endpoints and resolution tables. An application gets a snapshot of the configuration database at start-up. Any subsequent changes to the configuration do not affect the application until the definitions are reloaded. When you select **Reload Definitions**, the application re-reads all configuration information from the configuration database and applies it immediately. All new requests are processed using the updated resolution information. Working requests that were in progress at the time **Reload Definitions** was clicked are not affected by the update. The resolution information remains unchanged until the work request is completely processed.
- **Start**. Starts the host-initiated processing (HIP) environment for the selected application. Any listeners available for auto-start, as defined on the application property page of a listener that is associated with the application, are started when the application is started. After the application is started, **Start** is disabled and **Stop** is enabled.
- **Stop**. Stops the HIP environment for the selected application. All listeners are stopped when the application is stopped. All pending work is halted immediately and all listening activity is terminated immediately. After the application is stopped, **Stop** is disabled and **Start** is enabled.
- **New**. Displays a list of the following menu items:
    - **Listener**. Launches the **Local Environment** dialog box for you to define a new listening point.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Delete**. Deletes the application from the computer. You can delete an application if it is stopped. The deleted item is removed from the specific computer it was defined on and from the configuration database.
- **Rename**. Renames the selected application. The new name is reflected across all elements of the HIP console.
- **Refresh**. Redraws the screen to show any updates.

- **Export List**. Allows you to save the list of applications as a separate text or Unicode text file.
- **Properties**. Displays the ***application*** **Properties** dialog box and three tabbed property pages:
    - **General**
    - **Advanced**
    - **.NET assembly path**

  Use the property pages to view or change the properties of the application.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Listener

Use the ***listener* [*status*]** node to start or stop a listener and to determine what views are associated with the listener.

The term shown in brackets at the end of the node indicates status of the listener:

- **Stopped**. The execution environment and Windows Server 2003 service for the listener and its views are inactive.
- **Incomplete**. The listener is missing one or more views or determinants and, therefore, is not available.
- **Unavailable**. The listener was defined after the application was started.
- **Starting**. TI Manager is starting the execution environment and Windows Server 2003 service for the application and its objects.
- **Active**. The execution environment for the application is running and the listeners and local environments are active.

Double-click the ***listener* [*status*]** node to expand the node. The right pane displays the following information about the listener:

- **View**. The name of the view.
- **LE Name**. The name of the local environment.
- **Method Count**. The number of methods.
- **HE Count**. The number of host environments.
- **Comment**. Additional information about the listener.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** c ommand on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manag er. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column hea dings are in the their default order.

Note
If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the ***listener* [*status*]** node to display the following 10 options:

- **Start**. Starts the host-initiated processing (HIP) service listening on all endpoints defined for the local environment. The HIP application is then ready to receive incoming host requests and to execute methods in accordance with the method

resolution criteria. After the listener is started, **Start** is disabled and **Stop** is enabled. After the listener is started, **[started]** appears to the right of the local environment name in the left pane.

- **Stop**.Stops the HIP service listening on all endpoints defined for the local environment. The HIP application no longer accepts, rejects, services, or queues incoming host requests. After the listener is stopped, **Stop** is disabled and **Start** is enabled. After the listener is stopped, **[stopped]** appears to the right of the local environment name in the left pane.

- **Pause**. Temporarily suspends the HIP service listening on all endpoints defined for the local environment. The application continues to execute work in progress and work items queued for execution, but it no longer accepts or queues incoming requests. A number of requests are queued internally by the low-level network transport components (for example, for TCP, Windows XP stores up to 5 requests while Microsoft Windows Server™ 2003 stores up to 200 requests by default). After the listener is resumed, the pending requests are delivered to the listener. Depending on the number of the processing queue entries available, some of these requests might be finally rejected by the listener. After the listener is paused, **Pause** is disabled, **Resume** is enabled, and **[paused]** appears to the right of the local environment name in the left pane.

- **Resume**. Starts the HIP service listening again on all endpoints defined for the local environment. The HIP application is then ready to receive incoming host requests and to execute methods as defined by the method resolution criteria. After the listener resumes, **Resume** is disabled, **Pause** is enabled, and **[started]** appears to the right of the local environment name in the left pane.

- **View**. Displays the following menu items:

    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.

    - **Large Icons**. Displays large icons for items in the right pane.

    - **Small Icons**. Displays small icons for items in the right pane.

    - **List**. Displays only the small icons and the names of the nodes in the right pane.

    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.

    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.

- **Delete**. Deletes the application from the computer. You can delete an application if it is stopped. The deleted item is removed from the specific computer it was defined on and from the administrative data store.

- **Refresh**. Redraws the screen to show any updates.

- **Export List**. Allows you to save the list of views as a separate text or Unicode text file.

- **Properties**. Displays the ***listener*** **Properties** dialog box and three tabbed property pages:

    - **General**

    - **Endpoints**

    - **Application**

Note
When viewed from this node, the general and endpoint property pages are read-only. If you want to change a general or end point property, right-click the specific ***local environment*** **Node** under the **Local Environments Node**, and then left-click **P roperties** on the shortcut menu.

- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

View Node (listener)

Use the ***view*** node to determine what methods and host environments are associated with the view.

Double-click the ***view***node to expand the node. The right pane displays either the host environments (HE) associated with the object view or the methods on the view, depending on the choice you select on the shortcut menu.

Right-click the ***view*** node to display the following six options:

- **List**.Displays the following menu items:

    - **HE Associations**.The host environments associated with the view on the application.

    - **Methods**.The methods associated with the view.

    A view can have one or more host environments and one or more methods associated with it. To accommodate listing all the properties of a view, this shortcut menu item allows you to select the properties to be visible in the list view.

- **View**. Displays the following menu items:

    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.

    - **Large Icons**. Displays large icons for items in the right pane.

    - **Small Icons**. Displays small icons for items in the right pane.

    - **List**. Displays only the small icons and the names of the nodes in the right pane.

    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.

    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.

- **Refresh**. Redraws the screen to show any updates.

- **Export List**. Allows you to save the list of views as a separate text or Unicode text file.

- **Properties**. Displays the ***view*** **Properties** dialog box and three tabbed property pages:

    - **General**

    - **Host environments**

    - **Methods**

Note
When viewed from this node, the property pages are read-only. If you want to change a property, right-click the ***view*** **Node** under the ***object*** **Node**, and then left-click **Properties** on the shortcut menu. The properties viewed on those pages can be c hanged.

- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Local Environments Node

Use the **Local Environments** node to manage local environments. A local environment defines how a remote environment contacts the host-initiated processing (HIP) runtime.

Double-click the **Local Environments** node to expand the node. The right pane displays the following information about the local environments:

- **Local Environment**. The name of the local environment.
- **Type**. The type of network used to communicate with the host environment (either TCP/IP or SNA).
- **Transport Class**. The class of the transport object.
- **Endpoint Manager**. The IP address of the local host (for a TCP/IP network); the name of the LU alias (for an SNA network).
- **Endpoints**. The endpoints used to communicate with the host.
- **Comment**. Additional information about the local environment.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** c ommand on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manag er. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column hea dings are in the their default order.

Note
If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the **Local Environments** node to view the following five options:

- **New**.Displays the following menu items:
    - **Local environment**. Launches the **New Local Environment Wizard**.
- **View**. Displays the following menu item:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.

- **Small Icons**. Displays small icons for items in the right pane.
- **List**. Displays only the small icons and the names of the nodes in the right pane.
- **Detail**. Displays the small icons and the properties of the nodes in the right pane.
- **Customize**. Allows you to change the options to show or hide items displayed in the right pane.

- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of local environments as a separate text or Unicode text file.

Host Environments Node

Use the **Host Environments** node to manage host environments. The host environment defines which host environments can contact the HIP runtime.

Double-click the **Host Environments** node to expand the node. The right pane displays the following information about the node:

- **Host Environment**.The names of the host environments.
- **Type**. The type of network used to communicate with the host environment (either TCP/IP or SNA).
- **Data Conversion**. The data conversion routine used.
- **Send Time-out**. The number of seconds the servicing HIP application waits before it terminates the request if the expected data is not received.
- **Receive Time-out**. The number of seconds the servicing HIP application waits before it terminates the receive function if the expected data is not received.
- **Code Page**. The number of the code page used to transform the incoming and outgoing data to a form that can be used by the host application program to represent the character data.
- **Remote Endpoint Manager**. The IP address of the host or the host name registered in the DNS (for a TCP/IP network); the LU name associated with the host system (for an SNA network).
- **Comment**. Additional information about the host environment.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** c ommand on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manag er. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column hea dings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the **Host Environments** node to view the following five options:

- **New**.Displays the following menu item:
    - **Host environment**. Launches the **New Host Environment Wizard**.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display

each property as a separate column in the right pane.

- **Large Icons**. Displays large icons for items in the right pane.
- **Small Icons**. Displays small icons for items in the right pane.
- **List**. Displays only the small icons and the names of the nodes in the right pane.
- **Detail**. Displays the small icons and the properties of the nodes in the right pane.
- **Customize**. Allows you to change the options to show or hide items displayed in the right pane.

- **Refresh**. Redraws the screen to show any updates.

Objects Node (HIP)

Use the **Objects** node to view and manage COM and .NET Framework objects accessible from a host. Objects contain the metadata definitions for the server objects created as TI Projects in Visual Studio.

Double-click the **Objects** node to expand the node. The right pane displays the following information about the node:

- **Object**. The name of the object entry. The default name is the ProgID (for COM) or Namespace.Interface (for .NET), but you can change the name on the *object* context menu.
- **Type**. The type of object.
- **Component**. The programming identifier of the COM object or the interface name of the .Net object.
- **Method Count**. The number of methods on the object.
- **Comment**. Additional information about the object.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click on **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the **Objects** node to display the following five options:

- **New**.Displays the following menu item:
    - **Object**. Launches the **HIP Object Wizard**.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.

    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.

- **Refresh**. Redraws the screen to show any updates.

Object Node (HIP)

Object Node (HIP)

Use the ***object*** node to create and manage object views. An object view is a representation of the server object itself. A view can include one or more methods of an object, and not all methods have to be defined in a view. You can define one or more views for an object, which enables you to restrict the methods of an object to specific endpoints and host environment pairs.

Double-click the ***object***node to expand the node. The right pane displays the following information about the view selected in the left pane:

- **View**. The name of the view.
- **LE Name**. The name of the local environment.
- **Security Policy**. The name of the security policy.
- **Method Count**. The number of methods.
- **HE Count**. The number of host environments.
- **Comment**. Additional information about the view.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** c ommand on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manag er. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column hea dings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the ***object***node to display the following six options:

- **New**. Displays the following menu item:
    - **View**. Launches the **New Object View Wizard**.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.

    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of objects as a separate text or Unicode text file.
- **Properties**. Displays the ***object*** **Properties** dialog box and two tabbed property pages:
    - **General**
    - **Methods**

  Use these property pages to view or change the properties of the object.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Host Environment Associations Listing

Use the host environment associations listing to view the host environments associated with the view.

This listing displays the following information about the host environment:

- **Host Environment**.The name of the host environment.
- **Type**. The type of network used to communicate with the host environment (either TCP/IP or SNA).
- **Remote Endpoint Manager**.The IP address of the host or the host name registered in the DNS (for a TCP/IP network); the LU name associated with the host system (for an SNA network).
- **Comment**.Additional information about the host environment.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the host environmentname to display the following four options:

- **Delete**. Deletes the host environment association (not the host environment itself). You can delete the host environment association anytime.
- **Refresh**. Redraws the screen to show any updates.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Methods Listing

Methods Listing

Use the methodslistingto view the properties of the methods on the object view.

This listing displays the following information about the method:

- **Method**. The name of the method.
- **Endpoint**. The endpoint used to communicate with the host.
- **Resolution Type**. The type of conflict to be conducted in case of a conflict.
- **Msg Handler**.
- **Resolution String**.
- **Position**. The starting point in the data stream where the TI runtime looks for the data defined in the resolution data field to determine what method is to be executed.
- **Comment**. Additional information about the view.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** c ommand on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manag er. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column hea dings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the methodname to view the following two options:

- **Refresh** Redraws the screen to show any updates.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

View Node (object)

Windows-Initiated Processing Node

Use the **Windows-Initiated Processing** node to view the major elements used in Windows-initiated processing (WIP) environment. The major WIP elements are:

- Remote environments
- Objects

Double-click the **Windows-Initiated Processing** node to expand the node. The right pane displays the following information about the node:

- **Name**. The name of the major WIP elements.

Right-click the **Windows-Initiated Processing** node to view the following five options:

- **Tracing**. Launches the **Windows-Initiated Processing Trace Options** dialog box. You can select one or more of the following categories for tracing and select one or more options within a category:
    - **General**. Provides high-level information about the end-to-end global processing.
    - **Transport**. Provides detailed connection information about the activities on the SNA or TCP network.
    - **Convert**. Provides detailed information about the data conversion between COM and .NET data on the servers and COBOL or RPG data on the host.
    - **Read Lib**. Provides information about the contents of the type library; used to augment the information in the **Convert** trace.
    - **Proxy**. Provides detailed information about object instantiation, state transitions, and method invocation.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of elements as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Remote Environments Node

Use the **Remote Environments** node to manager remote environments. A remote environment defines the characteristics of the non-Windows host environment that receives requests from Windows-initiated processing (WIP) components.

Double-click the **Remote Environments** node to expand the node. The right pane displays the following information about the node:

- **Remote Environment**. The names of the remote environment.
- **Type**. The type of remote environment.
- **Comment**. Additional information about the remote environment.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the **Remote Environments** node to display the following five options:

- **New**. Displays the following menu items:
    - **Remote Environment**. Launches the **New Remote Environment Wizard**.
    - **Capture RE**.Launches the **New Remote Environment Wizard** to create a remote environment type that captures responses and saves those responses in a recording file. After being saved, the responses can be played back using the playback remote environment.
    - **Playback RE**.Launches the **New Remote Environment Wizard** to create a remote environment type that plays back responses stored in a recording file.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.

    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of remote environments as a separate text or Unicode text file.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

Remote Environment Node

Remote Environment Node

Use the ***remote environment*** node to view and manage a remote environment.

Double-click the ***remote environment*** node to expand the node. The right pane displays the following information about the remote environment selected in the left pane:

- **Component**. The name of the component.
- **Type**.
- **Comment**. Additional information about the remote environment.

Important
If you view the list in the right pane of TI Manager and change the order of the columns using the **Add/Remove Columns** command on the shortcut menu, the order of the column headings might not be correct after you close and re-open TI Manager. The next time you open TI Manager, the values in the columns are displayed in the new order you set, but the column headings are in the their default order.

If you observe that the column headings are no longer in the order you set:

1. Right-click the node, point to **View**, and then click **Add/Remove Columns**.
2. On the **Add/Remove Columns** dialog box, click **Restore Defaults**.
3. Click a different node, then click the node you were just working on.

Note
The columns should now be in their original order.

Right-click the ***remote environment*** node to display the following nine options:

- **Activate**.
- **Deactivate**.
- **View**. Displays the following menu items:
    - **Add/Remove Columns**. Allows you to choose the properties that are displayed in the list view. You can display each property as a separate column in the right pane.
    - **Large Icons**. Displays large icons for items in the right pane.
    - **Small Icons**. Displays small icons for items in the right pane.
    - **List**. Displays only the small icons and the names of the nodes in the right pane.
    - **Detail**. Displays the small icons and the properties of the nodes in the right pane.
    - **Customize**. Allows you to change the options to show or hide items displayed in the right pane.
- **Delete**. Deletes the remote environments selected in the ***remote environments*** node. The deleted item is removed from the ***remote environments*** node and from the administrative data store. If an RE is deleted while it still has objects assigned to it, the objects become unassigned.

- **Rename**. Renames the selected remote environment. The new name is reflected across all the elements of the WIP console.
- **Refresh**. Redraws the screen to show any updates.
- **Export List**. Allows you to save the list of remote environments as a separate text or Unicode text file.
- **Properties**. Displays the ***remote environment*** **Properties** dialog box and several tabbed property pages:
    - **General**
    - **TCP/IP**
    - **LU 6.2**
    - **MQ Series**
    - **Target**
    - **Recording**
    - **Locale**
    - **Security**
    - **CICS**
    - **IMS**

  Use these property pages to view or change the properties of the remote environment.
- **Help**. Displays a Help topic (this topic) that explains the items that appear in the TI Manager console and the actions you can take.

TI Manager Wizards and Dialog Boxes

Transaction Integrator (TI) Manager provides wizards and special dialog boxes to help you complete various tasks.

The following wizards help you with host-initiated processing (HIP).

New Application Dialog Box

Credentials for Service <application name> Dialog Box

New Application Deployment Wizard

Define Implementation Characteristics for the .NET Object Wizard Page

New Local Environment Wizard

New Host Environment Wizard

New Security Policy Wizard

Object Wizard (for HIP)

New Object View Wizard

Local Environment Dialog Box

Reload TIMs Wizard

The following wizards help you with Windows-initiated processing (WIP):

New Remote Environment Wizard

Object Wizard (for WIP)

New Application Dialog Box

Use the **New Application** dialog box to define an application that does not have executable objects associated with it.

Use this	To do this
Computer name	View the name of the computer where the application runs.
Application	Type the name of the application. The name can be a maximum of 25 alpha-numeric characters. The first character in the name must be a letter, and the name cannot contain any embedded spaces.
Comment	Type a comment that provides additional information about the use of the application in the HIP environment. The comment can be a maximum of 259 alpha-numeric characters.

New Application Deployment Wizard

The **New Application Deployment Wizard** helps you add a new application by guiding you through the definitions of the application, local environment, host environment, and objects. The wizard can be used to define additional local environments, host environments, or objects and link them to existing definitions. You can access the Wizard from the shortcut menu on the ***computer*** node in the TI Manager console tree.

In This Section

Welcome to the New Application Deployment Wizard Page

Use the **Welcome to the New Application Deployment Wizard** page to view the definition of an application deployment and to control whether the welcome page is displayed the next time the wizard is used.

Use this	To do this
Do not show this welcome page again.	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Reference

Configure a New Local Environment Wizard Page

Configure a New Local Environment Wizard Page

Use the **Configure a New Local Environment** wizard page to identify the basic characteristics of the new local environment. Select an existing local environment from the dropdown list or type the name of the new local environment. To define its characteristics, select a specific network type and transport class.

Use this	To do this
Local environment	Type the name for the local environment. The name can be a maximum of 259 alpha-numeric characters. The name cannot be the same as that of an existing local environment.
Network type	Select the type of network used to communicate with the host.
Transport class	Select the class of the transport object. The list changes according to the selected **Network type**.
Endpoint manager	For a TCP/IP network, this is always set to the local host and disabled. For an SNA network, type the name of the LU alias. In either case, the name can be a maximum of 259 Unicode characters.

Reference

Configure Local Environment Endpoints (TCP/IP) Wizard Page

Configure Local Environment Endpoints (SNA) Wizard Page

Configure Local Environment Endpoints (TCP/IP) Wizard Page

Use the **Configure Local Environment Endpoints** (TCP/IP)wizard page to define the endpoints used to communicate with the host. To define the TCP/IP ports or service names for the local environment, type a port number or name, and then click **Add**.

Use this	To do this
Local environment	View the name of the local environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
New port or service name	Type the port number or service name of the local environment. The port number can be a maximum of 5 numeric characters and must be greater than 0 and less than 32768. The service name can be a maximum of 259 alpha-numeric characters. The format of the name must conform to the WinSock Service Name convention. The port number or name cannot be the same as that of an existing number or name in the **Defined ports and service names**.
Add	Click to validate the port number or service name you typed. If the number or name is valid, it appears in **Defined ports and service names**.
Defined ports and service names	View the existing valid ports and services names for the local environment.
Remove	Click to remove a selected port number or service name from the **Defined ports or service names** available for use in the local environment.

Reference
Configure a New Host Environment Wizard Page

Configure Local Environment Endpoints (SNA) Wizard Page

Use the **Configure Local Environment Endpoints** (SNA)wizard page to define the endpoints used to communicate with the host. Type a transaction program name or mirror transaction ID, and then click **Add**.

Use this	To do this
Local environment	View the name of the local environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
New transaction program name	Type the transaction program (TP) name or the link mirror transaction ID of the local environment. The name or ID can be a maximum of 64 alphabetic characters. The format of the name must conform to the IBM SNA Transaction Program Names convention. The name or ID cannot be the same as that of an existing name or ID in the **Defined transaction program names**.
Add	Click to validate the transaction program (TP) name or the link mirror transaction ID you typed. If the TP name or the link mirror transaction ID is valid, it appears in **Defined transaction program names**.
Defined transaction program names	View the existing TP names or the link mirror transaction IDs for the local environment.
Remove	Click to remove one or more TP names or link mirror transaction IDs selected from the **Defined transaction program names** available for use in the local environment.

Configure a New Host Environment Wizard Page

Configure a New Host Environment Wizard Page

Use the **Configure a New Host Environment** wizard page to describe the basic host characteristics that are concerned with data formats. Type the name of the host environment, and then type or select the attributes of the host.

Use this	To do this
Host environment	Type the name for the host environment. The name can be a maximum of 259 alpha-numeric characters. The name cannot be the same as that of an existing host environment. Caution If the host environment is located on the same computer as the HIP application, and the client program uses either host name **localhost** or IP address **127.0.0.1** to connect to the HIP application, the host environment should also use **localhost** or **127.0.0.1** instead of the real computer name or IP address. Failure to set the names or IP addresses identical for the host and client prevents the HIP runtime from delivering calls between the two, and causes the application to fail.
Data conversion	Select the data conversion routine used.
Host code page	Select the code page used by the host. Each available code page is listed by its symbolic value.
Network type	Select the type of network used to communicate with the host. The choices are: • TCP/IP (default) • SNA
Remote endpoint manager	The IP address of the host or the host name registered in the DNS (for a TCP/IP network); the LU name associated with the host system (for an SNA network). In either case, the name can be a maximum of 259 alpha-numeric characters.

Configure Host Environment Default Method Resolution Wizard Page

Configure Host Environment Default Method Resolution Wizard Page

Use the **Configure Host Environment Default Method Resolution** wizard page to identify the default characteristics of the typical interaction of the applications programs on the host with the application programs on the server. Select the default method resolution criteria for the host.

Use this	To do this
Host environment	View the name of the host environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
Default method resolution criteria	View the definition of the default behavior for setting up the method resolution criteria for a new object view.
Type	Select the type of resolution to be conducted: **Endpoint:** The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables the **Object**, **Input format** and **Output format** boxes and clears their contents. • **Transaction Request Message (TRM):** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant, MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request; the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables the **Object**, **Input format**, and **Output format** boxes. • **Enhanced Listener Message (ELM)**: • **Data:** Similar to **Endpoint** in that it adds the ability to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents. • **Link to Program Name:** Select **Link to Program Name** to resolve all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents.
Object	Select the object. The list of objects is populated from the Help string in the interface definition of objects defined as TRM resolution handlers. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS**

Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the user-defined type definitions in the MicrosoftTRMDef.tim file. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **TRMINMSLink** • **TRMINMSCCS** • **TRMINIBMCCS**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link Tran ID	View or select an existing TP name or the link mirror transaction ID for the local environment.

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (1)

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (1)

Use the first **Confige a New Security Policy** wizard page to identify the security policy and the source of the credentials. Type the name of the security policy, and then select the source for the credentials.

Use this	To do this
Security policy	Type the name for the security policy. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as the name of an existing security policy. The name for the new security policy is a required field; you will receive an error message if you click **Next** without providing a name. The name is used to associate the security policy with an object view in other wizard pages and dialog boxes.
Credentials source used to invoke the server	Identify the type or source of credentials that host-initiated processing will associate with the thread when the method on the server object is executed.
Host-initiated Single Sign-on	Select this option to use host user ID and password. This option is automatically disabled if Single Sign-on (SSO) is not installed or not available.
Windows credentials of the HIP application	Select this option to use Windows user ID and password specified on the HIP NT application service. This option is automatically selected if SSO is not installed or not available.

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (2)

Configure a New Security Policy Wizard Page (in the New Application Deployment Wizard) (2)

Use the second **Configure a New Security Policy** wizard page to identify the source of the host user ID and password and describe how they are translated into Windows-based credentials. This wizard page appears only if **Host-initiated Single Sign-on** (SSO)is selected on the previous **Configure a new security policy** wizard page.

Use this	To do this
Security policy	View the name of the security policy.
Affiliate application	Select the SSO affiliate application to be queried to gain access to the Windows credentials needed to execute methods on the server object. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen. The selected application will be added to the security policy. Note The dropdown list and **Next** are disabled if SSO is not installed or is not available.
Single Sign-on mapping use	Specify the credentials to be used when mapping to Single Sign-on.
Default credentials	Select this option to enter the user ID and password used if the request from the host does not contain a user ID and password or the user ID and password are set to spaces or nulls. This option enables the **Group application** and **User** boxes.
Group application	The default user group provides the default user ID and password.
User	Type or select the host user name used in the lookup call to SSO. Note The dropdown list and Next are disabled if SSO is not installed or is not available.

Specify or Locate an Object Wizard Page

Specify or Locate an Object Wizard Page

Use the **Specify or Locate an Object** wizard page to identify objects associated with the application. Select an object from the list, or, to create a new object, type the new object name.

Use this	To do this
Object	Select the name of the object. To create a new object, type the new object name. If you select the Transaction Integrat or metadata (TIM) file first, the name is populated with the ProgID or Namespace.Interface defined in the TIM.
Registered TIMs	Type the full path name, including the *.tim extension, to a TIM file, select a recently used file from the list, or click **Browse** and navigate to the file.

Method Resolution Criteria Dialog Box (in the New Application Deployment Wizard)

Method Resolution Criteria Dialog Box (in the New Application Deployment Wizard)

Use the **Method Resolution Criteria** dialog to provide detailed information about a specific method on the object view.

Use this	To do this
Method	View the name of the object's method for which the method resolution criteria are being set.
Endpoint	Select the endpoints on the local environment that are available for the type of resolution specified in **Type**. All endpoints in the LE are listed and available for selection. If an endpoint selected for one resolution type is already used with another resolution type then an error message will pop up when you click **Apply**. The error message explains which object and view has this endpoint used with another resolution type.
Method resolution criteria	View a description of the behavior for the IT runtime when it resolves a request to a method. The sequence of data flow events may require the TI to send and receive various amounts of data prior to obtaining the ability to make the connection between the incoming request and the target method.
Type	Select the type of resolution to be conducted: • **Endpoint** The endpoint resolution type is simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and it represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables **Object Name**, **Input format** and **Output format** and clears their contents. • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request, and the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables **Object**, **Input format**, and **Output format**. This option is available only for TCP/IP local environment/host environment pairs. • **Enhanced Listener Message (ELM)**: • **Data** Similar to **Endpoint** in that it adds the flexibility to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables **Object**, **Input format**, and **Output format** and clears their contents. • **Link to Program Name:** Resolves all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables **Object**, **Input format**, and **Output format** and clears their contents. This option is available only for SNA local environment/host environment pairs. Note Only **TRM-MSLink** and **Link to Program Name** are available for Link methods. Methods can be defined as Link in Visual Studio by setting the **Is Link** property to **True**.

Object Name	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS**
Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the UDT) definitions in the MicrosoftTRMDef.tim file in the installation TIMLibs directory. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **MS Link Request Format** • **IBM Listener Type 1 Request Format** • **IBM Listener Type 2 Request Format**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link	View the name of the program being linked to.
Program Name	Name of the TP program.
Resolution Data	View a definition of the data used by the IT runtime when it resolves a request to a method.
Data	Type the method resolution criteria for a method on the object view. The criteria can be a maximum of 256 alpha-numeric characters. This control is enabled for resolution types **Transaction Request Message (TRM)** and **Data**. This control is disabled for resolution type **Endpoint**.
Position	Type the resolution position. The position can be a maximum of nine numeric characters. This control is enabled for resolution type **Data** and disabled for resolution types **Transaction Request Message (TRM)** and **Endpoint**.

Configure a New Local Environment Wizard Page

Configure a New Local Environment Wizard Page

Use the **Configure a New Local Environment** wizard page to define the basic characteristics of the new local environment. Type the name of the new local environment. To define its characteristics, select a specific network type and transport class.

Use this	To do this
Local environment	Type the name for the local environment. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as that of an existing local environment. The name for the new local environment is a required field, and you will receive an error message if you click **Next** without providing a name.
Network type	Select the type of network used to communicate with the host. The choices are: • TCP/IP (default) • SNA
Transport class	Select the class of the transport object. The list of choices changes according to the selected **Network type**. The default transport class is TCPTransport Class.
Endpoint manager	Select or type the local LU alias to manage the endpoint. Note The Endpoint manager edit box is set to localhost and disabled if the Network type is set to TCP/IP.

Configure Local Environment Endpoints (TCP/IP) Wizard Page

Configure Local Environment Endpoints (SNA) Wizard Page

Configure Local Environment Endpoints (TCP/IP) Wizard Page

Use the **Configure Local Environment Endpoints** (TCP/IP)wizard page to define the endpoints used to communicate with the host. To define the TCP/IP ports or service names for the local environment, type a port number or name, and then click **Add**.

Use this	To do this
Local environment	View the name of the local environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
New port or service name	Type the port number or service name of the local environment. The port number can be a maximum of 5 numeric characters and must be greater than 0 and less than 32768. The service name can be a maximum of 259 alpha-numeric characters. The format of the name must conform to the WinSock Service Name convention. The port number or name cannot be the same as that of an existing number or name in the **Defined ports and service names**.
Add	Click to validate the port number or service name you typed. If the number or name is valid, it appears in **Defined ports and service names**.
Defined ports and service names	View the existing valid ports and services names for the local environment.
Remove	Click to remove a selected port number or service name from the **Defined ports or service names** available for use in the local environment.

Configure a New Host Environment Wizard Page

Configure a New Host Environment Wizard Page

Use the **Configure a New Host Environment** wizard page to identify the data format characteristics of the host. Type the name of the host environment, and then type or select the attributes of the host.

Use this	To do this
Host environment	Type the name for your host environment. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as that of an existing host environment. The name for the new host environment is a required field, and you will receive an error message if you click Next without providing a name. ⚠Caution If the host environment is located on the same computer as the HIP application, and the client program uses either host name **localhost** or IP address **127.0.0.1** to connect to the HIP application, the host environment should also use **localhost** or **127.0.0.1** instead of the real computer name or IP address. Failure to set the names or IP addresses identical for the host and client prevents the HIP runtime from delivering calls between the two, and causes the application to fail.
Data conversion	Select the data conversion routine to be used.
Host code page	Select the code page used by the host. Each available code page is listed by its symbolic value.
Network type	Select the type of network used to communicate with the host. The choices are: • TCP/IP (default) • SNA
Remote endpoint manager	The IP address of the host or the host name registered in the DNS (for a TCP/IP network); the LU name associated with the host system (for an SNA network). In either case, the name can be a maximum of 259 alpha-numeric characters.

Configure Host Environment Default Method Resolution Wizard Page

Configure Host Environment Default Method Resolution Wizard Page

Use the **Configure Host Environment Default Method Resolution** wizard page to identify the default characteristics of the typical interaction between applications programs on the host and the application programs on the server. Type or select the default method resolution criteria for the host.

Use this	To do this
Host environment	View the name of the host environment. The name was entered on a previous page of the wizard. To change the name, click **Back**.
Default method resolution criteria	View a definition of the default behavior for setting up the method resolution criteria for a new object view.

Type	Select the type of resolution to be conducted: • **Endpoint:** The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and represe nts a single synchronous exchange of data. When a new view is created and associated with the HE, the method re solves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables the **Object**, **I nput format**, **Output format**, and **Link Tran ID** boxes and clears their contents. • **Transaction Request Message (TRM):** The TRM resolution type is specific to the TCP/IP transport and to the IB M CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange seque nce. The first exchange represents the transaction request; the second exchange represents the request and reply data. Select **Transaction Request Message (TRM)** to resolve all the methods of a new object view using the resolutio n handler information in the **Object**, **Input format**, and **Output format** boxes. When a new view is created and a ssociated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selec ting one of the predefined **Transaction Request Objects** disablesthe **Input format** and **Output format** boxes; i t also disables the **Link Tran ID** box and clears its contents. Selecting a custom object enables the **Input format** a nd **Output format** boxes and sets their initial values to the Microsoft supplied TRM handlers items. • **Enhanced Listener Message (ELM)**: A streamlined, application-level protocol exchange sequence that sends to and receives from the host application a single data stream composed of a header followed by the application dat a. • **Data:** Similar to the **Endpoint** type in that it enables you to identify a string in the data stream directed to a port t hat is used to associate the request with a specific method in the view. This model is considered "raw sockets." It r epresents a single synchronous exchange of data. When a new view is created and associated with the HE, the me thod resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables the **Objec t**, **Input format**, **Output format,** and **Link Tran ID** boxes and clears their contents. • **Link to Program Name:** The Link resolution type is specific to the IBM CICS DPL model. The endpoint name is re presentative of the TP name that is the CICS mirror transaction ID. Select **Link to Program Name** to resolve all the methods of a new object view using the data information specifi ed when the object view was created. When a new view is created and associated with the HE, the method resolve s to the Link Tran ID field in the default HE resolution. Selecting **Link** disables the **Object**, **Input format**, and **Out put format** boxes and clears their contents.
Objec t	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to t he resolution handler. Microsoft provides four TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS** • **Microsoft HIS - Link Handler**

Input format	Select the format for the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is populated from the user-defined type definitions in the MicrosoftTRMDef.tim file. The **Input format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three input formats are defined that match the names of the resolution handler **Object**: • **TRMINMSLink** • **TRMINMSCCS** • **TRMINIBMCCS**
Output format	Select the format for the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream to be returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is populated from the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three output formats are defined that match the names of the resolution handler **Object**: • **TRMOUTMSLink** • **IBM Listener Reply Format (TRMOUTCCS)** • **Link Tran ID:** Select the TP name or Link Mirror Tran ID for the SNA local environment. This control is enabled only when the **Network Type** is set to SNA and the **Resolution Type** is set to Link.
Link Tran ID	View or select an existing TP name or the link mirror transaction ID for the local environment.

Configure the New View Wizard Page

Configure the New View Wizard Page

Use the **Configure the New View** wizard page to select the methods that are included in the object view. Type the name of the view. To select the methods to be included in the view, select the check box by the method name. Double-click the method name to edit it.

Use this	To do this
View	View the name of the object view.The name of the object view was entered on a previous page of the wizard. To change the name, click **Back**.

Object methods	View all the methods that are defined in the object. Each row in the list contains a summary of the resolution information for a single method. Rows cannot be deleted. The columns are:
	• **Include:** Select this option to include the method in the object view.
	• **Method:** Displays the name of the method. Double-click the method name to display the **Method Resolution Criteria** dialog box.
	• **Endpoint manager:** For a TCP/IP network, select or type the IP address or host name to manage the endpoint. For an SNA network, type the name of the LU alias. In either case, the name can be a maximum of 259 alpha-numeric characters.
	• **Endpoint:** Displays one of the endpoints defined in the local environment associated with the view. To change the content of this field, double-click the **Endpoint** field for a specific method.
	• **Resolution Type:** Displays one of the possible resolution types:
	  • **Endpoint**
	  If the local environment has all of its endpoints in use by object views, associated with the same host environment, that specify **Endpoint Resolution**, you will receive an error message.
	  If the local environment has all of its endpoints in use by object views, associated with the same host environment, that specify **TRM** or **Data** resolution, no endpoint is available for **Endpoint** resolution and **TRM** or **Data** resolution must be supplied for the other methods.
	  If the local environment has one or more endpoints available for endpoint resolution, the first method of the view appears. The first method has its endpoint set to the first endpoint in the local environment that is available for endpoint resolution and the resolution type is set to **Endpoint**. All the remaining methods have the **Endpoint**, **Resolution Type**, **Resolution Data**, and **Resolution Position** boxes cleared.
	  • **Transaction Request Message (TRM)**
	  If the local environment currently has all of its endpoints in use by object views, associated with the same host environment, that specify **Endpoint** or **Data** resolution, the list control is not available.
	  If an endpoint is available for TRM resolution, **Include** is selected for all methods and their endpoint is set to the first endpoint associated with the endpoint that is available for TRM resolution.
	  All methods have resolution type set to **Transaction Request Message (TRM)**; the **Resolution Data** and **Resolution Position** boxes are cleared.
	  • **Enhanced Listener Message (ELM)**
	  • **Data**
	  If the local environment currently has all of its endpoints in use by object views, associated with the same h

ost environment that specified **Endpoint** or **TRM** resolution, the list control is not available.

If an endpoint is available for data resolution, **Include** is selected for all methods and their endpoint is set t o the first endpoint associated with the endpoint that is available for data resolution.

All methods have resolution type set to **Data,** and the **Resolution Data** and **Resolution Position** boxes ar e cleared.

- **Link to Program**

To change the content of this field, double-click the **Resolution Type** field for a specific method.

- **Resolution Data** Identifies the data used to select the method to be executed. To change the content of this field, d ouble-click the **Resolution Data** field for a specific method.

- **Resolution Position** View the resolution position. If **Data Resolution** is selected, this information is used by the TI runtime to identify the starting point in the data stream in which to look for the data defined in the resolution data f ield to determine what method is to be executed. To change the content of this field, double-click the **Resolution P osition** field for a specific method.

TI Manager Wizards and Dialog Boxes

Reload TIMs Wizard

The **Reload TIMs Wizard** helps you add multiple Transaction Integrator metadata (TIM) files to the object view at one time. The wizard collects information about the following:

- Name and location of the .tim file
- Availability of the .tim for reloading

In This Section

Welcome to the Reload TIMs Wizard Page

Use the **Welcome to the Reload TIMs** Wizard page to add one or more Transaction Integrator metadata (TIM) files to the object view and to control whether the welcome page is displayed the next time the wizard is used.

Use this	To do this
Do not show this welcome page again.	Select this option if you will be using the wizard more than once and do not want to read the introduction each time the wizard is launched. Each time the wizard is launched, the welcome page will be hidden and the wizard will begin with the second page. To view the welcome page again, click **Back** on the second page of the wizard.

Specify or Locate Metadata Files to be Reloaded Wizard Page

Specify or Locate Metadata Files to be Reloaded Wizard Page

Use the **Specify or Locate Metadata Files to be Reloaded** Wizard page to select the Transaction Integrator metadata (TIM) files to be added.

Use this	To do this
Path	Type the full path name, including the .tim extension, to a TI metadata file, select a recently used file from the list, or click **Browse** and navigate to the file. Only .tim files that are not currently in use by other object views are displayed. The path can be a maximum of 255 Unicode characters, and the name of the .tim file must be unique.

Reloading of Metadata Files Wizard Page

Reloading of Metadata Files Wizard Page

Use the **Reloading of Metadata Files** Wizard page to view the Transaction Integrator metadata (TIM) files that will be reloaded. The Wizard analyzes the .tim files selected on the previous page to verify the number of methods, as well as the name and ID of each method.

Use this	To do this
Messages	View the status of each .tim file. If a file is acceptable for reloading, the file name is followed by **OK**. If a file is not acceptable for reloading, the file name if followed by a message indicating the reason for being rejected. Note The files given an **OK** are not actually reloaded until you click **Next**.

Configure a New Remote Environment Wizard Page

Configure a New Remote Environment Wizard Page

Use the **Configure a New Remote Environment** wizard page to identify the name and location of the remote environment. To define the remote environment, type the name of the remote environment, and then select the network type.

Use this	To do this
Name	Type the name for the remote environment. The name can be a maximum of 256 Unicode characters. The name cannot be the same as that of an existing remote environment. The name for the new remote environment is a required field; you will receive an error message if you click **Next** without providing a name.
Vendor	Select the vendor supplying the remote environment.
Network type	Select the type of network used to communicate with the remote environment. The options are: • **TCP/IP** (default) • **SNA**

Configure Host Environment and Programming Model Wizard Page

Configure Host Environment and Programming Model Wizard Page

Use the **Configure Host Environment and Programming Model** wizard page to identify information about the target host configuration and show where the host's programming model is defined.

Use this	To do this
Target host	Select a target host. For the TCP Network type, the available choices are: • **CICS** • **IMS** • **OS400** For the LU 6.2 (SNA) for the network type, the available choices are: • **CICS** • **IMS**

Programming model	Select a programming model. For the TCP network type, the available choices are:
	• For the CICS host
	  • **TCP TRM User Data**
	  • **TCP ELM User Data**
	  • **TCP TRM Link**
	  • **TCP ELM Link**
	• For the IMS host
	  • **IMS Connect**
	  • **IMS Implicit**
	  • **IMS Explicit**
	• For the OS400 host
	  • **Distributed Program Call**
	
	For the LU 6.2 (SNA) network type, the available choices are:
	• For the CICS host
	  • **CICS LU 6.2 User Data**
	  • **CICS LU 6.2 Link**
	• For the IMS host
	  • **IMS LU 6.2 User Data**

Configure Endpoint TCP/IP Wizard Page

Configure Endpoint TCP/IP Wizard Page

Use the **Configure Endpoint TCP/IP** wizard page to set the IP address and port number for the host environment.

Use this	To do this
IP/DNS Address	Type the address or select from the drop-down list. The IP address can be defined either by name or numerical address. The address can be a maximum of 256 alphanumeric characters. The drop-down list displays the most recently used IP addresses.
Port list	Select the port number from the drop down list. Click **Edit** to edit the selected port list, or create a new one by selecting <**new port list**> and clicking **Edit**.

Completing the New Remote Environment Wizard Page

Port List Editing Dialog Box

The **Port List Editing** dialog box allows you to create new TCP ports or edit existing ports.

To add a port to addition port list, select the port list on the previous panel, press edit.

The Defined ports will serially list the defined ports within the list. Highlight a port within the defined list, press remove to remove the port from the list.

To add a new port to the list, type the port number within the new port text box, press add. The port number will be added to the defined port list. Press OK, the new port will show up within the port list separated by semicolons within the port list.

To create a new port list, from the port list drop down menu, select <new port list>, press edit.

Use this	To do this
New port	Type the number of the new port. The port number can be a maximum of 256 positive numerals separated by semicolons. A port number can be defined with up to 5 positive digits, and more than one port can be defined to an address. The port number cannot be larger than 32767. The port numbers cannot be repeated.
Add	Click to add the new port number to the list of defined ports.
Remove	Click to remove the selected port number from the list.
Defined ports	View the port numbers already defined.

Configure Endpoint SNA Wizard Page

Use the **Configure SNA Endpoint** wizard page to set the local LU alias, the remote LU alias, and the APPC mode name for the host environment.

Use this	To do this
Local LU alias	Type the local LU alias. The alias can be a maximum of 256 alphanumeric characters. The drop-down list displays all the Local APPC LUs defined to the SNA Manager.
Remote LU alias	Type the remote LU alias. The alias can be a maximum of 256 alphanumeric characters. The drop-down list displays all the remote APPC LUs defined to the SNA Manager.
Mode name	Type the APPC mode used for the connection. You can obtain a list of configured modes from Host Integration Server **SNA Manager**. Note To use two-phase commit, the APPC mode must be Sync Level 2 capable.

Configure Endpoint IMS Connect Wizard Page

Use the **Configure Endpoint IMS Connect** wizard page to set the IP address and port number for the host environment and to identify the IBM-defined exit program on the host.

Use this	To do this
IP/DNS Address	Type the address or select from the drop-down list. The address can be a maximum of 256 alphanumeric characters. The drop-down list displays the most recently used IP addresses.
Port list	Type the TCP port number or select from the drop-down list. The number can be a maximum of 256 positive numerals separated by semicolons. The port numbers cannot be repeated. The dropdown list displays the most recently used port numbers.
ITOC information	Select either **HWSIMSO0** or **HWSIMSO1**, the IBM-defined exit associated with IMS connect on the host.
Format to use	View the choice of formats.
HWSIMSO0	Select this option to use the HWSIMSO0 exit program.
HWSIMSO1	Select this option to use the HWSIMSO1 exit program.
IMS system ID	Type the IMS system ID or select from the drop-down list. The ID can be a maximum of 8 alphanumeric characters. The drop-down list displays the most recently used IMS system IDs.
ITOC exit name	Type the ITOC exit name or select from the drop-down list. The name can be a maximum of 8 alphanumeric characters. The drop-down list displays the most recently used ITOC exit names.

Specify or Locate an Object Wizard Page

Specify or Locate an Object Wizard Page

Use the **Specify or Locate an Object** wizard page to specify or initiate a browse operation to locate the Transaction Integrator metadata file that represents the server object. For COM based interfaces, the file extension is .tlb, for .Net the file extension is .dll.

Use this	To do this
Path	Type the full path name to a metadata file. If the file does not end with the .tlb or .dll extension, an error message will appear. You can add more than one object at a time.
Browse	Launches the **Open** dialog box.
Remove	Removes the selected objects from the list.

Define Remote Environment Wizard Page

Define Environment Characteristics for the .NET Object Wizard Page

Use the **Define Environment Characteristics for the .NET Object** wizard page to define the IIS Virtual Directory in which Transaction Integrator should run.

Use this	To do this
Self-hosted	Select this to reference the TI assembly within the application itself. No IIS security will be available, and the ot her options on this page will be unavailable.
ASP .NET wor ker process	Select this to use IIS security.
Virtual direct ories	Select an IIS virtual directory. The list is populated from enumerating the IIS Virtual Directories on the local co mputer. Note that if you do not choose an environment, an error appears when you click **Next**. If there is no environm ent available, you must exit this wizard and define the appropriate environment.
Service	Choose **Remoting only**, **Remoting and Web Service**, or **Web Service only**.
Key file for pr oxy	Select the key (.snk) file that TI Manager uses to sign the proxy in the IIS virtual directory. The list is populated with files used previously.

Use this wizard to import WIP definitions.

In This Section

Welcome to the Import WIP Definitions Wizard Page

Click **Next** to continue.

Define Import Characteristics Page

Use this page to select a directory containing the exported definitions.

Duplicate Remote Environment Use

Select Original or Exported Definitions.

Import Directory Path

Type or browse to the desired directory.

Importing WIP Definitions Page

This page displays errors and other information during the import process.

Click **Next** when the process is complete.

Import WIP Definitions Wizard Finish Page

This page appears when the import process is complete.

Click **Finish** to close the wizard.

Export WIP Definitions Wizard

Use this wizard to export WIP definitions.

In This Section

Welcome to the Export WIP Definitions Wizard Page

Click **Next** to continue.

Define Export Characteristics Page

Directory use

Select **Use HIS Generated Directory** to have Transaction Integrator create a target directory.

Select **Use Specific Directory** to browse to a directory of your choice.

Remote Environment Selection Page

Specify the Remote Environments to be exported, and for each one whether Connection Information should be retained.

WIP Object Selection Page

Specify the WIP Objects to be exported.

Exporting WIP Definitions Page

You can view any relevant information in the **Messages** box.

Export WIP Definitions Wizard Finish Page

Click **Finish** to close the wizard.

TI Manager Properties

Transaction Integrator (TI) Manager provides property pages for viewing and setting properties. The property pages include the following:

Transaction Integrator (Configuration) Properties

- Timeout Tab

Application Properties

- General Tab (Application Properties)
- Advanced Tab (Application Properties)
- .NET Assembly Path Tab (Application Properties)

Listener Properties

- General Tab (Listener Properties)
- Endpoints Tab (TCP/IP Listener Properties)
- Endpoints Tab (SNA Listener Properties)
- Application Tab (Listener Properties)

Local Environment Properties

- General Tab (Local Environment Properties)
- Endpoints Tab (TCP/IP Local Environment Properties)
- Endpoints Tab (SNA Local Environment Properties)

Host Environment Properties

- General Tab (Host Environment Properties)
- Network Tab (Host Environment Properties)
- Conversion Tab (Host Environment Properties)
- Default Tab (Host Environment Properties)

Security Policy Properties

- General Tab (Security Policy Properties)
- Credentials Source Tab (Security Policy Properties)

Object Properties

- General Tab (Object Properties)

- Methods Tab (Object Properties)
- .NET Implementation Tab (Object Properties)

Object View Properties

- General Tab (View Properties)
- Host Environments Tab (View Properties)
- Methods Tab (View Properties)
- Method Resolution Criteria Dialog Box (Object Properties)

Remote Environment Properties

- General Tab (Remote Environment Properties)
- TCP/IP Tab (Remote Environment Properties)
- LU6.2 Tab (Remote Environment Properties)
- Target Tab (Remote Environment Properties)
- Recording Tab (Remote Environment Properties)
- Locale Tab (Remote Environment Properties)
- Security Tab (Remote Environment Properties)
- CICS Tab (for LU6.2 Link Properties)
- CICS Tab (for TCP/IP Properties)
- IMS Tab
- SSO tab (Security Policy Properties)

Object Properties

- General Tab (Object Properties)
- Hosting Tab (COM Object Properties)
- Remote Environment Tab (Object Properties)
- Security Tab (Remote Environment Properties)

Timeout Tab

Use the **Timeout** tab to set the maximum number of minutes the TI Manager console is allowed to be inactive while it is in **Configuration** mode.

Use this	To do this
Write mode timeout	Type the maximum number of minutes the TI Manager console can remain in configuration mode without a keystroke or mouse movement that changes the configuration. At the end of this time, the console returns to **View and operate** mode. The default is **30** minutes.

⚠**Caution**
The properties of the TI Manager console are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the console to function incorrectly.

Reference

Transaction Integrator (mode) Node

General Tab (Application Properties)

The **General** tab allows you to set the general properties of the application.

Use this	To do this
Application	View the name of the application.
Computer	View the name of the computer running the application.
Process ID	View the process ID of the HIPService. **0** indicates that HIPService is not running.
Worker threads	Type the number of processing threads to be used in the work of the application. The number of threads must be greater than 0 and fewer than 257.
Queued requests	Type themaximum number of requests that can be stored in the queue before new requests are rejected. The number of queued requests must be equal to or greater than the number of worker threads, and must be less than 2049.
Comment	Type additional information about the use of the object view in the HIP environment. The comment can be a maximum of 259 alpha-numeric characters.
Service starts automatically	Select this option to start the HIPService automatically at startup. Clear the check box to require manual start up.

⚠**Caution**
The properties of an application are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

See Also

Reference

Application

Advanced Tab (Application Properties)

The **Advanced** tab allows you to set the advanced properties of the application.

Use this	To do this
Minimum active worker threads	Type or select the minimum number of worker threads that the HIP runtime maintains. The number of threads must be greater than 0 and fewer than 193. The number cannot exceed the number of **Worker threads** set on the **General** tab property page. The default is **8** threads.
Cleanup worker threads	The group of properties controlling thread cleanup.
When no requests have been queued for	Type or select the number of seconds the HIP runtime will wait after the last client request has been received before it terminates the threads. The minimum wait is 1 second and the maximum wait is 3600 seconds. The default is **30** seconds.
Start an additional working thread	The group of properties controlling when new threads are started.
When more than *number* requests have been queued	Type or select the number of requests that must be received before additional worker threads are started. The minimum number of requests is 1, and the maximum number of requests is 99,999. The default is **15** requests. The number of requests cannot exceed the **Maximum queued requests** (set on the **General** tab) multiplied by the **During the previous *number* seconds** (set on this tab).
During the previous *number* seconds	Type or select the number of seconds the HIP runtime must wait before starting additional worker threads. The minimum number of seconds is 1, and the maximum number of seconds is 3600. The default is **5** seconds.
Increase context cache size	The group of properties controlling the size of the cache of incoming context requests over a period of time.
When more than *number* contexts have been created	Type or select the number of contexts that must be created before the HIP runtime increases the size of the cache. The request context is needed to pass the parameters of the request from the listener to a worker thread. The initial cache size is equal to the number of worker threads multiplied by 2, which is normally less than the maximum queue length. If the cache is empty, a new context is created but will be destroyed at the end because there is no place in the cache to put it in. Increasing the cache size allows the HIP runtime to save the context for future reuse to eliminate expensive operations of creating and releasing the context. The cache size can grow up to the maximum queue length. The minimum number of contexts is 1, and the maximum number of contexts is 192. The default is **30** contexts.

During the previous *number* seconds	Type or select the number of seconds the HIP runtime must wait before increasing the cache size. The minimum number of seconds is 1, and the maximum number of seconds is 3600. The default is **5** seconds.

⚠Caution

The properties of an application are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

Application

General Tab (Listener Properties)

The **General** tab displays the general properties of the application's local environment. The controls on the **General** tab are read-only.

Use this	To do this
Name	View the name of the local environment. To change the name of the local environment, right-click the **Local Environments** node.
Network type	View the type of network used to communicate with the host.
Transport class	View the class of the transport object.
Comment	View a comment about the local environment. To change an existing comment, right-click the **Local Environments** node.

Note

When viewed from the ***listener*** node, the general properties are read-only. If you want to change a general property, right-click the specific ***local environment*** **Node** under the **Local Environments Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

Caution

The properties of an listenerare not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

Listener

Endpoints Tab (SNA Listener Properties)

The **Endpoints** tab displays the defined endpoints in the local environment definition. The controls on the **Endpoints** tab are read-only. To add or remove endpoints from the local environment, use the **Properties** shortcut menu item on the **Local Environments** node.

Use this	To do this
New transaction program name	View the transaction program (TP) name or the link mirror transaction ID of the local environment.
Add	Not available.
Defined transaction programs names	View the existing TP names or the link mirror transaction IDs for the local environment.
Remove	Not available.

Note

When viewed from the ***listener*** node, the endpoint properties are read-only. If you want to change an endpoint property, right-click the specific ***local environment*** **Node** under the **Local Environments Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

Caution

The properties of an listenerare not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

See Also

Reference

Listener

Application Tab (Listener Properties)

The **Application** tab displays the local environment properties that are specific to the application. It allows you to specify whether the application will begin listening on the local environment endpoints automatically when the application is started.

Use this	To do this
Begin Listening on the local environment at application startup	When this option is selected, the application will automatically start listening for incoming host requests on each port defined in the local environment.

⚠**Caution**
The properties of an listener are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

See Also

Reference

Listener

General Tab (Local Environment Properties)

Use the **General** tab to set the general local environment properties, including its name and basic information about its network type.

Use this	To do this
Local environment	Type the name for the local environment. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as that of an existing local environment. You can change the name at any time, unless the local environment is an associated listener in an application that is active. The application must be stopped before the LE can be renamed. After the name is changed, the new name will appear in the **Application**, **Local Environments** and **Object** nodes.
Network type	Select the type of network used to communicate with the host. The choices are: • TCP/IP (default) • SNA. Note If the local environment is associated with any other configuration entity, you will receive an error when you attempt to apply the change.
Transport class	Select the class of the transport object. This list changes according to the selected **Network type**.
Endpoint manager	Select or type the local LU alias to manage the endpoint. Note The **Endpoint manager** edit box is set to **Localhost** and disabled if the **Network type** is set to **TCP/IP**.
Comment	Type any additional information about the local environment. The comment can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special).

Caution
The properties of a local environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the local environment to function incorrectly.

Local Environments Node

Local Environment Node

Endpoints Tab (TCP/IP Local Environment Properties)

Use the **Endpoints** tab to view, add, and delete endpoints in the local environment definition.

Use this	To do this
New port or service name	Type the port number or service name for the local environment. The port number can be a maximum of 5 numeric characters and must be greater than 0 and fewer than 32768. The service name can be a maximum of 64 alpha-numeric characters. The format of the name must conform to the WinSock Service Name convention. The port number or name cannot be the same as that of an existing number or name in **Defined ports and service names**.
Add	Click to validate the port number or service name you typed. If the number or name is valid, it then appears in **Defined ports and service names**. If the local environment is referenced by an application, the new port or service name will not be available for use until all the applications that use the local environment are restarted.
Defined ports and service names	View the valid ports and services names for the local environment.
Remove	Click to remove a selected port number or service name from **Defined ports or service names**.

⚠**Caution**
The properties of a local environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the local environment to function incorrectly.

Local Environment Node

Endpoints Tab (SNA Local Environment Properties)

Use the **Endpoints** tab to view, add, and delete endpoints in the local environment definition.

Use this	To do this
New transaction program name	Type the transaction program (TP) name or the link mirror transaction ID of the local environment. The name or ID can be a maximum of 64 alphabetic characters. The format of the name must conform to the IBM SNA Transaction Program Names convention. The name or ID cannot be the same as that of an existing name or ID in the **Defined transaction programs names**.
Add	Click to validate the transaction program (TP) name or the link mirror transaction ID you typed. If the TP name or the link mirror transaction ID is valid, it appears in **Defined transaction program names**.
Defined transaction programs names	View the existing TP names or the link mirror transaction IDs for the local environment.
Remove	Click to remove one or more TP names or link mirror transaction IDs selected from the **Defined transaction programs names** available for use in the local environment.

Caution
The properties of a local environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the local environment to function incorrectly.

Local Environments Node

Local Environment Node

General Tab (Host Environment Properties)

The **General** tab defines the basic characteristics of the host environment that will initiate requests to the Windows platform.

Use this	To do this
Host environment	Type the name for your host environment. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as that of an existing host environment.
Time-out in seconds	The **Send** and **Receive** time-out values are used by the host-initiated processing (HIP) runtime environment when it communicates with the host environment. The time-out values are used on transport-specific application program interfaces (APIs) to terminate the send and/or receive API functions if the expected data is not received in the specified amount of time.
Send	Type the number of seconds the HIP runtime should wait for an acknowledgement before it times out. The maximum number of seconds is 3,600; the default is **30** seconds.
Receive	Type the number of seconds the host should wait for a response before it times out. The maximum number of seconds is 3,600; the default is **30** seconds.
Comment	Type any additional information about the host environment. The comment can be a maximum of 259 alpha-numeric characters.

⚠**Caution**
The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

Host Environment Node

Network Tab (Host Environment Properties)

The **Network** tab defines the network characteristics that the host uses to interact with the Windows environment and to ensure that unauthorized requests are not inadvertently processed.

Use this	To do this
Network type	Select the type of network used to communicate with the host environment. The choices are: • TCP/IP (default) • SNA
Remote endpoint manager	For a TCP/IP network, select or type the IP address of the host or the host name registered in the DNS. For an SNA network, type the LU name associated with the host system. In either case, the name can be a maximum of 259 alpha-numeric characters.

Caution
The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

Host Environment Node

Conversion Tab (Host Environment Properties)

The **Conversion** tab defines the data type characteristics used by the host that makes requests to the Windows platform. The code page and elemental data conversion object are used by host-initiated processing (HIP) to transform the incoming and outgoing data to a form that can be used by the host application program.

Use this	To do this
Data conversion	Select the data conversion routine to be used.
Host code page	Select the code page used by the host. Each available code page is listed by its symbolic value.

Caution
The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

Host Environment Node

Default Tab (Host Environment Properties)

The **Default** tab of the properties page of a specific host environment defines the manner in which the host typically communicates with Transaction Integrator. These defaults are applied during the configuration for an object view.

Use this	To do this
Default method resolution criteria	View the definition of the default behavior for setting up the method resolution criteria for a new object view.
Type	Select the type of resolution to be conducted: **Endpoint**: The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables the **Object**, **Input format** and **Output format** boxes and clears their contents. • **Transaction Request Message (TRM)**: The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant, MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request; the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables the **Object**, **Input format**, and **Output format** boxes. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting one of the predefined **Transaction Request Objects** disablesthe **Input format** and **Output format** boxes; it also disables the **Link Tran ID** box and clears its contents. Selecting a custom object enables the **Input format** and **Output format** boxes and sets their initial values to the Microsoft-supplied TRM handler items. • **Data**: Similar to **Endpoint** in that it adds the ability to identify a string in the data stream directed to a port, that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. Selecting **Data** disables the **Object**, **Input format**, **Output format,** and **Link Tran ID** boxes and clears their contents. • **Link:** The Link resolution type is specific to the IBM CICS DPL model. The endpoint name is representative of the TP name that is the CICS mirror transaction ID. Select **Link** to resolve all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link** disables the **Object**, **Input format**, and **Output format** boxes and clears their contents.

Object	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS** • **Microsoft HIS - Link Handler**
Input format	Select the format for the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is populated from the user-defined type definitions in the MicrosoftTRMDef.tim file. The **Input format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three input formats are defined that match the names of the resolution handler **Object**: • **TRMINMSLink** • **TRMINMSCCS** • **TRMINIBMCCS**
Output format	Select the format for the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream to be returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is populated from the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is disabled for standard TRM handlers and enabled for custom TRM handlers, but three output formats are defined that match the names of the resolution handler **Object**: • **TRMOUTMSLink** • **IBM Listener Reply Format (TRMOUTCCS)** • **Link Tran ID:** Select the TP name or Link Mirror Tran ID for the SNA local environment. This control is enabled only when the **Network Type** is set to SNA and the **Resolution Type** is set to Link.

⚠Caution

The properties of a host environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the host environment to function incorrectly.

General Tab (Security Policy Properties)

The **General** tab of the properties page of a security policy defines the name of the policy and the source of the security credentials.

Use this	To do this
Policy	Type the name for the security policy. The name can be a maximum of 259 Unicode characters (alphabetic, numeric, space, and special). The name cannot be the same as the name of an existing security policy. The name for the new security policy is a required field; you will receive an error message if you click **Next** without providing a name. The name is used to associate the security policy with an object view in other wizard pages and dialog boxes.
Host-initiated Single Sign-on	Select this option to use host user ID and password. This option is automatically disabled if Single Sign-On (SSO) is not installed or not available.
Windows credentials of the HIP application	Select this option to use Windows user ID and password specified on the HIP NT application service. This option is automatically selected if Single Sign-On (SSO) is not installed or not available.
Comment	Type additional information about the security policy. The comment can be a maximum of 259 Unicode characters.

⚠**Caution**
The properties of a security policy are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the security policy to function incorrectly.

Security Policy Node

Credentials Source Tab (Security Policy Properties)

The **Credentials Source** tab of the properties page of a security policy defines the source of the host user ID and password and describes how they are translated into Windows-based credentials.

Use this	To do this
Security policy	View the name of the security policy.
Affiliate application	Select the SSO affiliate application to be queried to gain access to the Windows credentials needed to execute methods on the server object. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen. The selected application will be added to the security policy. Note The dropdown list is disabled if SSO is not installed or is not available.
Single Sign-on mapping use	Specify the credentials to be used when mapping to Single Sign-on.
Default credentials	Select this option to enter the user ID and password used if the request from the host does not contain a user ID and password or the user ID and password are set to spaces or nulls. This option enables the **Group application** and **User** boxes.
Group application	The default user group provides the default user ID and password.
User	Type or select the host user name used in the lookup call to SSO. Note The dropdown list is disabled if SSO is not installed or is not available.

Caution
The properties of a security policy are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the security policy to function incorrectly.

Method Resolution Criteria Dialog Box (in the New Object View Wizard)

Use the **Method Resolution Criteria** dialog to provide detailed information about a specific method on the object view.

Use this	To do this
Method	View the name of the object's method for which the method resolution criteria are being set.
Endpoint	Select the endpoints on the local environment that are available for the type of resolution specified in **Type**. All endpoints in the LE are listed and available for selection. If an endpoint selected for one resolution type is already used with another resolution type then an error message will pop up when you click **Apply**. The error message explains which object and view has this endpoint used with another resolution type.
Method resolution criteria	View a description of the behavior for the IT runtime when it resolves a request to a method. The sequence of data flow events may require the TI to send and receive various amounts of data prior to obtaining the ability to make the connection between the incoming request and the target method.
Type	Select the type of resolution to be conducted: • **Endpoint** The endpoint resolution type is simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and it represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables **Object Name**, **Input format** and **Output format** and clears their contents. • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request, and the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables **Object**, **Input format**, and **Output format**. This option is available only for TCP/IP local environment/host environment pairs. • **Enhanced Listener Message (ELM)**: • **Data** Similar to **Endpoint** in that it adds the flexibility to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables **Object**, **Input format**, and **Output format** and clears their contents. • **Link to Program Name:** Resolves all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables **Object**, **Input format**, and **Output format** and clears their contents. This option is available only for SNA local environment/host environment pairs. Note Only **TRM-MSLink** and **Link to Program Name** are available for Link methods. Methods can be defined as Link in Visual Studio by setting the **Is Link** property to **True**.

Object Name	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS**
Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the UDT) definitions in the MicrosoftTRMDef.tim file in the installation TIMLibs directory. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **MS Link Request Format** • **IBM Listener Type 1 Request Format** • **IBM Listener Type 2 Request Format**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link	View the name of the program being linked to.
Program Name	Name of the TP program.
Resolution Data	View a definition of the data used by the IT runtime when it resolves a request to a method.
Data	Type the method resolution criteria for a method on the object view. The criteria can be a maximum of 256 alpha-numeric characters. This control is enabled for resolution types **Transaction Request Message (TRM)** and **Data**. This control is disabled for resolution type **Endpoint**.
Position	Type the resolution position. The position can be a maximum of nine numeric characters. This control is enabled for resolution type **Data** and disabled for resolution types **Transaction Request Message (TRM)** and **Endpoint**.

Object Node (HIP)

General Tab (View Properties)

Use the **General** tab to view or change the basic information about the object view.

Use this	To do this
Object view	View the name of the object view.
Local environment	Select a local environment (LE). The LE determines the network type associated with the object view. If you are changing from one network type to another, be sure to remove all methods from the view before changing the LE. Note Changing the current LE in the view removes the host environments (HEs) associated with the view and all related information. Use the **Host Environments** tab to associate a new HE.
Security policy	Select a security policy to be associated with the view.
Comment	Type a comment that provides additional information about the use of the object view in the HIP environment. The comment can be a maximum of 259 alpha-numeric characters.

Note

When viewed from the ***view*** node under the application ***listener*** node, the general properties are read-only. If you want to change a general property, right-click the specific ***view*** **Node** under the ***object*** **Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

Caution

The properties on an object view are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the application to function incorrectly.

Host Environments Tab (View Properties)

Use the **Host Environments** tab to view or change detailed information about the host environments (HEs) associated with the object view.

Use this	To do this
Host environment	Select the host environment to associate with the object view. This list includes all the HEs that have the same network type as the local environment associated with the object view.
Configured host environments	View the HEs already associated with the object view.
Add	Click to add the HE to the object view and move the name to **Configured host environments**.
Remove	Click to remove the selected HE from the object view and from **Configured host environments**. The removed HE is moved to the list in **Host environment**.

Note

When viewed from the ***view*** node under the application ***listener*** node, the host environment properties are read-only. If you want to change a host environment property, right-click the specific ***view*** **Node** under the ***object*** **Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

Caution

The properties on an object view are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the object view to function incorrectly.

Methods Tab (View Properties)

Use the **Methods** tab to view or change the methods associated with the object view and the method resolution details. You can use this page to add and remove methods on the object view. Double-click a row in the grid to edit the resolution information.

Use this	To do this

Object methods	View all the methods that are defined in the object. Each row contains a summary of the resolution information for a single method. Rows in the list cannot be deleted. The columns are:
	• **Include** Select to include the method in the object view.
	• **Method** View the name of the method. Double-click the method name to launch the **Method Resolution Criteria** dialog box.
	• **Endpoint** View one of the endpoints defined in the local environment associated with the view. To change the content of this field, double-click on the **Endpoints** field for a specific method.
	• **Resolution Type** Displays one of the possible resolution types:
	  • **Endpoint** The endpoint resolution type is the simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and represents a single synchronous exchange of data.
	  • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant, MSLink model. It represents a double exchange sequence.
	  • **Enhanced Listener Message (ELM)**:
	  • **Data** Similar to **Endpoint** in that it adds the ability to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data.
	  • **Link to Program Name:** Select **Link to Program Name** to resolve all the methods of a new object view using the data information specified when the object view was created.
	To change the content of this field, double-click the **Resolution Type** field for a specific method.
	• **Resolution Data** Identifies the data used to select the method to be executed. To change the content of this field, double-click the **Resolution Data** field for a specific method.
	• **Resolution Position** Displays the resolution position. If **Data Resolution** is selected, this information is used by the TI runtime to identify the starting point in the data stream in which to look for the data defined in the resolution data field to determine which method is to be executed. To change the content of this field, double-click on the **Resolution Position** field for a specific method.

Note

When viewed from the ***view*** node under the application ***listener*** node, the method properties are read-only. If you want to change a method property, right-click the specific ***view*** **Node** under the **object Node**, and then left-click **Properties** on the shortcut menu. The properties on that page are read-write.

Caution

The properties on an object view are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the object view to function incorrectly.

Method Resolution Criteria Dialog Box (Object Properties)

Use the **Method Resolution Criteria** dialog to provide detailed information about a specific method on the object view.

Use this	To do this
Method	View the name of the object's method for which the method resolution criteria are being set.
Endpoint	Select the endpoints on the local environment that are available for the type of resolution specified in **Type**. All endpoints in the LE are listed and available for selection. If an endpoint selected for one resolution type is already used with another resolution type then an error message will pop up when you click **Apply**. The error message explains which object and view has this endpoint used with another resolution type.
Method resolution criteria	View a description of the behavior for the IT runtime when it resolves a request to a method. The sequence of data flow events may require the TI to send and receive various amounts of data prior to obtaining the ability to make the connection between the incoming request and the target method.
Type	Select the type of resolution to be conducted: • **Endpoint** The endpoint resolution type is simplest means of resolving a request to a method. A data stream directed to a port always executes a single method on a view. This model is considered "raw sockets," and it represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Endpoint** disables **Object Name**, **Input format** and **Output format** and clears their contents. • **Transaction Request Message (TRM)** The TRM resolution type is specific to the IBM CICS Concurrent Server model and the Microsoft variant MSLink model. It represents a double exchange sequence. The first exchange represents the transaction request, and the second exchange represents the request and reply data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Transaction Request Message (TRM)** enables **Object**, **Input format**, and **Output format**. This option is available only for TCP/IP local environment/host environment pairs. • **Enhanced Listener Message (ELM)**: • **Data** Similar to **Endpoint** in that it adds the flexibility to identify a string in the data stream directed to a port that is used to associate the request with a specific method in the view. This model is considered "raw sockets." It represents a single synchronous exchange of data. When a new view is created and associated with the HE, the method resolves to the first endpoint defined in the associated local environment. Selecting **Data** disables **Object**, **Input format**, and **Output format** and clears their contents. • **Link to Program Name:** Resolves all the methods of a new object view using the data information specified when the object view was created. When a new view is created and associated with the HE, the method resolves to the Link Tran ID field in the default HE resolution. Selecting **Link to Program Name** disables **Object**, **Input format**, and **Output format** and clears their contents. This option is available only for SNA local environment/host environment pairs. Note Only **TRM-MSLink** and **Link to Program Name** are available for Link methods. Methods can be defined as Link in Visual Studio by setting the **Is Link** property to **True**.

Object Name	Select the object. The list of objects is populated from the Help string in the interface definition of objects identified to the resolution handler. Microsoft provides three TRM resolution handlers: • **Microsoft HIS - TRM Handler MS Link** (default) • **Microsoft HIS - TRM Handler MSCCS** • **Microsoft HIS - TRM Handler IBMCCS**
Input format	Select the format of the data stream that represents the TRM sent by the client host application program. The list of TRM input formats is determined by the UDT) definitions in the MicrosoftTRMDef.tim file in the installation TIMLibs directory. The **Input format** box is blank by default, but three input formats are defined that match the names of the resolution handler **Object**: • **MS Link Request Format** • **IBM Listener Type 1 Request Format** • **IBM Listener Type 2 Request Format**
Output format	Select the format of the data stream that represents the reply to the TRM that was sent by the host application program. TI formats a data stream that is returned to the host client application program in the form defined by the output TRM. The list of TRM output formats is determined by the UDT definitions in the MicrosoftTRMDef.tim file. The **Output format** box is blank by default, but three output formats are defined that match the names of the resolution handler **Object**: • **MS Link Reply Format** • **IBM Listener Type 1 Reply Format** • **IBM Listener Type 2 Reply Format**
Link	View the name of the program being linked to.
Program Name	Name of the TP program.
Resolution Data	View a definition of the data used by the IT runtime when it resolves a request to a method.
Data	Type the method resolution criteria for a method on the object view. The criteria can be a maximum of 256 alpha-numeric characters. This control is enabled for resolution types **Transaction Request Message (TRM)** and **Data**. This control is disabled for resolution type **Endpoint**.
Position	Type the resolution position. The position can be a maximum of nine numeric characters. This control is enabled for resolution type **Data** and disabled for resolution types **Transaction Request Message (TRM)** and **Endpoint**.

General Tab (Remote Environment Properties)

Use the **General** tab to set the basic characteristics of the remote environment.

Use this	To do this
Type	View the type of remote environment, which describes the region on the mainframe with which your application is designed to work
Status	View the current state of the remote environment: • **Active**. The TI run-time environment accepts requests and attempts to communicate with the associated mainframe region. • **Inactive**. The TI run-time environment will not accept requests from client applications and returns an Inactive remote environment error message without attempting to communicate with the associated mainframe region. • **Disabled**.
Identifier	View the GUID for the remote environment. This identifier is useful when reviewing TI messages in the Windows Event Log.
Creator name	View the user ID of the user who created the remote environment.
Date created	View the date the remote environment was created.
Comment	Type or view a comment or description to help identify the new remote environment when its properties are displayed elsewhere in the product. You can enter up to 259 Unicode characters in this field. Useful information includes the name and location of the mainframe, and the name and telephone number of the system administrator.

⚠**Caution**
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

TCP/IP Tab (Remote Environment Properties)

Use the **TCP/IP** tab to define the network characteristics that the Windows environment uses to interact with the host.

Use this	To do this
IP/DNS Address	Type the address or select one from the drop-down list. The address can be a maximum of 256 alphanumeric characters. The drop-down list displays the most recently used IP addresses.
TCP ports list	Type the TCP port number. The number can be a maximum of 256 positive numerals separated by semicolons. The port numbers cannot be repeated. The drop-down list displays the most recently used port numbers.
Time-out if no response within *number* seconds	Type the number of seconds. The send and receive time-out values are used by the WIP runtime environment when it communicates with the host environment. The time-out values are used on transport-specific APIs to terminate the receive API function when no host data or acknowledgement is received in the specified amount of time. The number of seconds can be a maximum of 3600 and a minimum of 0.

Caution
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Remote Environment Node

CICS Tab (for TCP/IP Properties)

LU6.2 Tab (Remote Environment Properties)

Use the **LU 6.2** tab to define the network characteristics that the Windows environment uses to interact with the host.

Use this	To do this
Local LU alias	Select a local LU alias from the drop-down list, or type the alias to be used by this remote environment when contacting the mainframe. Create and configure this local LU alias through SNA Management (SNA Server)/SNA Manager (Host Integration Server) before you use the remote environment. The LU identified by the alias must correspond with a VTAM independent LU on the mainframe. The alias can be a maximum of 256 alphanumeric characters. The drop-down list displays all the local APPC LUs defined to the SNA Manager.
Remote LU alias	Select a remote LU alias from the drop-down list, or type the alias to be used by this remote environment when contacting the mainframe. Create and configure this remote LU alias through SNA Management before you use the remote environment. The partner LU identified by this alias must identify the ACBNAME of the CICS region, the partner LU associated between APPCMVS and IMS to reach IMS. The alias can be a maximum of 256 alphanumeric characters. The drop-down list displays all the remote APPC LUs defined to the SNA Manager.
Mode name	Select a mode name from the drop-down list, or enter the mode name to be used by this remote environment for sessions established with the mainframe. Create and configure this mode name through Host Integration Server SNA Manager before you use the remote environment. Ensure that a compatible mode has been defined on the mainframe. You can also obtain a list of configured modes from Host Integration Server **SNA Manager**. Note To use two-phase commit, the APPC mode must be Sync Level 2 capable.
Supports Sync Level 2 protocols	Select this option to enable Sync Level 2 protocols for this remote environment.
Time-out in seconds	View the time-out information used by the WIP runtime environment when it communicates with the host environment. The time-out values are used on transport-specific APIs to terminate the receive API function when no host data or acknowledgement is received in the specified amount of time. When a remote environment is first created, no timeout value is specified. The TI run-time environment will wait indefinitely for the mainframe transaction program to return output parameters and simultaneously block the calling client application until this response is received. This blocking behavior is typical for APPC applications. To avoid indefinite blocking, set a timeout value in the **Receive** box.
Receive	Type the number of seconds. The number of seconds can be a maximum of 3600 and a minimum of 0.

Caution
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Remote Environment Node

Security Tab (Remote Environment Properties)

Use the **Security** tab to set the security properties of the remote environment for SNA.

Use this	To do this
Enable Single Sign-on	Select this option to require that the TI run-time environment uses Single Sign-on (SSO). Clear this option to allow TI to communicate with the mainframe region without setting user ID and password information.
Affiliate application	Select the SSO affiliate application to be queried for credentials. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen.
COM+ Single Sign-on mapping use:	Identifies the source of the host user ID and password. Important This setting is for COM+ applications only. If you are using .NET applications, the credentials used by the TI runtime are the same credentials set on the IIS virtual directory where the .NET objects are stored. You can set or change the .NET credentials by using the "identity" element in the file web.config.
User credentials	Select this option to have the TI run-time environment obtain the user ID and password information associated with the user logon in which the client application is executing. Caution For the COM server to impersonate the security credentials of the client application, the client application must grant the COM server permission to impersonate it.
COM+ application credentials	Select this option to have the TI run-time environment obtain the user ID and password information as defined for a component's COM+ application. To administer this security information, use Component Services (COM+) in Windows Server 2003. This setting is ignored when a TI component is deployed in a COM+ application which itself is configured as a Library application (instead of a Server application) on the Activation tab of the COM+ application property sheet. A Library application runs using the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user name.
Allow application to override selected authentication	Select this option to enable the TI run-time environment to use the application override mechanism for obtaining user ID and password information. The client application must be written to support the TI security override mechanism. Clear this option to base the user ID and password solely on previously selected user or package credentials. This security option can be applied to a TI component deployed in a Library COM+ or ASP.NET application or in a Server COM+ or ASP.NET application. This option appears only if **Enable Single Sign-on** is selected.
Require client provided security	Select this option to require the client to provide the security credentials, either by using the client context or by making call-back security available. This option appears only if **Enable Single Sign-on** is cleared.
Use already verified or persistent verification authentication	Select this option to have the TI run-time environment use "Already Verified," "Persistent Verification" or "No authentication," depending on the configuration of the mainframe region. "Already Verified" sends only the user ID and no password. "Persistent Verification" sends a user ID and password on the first transaction from the given user and only the user ID thereafter. "No authentication" neither sends a user ID nor a password. The host configuration controls the actual authentication to be used when this option is enabled. In a CICS region, for example, these settings correspond to the ATTACHSEC options Identify, Persistent, and None, respectively. This security option can be applied to a TI component deployed in a Library application or in a Server application. This security option can be applied to a TI component deployed in a Library COM+ application or in a Server COM+ application.

⚠**Caution**
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

How To Impersonate Client Application Security Credentials

Security Tab (Remote Environment Properties)

Use the **Security** tab to set the security properties of the remote environment for TCP/IP.

Use this	To do this
Enable Single Sign-on	Select this option to require that the TI run-time environment uses Single Sign-on (SSO). Clear this option to allow TI to communicate with the mainframe region without setting user ID and password information.
Affiliate application	Select the SSO affiliate application to be queried for credentials. The list displays all the affiliate applications defined in the SSO. The display name of the affiliate application is a concatenation of the affiliate application name and description, separated by a hyphen.
COM+ Single Sign-on mapping use:	Identifies the source of the host user ID and password. Important This setting is for COM+ applications only. If you are using .NET applications, the credentials used by the TI runtime are the same credentials set on the IIS virtual directory where the .NET objects are stored. You can set or change the .NET credentials by using the Identity tag in the file web.config.
User credentials	Select this option to have the TI run-time environment obtain the user ID and password information associated with the user logon in which the client application is executing. Note This setting is ignored when a TI component is deployed in a COM+ application which itself is configured as a Library application (instead of a Server application) on the Activation tab of the COM+ application property sheet. A Library application runs using the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user name. Caution For the COM server to impersonate the security credentials of the client application, the client application must grant the COM server permission to impersonate it.
COM+ application credentials	Select this option to have the TI run-time environment obtain the user ID and password information as defined for a component's COM+ application. To administer this security information, use Component Services (COM+) in Windows Server 2003. This setting is ignored when a TI component is deployed in a COM+ application which itself is configured as a Library application (instead of a Server application) on the Activation tab of the COM+ application property sheet. A Library application runs using the Windows user credentials of the process that invoked it, and TI attempts to map this name to a corresponding host user name.
Allow application to override selected authentication	Select this option to enable the TI run-time environment to use the application override mechanism for obtaining user ID and password information. The client application must be written to support the TI security override mechanism. Clear this option to base the user ID and password solely on previously selected user or package credentials. This security option can be applied to a TI component deployed in a Library COM+ or ASP.NET application or in a Server COM+ or ASP.NET application. Note This option appears only if **Enable Single Sign-on** is selected.
Require client provided security	Select this option to require the client to provide the security credentials, either by using the client context or by making call-back security available. Note This option appears only if **Enable Single Sign-on** is cleared.

Caution
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

How To Impersonate Client Application Security Credentials

TCP/IP Tab (Remote Environment Properties)

Use the TCP/IP tab to set the IP address and port number for the host environment.

Use this	To do this
IP/DNS address	Type the address or select from the drop-down list. The address can be a maximum of 256 alphanumeric characters. The drop-down list displays the most recently used IP addresses.
Port list	Type the TCP port number. The number can be a maximum of 256 positive numerals separated by semicolons. The port numbers cannot be repeated. The drop-down list displays the most recently used port numbers.
Time-out in seconds	The **Send** and **Receive** time-out values are used by the TI runtime environment when it communicates with the host environment. The time-out values are used on transport-specific application program interfaces (APIs) to terminate the send and/or receive API functions if no host acknowledgement is received in the specified amount of time.
Receive	Type the number of seconds the host should wait for a response before it times out. The maximum number of seconds is 3,600; the default is **30** seconds.

Caution
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

CICS Tab (for LU6.2 Link Properties)

Use the **CICS** tab to set host-specific CICS properties.

Use this	To do this
Transaction name	Type or select the transaction name on CICS tied to CICS program DFHMIRS.
Allow use of explicit SYNCPOINT commands for non-transactional components	Select this option to allow a CICS transaction program that is accessed as a nontransactional component to call EXEC CICS SYNCPOINT and EXEC CICS SYNCPOINT ROLLBACK commands. Clear this option to make any CICS transactional component that calls SYNCPOINT commands fail with an ADPL CICS ABEND. LU 6.2 Resync services must be configured on the SNA Local LU. Enable Sync Point must be enabled on SNA Remote LU. The Mode Table associated with the call must have sync level 2 enabled. The typelib must have transaction support properly set. The AppInt .Net model doesn't support Transactional nor does AppInt Com over TCP/IP.

Caution
The properties of a remote environment are not intended to be set or changed programmatically. Setting or changing the properties programmatically might cause the remote environment to function incorrectly.

Enterprise Single Sign-On Help

Affiliate Applications Properties: General

Use this dialog box to view or change general properties for the affiliate application.

Use this	To do this
Application type	Enterprise Single Sign-On (SSO) defines several different application types. The different application types support different types of mappings between the Windows account and the account on the non-Windows system. The application types are: **Individual**: Individual applications support one-to-one mappings between the Windows account and the non-Windows account. In an Individual type application, one Windows account is mapped to one, and only one, non-Windows account. The mapping can be used in either direction, from Windows to non-Windows, or from non-Windows to Windows, or both, depending on the flags that have been set for this application. Thus, Individual applications may be used for Windows initiated SSO, Host initiated SSO, or both. **Group**: Group mapping consists of mapping a Windows group, which contains multiple Windows users, to a single account in the affiliate application. You can also specify multiple accounts for the SSO Application Users role. Each account that you specify can be associated with an external account. For example, it is possible to map a domain user (domain\userA) to one set of external credentials (ExternalUser1). The same domain\userA could also be a member of Domain Group (domain\group1) and this group could be mapped to a different set of external credentials (ExternalUser2). In this case, it is important that the administrator (who must be an Application Administrator or above) specifies the correct order for the Application Users accounts. The mapping for the first account (in the Order) of which the caller is a member is the one that will be used. In this case, if mapping for domain\userA to ExternalUser1 is set to Order 0, SSO will return this set of credentials for domain\UserA. Only an application administrator, SSO affiliate administrator, or SSO administrator can create a group mapping. You cannot specify the same group application for Windows-initiated SSO and Host-initiated SSO. **Host Group**: Host Group applications are conceptually the reverse of Group applications. They support mappings between a defined group of non-Windows accounts to a single Windows account. The single Windows account that will be used by the non-Windows accounts is defined by the Application Users account for the application. The group of non-Windows accounts that is allowed to access this application is defined by creating a mapping for each non-Windows account. Host Group applications may only be used for Host initiated SSO. Important Mappings can be created only for Windows domain accounts. Local accounts cannot be mapped. Important When you use group mappings, the members of the group can obtain the credential information for the group mapping.
Application name	Name of the affiliate application. You cannot change this property after you create the affiliate application.
Description	Brief description of the affiliate application.
Contact information	The main contact for this affiliate application that users can use. (Can be an e-mail address.)
Allow local accounts for access accounts	Determines whether you allow the use of local groups and accounts in the SSO system. You should select this option only in single-computer scenarios.

Use SSO Affiliate Admin Accounts for Application Admin accounts	Determines whether the Application Admin accounts will be the same as the SSO Affiliate Admin accounts. Default is not selected.

Enterprise Single Sign-On Help

Affiliate Applications Properties: Options

Use this dialog box to view or change options for the Affiliate Application.

Use this	To do this
Enabled	The status (enabled/disabled) of this affiliate application.
Allow Windows initiated SSO	Select if Windows initiated Enterprise Single Sign-On (SSO) is allowed.
Disable credential cache	The SSO Server stores credentials in a cache to expedite access. Default is not checked.
Tickets allowed	Determines whether the SSO system uses tickets for this affiliate application. You must be an SSO administrator to select this option.
Validate tickets	Determines whether the SSO system validates tickets when the user redeems them. You must be an SSO administrator to select this option.
Timeout tickets	Determines whether tickets have an expiration time. Default is checked. Unless it is required, do not disable ticket timeouts. You must be an SSO administrator to set this option.
Ticket timeout (in minutes)	Specifies a ticket timeout specific to the affiliate application. This can be set only when updating an affiliate application, not when creating it. If ticketing is enabled for this application and this property is not, the timeout specified at the SSO System (Global) level is used. You must be an SSO administrator to set this option.
Allow host initiated SSO	Select this if it is a host initiated SSO type application. Default is not checked.
Verify external credentials	Select to verify external credentials.

Create New Affiliate Application Wizard

Use this wizard to create a new Affiliate Application.

This section contains:

Create New Affiliate Application Wizard: Welcome

Click **Next** to continue.

Create New Affiliate Application Wizard: Accounts

Specify the access accounts for the new Affiliate Application. You can specify one or more accounts for both Application Administrators and Application Users.

Note
In certain Workgroup environments, clicking the **Browse** button will cause this screen to close. Instead of using the **Browse** button, simply type the name of the required accounts in the box.

For group type Affiliate Applications, it is important to note that when specifying multiple accounts for Application Users, the way in which the accounts are ordered is very important. This is because different ordering of accounts can result in different credentials being returned, which could potentially result in an authentication failure.

For example, UserA could be a member of two groups: Group1 and Group2. Each of these groups could in turn be mapped to an account as follows:

- Group1 is mapped to ExternalCredentials1
- Group2 is mapped to ExternalCredentials2

If the order specified for 'Application Users' is Group1;Group2, then when the credentials are requested for UserA, SSO returns ExternalCredentials1.

However, if the order specified for 'Application Users' is Group2;Group1, then SSO returns ExternalCredentials2.

Application Administrators

The Windows account(s) that will manage this Affiliate Application.

Application Users

The Windows account(s) for which mappings can be created.

Enterprise Single Sign-On Help

Create New Password Sync Adapter Wizard: Options

Specify options for the new Password Sync Adapter.

Use this	To do this
Enabled	Determines whether the adapter is enabled.
Receive password changes from adapter	Determines whether the adapter is allowed to receive external password changes. Default is not selected.
Verify old password	Determines whether the adapter will verify the old password when an external password change is received. If this option is selected then with an external password change the external adapter must supply the old external password as well as the new external password. The old external password is then compared with the existing external password in the Enterprise Single Sign-On (SSO) database for that external account. If they match, the password change is accepted. If they do not match, the password change is rejected. Default is selected.
Change Windows password	Determines whether the Windows password in Active Directory will also be changed when an external password change is received (full sync). Default is not selected.
Send Windows password changes to adapter	Determines whether Windows password changes made in Active Directory will be sent to the external adapter. Default is not selected.
Send old password to adapter	If selected, the old password value (from the SSO database) will also be sent to the external adapter as well as the new password value. Some external systems might require both the old and new password values to change the password. Default is not selected.
Allow mapping conflicts	Determines whether the adapter will allow mapping conflicts. A mapping conflict occurs when mappings are not unique. In a single SSO Individual application, mappings are always one-to-one: one Windows account is mapped to exactly one external account and vice versa. However, it is possible to assign more than one application to an adapter. Thus, it is possible to have a mapping in one application that conflicts with a mapping in the other. This purpose of this option is to prevent this from occurring. It is more secure to not allow mapping conflicts unless there is a specific, well understood requirement for this behavior. Default is not selected.

Create New Password Sync Adapter: Finish

Click **Finish** to close the Wizard.

Mapping Wizard

Use this wizard to create and configure mappings.

In This Section

Create New Mappings Wizard: Welcome

Use this page to enter basic information about the Affiliate Application.

Affiliate Application name

The name of the application to be mapped.

Description

A description (optional).

Create New Mappings Wizard: Mappings File Option

Use this page to determine whether a new or existing mappings file will be used.

Generate new mappings file

Select to generate a new file. Default is selected.

Use an existing mappings file

Select to use an existing file.

Create New Mappings Wizard: Files Location

Mappings file

If necessary, browse to a new file.

Log file

Use the default, or change if necessary.

Validate

Click to ensure that you have proper access and have not entered invalid information.

Create New Mappings Wizard: Accounts

Application Users Accounts

Select the appropriate accounts.

Validate

Click to see the results in the status window.

Create New Mappings Wizard: External User Name

This page collects information to generate an external account name based on the Windows account name.

Windows domain name using

Change or accept these domain name properties as appropriate.

Windows user name using

Change or accept these user name properties as appropriate.

Remove characters

Remove characters as necessary.

Prepend characters

Add characters to the beginning of the name.

Domain/user separator characters

Select separator characters.

Append characters

Add characters to the end of the name.

Limit the number of characters

Limit the number of characters for the name.

Example

Uses the data entered above to display the Windows domain name, Windows user name, and external user name.

Create New Mappings Wizard: Generate

Mappings file location

Displays the location entered previously.

Selected accounts

Displays the accounts specified previously.

Start

Click to generate mappings.

Stop

Click to pause mappings.

View log file

Click to open the mappings log file in Notepad.

Create New Mappings Wizard: Options

Mappings file location

Displays the location you entered previously.

View/Edit mappings file

Click to open the file for editing as necessary.

Enable mappings

Select to enable mappings after they are created. Default is selected.

Set password

Selecting this option allows you to choose one of the following:

- Same as external name
- Define from Windows user account
- Fixed value (enter and confirm a new password)

Create New Mappings Wizard: Password

This page collects information to generate a password based on the Windows account name.

Windows domain name using

Change or accept these domain name properties as appropriate.

Windows user name using

Change or accept these user name properties as appropriate.

Remove characters

Remove characters as necessary.

Prepend characters

Add characters to the beginning of the name.

Domain/user separator characters

Select separator characters.

Append characters

Add characters to the end of the name.

Limit the number of characters

Limit the number of characters for the name.

Example

Uses the data entered above to display the Windows domain name, Windows user name, and password.

Create New Mappings Wizard: Create

Use this page to create the mappings file with all of the information that has been collected.

Mappings file location

Confirm location of the file.

View mappings file

Click to view as necessary.

Start

Click to generate the mappings file.

Stop

Click to pause.

Create New Mappings Wizard: Finish

View Log File

Click to show the log file generated in the mapping process.

When I click finish, delete the mappings file

Select if desired. Default is selected unless you used an existing mappings file.

When I click finish, delete the log file

Select if desired. Default is selected unless you used an existing file.

Done

Click to close the wizard and display the results of the mapping process.

Enterprise Single Sign-On System

Use these topics to view and change the Enterprise Single Sign-On system properties.

This section contains:

Enterprise Single Sign-On

Use these menu commands to configure and run Enterprise Single Sign-On.

SSO System Properties: Accounts

This screen displays account properties for the overall Enterprise Single Sign-On (SSO) system.

Use this	To do this
SSO Administrators	The Windows account that will manage this SSO system.
SSO Affiliate Administrators	The Windows accounts that define who can create and manage all Affiliate Applications.

Enterprise Single Sign-On Help

SSO System Properties: General

This screen displays general properties for the overall SSO system.

Use this	To do this
Master secret server	The master secret server is the Enterprise Single Sign-On (SSO) server that stores the master secret (encryption key). The master secret server generates the master secret when an SSO Administrator requests it. The master secret server stores the encrypted master secret in the registry. Only SSO Administrators can access the master secret.
Ticket timeout (in minutes)	This property specifies the length of time for which a ticket that SSO issues is valid. To satisfy most of the scenarios in an enterprise that use SSO, the default ticket time-out is 2 minutes. The SSO Administrator can change this based on the application requirements.
Credential cache timeout (in minutes)	This property specifies the credential cache time-out for all SSO servers. SSO servers cache the credentials after the first lookup. By default, the credential cache time-out is 60 minutes. The SSO Administrator can change this to a suitable value based on the security requirements.

Enterprise Single Sign-On Help

SSO System Properties: Options

This screen displays options for the overall Enterprise Single Sign-On (SSO) system.

Use this	To do this
Allow tickets	Determines whether tickets are allowed at the system level. Only an SSO Administrator can configure tickets at the SSO system level and at the Affiliate Application level. If ticketing is disabled at the system level, it cannot be used at the Affiliate Application level either. It is possible to enable tickets at the system level and disable them at the Affiliate Application level.
Allow host initiated SSO	By default, host initiated Single Sign-On is not enabled in the Single Sign-On system, and must be enabled by the SSO Administrator.
From Windows to adapters	Determines whether Windows password changes (in Active Directory) will be sent to password sync adapters. Default is not selected.
From adapters to SSO database (partial sync)	Determines whether external password changes received from password sync adapters will cause the password to be changed in the SSO database. Default is not selected.
From adapters to Windows (full sync)	Determines whether external password changes received from password sync adapters will cause the Windows password to be changed in Active Directory. Default is not selected.

Enterprise Single Sign-On Help

Password Sync Adapter Properties: Options

Use this dialog box to view or change options for the Password Sync Adapter.

Use this	To do this
Enabled	Determines whether the adapter is enabled.
Receive password changes from adapter	Determines whether the adapter is allowed to receive external password changes. Default is not selected.
Verify old password	Determines whether the adapter will verify the old password when an external password change is received. If this option is selected then with an external password change the external adapter must supply the old external password as well as the new external password. The old external password is then compared with the existing external password in the Enterprise Single Sign-On (SSO) database for that external account. If they match, the password change is accepted. If they do not match, the password change is rejected. Default is selected.
Change Windows password	Determines whether the Windows password will also be changed in Active Directory when an external password change is received (full sync). Default is not selected.
Send Windows password changes to adapter	Determines whether Windows password changes will be sent to the external adapter. Default is not selected.
Send old password to adapter	If selected, the old password value (from the SSO database) will also be sent to the external adapter as well as the new password value. Some external systems might require both the old and new password values to change the password. Default is not selected.
Allow mapping conflicts	Determines whether the adapter will allow mapping conflicts. A mapping conflict occurs when mappings are not unique. In a single SSO Individual application, mappings are always one-to-one: one Windows account is mapped to exactly one external account and vice versa. However, it is possible to assign more than one application to an adapter. Thus, it is possible to have a mapping in one application that conflicts with a mapping in the other. This purpose of this option is to prevent this from occurring. It is more secure to not allow mapping conflicts unless there is a specific, well understood requirement for this behavior. Default is not selected.

Data Integration Help

Use the topics in this section to navigate through the Data Integration User Interface. Click a topic below for more information.

In This Section

- Data Source Wizard
- Data User Interface Elements
- Configuring a Data Source

Data Source Wizard

The Data Source Wizard guides you through the configuration process. The wizard dynamically adapts to both DB2 and VSAM data sources and displays the appropriate screens.

In This Section

Welcome Screen

Click **Next** to continue.

Data Source Screen

Data source platform

Select the appropriate platform from the dropdown list.

Network type

Select either TCP/IP or SNA LU 6.2 (APPC).

TCP/IP Network Connection Screen

Address or alias

When TCP/IP Connection is selected as the network transport, this field indicates the IP address of the host DB2 server.

Port

When TCP/IP Connection is selected as the network port, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is **IP port 446**.

Distributed transactions

When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the Host Integration Server TCP/IP Resync service.

APPC Network Connection Screen

Local LU alias

When APPC Connection is selected, this field is the name of the local LU alias configured in Host Integration Server.

Remote LU alias

When APPC Connection is selected, this field is the name of the remote LU alias configured in Host Integration Server.

Mode name

When APPC Connection is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA Server configuration.

Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security).

The default is typically QPCSUPP.

Distributed transactions

When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync service. This option works only with DB2 for OS/390 v5R1 or later.

DB2 Database Screen

Initial catalog

This field is the first entry in the Database section of the Connection properties.

This OLE DB property is used as the first part of a 3-part fully qualified table name.

In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual.

In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, one can be created using the Add option.

In DB2 Universal Database, this property is referred to as DATABASE.

If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization.

This is a required parameter.

This parameter is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.

Package collection

The name of the DRDA target collection (AS/400 library) where the Microsoft DAT should store and bind DB2 packages. This could be same as the Default Schema.

The DAT will create packages dynamically in the location to which the user points using the Package Collection parameter. By default, the DAT will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source.

A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example, PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users.

Default schema

The name of the Collection where the DAT looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The DAT uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection.

For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner").

For DB2/400, the Default Schema is the target COLLECTION name.

For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name.

If the user does not provide a value for Default Schema, the OLE DB Provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. This default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.

This parameter is equivalent to the DBPROP_DB2OLEDB_DEFAULTSCH OLE DB property ID.

Default qualifier

The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute allows the user to access database objects without fully-qualifying the objects using a collection (schema) qualifier. The DAT sends this value to DB2 using a SET CURRENT SQLID statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, no SET statement is issued by the DAT. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS).

Mainframe File System (VSAM) Screen

Host column description file

The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory where the Host Integration Server server or client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.

This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.

AS/400 File System Screen

Location

The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM.

This parameter is not used when connecting to mainframe systems.

Default library

This parameter indicates the default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.

This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.

Host file metadata assembly

The fully qualified file name of the Distributed Data Management (DDM) Host Column Description (HCD) file (created using the Data Access tool), or the fully qualified file name of a Host File Metadata Assembly generated by the Host File Designer in Visual Studio 2005.

This parameter can be a UNC string up to 256 characters in length.

This parameter is required when the data source information will be used with the BizTalk Adapter for Host Files or Managed Provider for Host Files, and is optional when connecting to an AS/400 using SNAOLEDB.

Adding a Column

This command displays the Column Properties Dialog box. You can also access this dialog box by selecting a column and clicking **Properties** from the context-sensitive menu.

To add a column

1. In the **Data Source Browser** window, click the **Action** menu.
2. Click **Add Column**. The **Column properties: General tab** appears.
3. Enter the **Name**, **Alias**, and **Comment** (optional). For more information on these properties, click the **Help** button. When you are finished, click **Apply**.
4. Click the **Host tab**. Select the appropriate **Type** and **CCSID**, and enter the **Length**, **Precision**, and **Scale**. For more information on these properties, click the **Help** button. When you are finished, click **Apply**.
5. Click the **Local tab**. Select the **Type** and check **Use qualifier** if appropriate. For more information on these properties, click the **Help** button. When you are finished, click **OK**.

Column properties: General

Name

The name of the column.

Alias

The alias for the column.

Comment

A comment (optional).

Column properties: Host

Type

The host data type, which determines how data is stored on the host.

CCSID

The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page.

This parameter defaults to U.S./Canada (37).

This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

Length

The length of the data type on the host.**Precision**

The precision (or number of digits in a numeric type), of the data type on the host.

Scale

The scale (or number of decimal digits in a numeric type), of the data type on the host.

Column properties: Local

Type

The data type presented (such as DBTYPE_STR). Data conversions take place from the host type to the local type.

Use qualifier

Determines whether or not a qualifier is to be used.

Table properties

Name

Type a name for your table.

Use table for file transfer

Selecting this option allows you to enter additional fields for your table, below.

Field delimiter

Enter the field delimiter for your table.

Record delimiter

Enter the record delimiter for your table.

Text qualifier

Enter the text qualifier for you table.

File creation type

Select Direct, Sequential, or Indexed from the list.

Sort

If you selected a File Creation Type of Indexed, you have the option of sorting in either Ascending or Descending order.

Key position

If you selected a File Creation Type of Indexed, you have the option of specifying a key position.

Key length

If you selected a File Creation Type of Indexed, you have the option of specifying a key length.

Options Property Page

The Data Access Tool configures the following default values at installation.

Files	Location
OLE DB UDL files	C:\My Documents\Host Integration Projects\Data Sources\
ODBC File DSNs	C:\Program Files\Common Files\ODBC\Data Sources
Host column description files	C:\My Documents\Host Integration Projects\Data Descriptions

Click any of the **Browse** buttons to select a new directory.

DB2 Locale Screen

Host CCSID

The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page.

This parameter defaults to U.S./Canada (37).

This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

PC code page

This parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows.

This parameter defaults to Latin 1 (1252).

This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Process binary as character

When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters.

This parameter is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.

Mainframe and AS/400 Locale Screen

Host CCSID

The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page.

This parameter defaults to U.S./Canada (37).

This parameter is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

PC code page

This parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows.

This parameter defaults to Latin 1 (1252).

This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Process binary as character

When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters.

This parameter is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.

Security Screen

Interactive sign-on

Authentication to a data source can be done using interactive sign-on or Single Sign-On. For interactive sign-on, the user name and password must match host credentials.

User name

A valid user name and password are normally required to access data sources on a host. These values are case sensitive. Do not select the **Single Sign-On** option if a specific user name and password are to be entered.

Password

A valid user name and password are normally required to access data sources on hosts. These values are case sensitive.

Allow saving password

You have the option of saving the password in the .udl file by selecting this check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the .udl file. For security purposes, however, it is strongly recommended that you set these properties manually, instead of using a .udl. Note that if you select this option when using the ODBC Driver for DB2, and then uninstall and reinstall Host Integration Server, the password will be erased.

Single Sign-On

Select this check box to enable using the Host Integration Security features providing a Single Sign-On to access this data source.

When this check box is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The user name and password fields are set based on the Windows 2000 logon.

When this check box is not selected, the **User name** and **Password** fields must normally contain appropriate values to access data sources on hosts.

Affiliate Application

If you selected Single Sign-On, choose an Affiliate Application from the list. The Enterprise Single Sign-On (SSO) Affiliate applications are logical entities that represent a system or sub-system such as a host, back-end system, or line of business application to which you are connecting using SSO. An affiliate application can represent a back-end system such as a mainframe or UNIX computer. It can also represent an application such as SAP, or a subdivision of the system, such as the "Benefits" or "Pay stub" sub-systems.

DB2 Validation Screen

Use this screen to validate your configuration.

Click **Connect** to perform a test connection.

Click **Packages** to create the DB2 packages required for executing SQL statements.

Click **Sample Query** to retrieve a list of tables in the default database collection.

Mainframe and AS/400 Validation Screen

Use this screen to validate your configuration.

Click **Connect** to test the connection to the mainframe or AS/400 system.

Click **Sample Query** to retrieve a list of files in the default library.

DB2 Saving Information Screen

Use this screen to name and save your configuration.

Data source name
Enter a name of your choice. This name is used when saving the data source configuration to one or more data source types.

OLE DB or Managed group, **ODBC** group
Make the appropriate selection(s) for your data source.

Mainframe and AS/400 Saving Information Screen

Use this screen to name and save your configuration.

Data source name
Enter a name of your choice. This name is used when saving the data source configuration to one or more data source types.

Universal data linkand **Initialization string file**
Make the appropriate selection(s) for your data source.

Advanced Options Screen

The settings on this screen are optional.

Connection pooling
Selecting this option will cache connections for reuse.

Cache authentication
This parameter determines whether the OLE DB Provider for AS/400 and VSAM caches authentication information, such as a password, in an internal cache. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and defaults to false.

This parameter is equivalent to the DBPROP_CACHE_AUTHINFO OLE DB property ID.

Mode (Read/ReadWrite)
Determines whether the connection is read-only, or if it allows modifications to the database.

Repair host keys
This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry.

This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.

Read only
Selecting this option prevents a data source from being updated.

Alternate TP Name
This is the transaction program name on a DB2 DRDA application server.

Strict Validation
Select this option if desired.

Finish Screen

This screen displays a summary and status of your configuration. Click **Finish** to implement your actions.

Data User Interface Elements

The topics in this section describe the elements in the Data Integration User Interface.

In This Section

Data Source Browser

Data Source Folder

Data Source Item

Data Descriptions Folder

Data Description File

Data Description Table

Data Description Column

Table Properties

Data Source Browser

The Data Source Browser is the window where you configure and manage your data sources.

The window is divided into three parts: a tree view containing the data sources and data descriptions, a list view containing details of a selected node, and a result view containing the text results of an action (such as a package creation).

The procedures in the following topics describe how to manage data. Many commands are also accessible through a context-sensitive menu which appears when you right-click any section of the Browser window. In addition, the F5 key refreshes the tree view, the Delete key deletes the currently selected item, and the F1 key opens the online Help.

Data Source Folder

This folder contains data sources and groups of data sources.

Data Source Item

Right-clicking a data source allows you to view, edit, test, delete, or rename it.

Data Descriptions Folder

This folder displays the names of all configured data descriptions. Click the individual files to view their properties.

Data Description File

Right-click a data description to view its properties, or to edit or delete the file.

Data Description Table

A Data description table contains the meta-data describing a file or table on a mainframe, AS/400, or System 36 file system. A table description holds information about the various columns in that table.

Data description tables are stored in "Host Column Description" files and can be found under the "Host Column Descriptions" folder in the DAT browser.

Data Description Column

A Data description column contains the meta-data describing a field or column of a mainframe, AS/400, or System 36 file system table or file. This meta-data includes the column name, its host type, and its local type.

Data description columns are stored in "Host Column Description" files and can be found under the "Host Column Descriptions" folder in the DAT browser.

Table Properties

Displays the properties for the selected table.

Configuring a Data Source

The following sections contain information about configuring a data source.

In This Section

Configuring a Data Source for OLE DB Provider for AS/400 and VSAM

Configuring a Data Source for the ODBC Driver for DB2

Configuring a Data Source for OLE DB Provider for AS/400 and VSAM

You must configure data source information for each AS/400 or mainframe system data source object that is to be accessed using OLE DB Provider for AS/400 and VSAM. The default parameters for OLE DB Provider for AS/400 and VSAM are used only when these parameters are not configured for each data source.

Microsoft Data Link, a core element of Microsoft Data Access Components (MDAC), provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of universal data link (.udl) files. The Data Source Wizard in the Microsoft Data Access Tool can help define UDL files. OLE DB consumer applications, such as Data Transformation Services in Microsoft SQL Server can use the UDL files to connect to IBM data sources, such as DB2 and the mainframe file system.

To configure a data source for OLE DB Provider for AS/400 or VSAM

You must create a data link to configure parameters for your OLE DB data source. You can create a new data link by clicking the shortcut in the Host Integration Server program folder.

The properties of a universal data link file can be edited by opening the file from Windows Explorer.

The **Provider** tab lets you select the OLE DB provider (the provider name string) to be used in this .udl file from a list of possible OLE DB providers. Select **Microsoft OLE DB Provider for AS/400 and VSAM**.

The **Connection** tab lets you configure the basic properties required to connect to a data source. For **OLE DB Provider for AS/400 and VSAM**, the connection properties include the following values:

Property	Description
Data Source	This is an optional parameter that can be used to describe the data source.
Network	This drop-down list allows for selecting the type of network connection to use. The options are **TCP/IP Connection** or **SNA Connection**. If **TCP/IP Connection** is selected, click **More Options**, to open a dialog box for configuring TCP/IP network settings. The parameters you can configure include the IP address of the remote host (or a host name alias for this computer) and the Network Port (TCP/IP port) used to communicate with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **SNA Connection** is selected (using LU 6.2), click **More Options** to open a dialog box for configuring SNA network settings. The parameters you can configure include the following: the APPC local LU alias, the APPC remote LU alias, and the APPC mode used to communicate with the host. The default value for the APPC mode ordinarily uses QPCSUPP. The local and remote LU alias fields do not have default values.
Single Sign-On	This option enables using the Host Integration Security features providing a single sign-on to access this OLE DB data source. When this option is selected, the **User name** and **Password** fields are dimmed and become inaccessible. The **User name** and **Password** fields are set based on the Windows logon values. When this option is not selected, the **User name** and **Password** fields ordinarily contain appropriate values to access data sources on hosts.
User name	A valid user name and password are ordinarily required to access data sources on hosts. These values are case sensitive. The user must click the option button that requires a specific user name and password to be entered.
Password	A valid user name and password are ordinarily required to access data sources on hosts. These values are case sensitive. The user will have to clear the **Blank password** check box, if it is selected, to enter a password. Optionally, the user can choose to save the password in the .udl file by selecting the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file.

Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems.
Default Library	This parameter indicates the default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
Host Column Description File	The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be a UNC string up to 256 characters long. A path does not must be included in the name if the HCD file is located in the system directory where the Host Integration Server server or client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection parameters. The connection can only be tested after all the required parameters are entered. When this button is selected, a session will be established to the host computer using OLE DB Provider for AS/400 and VSAM.

The **Advanced** tab exposes OLE DB standard properties. For **OLE DB Provider for AS/400 and VSAM**, the advanced properties include the following values:

Property	Description
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. By default, this parameter uses U.S./Canada (37). This parameter is equivalent to the SNAOLEDB_HOSTCCSID OLE DB property ID.
PC Code Page	The *PC Code Page* parameter indicates the code page to be used on the personal computer for character code conversion. This parameter is required when processing binary data as character data. Unless the **Process Binary as Character** check box is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows. By default, this parameter uses Latin 1 (1252). This parameter is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Read only	When the *Read Only* parameter is checked in the **Advanced** tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the *Mode* parameter to Read (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. By default, this parameter is false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
Process Binary as Character	When this option is checked (property is set to true), the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. By default, this parameter is false. This parameter is equivalent to the SNAOLEDB_BINASCHAR OLE DB property ID.

The **All** tab lets you configure additional properties used to connect to a data source. Some of the properties in the **All** tab are required. These properties can be edited by selecting a property from the displayed list and selecting **Edit Value**. For Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the following values:

Property	Description
APPC Local LU Alias	The name of the local LU alias configured in the Host Integration Server computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server computer configuration. Valid values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also valid: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). By default, this parameter ordinarily is QPCSUPP. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the Host Integration Server computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
Cache Authentication	This parameter determines whether the OLE DB Provider for AS/400 and VSAM caches authentication information, such as a password, in an internal cache. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and is false by default. This parameter is equivalent to the DBPROP_CACHE_AUTHINFO OLE DB property ID.
Connection Timeout	The time (in seconds) to wait for initialization to finish. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and is 0 by default. This parameter is equivalent to the DBPROP_INIT_TIMEOUT OLE DB property ID.
Data Source	This is an optional parameter that can be used to describe the data source. This parameter is equivalent to the DBPROP_INIT_DATASOURCE OLE DB property ID.
Default Library	This parameter indicates the default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
Encrypt Password	This parameter determines whether special security mechanisms are used to ensure password privacy. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and is false by default. This parameter is equivalent to the DBPROP_AUTH_ENCRYPT_PASSWORD OLE DB property ID.

Extended Properties	This parameter is a string that contains provider-specific, extended connection information. Properties passed through this parameter should be delimited by semicolons and are interpreted by the OLE DB provider's underlying network client. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property parameters. This parameter is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the data as represented on the host. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the host column CCSID and default ANSI code page. By default, this parameter is U.S./Canada (37). This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Host Column Description File	The fully qualified file name of the Distributed Data Management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters long. A path does not have to be included in the name if the HCD file is located in the system directory where the Host Integration Server Server or Client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
Impersonation Level	This parameter indicates the level of impersonation that the server can use when impersonating the client computer. This property applies only to network connections other than remote procedure call (RPC) connections; these impersonation levels are similar to those provided by RPC. The values of this property correspond directly to the levels of impersonation that can be specified for authenticated RPC connections, but can be applied to connections other than authenticated RPC. This parameter can be set to one of the following values: Anonymous — The client computer is anonymous to the server. The server process cannot obtain identification information about the client computer and cannot impersonate the client computer. Delegate — The process can impersonate the client's security context while acting on behalf of the client. The server process can also make outgoing calls to other servers while acting on behalf of the client. Identity — The server can obtain the client's identity. The server can impersonate the client computer for access control list (ACL) checking, but cannot access system objects as the client computer. Impersonate — The server process can impersonate the client's security context while acting on behalf of the client computer. This information is obtained when the connection is established, not on every call. By default, this parameter uses Impersonate. This parameter is equivalent to the DBPROP_INIT_IMPERSONATION_LEVEL OLE DB property ID.
Integrated Security	This parameter is a string that contains the name of the authentication service used by the server to identify the user using the identity provided by an authentication domain. For example, for Microsoft® Windows 2000 Integrated Security, this is Security Support Provider Interface (SSPI). If this parameter is a null pointer, the default authentication service should be used. When this property is used, no other DBPROP_AUTH* properties are needed and, if provided, their values are ignored. This parameter is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Locale Identifier	This parameter specifies the locale to use. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and is 437 by default. This parameter is equivalent to the DBPROP_INIT_LCID OLE DB property ID.

Location	This parameter indicates the remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems. This parameter is equivalent to the DBPROP_INIT_LOCATION OLE DB property ID.
Mask Password	This parameter indicates whether the password should be sent to the data source or enumerator in a masked form. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to false. This parameter is equivalent to the DBPROP_AUTH_MASK_PASSWORD OLE DB property ID.
Mode	After a connection is established, this parameter represents a bit mask of the access permissions that will be applied to the data file. As implemented by the OLE DB Provider for AS/400 and VSAM, access permissions apply to host file locks and do not apply to record locks. The allowable values include the following: Read, ReadWrite, Share Deny None, Share Deny Read, Share Deny Write, Share Exclusive, and Write. This parameter can be a combination of zero or more of the following: DB_MODE_READ — Read-only. DB_MODE_WRITE — Write-only. DB_MODE_READWRITE — Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_READ — Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE — Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE — Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_SHARE_DENY_NONE — Neither read nor write access can be denied to others. This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target DDM service access port when connecting through TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.
Network Transport Library	This parameter, which represents the dynamic-link library used for transport, designates whether the OLE DB provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCPIP or SNA. If TCPIP is selected, then values for Network Address and Network Port are required. TCP/IP connectivity to the mainframe is not supported by the OLE DB Provider for AS/400 and VSAM. If SNA is selected, then values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. This value defaults to SNA. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is shown as asterisks in this dialog box for security purposes. Optionally, you can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.

PC Code Page	This parameter indicates the code page used for character code conversion. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in the Windows operating system. If this parameter is set to **Binary** or **65535**, then no character code conversions take place. This parameter defaults to Latin 1 (1252). This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Persist Security Info	This parameter indicates whether the data source object is allowed to persist sensitive authentication information such as a password along with other authentication information. Optionally, a user can choose to save the password in the .udl file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option persists the authentication information in plain text within the .udl file. This parameter defaults to false. This parameter is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	This parameter indicates whether to **Process Binary as Character** fields (CCSID of 65535) as character data type fields on a per data source basis. The **Host CCSID** and **PC Code Page** values are required input parameters when this parameter is true. The default for this parameter is false. Do not process binary fields as character fields. This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.
Protection Level	This parameter indicates the level of protection of data sent between client computer and server. The values of this property correspond directly to the levels of protection that can be specified for authenticated RPC connections. This parameter can be set to one of the following values: DB_PROT_LEVEL_NONE — Performs no authentication of data sent to the server. DB_PROT_LEVEL_CONNECT — Authenticates only when the client computer establishes the connection with the server. DB_PROT_LEVEL_CALL — Authenticates the source of the data at the beginning of each request from the client computer to the server. DB_PROT_LEVEL_PKT — Authenticates that all data received is from the client computer. DB_PROT_LEVEL_PKT_INTEGRITY — Authenticates all data received is from the client computer and that it has not been changed in transit. DB_PROT_LEVEL_PKT_PRIVACY — Authenticates all data received is from the client computer, that it has not been changed in transit, and protects the privacy of the data by encrypting it. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to the connect level of protection. This parameter is equivalent to the DBPROP_INIT_PROTECTION_LEVEL OLE DB property ID.
Read only	When the *Read Only* parameter is checked in the Advanced tab, the OLE DB Provider for AS/400 and VSAM creates a read-only data source by setting the *Mode* parameter to Read (DB_MODE_READ). A user has read access to files and cannot do update operations.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.

Strict Validation	This parameter indicates whether strict validation should be used and defaults to false. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.
User ID	A valid user name is normally required to access data sources on hosts. This value is case-sensitive. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

Configuring a Data Source for the ODBC Driver for DB2

To configure a data source for the ODBC Driver for DB2

1. In Windows, click **Start**, click **Settings**, and then click **Control Panel**.
2. Double-click the **ODBC** icon to display the **ODBC Data Source Administrator** dialog box.
3. If you are configuring an existing data source, select the data source name and click **Configure** to display the **Microsoft ODBC Driver for DB2 Configuration** dialog box.
4. If you are configuring a new data source click either the **User DSN** tab, the **File DSN** tab, or the **System DSN** tab. Click **Add**, select **Microsoft ODBC Driver for DB2 Driver**, and then click **Finish** to display the **Microsoft ODBC Driver for DB2 Configuration** dialog box.
5. Type the appropriate values in the fields, and then click **Apply**.

The **Microsoft ODBC Driver for DB2 Configuration** dialog box contains the following five tabs:

The **General** tab contains the following fields:

Parameter	**Comments**
Data Source Name	A blank field for specifying the name of the data source. Enter a string that identifies this ODBC data source. The data source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file, which is stored in C:\Program Files\Common Files\ODBC\Data Sources.
Description	A blank field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

The **Connection** tab allows the user to configure the basic attributes required to connect to a data source. For the Microsoft ODBC Driver for DB2, the **Connection** tab has the following fields:

Parameter	**Comments**
APPC Connection and TCP/IP Connection	An option button (radio button) is used to select the network transport. Valid options are APPC Connection (SNA LU 6.2) or TCP/IP Connection. For the default, APPC Connection, the values for APPC local LU alias, APPC remote LU alias, and APPC Mode Name are required. For TCP/IP Connection, the values for IP address and Network port are required.
APPC local LU alias	When APPC Connection is selected, this field is the name of the local LU alias configured in Host Integration Server.
APPC remote LU alias	When APPC Connection is selected, this field is the name of the remote LU alias configured in Host Integration Server.

APPC mode name	When APPC Connection is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). The default is typically QPCSUPP.
IP address	When TCP/IP Connection is selected as the network transport, this field indicates the IP address of the host DB2 server.
Network port	When TCP/IP Connection is selected as the network port, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is **IP port 446**.

The **Connection** tab also includes a **Test connection** button that may be used to test the connection parameters. A connection can only be tested after all of the required parameters for the **Connection** tab and other ODBC data source parameters are configured properly. When this button is clicked, a session is established with the remote DB2 system using ODBC Driver for DB2.

The **Security** tab allows the user to configure optional attributes used to restrict connections to a data source. For the Microsoft ODBC Driver for DB2, the **Security** tab has the following fields:

Parameter	Comments
Authentication	An option button (radio button) is used to select the type of authentication. Valid options are **Use this username** or **Use Single Sign-On**. For the default **Use this username** option, the value for the user name is required.
Use this username	When this option is selected, authentication is based on the user name entered in the textbox. A valid user name is normally required to access data on DB2. A user name can remain optionally in the DSN. The ODBC Driver for DB2 will prompt the user at run-time to enter a valid password. Additionally, the prompt dialog box will enable the user to override the user name that is stored in the DSN.
Use Single Sign-On	An option button to select whether Single Sign-On or a specific user name should be used. Single Sign-On is an optional Host Security feature. Single Sign-On enables the administrator to create data source definitions that isolate the logon process from the end user. The user context for Single Sign-On is the user context associated with the SNA DB2 service.

The AS/400 computer is case-sensitive with regard to user IDs and passwords. When connecting to DB2 for OS/400, user names and passwords must be in uppercase. The AS/400 only accepts a DB2 for OS/400 user ID and password in uppercase. If a DB2 for OS/400 connection fails due to incorrect authentication, the ODBC driver resends the authentication, forcing the user ID and password into uppercase.

When connecting to DB2 on IBM mainframes, user names and passwords can be of mixed case; the mainframe is not case-sensitive. The ODBC driver sends these values in uppercase.

DB2 Universal Database (UDB) is case sensitive. The user ID is stored in uppercase. The password is stored in mixed case and users must enter the password in the correct case. The ODBC driver sends the password exactly in the case entered by the user. The user ID should contain only the user name, not a combination of the Windows domain name and username.

The **Target Database** tab allows the user to configure required, as well as optional, attributes used to define the target DB2 system. For the ODBC Driver for DB2, the **Target Database** tab has the following fields:

Parameter	Comments
Initial catalog	This parameter is used as the first part of a three-part fully qualified DB2 table name. It is referred to by different names depending on the DB2 platform. In DB2 for OS/390 and DB2 for MVS, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 that you need to connect to on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.
Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This can be the same as the default schema. The ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver creates packages dynamically in the location that the user points to using the Package Collection parameter. By default, the ODBC Driver for DB2 automatically creates one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the user ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source. Problems can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (for example, PUBLIC), then the package is created only for use by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example., PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users. The ODBC Driver for DB2 ships with two utility programs for use by administrators to create packages. The crtpkg.exe tool is a command line utility for the administrator to create packages. The crtpkgw.exe tool is a Windows GUI utility used for the same purpose. Either of these utilities can be run using a privileged user ID to create packages in collections accessed by multiple users. These utilities will create sets of packages and grant EXECUTE privilege to PUBLIC for all (see descriptions under the Default Isolation parameter). The packages created are as follows: AUTOCOMMIT package (MSNC001 is only applicable on DB2/400) READ_UNCOMMITTED package (MSUR001) REPEATABLE_READ package, (MSRS001) READ_COMMITTED package, (MSCS001) SERIALIZABLE package (MSRR001). After being created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables.
Default schema	The name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default schema is the SCHEMA name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or owner). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, the ODBC driver uses the USER_ID provided at logon. For DB2/400, the driver uses QSYS2 if no collection is found matching the USER_ID value. This default is inappropriate in many cases so it is essential that the Default Schema value in the data source be defined.
DBMS Platform	The target DB2 platform property value is used to optimize performance of the ODBC driver when executing operations such as data conversion. The default value is DB2/MVS.

Default Qualifier	The name of the schema (collection/owner) with which to fully qualify unqualified object names. This attribute allows the user to access database objects without fully-qualifying the objects using a collection (schema) qualifier. The ODBC driver sends this value to DB2 using a SET CURRENT SQLID statement, instructing the DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statements. If you do not set a value for default qualifier, then no SET statement is issued by the ODBC driver. This ODBC connection attribute is only valid when connecting to DB2 for MVS (OS/390, z/OS).
Alternate TP Name	The remote transaction program name is optional. For example, it is used when configuring an off-line DB2 demo link service connection.
Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and one of the HIS Resync services.
Process binary as character	When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. See the **Locale** tab.

The **Locale** tab allows the user to configure the parameters used for character conversion between the client computer and the DB2 server. Two versions of the **Locale** tab are possible depending on which versions of SNA Server client software and ODBC for DB2 Driver client software are installed.

For the ODBC Driver for DB2, the **Locale** tab has the following fields:

Parameter	**Comments**
Host CCSID	The coded character set identifier (CCSID) matching the DB2 data as represented on the remote computer. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the DB2 column CCSID and configured ANSI code page. This parameter defaults to U.S./Canada (37).
PC code page	This parameter indicates the personal computer code page to use. It is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

Click **OK** or **Cancel** when data entry is finished. If you click **OK**, the values specified become the defaults when an application connects to this data source. These default values can be changed at any time using this procedure to reconfigure the data source. An ODBC application can override these defaults by connecting to the data source using a connection string with alternate values.

Network Integration Help

Use the topics in this section to navigate through the Network Integration user interface.

In This Section

Print Service Properties

Click **No Event Log for Skipping Transparent Section** to prevent an entry in the Event Log every time print services skips a transparent section found while printing a host print job. Skipping transparent sections can be enabled from the **Advanced** tab of a print session properties page.

3270

Click **Flush Final FF** causes Host Print services to explicitly form feed the document at the end of a print job. This is not needed for most print jobs and configurations.

Click **Use Proportional Font Change** to prevent overlapping characters in documents containing nonfixed-type fonts printed through Host Print services. Most standard 3270 data streams are designated for fixed-type fonts.

Click **Ignore Characters 3F and Under** to cause the print service to ignore Hexadecimal characters 3F and below. In LU 1 data streams, this option causes hexadecimal characters below 40 to be replaced by spaces.

Click **Delay Print Start** to delay the start of the print job until printable data is received by Host Print services. In a few environments, hosts may poll the Host Print service for activity by sending "empty jobs". In such cases, not selecting this option may cause blank pages to be printed between actual print jobs.

LU 3 Only

Click **Do All FF** to force the printer driver to honor all form feed commands. (In most jobs, this is unnecessary and may lead to unwanted blank pages.)

Click **Always do NL** to insert a new line when the print services determines that the Maximum Print Position has been reached for a particular line of data. Selecting this option will prevent data from printing over an existing line.

Click **No Space After FF** to prevent print services from inserting a space character following a form feed.

Click **Support Embedded Printer Codes** to allow unmarked embedded characters, such as EBCDIC X'27' characters, to pass through print services to the printer.

LU 1 Only

Click **Use Fixed Tabs** to disable normal tab functionality (such as aligning tabs in columns) and interpret each tab as a fixed number of spaces. The number of spaces for a tab stop is based on the size of the first tab in the Set Horizontal Format SCS control code.

APPC

Set the **Activation Retry Limit** to the number of times print services will attempt to activate the APPC conversation following a terminated connection. The default value is –1 (infinite), meaning that attempts to activate the session will continue until it is successful or terminated manually.

Click **Infinite Retry Limit** to force the system to retry printing the job until it is successful.

Set the **Activation Retry Interval** to the number of seconds to wait before trying to print the job again. The default value is 10 seconds.

Print Session Properties

The following tabs are available on the Print Session 3270 Properties sheet:

Print Session Properties: General

Session Name

To print 3270 jobs, you must define the session name, which is a descriptive name to distinguish different printers on the network.

Comment

Optionally, type a comment of 25 characters or less.

Session Activation

Click **Manual** to activate the print session manually, or **Automatic** to activate the print session automatically when the Host Print service is started.

Host Code Page

Click **Language**, and then select a **languagecode** from the drop-down list.

If your language code does not appear in the drop-down list, click **Custom**, then click on the **File** button. The **Select Custom Page File** dialog box appears. Select your custom code page and click **Open**.

Note
The custom page support in Host Print service provides Arabic and Hebrew code page support for left-to-right output only. T he Host Print service does not support bi-directional data streams from right to left.

Destination

The default printer should appear in the box. Otherwise, click **Printer** to open the **Print Setup** dialog box. Make your selections and click **OK**.

Click **File** to send your job to a file. Check **Unique** to activate the **Reset** button. This feature allows you to reset the print job sequential numbering scheme (for example, when the number gets too high). Click **Reset**, and then click **Yes** to reset to the printer file extension numbering.

Note
You need to select a printer driver to print to a file. Select a valid printer driver, then select File in the Destination box. Otherw ise, you get an error message.

Print Session Properties: 3270

LU Name

Choose a **3270 printer LU** for the print session from the **LU Name** drop-down list. The drop-down list shows all of the LUs in an SNA Subdomain. If no 3270 printer LUs appear, you need to define one.

Job Termination When

Set job termination to either When End Bracket Received or When Unbind Received.

Selecting **When End Bracket Received** means the Host Print service will treat receiving the End Bracket notification from the host as an indication that the job is complete. Otherwise, the Print service defaults to spooling the job until the session ends: **When Unbind Received**.

Note
If the host application sends print jobs that comprise multiple SNA brackets, set job termination to When End Bracket Receiv ed.

Job Timeout

To set a parameter for terminating print jobs, click the **Timeout Job After** box. Click the **Seconds Inactivity** up and down buttons to set the time limit for terminating print jobs. In some cases, an LU 3 print job is sent down from the host over an

extended period of time. Selecting a Job Timeout ensures that the portions of the job are regularly form-fed. This option also provides normal timeout functionality for other 3270 print jobs.

Monitor Job

Click **Request Definite Response** if you want to invoke an advanced feature for applications that require a high level of assurance that a job completed. This feature sends a message to the host stating that the print job completed.

Note
If you select the Request Definite Response feature, the host job must mark the data as RQD (definite response required).

Print Session Properties: Job Format

Do Not Format Print Job

Do Not Format Print Job allows print jobs that are formatted with host software to bypass the Microsoft® Windows®-based printing format system. The Windows-based Host Print service treats all received data as transparent. All data is passed directly to the printer.

Format Print Job

Print jobs from a host system can be formatted one of two ways:

GDI

The Windows Graphical Device Interface (GDI) is used to format the print job. SCS codes in the data are interpreted and represented, and the GDI automatically supports all the configurable options such as font, margins, duplex, paper-source etc. Transparent sections (for example, containing PCL escape sequences) are just ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Selecting this option disables the Ignore **Transparent Sections for PDT Formatting** on the **Advanced** tab.

Note
If your print job has a mixture of SCS codes and PCL escapes, then you should use a PDT. The PDT should contain mappings f or the SCS code functionality, and the PCL escapes should pass directly to the printer without being mapped.

PDT

A Printer Definition Table (PDT) is used to specify the output format, control codes, and transfer of characters to a printer. When you use a PDT, the Windows based printer driver is not used. The PDT defines all information used to generate the print output. Click the **PDT File** button to select a compiled Printer Definition File.

To create a new PDT, you must first create a Printer Definition File (PDF), and then compile the PDF into a PDT. (If an uncompiled PDF file is selected, the compilation is performed automatically each time the print session is used. This feature has a performance overhead and is available mainly for ease of development). The PDF is a text file that defines macros and session parameters.

The PDT may override changes you make to **Font**, **Margins**, or **Page Setup**, although it is now possible to support these options in the PDT file. If you want to print in a particular font with a PDT, you should alter the startup sequence in the PDT to tell the printer which font you require. When a PDT file is used, Host Print service uses the definitions of NL, CR, FF, and LF from the PDT file to allow it to format the print job correctly.

Click **Printer Language is Hewlett-Packard (HP) PCL** if your PDT contains PCL commands. Limited support for Manager-defined font, margins and paper setup settings is automatically supported for HP (PCL), with full support available for customizing the Printer Definition File.

Font

To make changes to the font, click **Font**. Click the **Font** button. Make your selections in the Windows-based **Font** dialog box,and then click **OK**.

Use Fixed Font Size

Select the **Use Fixed Font Size** to select a user-defined font size. When this box is checked, the Host Print service will use the configured point size regardless of whether the data will fit (it will be clipped to fit the page if it is too large). When this option is selected, the Horizontal and Vertical scaling options on the **Advanced** tab are not available.

Print Session Properties: Page Layout

All these options are automatically available using the Windows GDI. Supporting these options using a PDT file may require extra configuration.

Horizontal Controls

Characters per line

The default is 132 characters per line. Type 80, 158, or another number for characters per line to change the default. The maximum line length is 255 characters.

Click **Override Host Commands** to force the specified settings and ignore host commands.

Vertical Controls

Lines per Page

Select **Lines Per Page** and then set the number of lines to be printed on each page.

Lines Per Inch

Select **Lines Per Inch** and then set either 6 or 8 lines per inch to set the default.

Click **Override Host Commands** to force the specified settings and ignore host commands.

Margin Settings

To change the margins, select **Margins**, and then click **Setup**. The **Page Setup** dialog box appears. Make your changes, and then click **OK**.

Page settings

Settings for Paper Source, Page Size, and Orientation are controlled from the Printer section. Click **Override Host Commands** to force the specified settings and ignore host commands.

Print Session Properties: Advanced

Filter DLL

Click **Filter DLL** to pass the printer data stream to a third-party or user-supplied DLL. Clicking **Filter** activates the **DLL File** button. The **Select Filter DLL** dialog box appears. Make your selection, then click **Open**.

Ignore Transparent Sections for PDT Formatting

Selecting this option will cause those sections of the print data stream that have been marked as transparent to be ignored when using a PDT file to format the data. Note, when using the GDI to format the data, transparent sections are automatically ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Do Not Scale Horizontally

Selecting this option will turn off the horizontal scaling feature of the printer driver.

Do Not Scale Vertically

Selecting this option will turn off the vertical scaling feature of the printer driver.

3270 Printing

Transparency is ASCII

Click **Transparency is ASCII** to indicate that transparent data from the host is in ASCII and needs no translation from EBCDIC to ASCII. Selecting **Transparency is ASCII** causes the Windows-based Host Print service to not put the received data through an EBCDIC to ASCII translation table before printing.

Transparency Custom Byte

Transparency Custom Byte indicates the character designated to start a sequence of transparent data (the transparent data may or may not be ASCII). The IBM standard is 0x35, but if the host print job uses another value (for example 0x36, and so on), then this should be specified here.

No Line Formatting

Prevents the SNA Print Service from inserting its own Carriage Return/Line Feed (CR/LF) according to the dimensions specified in the Default Page Width field (also on this property page). As No Line Formatting is a special case, this box is usually not checked. It is a useful option when using physical printers that do their own wrapping or are told to do their own wrapping with an Esc sequence. The Esc sequence that causes a printer to do its own End-of-line wrap on PCL printers is <Esc>&s0C.

Printer Time Out

Default is 10 seconds. This parameter optimizes performance and system resources. If the printer is always available, system resources are consumed. However, if the printer is constantly being "opened" and "closed" with each print job sent, performance suffers. By setting the time out, the printer will remain available for jobs sent close together to improve performance, and yet "close" during non-busy times to free up resources.

Print Session Properties

The following tabs are available on the Print Session 3270 Properties sheet:

Print Session Properties: APPC

Remote APPC LU

Choose **Alias** or **Fully Qualified Name** to select another remote APPC LU.

You must supply either a **Remote APPC LU Alias** or a **Fully Qualified Name** before you can leave this page. If you want to use a **Fully Qualified Name**, you need to select a **Remote APPC LU Alias** first, then select a **Local LU Alias**. Then you must go back and change from the **Remote APPC LU Alias** to the **Remote APPC LU Fully Qualified Name**. If you select **Fully Qualified Name** first, the **Local LU Alias** does not get initialized.

Network Name + LU Name in NETNAME.LUNAME syntax (for example, APPN.NORTHB).

Local LU Alias

Select the local LU alias from the drop-down list.

Mode Name

The default mode name is QPCSUPP. Click the drop-down list arrow to make another selection. The choices are: **#INTERSC**, **BLANK**, **QPCSUPP**, **QSERVER**.

AS/400 Device Name

You must enter the name for the AS/400 printer device, which is a descriptive name that distinguishes different printers on the network.

System Type

Select the type of system you are printing from; either AS/400, System/36, AS/36.

AS/400

Msg Queue Name

Enter the qualified name of the message queue to which operational messages for this device are sent.

Msg Lib Name

Enter the name of the library in which the message queue is located.

System/36, AS/36

APPC Print Session Properties: Security

User ID

Type your **User ID**.

Password

Type your **Password**. Click tab to put the cursor in the **Confirm** password box.

Confirm Password

Type your password again and click **OK**.

Print Session Properties: Job Format

Job

Do Not Format Print Job allows print jobs that are formatted with host software to bypass the Windows-based printing format system. The Windows-based Host Print service treats all received data as transparent. All data is passed directly to the printer.

HPT

Displays the **Host Print Transform Properties** box, where you can designate the printer type and paper sources.

The Host Print Transform feature changes print data on the AS/400 to the ASCII format needed by a PC printer.

Select a manufacturer type and model number. If you cannot find the type and model number in the list you can type them

in the box. If you do not know the manufacturer type and model number, see your system administrator or see the help on the AS/400.

Important
You must enter an asterisk "*" before the manufacturer type and model number. Make sure there are no spaces between t he asterisk, manufacturer type and model number, for example: *HPIIISI, or *IBM3812.

Format Print Job

Print jobs from a host system can be formatted one of two ways:

GDI

The Windows Graphical Device Interface (GDI) is used to format the print job. SCS codes in the data are interpreted and represented, and the GDI automatically supports all the configurable options such as font, margins, duplex, paper-source etc. Transparent sections (for example, containing PCL escape sequences) are just ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of discarded data. This logging can be globally disabled from the Host Print service properties page.

Selecting this option disables the Ignore **Transparent Sections for PDT Formatting** on the **Advanced** tab.

Note
If your print job has a mixture of SCS codes and PCL escapes, then you should use a PDT. The PDT should contain mappings f or the SCS code functionality, and the PCL escapes should pass directly to the printer without being mapped.

PDT

A Printer Definition Table (PDT) is used to specify the output format, control codes, and transfer of characters to a printer. When you use a PDT, the Windows based printer driver is not used. The PDT defines all information used to generate the print output. Click the **PDT File** button to select a compiled Printer Definition File.

To create a new PDT, you must first create a Printer Definition File (PDF), and then compile the PDF into a PDT. (If an uncompiled PDF file is selected, the compilation is performed automatically each time the print session is used. This feature has a performance overhead and is available mainly for ease of development). The PDF is a text file that defines macros and session parameters.

The PDT may override changes you make to **Font**, **Margins**, or **Page Setup**, although it is now possible to support these options in the PDT file. If you want to print in a particular font with a PDT, you should alter the startup sequence in the PDT to tell the printer which font you require. When a PDT file is used, Host Print service uses the definitions of NL, CR, FF, and LF from the PDT file to allow it to format the print job correctly.

Click **Printer Language is Hewlett-Packard (HP) PCL** if your PDT contains PCL commands. Limited support for Manager defined font, margins and paper setup settings is automatically supported for HP (PCL), with full support available for customizing the Printer Definition File.

Font

To make changes to the font, click **Font**. Click the **Font** button. Make your selections in the Windows-based **Font** dialog box,and then click **OK**.

Use Fixed Font Size

Select the **Use Fixed Font Size** to select a user defined font size. When this box is checked, the Host Print service will use the configured point size regardless of whether the data will fit (it will be clipped to fit the page if it is too large). When this option is selected, the Horizontal and Vertical scaling options on the **Advanced** tab are not available.

APPC Print Session Properties: Advanced

Filter DLL

Click **Filter DLL** to pass the printer data stream to a third-party or user-supplied DLL. Clicking **Filter** activates the **DLL File** button. The **Select Filter DLL** dialog box appears. Make your selection, then click **Open**.

Ignore Transparent Sections for PDT Formatting

Selecting this option will cause those sections of the print data stream that have been marked as Transparent to be ignored when using a PDT file to format the data. Note, when using the GDI to format the data, Transparent sections are automatically ignored. When such data is discarded, a log is written to the Event Log, containing the first 32 bytes of

discarded data. This logging can be globally disabled from the Host Print service properties page.

Do Not Scale Horizontally

Selecting this option will turn off the horizontal scaling feature of the printer driver.

Do Not Scale Vertically

Selecting this option will turn off the vertical scaling feature of the printer driver.

Print LU Properties: General

LU Number

Enter the LU Number.

LU Name

Enter the LU Name.

Connection

The connection for this LU is shown. The connection cannot be changed here.

Pool

If the LU has already been assigned to a pool, the pool name appears here.

Comment

Optionally, enter a comment of not more than 25 characters.

Use Compression

Selecting this option will compress the data stream and reduce the local area network traffic.

User Workstation Secured

Selecting this option allows only this workstation to access the Host LU.

TN3270 Properties: Settings

Idle Timeout

Specify time limits. If the session is inactive for this length of time, then TN3270 service disconnects the client computer.

Init Status Delay

Specify time limits. This is the delay between the time when TN3270 service connects to a host session and the time the TN3270 service starts updating the client computer screen. There are often a large number of startup messages when the TN3270 service first connects to a host session, and this option gives the user the opportunity not to receive them all.

Message Close Delay

Specify time limits. When TN3270 service forces a client computer to disconnect (for example, when the Host Integration Server session to the host has been lost), it sends the client computer an error message to be displayed on the screen. This value specifies the time between sending the message to the client computer and closing the socket with the client computer (which causes some client computers to clear the screen, and so erase the message).

Refresh Cycle Time

Specify time limits. This is the delay between updates of the status on the display.

Default RU Sizes - Inbound and Outbound

This controls the RU size (SNA message size) used by the TN3270 service for logon messages to and from the host. The minimum value for inbound or outbound RU size is 256 bytes. If the host application sends large logon screens, these values should be increased.

Certificate CN

The common name of the certificate used if TLS/SSL is enabled.

Print Service Properties

Click **No Event Log for Skipping Transparent Section** to prevent an entry in the Event Log every time print services skips a transparent section found while printing a host print job. Skipping transparent sections can be enabled from the **Advanced** tab of a print session properties page.

3270

Click **Flush Final FF** causes Host Print services to explicitly form feed the document at the end of a print job. This is not needed for most print jobs and configurations.

Click **Use Proportional Font Change** to prevent overlapping characters in documents containing nonfixed-type fonts printed through Host Print services. Most standard 3270 data streams are designated for fixed-type fonts.

Click **Ignore Characters 3F and Under** to cause the print service to ignore Hexadecimal characters 3F and below. In LU 1 data streams, this option causes hexadecimal characters below 40 to be replaced by spaces.

Click **Delay Print Start** to delay the start of the print job until printable data is received by Host Print services. In a few environments, hosts may poll the Host Print service for activity by sending "empty jobs". In such cases, not selecting this option may cause blank pages to be printed between actual print jobs.

LU 3 Only

Click **Do All FF** to force the printer driver to honor all form feed commands. (In most jobs, this is unnecessary and may lead to unwanted blank pages.)

Click **Always do NL** to insert a new line when the print services determines that the Maximum Print Position has been reached for a particular line of data. Selecting this option will prevent data from printing over an existing line.

Click **No Space After FF** to prevent print services from inserting a space character following a form feed.

Click **Support Embedded Printer Codes** to allow unmarked embedded characters, such as EBCDIC X'27' characters, to pass through print services to the printer.

LU 1 Only

Click **Use Fixed Tabs** to disable normal tab functionality (such as aligning tabs in columns) and interpret each tab as a fixed number of spaces. The number of spaces for a tab stop is based on the size of the first tab in the Set Horizontal Format SCS control code.

APPC

Set the **Activation Retry Limit** to the number of times print services will attempt to activate the APPC conversation following a terminated connection. The default value is –1 (infinite), meaning that attempts to activate the session will continue until it is successful or terminated manually.

Click **Infinite Retry Limit** to force the system to retry printing the job until it is successful.

Set the **Activation Retry Interval** to the number of seconds to wait before trying to print the job again. The default value is 10 seconds.

Configuring an IP-DLC Connection

As with other connections, configuration requires setting parameters on the Connection properties dialog. It is recommended that you read this section before beginning the configuration process, so you can gather all the necessary information before you start.

To configure an IP-DLC connection

1. If you have just created a new IP-DLC link service connection, the **Connection** properties dialog will automatically appear. If it does not, or if you are configuring an already-existing IP-DLC link service connection, right-click the IP-DLC link service connection in the results pane of the MCC snap-in, and click **Properties**.
2. Fill in the required parameters according to the tables below.

General Page

The **General** page is similar to that used for other connections in Microsoft® Host Integration Server.

Property	**Comments**
Name	Name of the connection.
Link service	This list displays all currently configured IP-DLC link services.
Comment	Descriptive comment (optional).
Activation	Specifies conditions under which connection is activated.
On server startup	Connection is activated on server startup.
On demand	Connection is activated on demand.
By administrator	Connection can only be activated by system administrator.
Allowed direction	Specifies the connection directions. For more information, see the note under Peer system later in this table.

Outgoing calls	Connection is outgoing.
Incoming calls	Connection is incoming.
Both directions	Connection can be both incoming and outgoing.
Remote end	Specifies which system is the remote end.
Host system	Selecting this option signifies that the connection will be used for Dependent LU Server (DLUS) traffic and may have dependent LUs. You cannot associate independent APPC LUs with an IP-DLC connection remote end type of host system.
Peer system	Selecting this option signifies that the connection will be used for independent APPC LU sessions. You cannot associate dependent 3270 LUs with an IP-DLC connection remote end type of peer system. Because peer system IP-DLC connections do not support DLUS traffic, selecting this option will disable all controls on the **Address** page and the IP-DLC page (shown later in this topic). Only one peer connection can be associated with an IP-DLC link service. Note: Selecting Peer system automatically sets Activation to **On Server Startup** and Allowed direction to **Both**.

Address Page

Use this page to configure DLUS properties for the connection. The DLUS on the mainframe system operates in conjunction with the Dependent LU Requester (DLUR) on the local Host Integration Server computer. Together they route dependent (for example, 3270) sessions across the APPN network using the IP-DLC link service.

If you selected the Remote end as Peer system on the **General** page, all controls on this page will be disabled.

Property	**Comments**
Primary DLUS	Fill in these required fields for the primary server with the appropriate names.
Network name	Maximum of eight characters of SNA type A string, representing the APPN network in which to locate the primary DLUS.
Backup DLUS	Fill in these fields for the backup server with the appropriate names. These fields are optional.
Preferred route	Optionally, enter the IP address, host name, or fully qualified name for the NNS as routing server through which to connect to the DLUS. Using a separate NNS may improve host performance by offloading the DLUS host computer from operating as an NNS directory server. The IP-DLC link service will attempt to establish the connection to the DLUS using the preferred route address.

System Identification Page

The **System Identification** page is similar to that used for other connections in Host Integration Server.

If you selected the Remote end as Peer system on the **General** page, all controls on this page will be disabled.

Property	Comments
Network name	Network name.
Control Point Name	Control point name.
Node ID	Required. Enter a hexadecimal value to uniquely identify the physical unit (PU) for the host connection. This value must match an existing remote LEN-style PU definition. Default value is 05D FFFFF. The node ID value must match the value configured on the host DLUS computer.
Link compression	Optional. Choose a setting from the list. Default value is **None**.
Remote node name	Specify information for the remote DLUS.
Node ID	Required. Enter a hexadecimal value to uniquely identify the physical unit (PU) for the host connection. This value must match an existing remote LEN-style PU definition for the DLUS. There is no default value.

IP-DLC Page

Use this page to optionally set parameters specific to the IP-DLC connection.

If you selected the Remote end as Peer system on the **General** page, all controls on this page will be disabled.

Property	Comments
Connection retry limits	Optionally, use these controls to specify retry limits for activating a connection.
None	Specifies no retries.
Limited	Specifies the number of retries, from 1 through 65534. Default value is 8.
Delay after retry	Specifies the wait period after a retry, from 1 through 327670 seconds. Value must be a multiple of five. Default value is 10 seconds.
DLUR retry limits	Optional. Use these controls to specify retry action in case the DLUR connection fails. Default setting is Infinite.
Infinite	Specifies an infinite number of retries.
None	Specifies no retries.
Limited	Specifies the number of retries, from 1 through 65534. Default value is 8.
Delay after retry	Specifies the wait period after each retry, from 1 through 65535 seconds. Default value is 10 seconds.

Configuring an IP-DLC Link Service

As with other link services, configuration requires setting parameters on the **Link Service Properties** dialog box. It is recommended that you read this section before beginning the configuration process, so you can gather all the necessary information before you start.

To configure an IP-DLC link service

1. If you have just created a new IP-DLC link service, the **IP-DLC Link Service Properties** dialog box will automatically appear. To reconfigure an existing IP-DLC link service, right-click the IP-DLC link service in the scope pane of the MCC snap-in, click **Properties**, and then click the **Configure** button to load the IP-DLC Link Service Properties dialog box.
2. Fill in the required parameters according to the following table.
3. Click **OK** to persist the settings to the configuration file and registry. The **Insert Link Service** dialog box appears.
4. Click **Complete Configuration of the IP-DLC Link Service**.

Property	**Comments**
Service name	Displays the name of the link service being configured. For a new link service, the name is predefined as SNAIP#, where # is the ordinal number of the link service.
Service title	Enter a user-friendly text description of up to 128 characters. This name will be displayed in the Service Control Manager. The default value is IP-DLC Link Service #N, where N is the ordinal number of the link service.
Primary NNS	Enter the IP address, host name, or fully qualified name of the primary network node server. There is no default value.
Backup NNS	Optionally, enter the IP address, host name, or fully qualified name of the backup network node server. There is no default value.
No Preferred NNS	Selecting this will allow the IP-DLC link service to use the first available network node server. If this option is not selected, the link service will always use the Primary NNS when it becomes available.
Local address	This set of parameters assigns the link service to a particular IP address on the local computer. Every link service must be associated with a local IP address or logical connection, and neither the IP address nor the logical connection can be used by another IP-DLC link service on the local computer.
