Host Integration Server 2000

Microsoft Host Integration Server 2000

Microsoft Host Integration Server provides comprehensive host access and integration, extending Microsoft Windows to other systems by integrating host applications, data sources, messaging, and security systems. This enables the reuse of IBM mainframe and midrange data and applications across distributed environments.

Host Integration Server offers a strong, dependable, and secure platform on which to leverage and extend existing investments in SNA and Web technologies. Host Integration Server enables rapid adaptation to new business opportunities while preserving existing infrastructure investments.

Microsoft Host Integration Server 2000 Developer's Guide

Microsoft® Host Integration Server 2000 provides comprehensive bi-directional services for integrating Microsoft Windows® with legacy systems. Host Integration Server 2000 extends Windows to other platforms by providing interoperability in three areas:

- Application Integration Services
- Data Integration Services
- Network Integration Services

For more information on the features and use of Host Integration Server 2000, see the topics in the Getting Started section of the on-line help.

Most of the services provided by Host Integration Server 2000 expose a programming interface which allows you to extend the functionality of the product and integrate it more tightly in your own environment. This guide describes these interfaces, and provides guidance on how to use them.

This section contains:

Application Integration

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information required to develop software to integrate applications in an environment using Microsoft Host Integration Server 2000.

This section contains:

Introduction to Application Integration

This section of the *Microsoft Host Integration Server 2000 Developer's Guide* provides information required to develop software to integrate applications in an environment using Microsoft® Host Integration Server 2000. Several methods are provided using Host Integration Server for integrating applications:

- COM Transaction Integrator (COMTI) to integrate COM applications with CICS and IMS transactions on IBM mainframes and minicomputers (see the COM Transaction Integrator for CICS and IMS section under Application Integration Services in the Host Integration Server user documentation).
- MSMQ-MQSeries Bridge to develop applications to send messages between IBM MQSeries and Microsoft Message Queue Server (MSMQ) in an environment using the Microsoft MSMQ-MQSeries Bridge in Microsoft Host Integration Server 2000.
- Data access and data tools to develop applications for data access, data replication, and data tools for integrating with AS/400 and VSAM files on IBM mainframes and minicomputers and IBM DB2 databases hosted on IBM VMS, OS/390, AS/400, IBM AIX, Microsoft Windows® 2000, and Microsoft Windows NT® Server (see Introduction to Data Integration).

COMTI allows developers to integrate mainframe-based transaction programs (TPs) with component-based Windows applications. With COMTI, you can integrate existing mainframe-base transaction programs with Windows-based COM or distributed COM (DCOM) applications. You may not even have to modify your mainframe TP if the business logic is separate from the presentation logic. The wizards available in the COMTI Component Builder and COMTI Manager guide you through the process, step-by-step.

COMTI is appropriate when a synchronous or transactional solution is needed where both systems being integrated are running at all times. For applications only requiring an asynchronous integration solution, a messaging-based solution using the MSMQ-MQSeries Bridge is preferred over COMTI.

This section of the *Microsoft Host Integration Server 2000 Developer's Guide* provides information required to develop applications to send messages between IBM MQSeries and Microsoft Message Queue Server (MSMQ) in an environment using the Microsoft MSMQ-MQSeries Bridge in Microsoft Host Integration Server 2000. This section provides documentation for developers on programming issues using the MSMQ-MQSeries Bridge including message queue naming, message conversion, and the MSMQ-MQSeries Bridge Extensions.

Applications that integrate message queuing and the use MSMQ-MQSeries Bridge in a Host Integration Server 2000 environment can be developed using several different development tools and application programming interfaces including:

- C or C++ applications that use the MSMQ-MQSeries Bridge Extensions to extend the MSMQ-MQSeries Bridge.
- Microsoft Visual Basic® applications that use MSMQ-MQSeries Bridge Extensions to extend the MSMQ-MQSeries Bridge.

To use this guide effectively, you should be familiar with:

- Microsoft Host Integration Server 2000
- One of the following operating environments:
    - Microsoft Windows 2000
    - Microsoft Windows NT Server or Workstation
    - Microsoft Windows 98
    - Microsoft Windows 95
- Microsoft Message Queue Server
- IBM MQSeries

Depending on the application programming interface and development tools used, you should be familiar with:

- Microsoft COM objects
- Active Server Pages

MSMQ-MQSeries Bridge Programming

The MSMQ-MQSeries Bridge provides the ability to send and receive messages between Microsoft Message Queue Server (MSMQ) and IBM MQSeries and easily and efficiently. The MSMQ-MQSeries Bridge Extensions allow a programmer to develop and control how these message transfers will occur and how properties of a message are translated.

The main programming issues when using the MSMQ-MQSeries Bridge Extensions fall into three areas:

- Queue addressing
- Message conversion
- Limitations to specific API functions

Queue addressing deals with how to specify the name of an MQSeries destination queue in an MSMQ API call, or the name of an MSMQ destination queue in an MQSeries API call. Message conversion deals with how the MSMQ-MQSeries Bridge converts MSMQ message properties to MQSeries message data structures, and how the MSMQ-MQSeries Bridge converts MQSeries message data structures to MSMQ properties. These topics are covered in detail in separate sections below. Limitations to the MSMQ-MQSeries Bridge Extensions are discussed in detail in the section on programming considerations.

This section contains:

Platforms Supported by MSMQ-MQSeries Bridge Extensions

The Microsoft MSMQ-MQSeries Bridge Extensions can access message queues on the following IBM MQSeries systems through SNA LU6.2 or TCP/IP using Microsoft® Host Integration Server 2000 and the MSMQ-MQSeries Bridge:

- IBM MQSeries for OS/390 Version 2 Release 1 (V2.1)
- IBM MQSeries for AS/400 Version 4 Release 3 (V4R3MO)
- IBM MQSeries for Windows NT Version 5 Release 1 (V5.1)
- IBM MQSeries for Windows NT Version 5 (V5.0)
- IBM MQSeries for Windows NT Version 2 (V2.0)

The Microsoft MSMQ-MQSeries Bridge Extensions require the following computer-to-host connectivity software when using SNA LU6.2 as the network transport:

- Microsoft Host Integration Server 2000
- Microsoft Host Integration Server 2000 End User Client
- Microsoft Host Integration Server 2000 Administrator Client

The Microsoft MSMQ-MQSeries Bridge Extensions require that the Microsoft MSMQ-MQSeries Bridge be installed on one of the following operating systems:

- Microsoft Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Data Center
- Microsoft Windows NT® Server 4.0 Enterprise Edition with Service Pack 6a or later

On Windows 2000, the MSMQ-MQSeries Bridge requires that Message Queuing be set up as an MSMQ server, not a workgroup, with routing enabled. On Windows NT 4.0 Enterprise Edition, the prerequisites require MSMQ 1.0 be installed (MSMQ can be installed from the Windows NT 4.0 Option Pack) and MSMQ be set up as a Routing Server, Primary Enterprise Controller (PEC), Primary Site Controller (PSC) or Backup Site Controller (BSC).

The Microsoft MSMQ-MQSeries Bridge Manager used to configure and manage the MSMQ-MQSeries Bridge can be installed on one of the following operating systems:

- Microsoft Windows 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Data Center
- Microsoft Windows 2000 Professional
- Microsoft Windows 2000 with Terminal Service
- Microsoft Windows NT Server 4.0 Enterprise Edition with Service Pack 6a or later
- Microsoft Windows NT Server 4.0 with Service Pack 6a or later
- Microsoft Windows NT Server 4.0 Terminal Server Edition with Service Pack 6 or later
- Microsoft Windows NT Workstation 4.0 with Service Pack 6a or later

On Windows 2000 Professional or Windows 2000 with Terminal Service, the MSMQ-MQSeries Bridge Manager requires that Message Queuing not be set up in a workgroup. On Windows NT Workstation 4.0 or Windows NT Server 4.0 Terminal Server Edition, any configuration of MSMQ 1.0 is supported.

The MSMQ-MQSeries Bridge supplied with Host Integration Server 2000 supports only the Windows 2000 and the Intel Windows NT 4.0 Enterprise Edition platforms. Older versions of SNA Server 4.0 supported Windows NT on the Alpha architecture, however this configuration is not supported by the MSMQ-MQSeries Bridge.

IBM MQSeries support is available on a variety of other platforms. The MQSeries-MSMQ Bridge has not been tested with these other implementations.

Queue Addressing Using MSMQ-MQSeries Bridge

This section explains how to specify the name of an MQSeries destination queue in an MSMQ call, or the name of an MSMQ destination queue in an MQSeries call. This information is needed to specify the destination queue where you are sending a message.

This section contains:

Addressing an MQSeries Queue in MSMQ

In MSMQ, address MQSeries queues as if they are on the MSMQ network. For the MSMQ machine name, specify the MQSeries Queue Manager name. For the MSMQ queue name specify the MQSeries queue name.

For example, if the MQSeries Queue Manager is **MQS1** and the queue name is **MQS_QUEUE4**, then the MSMQ path name is **MQS1\MQS_QUEUE4**.

Note For detailed information on queue addressing, see the section on Queue format names under Converting Messages from MSMQ to MQSeries

Sending a Message to an MQSeries Queue in MSMQ

To send a message to an MQSeries queue, follow the normal MSMQ procedure. Determine the MSMQ format name corresponding to the path name. More precisely, you must determine the format name of the MSMQ foreign queue representing the MQSeries queue. If the foreign queue does not already exist, you can create it and determine its format name by calling **MQCreateQueue**. If the foreign queue already exists, then you can call **MQPathNameToFormatName**, or you can determine the format name in the MSMQ Explorer.

Call **MQOpenQueue** with the format name argument to open the queue for send access.

Call **MQSendMessage** and specify the destination queue handle returned by **MQOpenQueue**.

In the MSMQ-to-MQSeries direction, MSMQ-MQSeries Bridge sends transacted messages using the MSMQ->MQS message pipe and untransacted messages using the MSMQ->MQS Transactional message pipe.

Addressing an MSMQ Queue in MQSeries

There are two ways to address an MSMQ queue from MQSeries:

- By the MSMQ format name
- By the MSMQ path name

By either method, you specify the name in the object descriptor (**MQOD** structure) of the MQSeries message.

Note MSMQ-MQSeries Bridge supports the following types of format names:

```
PUBLIC=<GUID>
PRIVATE=<machine GUID>\<file number>
DIRECT=OS:<Path name>
```

Converting Messages Sent from MQSeries to MSMQ

Sending a Message to an MSMQ Queue in MQSeries

To send a message from MQSeries to MSMQ, use the following procedure. Specify the MSMQ format or path name of the destination queue in the object descriptor. Call **MQOPEN** to open the queue. Call **MQPUT** or **MQPUT1** to send the message.

The addressing syntax lets you send a message by either MQS->MSMQ message pipe or MQS->MSMQ Transactional message pipe. For an explanation of the service types, see the section on Normal and High Service.

Converting Messages Using MSMQ-MQSeries Bridge

This section describes how the MSMQ-MQSeries Bridge converts MSMQ message properties to MQSeries message data structures and how MQSeries data structures are converted to MSMQ message properties.

When the MSMQ-MQSeries Bridge transmits a message, it converts the message properties between the MSMQ and MQSeries formats. When equivalent properties exist in the two systems, the MSMQ-MQSeries Bridge assigns the property values directly. For example, the MSMQ *messagebody* property is converted to the MQSeries *messagebuffer*. The MSMQ *messagebodylength* is converted to the MQSeries *messagebufferlength*.

When partially equivalent properties exist in the two systems, the MSMQ-MQSeries Bridge assigns the properties according to conversion rules. For example, the MQSeries property **MQMD.Report** is converted to the MSMQ properties **PROPID_M_ACKNOWLEDGE** and **PROPID_M_JOURNAL**.

When a property has no equivalent, the MSMQ-MQSeries Bridge either ignores the property or assigns a default value. For example, the MSMQ property **PROPID_M_AUTH_LEVEL** refers to a specific MSMQ authentication method that is not supported by MQSeries. In a message sent from MSMQ to MQSeries, this property is ignored. In a message received by MSMQ from MQSeries, the MSMQ-MQSeries Bridge assigns the MSMQ default value to the property.

You can supplement or override the conversions described here using the MSMQ message extension property (**PROPID_M_EXTENSION**). For information on overriding the default conversions, see Message Extensions.

When you send a message from MSMQ (Microsoft Message Queue) to IBM MQSeries, MSMQ-MQSeries Bridge converts the MSMQ message properties to an MQSeries data structure. In order to do this, MSMQ-MQSeries Bridge maps the various message properties of the MSMQ message as nearly as possible to equivalent MQSeries fields. The following sections describe the conversion rules by which this is done.

This section contains:

Converting Messages Sent from MSMQ to MQSeries

The information in this section applies to messages that you send from MSMQ to MQSeries. For messages sent from MQSeries to MSMQ, see Converting Messages from MQSeries to MSMQ.

This section is divided into two main subsections, which provide essentially the same information but from complementary points of view.

The first section on Converting MSMQ Properties describes the conversion rules from the sender's point of view. This section explains how MSMQ-MQSeries Bridge converts each MSMQ property that you include in a message.

The second section on Building an MQSeries Message explains the rules from the receiver's point of view. Read this section to learn how MSMQ-MQSeries Bridge builds a complete MQSeries message containing all the needed fields, whether or not they have exact MSMQ equivalents.

You can supplement or override the conversions described here using the MSMQ message extension property (**PROPID_M_EXTENSION**).

This section contains:

Converting MSMQ Properties

This section explains how MSMQ-MQSeries Bridge converts the MSMQ properties that you include in a message to MQSeries. For information on MQSeries fields that have no MSMQ equivalents, see the following section on Building an MQSeries Message.

Message Body (PROPID_M_BODY)

The MSMQ message body is equivalent to the **MQPUT** or **MQGET** message buffer of MQSeries. The length of the **MQPUT** buffer is the MSMQ message body size.

The following table lists the MSMQ properties and the MQSeries fields to which they are converted:

MSMQ Property	Converted to MQSeries Field
PROPID_M_BODY	Message buffer
PROPID_M_BODY_SIZE	Message buffer length

Queue Format Names (PROPID_M_..._QUEUE)

Each MSMQ message contains the format name of a destination queue, and optionally the format names of response and/or administration queues. The MSMQ-MQSeries Bridge converts the names to the equivalent MQSeries object and queue manager names.

If a message contains both a response queue and an administration queue, MSMQ-MQSeries Bridge ignores the administration queue.

The following table lists the MSMQ properties and the MQSeries fields to which they are converted:

MSMQ Properties	Converted to MQSeries Fields
PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN	MQOD.ObjectName and MQOD.ObjectQMgrName
PROPID_M_RESP_QUEUE and PROPID_M_RESP_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr
PROPID_M_ADMIN_QUEUE and PROPID_M_ADMIN_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr

Message Class (PROPID_M_CLASS)

MSMQ-MQSeries Bridge converts the MSMQ message class (**PROPID_M_CLASS**) to the MQSeries message type and feedback. It translates the message class values according to the following table.

Value of MSMQ property	Converted to MQSeries value	
PROPID_M_CLASS	MQMD.MsgType	MQMD.Feedback
MQMSG_CLASS_NORMAL	MQMT_REQUEST or MQMT_DATAGRAM	MQFB_NONE
MQMSG_CLASS_ACK_REACH_QUEUE	MQMT_REPORT	MQFB_COA
MQMSG_CLASS_ACK_RECEIVE		MQFB_COD
MQMSG_CLASS_NACK_RECEIVE_TIMEOUT		MQFB_EXPIRATION
MQMSG_CLASS_NACK_REACH_QUEUE_ TIMEOUT		MQFB_EXPIRATION
MQMSG_CLASS_NACK_Q_EXCEED_QUOTA		MQRC_Q_FULL
MQMSG_CLASS_NACK_ACCESS_DENIED		MQRC_NOT_AUTHORIZED
MQMSG_CLASS_NACK_ERROR		MQFB_APPL_TYPE_ERROR
Any other value		MQFB_NONE

Note that for MQMSG_CLASS_NORMAL is converted to MQMD_REQUEST if the message includes a response queue (PROPID_M_RESP_QUEUE) or if PROPID_M_RESP_QUEUE is missing, NULL, or an empty string.

Message Expiration (PROPID_M_TIME...)

MSMQ provides two message expiration properties, PROPID_M_TIME_TO_REACH_QUEUE and PROPID_M_TIME_TO_BE_RECEIVED, both in units of seconds. MQSeries provides a single expiration field, MQMD.Expiry, whose units are tenths of a second.

MSMQ-MQSeries Bridge converts the values as follows:

Value of MSMQ properties PROPID_M_TIME_TO_REACH_QUEUE and PROPID_M_TIME_TO_BE_RECEIVED	**Converted to MQSeries value of MQMD.Expiry**
Both values are INFINITEa	MQEI_UNLIMITED
One or both values are not INFINITE	10 times the smaller of the two MSMQ values

Note that MSMQ typically interprets INFINITE as 90 days. In practice, the MSMQ-MQSeries Bridge does not apply the INFINITE conversion because MSMQ decrements the values slightly during transmission. If you need an MQMD.Expiry value of exactly MQEI_UNLIMITED, you should send this value in the message extension.

Message Acknowledgment (PROPID_M_ACKNOWLEDGE)

MSMQ-MQSeries Bridge supports the MSMQ and MQSeries acknowledgment mechanisms. You can send an MSMQ message to MQSeries and receive an automatic acknowledgment from the MQSeries Queue Manager.

To do this, set the MSMQ acknowledgment property (PROPID_M_ACKNOWLEDGE) to a value that requests an acknowledgment. Also specify the administration or response queue name (PROPID_M_ADMIN_QUEUE or PROPID_M_RESP_QUEUE), to which the acknowledgment is sent (see the section on Queue Format Names).

MSMQ-MQSeries Bridge converts the acknowledgment property to the MQSeries MQMD.Report field, as listed in the following table. When MQSeries receives the message, it returns the appropriate acknowledgment via MSMQ-MQSeries Bridge.

Value of MSMQ Property PROPID_M_ACKNOWLEDGE	**Converted to MQSeries value of MQMD.Report**
MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE	MQRO_EXCEPTION | MQRO_COAb
MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE	MQRO_EXCEPTION | MQRO_EXPIRATION | MQRO_CODb
MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE	MQRO_EXCEPTION
MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE	MQRO_EXCEPTION | MQRO_EXPIRATIONb
MQMSG_ACKNOWLEDGMENT_NONE	MQRO_NONE

If both PROPID_M_ACKNOWLEDGE and PROPID_M_JOURNAL are included in an MSMQ message, the value of the MQSeries MQMD.Report field is computed by a bitwise or of the values converted from the two MSMQ properties (see Other MSMQ Properties).

If the MSMQ_PROPID_M_ACKNOWLEDGE property has a value of MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE, the value of MQSeries MQMD.Report field is computed by a bitwise or of MQRO_EXCEPTION and MQRO_COA.

If the MSMQ_PROPID_M_ACKNOWLEDGE property has a value of MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE, the value of MQSeries MQMD.Report field is computed by a bitwise or of MQRO_EXCEPTION, MQRO_EXPIRATION,

and MQRO_COD.

If the MSMQ PROPID_M_ACKNOWLEDGE property has a value of MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE, the value of MQSeries MQMD.Report field is computed by a bitwise or of MQRO_EXCEPTION and MQRO_EXPIRATION.

Other MSMQ Properties with Equivalent Properties

The following MSMQ properties have MQSeries equivalents. The MSMQ-MQSeries Bridge converts the values of each property as listed in the table.

To save space in the table, the prefixes PROPID_M_ and MQMD are omitted from the MSMQ property names and the MQSeries field names, respectively. For example, the first row of data means that PROPID_M_BODY_TYPE is converted to MQMD.Format.

MSMQ property		**Converted to MQSeries**	
PROPID_M_	Value	MQMD.	Value

BODY_TYPE	VT_BSTR Any other value	Format	MQFMT_STRING MQFMT_NONE
CORRELATIONID	Value (20 bytes)	CorrelId	"FQ2Q" + value
DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS	Persistence	MQPER_ PERSISTENT NOT_PERSISTENT
JOURNAL	MQMSG_ DEADLETTER MQMSG_JOURNAL MQMSG_JOURNAL_NONE	Reporta	MQRO_ DEAD_LETTER_Q (Ignored) DISCARD_MSG
LABEL LABEL_LEN	Value	ApplIdentityData	Value (MQCHAR32)
MSGID	Value (20 bytes)	MsgId	"FQ2Q" + value
PRIORITY	0 1 2 3 4 5 6 7	Priority	1 3 4 5 6 7 8 9
SENTTIME	Seconds since Jan. 1, 1970	PutDate PutTime	YYYMMDD format HHMMSSTH format

If both PROPID_M_ACKNOWLEDGE and PROPID_M_JOURNAL are included in an MSMQ message, the MQSeries MQMD.Report field is computed by a bitwise or of the values converted from the two MSMQ properties (see Message Acknowledgement).

Unconverted Properties

The following MSMQ properties have no equivalents in MQSeries. The MSMQ-MQSeries Bridge ignores these properties and does not transmit them to MQSeries.

- PROPID_M_APPSPECIFIC
- PROPID_M_ARRIVEDTIME
- PROPID_M_AUTH_LEVEL
- PROPID_M_AUTHENTICATED
- PROPID_M_CONNECTOR_TYPE
- PROPID_M_DEST_SYMM_KEY
- PROPID_M_DEST_SYMM_KEY_LEN
- PROPID_M_ENCRYPTION_ALG
- PROPID_M_HASH_ALG
- PROPID_M_PRIV_LEVEL
- PROPID_M_PROV_NAME
- PROPID_M_PROV_NAME_LEN
- PROPID_M_PROV_TYPE
- PROPID_M_SECURITY_CONTEXT
- PROPID_M_SENDER_CERT
- PROPID_M_SENDER_CERT_LEN
- PROPID_M_SENDERID
- PROPID_M_SENDERID_LEN
- PROPID_M_SENDERID_TYPE
- PROPID_M_SIGNATURE
- PROPID_M_SIGNATURE_LEN

- PROPID_M_SRC_MACHINE_ID
- PROPID_M_TRACE
- PROPID_M_VERSION

Transaction Properties

The following MSMQ properties are not converted to MQSeries fields or values.

- PROPID_M_XACT_STATUS_QUEUE
- PROPID_M_XACT_STATUS_QUEUE_LEN

See the section on Transaction Support Using MSMQ-MQSeries Bridge for more information on transactions.

Building an MQSeries Message

This section explains how the MSMQ-MQSeries Bridge builds a complete MQSeries message, including all needed fields whether or not they have MSMQ equivalents. The conversion to MQSeries fields from MSMQ properties is listed from the MQSeries perspective.

For information on these same conversion rules from the MSMQ perspective, see the previous section on Converting MSMQ Properties.

Message Buffer

The **MQPUT** or **MQGET** message buffer of MQSeries is equivalent to the message body property of MSMQ. The length of the **MQPUT** buffer is the MSMQ message body size.

The following table lists the MQSeries fields and the MSMQ properties from which they are converted.

MQSeries Fields	Converted from MSMQ Property
Message buffer	PROPID_M_BODY
Message buffer length	PROPID_M_BODY_SIZE

Object Descriptor (MQOD)

The MSMQ-MQSeries Bridge retrieves the MQSeries object descriptor fields from the MSMQ format name of the destination queue.

The following table lists the MQSeries fields and the MSMQ properties from which they are converted.

MQSeries Fields	Converted from MSMQ Property
MQOD.ObjectName and MQOD.ObjectQMgrName	PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN

Message Descriptor (MQMD)

Some fields of the MQSeries message descriptor have no equivalent in MSMQ. The MSMQ-MQSeries Bridge assigns default values to these fields. Alternatively, you can pass explicit values of the MQMD fields using the MSMQ message extension property (PROPID_M_EXTENSION).

The following table lists the MQSeries fields and the default value assigned by MSMQ-MQSeries Bridge.

MQSeries MQMD Fields	Default Value Assigned by MSMQ-MQSeries Bridge
MQMD.AccountingToken	MQACT_NONE
MQMD.CodeCharSetId	MQCCSI_Q_MGR
MQMD.Encoding	MQENC_NATIVE
MQMD.PutApplName	NULL
MQMD.PutApplType	NULL
MQMD.StrucId	MQMD_STRUC_ID
MQMD.Version	MQMD_VERSION_1

Some fields of the MQSeries message descriptor have no equivalent in MSMQ and the MSMQ-MQSeries Bridge does not assign default values to these fields. You can assign explicit values for these MQMD fields using the MSMQ message extension property (PROPID_M_EXTENSION).

The following table lists the MQSeries fields for which no default value is assigned by MSMQ-MQSeries Bridge.

MQSeries MQMD Fields	Default Value Assigned by MSMQ-MQSeries Bridge
MQMD.UserIdentifier	No default value is assigned

Many of the MQMD fields are equivalent to one or more MSMQ properties. The conversion rules are listed in the following table.

You can override the conversion rules by passing explicit MQMD values in the MSMQ message extension property.

To save space in the table, the prefix MQMD. is omitted from the MQSeries field names. For example, the first row of data means that MQMD.ApplIdentityData is built from the MSMQ properties PROPID_M_LABEL and PROPID_M_LABEL_LEN.

MQSeries MQMD Field	MQSeries MQMD Field Value	Converted From MSMQ Property
ApplIdentity	Value (MQCHAR32)	The value of PROPID_M_LABEL and PROPID_M_LABEL_LEN
CorrelId	"FQ2Q" + value	The value of PROPID_M_CORRELATIONID (20 bytes).
Expiry	MQEI_UNLIMITED	Both PROPID_M_TIME_TO_BE_RECEIVED and PROPID_M_TIME_TO_REACH_QUEUE have value of INFINITE
Expiry	10 times the smaller of the two MSMQ values	PROPID_M_TIME_TO_BE_RECEIVED or PROPID_M_TIME_TO_REACH_QUEUE have a value that is not INFINITE
Feedback	MQFB_EXPIRATION	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_RECEIVE_TIMEOUT
Feedback	MQFB_APPL_TYPE_ERROR	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_REACH_QUEUE_TIMEOUT
Feedback	MQRC_Q_FULL	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_Q_EXCEED_QUOTA
Feedback	MQRC_NOT_AUTHORIZED	PROPID_M_CLASS has a value of MQMSG_CLASS_NACK_ACCESS_DENIED
Feedback	MQFB_COA	PROPID_M_CLASS has a value of MQMSG_CLASS_ACK_REACH_QUEUE
Feedback	MQFB_COD	PROPID_M_CLASS has a value of MQMSG_CLASS_ACK_RECEIVE
Feedback	MQFB_NONE	PROPID_M_CLASS has any other value
Format	MQFMT_STRING	PROPID_M_BODY_TYPE has a value of VT_BSTR
Format	MQFMT_NONE	PROPID_M_BODY_TYPE has any other value
MsgId	"FQ2Q" + value	The value of PROPID_M_MSGID (20 bytes)
MsgType	MQMT_DATAGRAM	PROPID_M_CLASS has a value of MQMSG_CLASS_NORMAL
MsgType	MQMT_REQUESTREPORT	PROPID_M_CLASS has any other value
Persistence	MQPER_PERSISTENT	PROPID_M_DELIVERY has a value of MQMSG_DELIVERY_RECOVERABLE
Persistence	MQPER_NOT_PERSISTENT	PROPID_M_DELIVERY has a value of MQMSG_DELIVERY_EXPRESS
Priority	1	PROPID_M_PRIORITY has a value of 0
Priority	3	PROPID_M_PRIORITY has a value of 1
Priority	4	PROPID_M_PRIORITY has a value of 2
Priority	5	PROPID_M_PRIORITY has a value of 3
Priority	6	PROPID_M_PRIORITY has a value of 4
Priority	7	PROPID_M_PRIORITY has a value of 5
Priority	8	PROPID_M_PRIORITY has a value of 6
Priority	9	PROPID_M_PRIORITY has a value of 7
PutDate	YYYMMDD format	The date from the MSMQ PROPID_M_SENTTIME property which has a value of seconds since Jan. 1, 1970
PutTime	HHMMSSTH format	The time from the MSMQ PROPID_M_SENTTIME property which has a value of seconds since Jan. 1, 1970
ReplyToQ	Retrieved from MSMQ format name	The MSMQ format name from PROPID_M_RESP_QUEUE if this property is included and is not NULL or an empty string.
ReplyToQ	Retrieved from MSMQ format name	The MSMQ format name from PROPID_M_ADMIN_QUEUE if PROPID_M_RESP_QUEUE is not included or is NULL or an empty string.
ReplyToQMgr	Retrieve from MSMQ format name	The MSMQ format name from PROPID_M_RESP_QUEUE if this property is included and is not NULL or an empty string.
ReplyToQMgr	Retrieve from MSMQ format name	The MSMQ format name from PROPID_M_ADMIN_QUEUE if PROPID_M_RESP_QUEUE is not included or is NULL or an empty string.
Report	MQRO_EXCEPTION|COA	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
Report	MQRO_EXCEPTION|EXPIRATION|COD	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_FULL_RECEIVE
Report	MQRO_EXCEPTION	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
Report	MQRO_EXCEPTION| EXPIRATION	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
Report	MQRO_NONE	PROPID_M_ACKNOWLEDGE has a value of MQMSG_ACKNOWLEDGMENT_NONE
Report	MQRO_DEAD_LETTER_Q	PROPID_M_JOURNAL has a value of MQMSG_DEADLETTER

Report	The MSMQ value is ignored	PROPID_M_JOURNAL has a value of MQMSG_JOURNAL
Report	MQRO_DISCARD_MSG	PROPID_M_JOURNAL has a value of MQMSG_JOURNAL_NONE

In practice, the MSMQ-MQSeries Bridge does not assign MQEI_UNLIMITED as value for MQMD.Expiry because MSMQ interprets INFINITE values typically as 90 days and decrements them slightly during transmission. To assign an MQMD.Expiry value of exactly MQEI_UNLIMITED, send this value in the message extension.

The MSMQ-MQSeries Bridge assigns MQMT_DATAGRAM as value for MQMD.MsgType if the MSMQ PROPID_M_RESP_QUEUE is missing, NULL, or an empty string. Otherwise a value of MQMT_REQUEST is assigned to MQMD.MsgType.

If both PROPID_M_ACKNOWLEDGE and PROPID_M_JOURNAL are included in an MSMQ message, MQMD.Report is computed by a bitwise or of the values converted from the two MSMQ properties.

Converting Messages Sent from MQSeries to MSMQ

When you send a message from IBM MQSeries to MSMQ, the MSMQ-MQSeries Bridge converts the message from an MQSeries data structure to an MSMQ message property. In order to do this, MSMQ-MQSeries Bridge maps the various data fields of the MQSeries message as nearly as possible to equivalent MSMQ message properties.

This section describes the conversion rules by which this is done. The information in this section applies to messages that you send from MQSeries to MSMQ. For messages sent from MSMQ to MQSeries, see the preceding section on Converting Messages Sent from MSMQ to MQSeries.

The section is divided into two main subsections, which provide essentially the same information but from complementary points of view. The first section, Converting MQSeries Fields, describes the conversion rules from the sender's point of view. This section explains how the MSMQ-MQSeries Bridge converts each MQSeries field that you include in a message. The second section, Building an MSMQ Message, explains the rules from the receiver's point of view. Read this section to learn how MSMQ-MQSeries Bridge builds a complete MSMQ message containing all the needed properties, whether or not they have exact MQSeries equivalents.

Besides the conversions described here, the MSMQ-MQSeries Bridge transmits the original MQSeries message descriptor fields in the MSMQ message extension property (PROPID_M_EXTENSION). For information on this subject, see the section on Message Extension.

This section contains:

Converting MQSeries Fields

This section explains how the MSMQ-MQSeries Bridge converts the fields of an MQSeries message to MSMQ. For information on MSMQ properties that have no MQSeries equivalents, see the section below on Building an MSMQ Message.

Message Buffer

The **MQGET** or **MQPUT** buffer of MQSeries is equivalent to the message body property of MSMQ.

The following table lists the MQSeries fields and the MSMQ properties that they are converted to.

MQSeries Fields	Converted to MSMQ Property
Message buffer	PROPID_M_BODY
Message buffer length	PROPID_M_BODY_SIZE

Object Descriptor (MQOD)

The MSMQ-MQSeries Bridge converts the MQSeries remote queue manager and queue names to the MSMQ destination queue name. The MQSeries fields are interpreted as an MSMQ format name or path name, as described below.

The following table lists the MQSeries fields and the MSMQ properties that they are converted to.

MQSeries Fields	Converted to MSMQ Property
MQOD.ObjectName and MQOD.ObjectQMgrName	PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN

Character Substitutions in Object Descriptor Conversion

Certain characters are supported in MSMQ format names but not in MQSeries names. When you assign the MQSeries MQOD.ObjectName, the MSMQ-MQSeries Bridge performs character substitutions to the MSMQ format names. The table below lists special characters in MQSeries names and what these characters are converted to in MSMQ format names by the MSMQ-MQSeries Bridge.

Characters in MQSeries MQOD Field Names	Characters Substituted in MSMQ Format Names
/ (forward slash))	: (colon) or \ (backslash)
_ (underscore)	- (hyphen) or = (equal)
P_ (at start of MQOD.ObjectName)	PRIVATE=

The MSMQ-MQSeries Bridge converts the characters back when it transmits the MQSeries message to MSMQ. The characters are interpreted according to context to generate a legal MSMQ name. For example, MSMQ-MQSeries Bridge converts the format name

```
DIRECT_OS/MACHINE2/QUEUE4
```

to

```
DIRECT=OS:MACHINE2\QUEUE4.
```

Note that this character substitution is only for format names, not for machine or path names. If you want to address MSMQ path names, do not include hyphens or other characters not supported by MQSeries. For example, the path name

```
MACHINE2\MY-QUEUE
```

is legal in MSMQ, but you cannot specify the hyphen character in MQSeries.

Format Name Method of Object Descriptor Conversion

Subject to the following conditions, the MSMQ-MQSeries Bridge interprets the MQSeries MQOD.ObjectName field as the format

name of the MSMQ destination queue:

The MQOD.ObjectQMgrName is an MQSeries alias for an MSMQ machine.

The MQOD.ObjectName begins with PUBLIC_, P_, or DIRECT_OS/.

If these conditions apply, the MSMQ-MQSeries Bridge converts the MQSeries MQOD.ObjectName to the MSMQ format name of the destination queue using one of the following methods based on the value of MQOD.ObjectName:

```
PUBLIC=<GUID>
PRIVATE=<machine GUID>\<file number>
DIRECT=OS:<path name>.
```

If you know the GUID of the destination queue, the PUBLIC=<GUID> syntax gives better performance than the DIRECT=OS:<path name> syntax. Also note that non-transacted private queues are supported only on the MSMQ-MQSeries Bridge computer.

Path Name Method of Object Descriptor Conversion

If the conditions for the format name method do not hold, the MSMQ-MQSeries Bridge interprets MQOD.ObjectQMgrName\MQOD.ObjectName as an MSMQ path name. The remote queue manager name must be an alias for an MSMQ machine that you have previously defined in MQSeries.

For example, if MQOD.ObjectQMgrName is MACHINE2 and MQOD.ObjectName is QUEUE4, the MSMQ-MQSeries Bridge sends the message to an MSMQ queue having the path name MACHINE2\QUEUE4.

The MSMQ-MQSeries Bridge determines the MSMQ format name corresponding to this path name in order to forward the message.

Note that the MQSeries name fields are limited to 48 characters each. If the path name is longer than this, use the format name method instead.

Queue Alias Method of Object Descriptor Conversion

Optionally, you can address an MSMQ queue using an MQSeries queue alias. If you use this method, set MQOD.ObjectName to the queue alias. Leave MQOD.ObjectQMgrName blank, or set it to the MQSeries Queue Manager where the transmission queue is located.

Examples of Object Descriptor Conversion

In the following examples, you want to send a message to an MSMQ destination having the following identifiers:

```
Machine name = MACHINE2
Queue name = QUEUE4
GUID = A56F41B4-9869-11D0-AF8F-0000E8D1C3A7
```

MSMQ-MQSeries Bridge is installed on a machine called BRIDGEMQ1. You have defined the aliases BRIDGEMQ1 and BRIDGEMQ1% for this machine in MQSeries. In the MSMQ-MQSeries Bridge Manager, you have configured BRIDGEMQ1 for MQS->MSMQ message pipe and BRIDGEMQ1% for MQS->MSMQ transactional message pipe.

You may address a message to this queue in any of the following ways:

Format Name method

Using the format name method and MQS->MSMQ message pipe, the MQSeries name would become:

```
MQOD.ObjectQMgrName = "BRIDGEMQ1"
MQOD.ObjectName = "PUBLIC_A56F41B4_9869_11D0_AF8F_0000E8D1C3A7"
```

-or-

```
MQOD.ObjectQMgrName = "BRIDGEMQ1"
```

```
MQOD.ObjectName = "DIRECT_OS/MACHINE2/QUEUE4"
```

Using the format name method and MQS->MSMQ transactional message pipe, the MQSeries name would become

```
MQOD.ObjectQMgrName = "BRIDGEMQ1%"
MQOD.ObjectName = "PUBLIC_A56F41B4_9869_11D0_AF8F_0000E8D1C3A7"
```

-or-

```
MQOD.ObjectQMgrName = "BRIDGEMQ1%"
MQOD.ObjectName = "DIRECT_OS/MACHINE2/QUEUE4"
```

Optionally, you can define the MQSeries aliases MACHINE2 and MACHINE2% for the MSMQ destination machine. You now have two additional ways to address the queue:

Using the path name method and MQS->MSMQ message pipe, the MQSeries name would become

```
MQOD.ObjectQMgrName = "MACHINE2"
MQOD.ObjectName = "QUEUE4"
```

Using the path name method and MQS->MSMQ transactional message pipe, the MQSeries name would become

```
MQOD.ObjectQMgrName = "MACHINE2%";
MQOD.ObjectName = "QUEUE4"
```

In yet another option, you can define the MQSeries aliases QUEUE4 and QUEUE4% for the MSMQ destination queues. If you do this, you can address the queue using the following syntax:

Using the queue alias method and normal service, the MQSeries name would become

```
MQOD.ObjectQMgrName = ""
MQOD.ObjectName = "QUEUE4"
```

Using the queue alias method and high service, the MQSeries name would become

```
MQOD.ObjectQMgrName = ""
MQOD.ObjectName = "QUEUE4%"
```

Message Descriptor (MQMD)

The MSMQ-MQSeries Bridge converts most of the MQSeries Field values to MSMQ property values.

MQMD.Report Field

The MSMQ-MQSeries Bridge supports the MQSeries and MSMQ acknowledgment mechanisms. You can send an MSMQ message to MQSeries and receive an automatic acknowledgment from the MSMQ Queue Manager.

To do this, set the MQMD.Report field of the MQSeries message to a value that requests an acknowledgment. Also set the MQMD.ReplyToQ and MQMD.ReplyToQMgr fields, which specify where the acknowledgment is sent.

The MSMQ-MQSeries Bridge converts MQMD.Report to the MSMQ acknowledgment property. When MSMQ receives the message, it returns the appropriate acknowledgment via the MSMQ-MQSeries Bridge.

The MSMQ-MQSeries Bridge also supports the MQSeries and MSMQ dead letter mechanism. For this purpose, MSMQ-MQSeries Bridge converts the MQMD.Report values to the MSMQ journaling property.

The conversions are listed in the following table.

Value of MQSeries Field MQMD.Report	**Converted to MSMQ Property an Value**

MQRO_NONE	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NONE
MQRO_EXCEPTION	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXCEPTION_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXCEPTION_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_REACH_QUEUE
MQRO_EXPIRATION	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_EXPIRATION_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_EXPIRATION_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE
MQRO_COA	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_COA_WITH_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_COA_WITH_FULL_DATA (Note 1)	The value of PROPID_M_ACKNOWLEDGE is set to MQMSG_ACKNOWLEDGMENT_FULL_REACH_QUEUE
MQRO_DEAD_LETTER_Q	The value of PROPID_M_JOURNAL is set to MQMSG_DEADLETTER
MQRO_DISCARD_MSG	The value of PROPID_M_JOURNAL is set to MQMSG_JOURNAL_NONE
MQRO_NEW_MSG_ID	(Not converted)
MQRO_PASS_MSG_ID	(Not converted)
MQRO_COPY_MSG_ID_TO_CORREL_ID	(Not converted)
MQRO_PASS_CORREL_ID	(Not converted)

Note For these report values, the MSMQ-MQSeries Bridge duplicates part or all of the message buffer in the MSMQ message extension (PROPID_M_EXTENSION). The increased message size may degrade performance.

MQMD.MsgType and MQMD.Feedback Fields

The values of the MQSeries MQMD.MsgType and MQMD.Feedback fields are converted to the MSMQ message class property.

The conversions are listed in the following table based on the value of MQMD.MsgType when MQMD.Feedback is MQFB_NONE.

Value of MQSeries MQMD.MsgType	**Converted to Value of MSMQ PROP_M_CLASS**
MQMT_SYSTEM_FIRST	MQMSG_CLASS_NORMAL
MQMT_SYSTEM_LAST	MQMSG_CLASS_NORMAL
MQMT_DATAGRAM	MQMSG_CLASS_NORMAL
MQMT_REQUEST	MQMSG_CLASS_NORMAL
MQMT_REPLY	MQMSG_CLASS_NORMAL
MQMT_APPL_FIRST	MQMSG_CLASS_NORMAL
MQMT_APPL_LAST	MQMSG_CLASS_NORMAL

The conversions are listed in the following table based on the value of MQMD.Feedback when MQMD.MsgType is MQMT_REPORT.

Value of MQSeries MQMD.Feedback	**Converted to Value of MSMQ PROP_M_CLASS**
MQFB_EXPIRATION	MQMSG_CLASS_NACK_RECEIVE_TIMEOUT
MQFB_COA	MQMSG_CLASS_ACK_REACH_QUEUE
MQFB_COD	MQMSG_CLASS_ACK_RECEIVE
MQFB_APPL_TYPE_ERROR	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_ZERO	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_NEGATIVE	MQMSG_CLASS_NACK_ERROR
MQFB_DATA_LENGTH_TOO_BIG	MQMSG_CLASS_NACK_ERROR
MQFB_BUFFER_OVERFLOW	MQMSG_CLASS_NACK_ERROR
MQFB_LENGTH_OFF_BY_ONE	MQMSG_CLASS_NACK_ERROR

MQFB_NONE	(Not converted)
MQFB_SYSTEM_FIRST	(Not converted)
MQFB_SYSTEM_LAST	(Not converted)
MQFB_APPL_FIRST	(Not converted)
MQFB_APPL_LAST	(Not converted)
MQFB_TM_ERROR	(Not converted)
MQFB_IIH_ERROR	(Not converted)
MQFB_NOT_AUTHORIZED_FOR_IMS	(Not converted)
MQFB_IMS_ERROR	(Not converted)
MQFB_IMS_FIRST	(Not converted)
MQFB_IMS_LAST	(Not converted)
MQFB_QUIT	(Not supported)
MQRC_NOT_AUTHORIZED	MQMSG_CLASS_NACK_ACCESS_DENIED
MQRC_Q_FULL	MQMSG_CLASS_NACK_Q_EXCEED_QUOTA
MQRC_PERSISTENT_NOT_ALLOWED	MQMSG_CLASS_NACK_ERROR
MQRC_MSG_TOO_BIG_FOR_Q_MGR	MQMSG_CLASS_NACK_ERROR
MQRC_MSG_TOO_BIG_FOR_Q	MQMSG_CLASS_NACK_ERROR
MQRC_PUT_INHBITED	(Not converted)

MQMD.ReplyToQ and MQMD.ReplyToQMgr Fields

The MSMQ-MQSeries Bridge converts the MQSeries ReplyToQMgr and ReplyToQ fields to an MSMQ format name. The name is assigned both to the response queue property and to the administration queue property of the new MSMQ message.

The MSMQ-MQSeries Bridge interprets the ReplyToQMgr and the ReplytoQ fields in the same way as the destination queue name:

If MQMD.ReplyToQMgr is the MSMQ-MQSeries Bridge machine name and MQMD.ReplyToQ begins with PUBLIC_, P_, or DIRECT_OS/, MSMQ-MQSeries Bridge interprets MQMD.ReplyToQ as an MSMQ format name.

Otherwise, the MSMQ-MQSeries Bridge interprets MQMD.ReplyToQMgr\MQMD.ReplyToQ as an MSMQ path name and determines the MSMQ format name.

For information on character substitutions within the names and other syntax information, see the section on Object Descriptor.

The following table lists the MQSeries fields and the MSMQ properties that they are converted to.

MQSeries Fields	**Converted to MSMQ Property**
MQOD.ReplyToQMgr and MQOD.ReplyToQ	PROPID_M_RESP_QUEUE
MQOD.ReplyToQMgr and MQOD.ReplyToQ	PROPID_M_ADMIN_QUEUE (same value as PROPID_M_RESP_QUEUE)

Other MQMD Fields

The following table lists the conversions of additional MQMD fields, besides the ones described above, to MSMQ properties.

> **Note** To save space in the table, the prefixes **MQMD.** and **PROPID_M_** are omitted from the MQSeries field names and the MSMQ property names, respectively. For example, the first row of data means that **MQMD.ApplIdentityData** is converted to **PROPID_M_LABEL** and **PROPID_M_LABEL_LEN**.

MQSeries field		**Converted to MSMQ**	
MQMD.	Value	PROPID_M_	Value
ApplIdentityData	Value (MQCHAR32)	LABEL	Value
CorrelId	Value (MQBYTE24)	CORRELATIONID	Last 20 bytes of value
Expiry	MQEI_UNLIMITED Value > 0 (tenths of seconds)	TIME_TO_BE_RECEIVED	INFINITE Value/10 (seconds)
Format	MQFMT_STRING Any other value	BODY_TYPE	VT_BSTR Not converted

Persistence	MQPER_ PERSISTENT NOT_PERSISTENT	DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS
Priority	0, 1 2, 3 4 5 6 7 8 9	PRIORITY	0 1 2 3 4 5 6 7
UserIdentifier	Value	SENDERID	SID value (if the user is registered in Windows NT) Not converted (if the user is not registered)

Unconverted MQSeries MQMD Fields

The following MQSeries fields have no equivalents in MSMQ. The MSMQ-MQSeries Bridge ignores these fields and does not transmit them to MSMQ.

Like all MQMD fields, MSMQ-MQSeries Bridge stores the fields in the MSMQ message extension property.

- MQMD.AccountingToken
- MQMD.ApplOriginData
- MQMD.BackoutCount
- MQMD.Encoding
- MQMD.MsgId
- MQMD.PutApplName
- MQMD.PutApplType
- MQMD.PutDate
- MQMD.PutTime
- MQMD.StrucId

When the value of MQMD.CodeCharSetID is MQCCSI_Q_QMG, the MSMQ-MQSeries Bridge ignores this field and does not transmit it to MSMQ. When the value of MQMD.CodeCharSetID is MQCCSI_Q_QMG, this value is not supported by the MSMQ-MQSeries Bridge.

When the value of MQMD.Version is "MQPMO_VERSION_1", the MSMQ-MQSeries Bridge ignores this field and does not transmit it to MSMQ.

Building an MSMQ Message

This section explains how the MSMQ-MQSeries Bridge builds a complete MSMQ message, including all needed properties, whether or not they have MQSeries equivalents.

Message Body (**PROPID_M_BODY**)

The MSMQ message body is equivalent to the **MQPUT** or **MQGET** message buffer of MQSeries. The length of the **MQPUT** buffer is the MSMQ message body size.

The following table lists the MSMQ properties and the MQSeries fields from which they are converted.

MSMQ Property	Converted from MQSeries Field
PROPID_M_BODY	Message buffer
PROPID_M_BODY_SIZE	Message buffer length

Queue Format Names (**PROPID_M_..._QUEUE**)

MSMQ-MQSeries Bridge retrieves the MSMQ format names of the destination, response, and administration queues from the MQSeries queue and queue manager names.

The following table lists the MSMQ properties and the MQSeries fields from which they are converted.

MSMQ Properties	Converted from MQSeries Fields
PROPID_M_DEST_QUEUE and PROPID_M_DEST_QUEUE_LEN	MQOD.ObjectName and MQOD.ObjectQMgrName
PROPID_M_RESP_QUEUE and PROPID_M_RESP_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr
PROPID_M_ADMIN_QUEUE and PROPID_M_ADMIN_QUEUE_LEN	MQMD.ReplyToQ and MQMD.ReplyToQMgr

Message Class (PROPID_M_CLASS)

The MSMQ-MQSeries Bridge assigns the MSMQ message class based on the MQSeries MQMD.MsgType and MQMD.Feedback values. For detailed information, see the section MQMD.MsgType and MQMD.Feedback Fields.

The following table lists the MSMQ properties and the MQSeries fields from which they are converted.

MSMQ Properties	Converted from MQSeries Fields
PROPID_M_CLASS	MQMD.MsgType and MQMD.Feedback

Message Expiration (PROPID_M_TIME...)

The MSMQ-MQSeries Bridge converts the MQSeries MQMD.Expiry value (in tenths of seconds) to the MSMQ PROPID_M_TIME_TO_BE_RECEIVED (in seconds). If MQMD.Expiry is set to MQEI_UNLIMITED, then the value of MSMQ PROPID_M_TIME_TO_BE_RECEIVED is set to INFINITE. For other values of MQMD.Expiry greater than zero, the value of MSMQ PROPID_M_TIME_TO_BE_RECEIVED is converted by dividing MQMD.Expiry by 10. The MSMQ-MQSeries Bridge does not set PROPID_M_TIME_TO_REACH_QUEUE.

VALUE of MSMQ Properties	Converted from MQSeries Fields
PROPID_M_TIME_TO_BE_RECEIVED	MQMD.Expiry

Message Acknowledgment and Journaling (PROPID_M_ACKNOWLEDGE, PROPID_M_JOURNAL)

The MSMQ message acknowledgment and journaling are converted from values of MQMD.Report. For details, see the section above on MQMD.Report.

MSMQ property	Converted from MQSeries
PROPID_M_ACKNOWLEDGE PROPID_M_JOURNAL	MQMD.Report

Other MSMQ Properties (PROPID_M_...)

Fields without MQSeries equivalents

Some MSMQ properties have no equivalent in MQSeries. The MSMQ-MQSeries Bridge assigns the following values to these

properties.

MSMQ property	Value assigned by MSMQ-MQSeries Bridge
PROPID_M_APPSPECIFIC	None
PROPID_M_AUTH_LEVEL	Default
PROPID_M_CONNECTOR_TYPE	None
PROPID_M_DEST_QUEUE	Default
PROPID_M_DEST_QUEUE_LEN	Default
PROPID_M_DEST_SYMM_KEY	None
PROPID_M_ENCRYPTION_ALG	None
PROPID_M_HASH_ALG	None
PROPID_M_MSGID	Assigned by MSMQ
PROPID_M_PRIV_LEVEL	Default
PROPID_M_PROV_NAME	None
PROPID_M_PROV_TYPE	None
PROPID_M_SECURITY_CONTEXT	Default
PROPID_M_SENDER_CERT	Default
PROPID_M_SENTTIME	Time when MSMQ-MQSeries Bridge transmits the message to MSMQ
PROPID_M_SIGNATURE	None
PROPID_M_SRC_MACHINE_ID	GUID of the MSMQ-MQSeries Bridge machine
PROPID_M_TRACE	Default
PROPID_M_VERSION	0x0010

Equivalent MSMQ Properties

The following MSMQ properties have MQSeries equivalents. The MSMQ-MQSeries Bridge converts the values of each property as listed in the table.

> To save space in the table, the prefixes PROPID_M_ and MQMD. are omitted from the MSMQ property names and the MQSeries field names, respectively. For example, the first row of data means that PROPID_M_BODY_TYPE is converted from MQMD.Format.

MSMQ property		Converted from MQSeries	
PROPID_M_	**Value**	MQMD.	**Value**
BODY_TYPE	VT_BSTR Not converted (default)	Format	MQFMT_STRING Any other value
CORRELATIONID	Last 20 bytes of value	MsgId	Value (MQBYTE24)
DELIVERY	MQMSG_DELIVERY_ RECOVERABLE EXPRESS	Persistence	MQPER_ PERSISTENT NOT_PERSISTENT
LABEL LABEL_LEN	Value	ApplIdentityData	Value (MQCHAR32)
PRIORITY	0 1 2 3 4 5 6 7	Priority	0, 1 2, 3 4 5 6 7 8 9
SENDERID SENDERID_TYPE	SID value MQMSG_SENDERID_TYPE_SID Not converted MQMSG_SENDERID_TYPE_NONE	UserIdentifier	Value, if the user is registered in Windows NT If the user is not registered in Windows NT

The MSMQ-MQSeries Bridge Extensions Mechanism

Besides the automatic conversion of MSMQ (Microsoft Message Queue) and IBM MQSeries messages, the Microsoft® MSMQ-MQSeries Bridge provides a mechanism for sending and receiving explicit MQSeries field values. The Microsoft® MSMQ-MQSeries Bridge Extension Property API supports the message extension property (PROPID_M_EXTENSION) of Microsoft Message Queue Server (MSMQ). The message extension property provides a way for applications to attach any type of data—in essence, custom properties—to an MSMQ message.

Similar to the MSMQ message body property (PROPID_M_BODY), the message extension can have any length. However, the message extension has a defined structure that lets an application label its data with a GUID (Globally Unique Identifier) code. Applications can attach multiple extension fields, each labeled with its own GUID and all included in a single message extension property. This is done using the MSMQ message extension property (PROPID_M_EXTENSION).

This section contains:

Data Structure of a Message Extension

A message extension is an MSMQ message property of arbitrary length. The property symbol of a message extension is PROPID_M_EXTENSION and its type indicator is VT_UI1|VT_VECTOR. A message extension is a sequential buffer containing any number of MSMQ extension fields.

Each extension field comprises three subfields:

Subfield	Length of Subfield (bytes)	Description
GUID	16	A GUID identifier, typically of the application that created the extension field.
Length	4	The Length of the Data subfield in bytes.
Data	Value of the length subfield	Any data that is part of the message extension.

For use with the MSMQ-MQSeries Bridge, the GUID identifier is set to the MSMQ-MQSeries Bridge GUID value.

The MSMQ message extension length property, PROPID_M_EXTENSION_LEN, is of type indicator VT_UI4 and represents the overall size in bytes of all message extensions attached to a message. MSMQ sets the message extension length automatically when you send a message. When you receive or peek at a message, you can look into the message extension length to detect whether the message contains any message extension fields and to determine the necessary receive buffer size.

The MSMQ-MQSeries Bridge Extension API functions work with an alternative data representation for a message extension, called an EP object. An EP object contains the same fields and subfields as a message extension, but in a format adapted for programming.

How MSMQ-MQSeries Bridge Creates a Message Extension

When the MSMQ-MQSeries Bridge processes a message from MQSeries, it creates a `PROPID_M_EXTENSION` property, which it includes in the message that it transmits to MSMQ.

This section contains:

MQMD Extension Field

Ordinarily, the message extension contains a single extension field with the following structure:

- The MSMQ-MQSeries Bridge GUID code is stored in the GUID subfield of the extension.

The sizeof(MQMD) is stored in the length subfield of the extension.

The MQMD is copied byte-for-byte into the data buffer of the extension.

The MSMQ-MQSeries Bridge GUID is the value of the sg_MSMQExtMQMD constant which is defined in the mqsrext.h include file found in the SDK\Include subdirectory.

The MQMD extension has the following GUID for MQMD version 2.

```
static const GUID sg_MSMQExtMQMDE =
{ 0x18ae68f5, 0x989b, 0x11d3,
    { 0x8d, 0xf9, 0x0, 0x0, 0xf8, 0x1a,  0xea, 0x1f }
};
```

Error Extension Field

If the MSMQ-MQSeries Bridge encounters an MQSeries error when it transmits a message from MSMQ, it records the error in the extension property and places the message on the dead letter queue.

To do this, the MSMQ-MQSeries Bridge adds an extension property to the MSMQ message, if it doesn't already exist. Within the extension property, MSMQ-MQSeries Bridge creates an extension field containing the following data:

The GUID subfield contains a MSMQ-MQSeries Bridge error GUID (different from the GUID used for MQMD).

- The length subfield contains the value 4.

The data subfield contains a reason code, identical to the codes returned by the MQSeries function **MQPUT**.

The MSMQ-MQSeries Bridge error GUID is the value of the sg_MSMQExtReasonCode constant, which is defined in the mqsrext.h include file found in the SDK\Include subdirectory.

If desired, an MSMQ application can read messages from the dead letter queue and interpret the reason codes.

Other Extension Fields

If you send an MQSeries message having certain values of MQMD.Report, the MSMQ-MQSeries Bridge adds a second extension field to the new MSMQ message. This field is for internal use only, not for use in your applications. The MSMQ-MQSeries Bridge distinguishes the Report extension field from the MQMD and error extension fields by labeling them with different GUIDs.

For further information, see Converting Messages Sent from MQSeries to MSMQ.

How MSMQ-MQSeries Bridge Converts a Message Extension

If you send an MSMQ message including a message extension to MQSeries, the MSMQ-MQSeries Bridge converts the extension in the following way:

The MSMQ-MQSeries Bridge looks for an extension field identified by the MSMQ-MQSeries Bridge GUID. If it finds one, it reads the MQMD structure from the extension field.

- MSMQ-MQSeries Bridge ignores any other extension fields that may be present in the message extension.

MSMQ-MQSeries Bridge includes the MQMD structure that it reads from the extension field in the new MQSeries message.

The MQMD structure in the message extension overrides the default MQMD conversions, which are described in the section on Converting Messages Sent from MSMQ to MQSeries.

A few exceptions to the above rules are described in the following sections.

This section contains:

- Sender and User Identifiers
- Version Identifiers

Sender and User Identifiers

MSMQ-MQSeries Bridge reads the value of MQMD.UserIdentifier stored in the message extension and assigns the value to the MQMD.UserIdentifier field in the new MQSeries message.

Version Identifiers

MQSeries uses the following fields for version identification:

- MQMD.StrucId
- MQMD.Version

When the MSMQ-MQSeries Bridge converts a message extension, it confirms that the values of these fields are for a version of MQSeries that the Bridge supports. If they are not, MSMQ-MQSeries Bridge places the message on the dead letter queue and does not transmit it to MQSeries.

For the supported versions of MQSeries, see Platforms Supported By MSMQ-MQSeries Bridge Extensions. For the permitted values of the version identification fields, see Converting Messages Sent from MSMQ to MQSeries.

Using Message Extensions

This section suggests a few ways that you can use the message extension property in your messaging applications.

This section contains:

Sending an MQSeries Message to MSMQ

MSMQ-MQSeries Bridge stores the complete MQMD structure of an MQSeries message in an MSMQ message extension. An MSMQ application can read the extension and retrieve the original MQMD structure.

In this way, an MSMQ application can retrieve the original values of every MQMD field, regardless of the MSMQ-MQSeries Bridge conversions.

Sending an MSMQ Message to MQSeries

When you send an MSMQ message to MQSeries, you can include a message extension. This can be an extension that you originally received from MQSeries, or one that you created yourself. MSMQ-MQSeries Bridge reads the message extension and uses it to set the MQMD fields of the converted message that it sends to MQSeries.

You can use this feature for two purposes:

- To override the default conversions described in the section Converting Messages Sent from MSMQ to MQSeries

To supplement the default conversions by assigning MQMD fields that have no MSMQ equivalent

The following are some examples of fields that have no equivalents or only partial equivalents (different permitted values or length) among the MSMQ message properties:

- MQMD.AccountingToken
- MQMD.ApplOriginData
- MQMD.CorrelId
- MQMD.MsgId
- MQMD.MsgType
- MQMD.PutApplName
- MQMD.PutApplType
- MQMD.ReplyToQ
- MQMD.ReplyToQMgr
- MQMD.Report

Suppose you want to send a message to an MQSeries application including an MQMD.MsgType value of MQMD_REPLY. The default message conversions provide no way to set this particular value. You can send the value by storing an MQMD data structure in a message extension.

Programming a Message Extension

In an MSMQ application, you can program a message extension containing an arbitrary number of extension fields. For use with MSMQ-MQSeries Bridge, build the extension according to the following specifications.

It is recommended that you use MSMQ-MQSeries Bridge Extension Property API to construct the extension with the required syntax. Create a PROPID_M_EXTENSION property containing at least one extension field.

Store the MSMQ-MQSeries Bridge GUID code in the GUID subfield of exactly one extension field. The GUID is the value of the sg_MSMQExtMQMD constant, which is defined in the mqsrext.h include file of the Extension Property API. Store the sizeof(MQMD) in the length subfield. Copy a complete MQMD structure byte-for-byte into the data buffer subfield.

When you send the message to MQSeries, the MSMQ-MQSeries Bridge converts the extension field identified by the MSMQ-MQSeries Bridge GUID. Any other extension fields are ignored.

The MSMQ-MQSeries Bridge Extension Property API

The MSMQ-MQSeries Bridge Extension Property API is recommended for programming and working with message extensions. The API provides a library of functions that help you create and interpret message extensions. The MSMQ-MQSeries Bridge Extension Property API is supplied as part of the Host Integration Server SDK.

Your MSMQ applications can use the API to:

- Read message extensions that you receive from MQSeries
- Create or modify message extensions that you send to MQSeries
- Read or create message extensions for any other MSMQ messaging purpose

The MSMQ-MQSeries Bridge Extension Property API lets you create and work with the MSMQ message extension property easily. This section provides a few guidelines for using the API functions.

The MSMQ-MQSeries Bridge Extension Property API operates directly on the EP representation of a message extension. In particular, the API functions support the following programming approach:

- Creating or deleting an EP object.
- Creating, finding, reading, writing, or deleting extension fields in an EP object.

Converting an EP object to a message extension. (PROPID_M_EXTENSION) that you can send in an MSMQ message.

- Converting a message extension that you received in an MSMQ message to an EP object.

You cannot send an EP object directly in an MSMQ message. You must first convert it to a message extension (PROPID_M_EXTENSION).

To use the message extension API, include the `MSMQext.h` header file in your applications. This header files contains constants and function prototypes for the Extension Property API functions. This header file is located in the SDK\Include directory on the Host Integration Server CD-ROM and is installed when the SDK package is selected.

If you are using the API in conjunction with MSMQ-MQSeries Bridge, also include the mqsrext.h header file located in the SDK\Include directory. This file defines the GUID that labels the extension fields.

The Extension Property API functions are handle-based. The following is a summary of the MSMQ-MQSeries Bridge Extension Property API functions. For complete details, see the individual function descriptions in the MSMQ-MQSeries Bridge Extensions Reference.

Function	Description
EPAdd	Adds a new extension field to an EP object.
EPClose	Frees the extension handle and associated memory of an EP object.
EPDelete	Deletes an extension field from an EP object.
EPDeleteAll	Deletes all extension fields or all extensions fields matching a specific GUID from an EP object.
EPGet	Positions to and optionally retrieves a requested extension field from an EP object, storing the GUID, length, and data subfields in separate variables. **EPGet** can also be used to locate extension fields containing a specified GUID.
EPGetBuffer	Converts an EP object to a message extension and packs the message extension into the supplied buffer.
EPOpen	Creates an EP object and optionally unpacks the supplied message extension buffer into it.
EPUpdate	Writes new data to an existing extension field of an EP object.

Programming Considerations Using MSMQ-MQSeries Bridge Extensions

The limitations of specific API functions results from the fact that MSMQ-MQSeries Bridge transmits messages, not API calls, between queuing systems. The Microsoft MSMQ-MQSeries Bridge transmits messages across the MSMQ-MQSeries interface. The MSMQ-MQSeries Bridge does not transmit API calls across the interface. Thus, MSMQ API calls operate only within the MSMQ environment, and MQSeries API calls operate only within the MQSeries environment. This principle limits the ways you can create and access queues.

All MSMQ API functions operate only within the MSMQ environment, up to and including foreign computers and queues. For example, you can use the following functions:

MQLocateBegin, **MQLocateNext**, and **MQLocateEnd** to search for foreign queues

MQGetMachineProperties, **MQGetPrivateComputerInformation**, **MQGetQueueProperties**, and **MQGetQueueSecurity** functions to retrieve the properties of foreign queues

MQOpenQueue to open a foreign queue

MQSetQueueProperties and **MQSetQueueSecurity** to set the properties of foreign queues

MQCloseQueue to close a foreign queue

When creating a queue, you can call the MSMQ function **MQCreateQueue** to create a foreign queue representing an MQSeries queue, but you cannot create the actual MQSeries queue itself. Similarly, you cannot create an MSMQ Queue by calling the MQSeries function **MQOPEN**.

To communicate across the MSMQ-MQSeries interface, your MSMQ and MQSeries applications should each create their own queues. Alternatively, you can use administration tools such as the MSMQ Manager or the MQSeries command interface to create the queues.

For proper message delivery, you must ensure that the destination queue for each message actually exists.

You can use the MSMQ **MQPathNameToFormatName** function to determine an MSMQ format name for an MQSeries queue. The format name actually refers to the MSMQ foreign queue. The MSMQ-MQSeries Bridge processes the format name that it finds in a message and directs the message to the MQSeries queue.

When opening a queue, a call to the MSMQ function **MQOpenQueue** opens the foreign queue, not the MQSeries queue itself. The MSMQ-MQSeries Bridge opens the MQSeries queue as necessary when it transmits a message. If you are sending messages to more that one MQSeries queue, you must open each one separately using its own MSMQ format name.

In the opposite direction, the MQSeries function **MQOPEN** opens the transmission queue for the MSMQ machine. The MSMQ-MQSeries Bridge opens the MSMQ queue when it transmits a message.

When sending an MSMQ message to a foreign queue with **MQSendMessage**, MSMQ delivers the message to the connector queue in the MSMQ-MQSeries Bridge machine. The MSMQ-MQSeries Bridge converts and transmits the message to MQSeries queue. MQSeries delivers a message sent by **MQPUT** to a transmission queue. The MSMQ-MQSeries Bridge reads the message from the MQSeries transmission queue. After converting the message from MQSeries to MSMQ message properties, MSMQ-MQSeries Bridge transmits the message to the destination MSMQ queue.

When receiving a message, the MSMQ-MQSeries Bridge does not transmit receive requests across the MSMQ-MQSeries interface. An MSMQ application can receive a message only from a native MSMQ queue (the **MQReceiveMessage** function). An MQSeries application can receive only from a native MQSeries queue (the **MQGET** function).

When sending a message from MQSeries to MSMQ, if you want the MQSeries message to have a value for MQMD. ApplIdentityData, you need the set both of the following:

- Set the open option with MQOO_SET_IDENTITY_CONTEXT
- Set the put option with MQPMO_SET_IDENTITY_CONTEXT

When a message is retrieved from MSMQ, the MSMQ-MQSeries Bridge will have converted the MSMQ PROPID_M_LABEL and PROPID_M_LABEL_LEN properties from the MQSeries MQMD.ApplIdentityData field value.

The MQMDE extension has the following GUID for MQMD version 2.

```
static const GUID sg_MSMQExtMQMDE =
{ 0x18ae68f5, 0x989b, 0x11d3,
```

```
    { 0x8d, 0xf9, 0x0, 0x0, 0xf8, 0x1a,  0xea, 0x1f }
};
```

This section contains:

- Transaction Support Using MSMQ-MQSeries Bridge
- Security Using MSMQ-MQSeries Bridge
- Troubleshooting the MSMQ-MQSeries Bridge Extensions

Transaction Support Using MSMQ-MQSeries Bridge

The MSMQ-MQSeries Bridge supports both MSMQ and MQSeries transactions. The procedure for sending a group of transacted messages is similar in either direction, from MSMQ to MQSeries or from MQSeries to MSMQ. Your application should follow these three basic procedures:

- Open a transaction
- Send the messages
- Commit the transaction

At this point, the group of messages reaches the MSMQ connector queue or the MQSeries transmission queue. Only then does the MSMQ-MQSeries Bridge transmit the messages to the other messaging system. If your application aborts the transaction instead of committing, MSMQ-MQSeries Bridge does not handle the messages at all.

Even after you commit a transaction, it is still possible that MSMQ-MQSeries Bridge cannot transmit all the messages. This may occur, for example, if some of the messages are addressed to queues that don't exist in the recipient messaging system. MSMQ-MQSeries Bridge places any undeliverable messages on its dead letter queue.

In the MSMQ-to-MQSeries direction, the MSMQ-MQSeries Bridge sends transacted messages by a transactional message pipe and untransacted messages by regular message pipe. In the MQSeries-to-MSMQ direction, MQS->MSMQ message pipe, and MQS->MSMQ transactional message pipe do not depend on transaction status.

Security Using MSMQ-MQSeries Bridge

Message authentication and message body encryption are supported from the MSMQ sending application up to the MSMQ-MQSeries Bridge. Authentication and message body encryption from the MSMQ-MQSeries Bridge to MQSeries, or from MQSeries to MSMQ, are not currently supported.

Troubleshooting the MSMQ-MQSeries Bridge Extensions

The Microsoft MSMQ-MQSeries Bridge generally ignores warnings that it receives from MSMQ or MQSeries, but errors are not ignored. Where possible, the MSMQ-MQSeries Bridge transmits messages despite any warnings.

If the MSMQ-MQSeries Bridge is unable to transmit a message to MSMQ or MQSeries, it places the message on one of its dead letter queues. This can happen, for example, if a message contains an unsupported MSMQ or MQSeries version identifier or if MSMQ-MQSeries Bridge encounters an error in the recipient messaging system.

The dead letter queues are MSMQ queues located on the MSMQ-MQSeries Bridge machine. There are two dead letter queues used for this purpose with the following names:

Dead Letter Queue Names	Comments
MQBridge dead letter	Used for untransacted messages when errors occur.
MQBridge xact dead letter	Used for transacted messages when errors occur.

Note that these are different from the MSMQ and MQSeries dead letter queues, where the messaging systems place expired or incorrectly addressed messages.

You can determine whether there are messages on the dead letter queues using the MSMQ-MQSeries Bridge Manager.

If the MSMQ-MQSeries Bridge cannot deliver a message to MQSeries, it records the error in the extension property PROPID_M_EXTENSION of the original MSMQ message and places the message on the dead letter queue. This extension property can be examined to determine the nature of the error encountered.

Registry Settings Used By MSMQ-MQSeries Bridge Extensions

The Microsoft MSMQ-MQSeries Bridge Extensions uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup** key. These registry settings include the following subkeys:

Subkey	Comment
RootDir	Stores the path to root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the MSMQ-MQSeries Bridge Extensions DLL and other support DLLs are installed.

MSMQ-MQSeries Bridge Reference

This section of the Microsoft® Host Integration Server 2000 Developer's Guide lists the extensions and components that make up the MSMQ-MQSeries bridge.

This section contains:

MSMQ-MQSeries Bridge Extensions Reference

This section provides an alphabetic reference to all of the API calls for the MSMQ-MQSeries Bridge Extension Property API.

This section contains:

EPAdd

The **EPAdd** function adds a new extension field at the end of an existing EP object and optionally returns a cursor pointing to the new extension field in the EP object.

```
HRESULT EPAdd(
    HANDLE hExtension,
    PCGUID pFieldID
    void *pFieldData,
    DWORD dwDataLength,
    PHANDLE phCursor
    );
```

Parameters

hExtension
Supplied parameter. The EP object handle to the EP object that is to have data added.
pFieldID
Supplied parameter. A pointer to the GUID of the new extension field. A GUID is 16 bytes in length.
pFieldData
Supplied parameter. A pointer to the buffer containing the data for the new extension field.
dwDataLength
Supplied parameter. The length of the buffer containing the data for the new extension field.
phCursor
Supplied and returned parameter. A pointer to a cursor, which points to the new extension field. If *phCursor* is NULL when this function is called, the cursor is not created.

Return Codes

MQ_OK
The function executed successfully.
MQ_ERROR_ALLOC_FAIL
The function failed because memory could not be allocated for the internal data buffers used to extend the EP object.
MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.
MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.

Remarks

In an EP object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the EPDeleteAll function is called with a *pFieldID* of NULL.

The following example illustrates how to use this function.

```
HANDLE hExt;
HANDLE hCursor;
GUID guid;
...
/* Add a new field containing the data "test" */
EPAdd(hExt, &guid, "test", 5, NULL);

/* Add a new field and create a cursor */
EPAdd(hExt, &guid, "another test", 13, &hCursor);
```

See Also

EPDelete, EPDeleteAll

EPClose

The **EPClose** function closes an open EP object freeing the extension handle and associated memory of an EP object. The entire contents of the object are deleted.

```
HRESULT EPClose(
    PHANDLE phExtension
    );
```

Parameters

phExtension
Supplied and returned parameter. A pointer to an existing EP object handle to close.

Return Codes

MQ_OK
The function executed successfully.
MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.
MQ_ERROR_INVALID_PARAMETER
The function failed because the parameter passed to this function is invalid.

Remarks

If the EP object handle is successfully closed, *phExtension* is reset to NULL on output.

See Also

EPOpen

EPDelete

The **EPDelete** function deletes a single extension field from an existing EP object.

```
HRESULT EPDelete(
    HANDLE hExtension,
    PHANDLE phCursor
    );
```

Parameters

hExtension
Supplied parameter. The EP object handle to the EP object that is to have extension field deleted.

phCursor
Supplied and returned parameter. On input, *phCursor* is a cursor pointing to the extension field to be deleted. On output, *phCursor* is set to the next extension field in the extension, or to NULL if there are no more fields.

Return Codes

MQ_OK
The function executed successfully.

MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.

Remarks

After successful deletion, the cursor is set to point to the next field after the deleted one. If the last field is deleted, the cursor is set to NULL (to the beginning).

In an EP object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the EPDeleteAll function is called with a *pFieldID* of NULL.

See Also

EPDeleteAll

EPDeleteAll

The **EPDeleteAll** function deletes all extension fields from an existing EP object or all extension fields matching a specific GUID.

```
HRESULT EPDeleteAll(
    HANDLE hExtension,
    PCGUID pFieldsId,
    PHANDLE phCursor
    );
```

Parameters

hExtension
Supplied parameter. The EP object handle to the EP object that is to have extension field deleted.

pFieldsId
Supplied parameter. A pointer to a 16-byte buffer containing the GUID of the fields to delete. If this parameter is NULL, all extension fields are deleted.

phCursor
Supplied and returned parameter. On output, this field is a pointer to an extension field cursor. The cursor is positioned at the first field of the next higher GUID after the one that was deleted. If there are no more GUIDs or if all fields were deleted, *phCursor* is set to NULL. The *phCursor* may be NULL on input if no cursor is desired.

Return Codes

MQ_OK
The function executed successfully.

MQ_ERROR_EXTENSION_FIELD_NOT_FOUND
The function failed because the extension field matching the specified GUID could not be found.

MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.

Remarks

If the *phCursor* parameter is not NULL, **phCursor* will point to the next field after all the deleted ones (even if MQ_ERROR_EXTENSION_FIELD_NOT_FOUND is returned). If the last field is deleted, the cursor is set to NULL.

In an EP object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the EPDeleteAll function is called with a *pFieldID* of NULL.

The following example illustrates how to use this function.

```
HANDLE hExt;
GUID guid;
HANDLE hCursor;
...
/* Delete all fields having a specified GUID and set a cursor */
EPDeleteAll(hExt, &guid, &hCursor);

/* Delete all extension fields */
EPDeleteAll(hExt, NULL, NULL);
```

See Also

EPDelete

EPGet

The **EPGet** function reads a specified extension field from an EP object, storing the GUID, length, and data subfields in separate variables. **EPGet** can also be used to locate extension fields containing a specified GUID

```
HRESULT EPGet(
    HANDLE hExtension,
    NAVTYPE Directive,
    PHANDLE phCursor
    GUID *pFieldID,
    void *pFieldData,
    PDWORD pdwDataLength,
    );
```

Parameters

hExtension
Supplied parameter. The EP object handle.

Directive
Supplied parameter. This parameter and *phCursor* together control the behavior of the function. Possible values and their usage are discussed in the table following this parameter list.

phCursor
Supplied and returned parameter. A pointer to a cursor, which points to the matching extension field. If *phCursor* is NULL, the first field having a GUID matching *pFieldID* is read, and the cursor is positioned to this field. See the *Directive* argument for specific details.

pFieldID
Supplied and returned parameter. If the *Directive* argument is EP_NEXT_KEY_FIELD, *pFieldId* is a pointer to a 16-byte buffer containing the GUID to be read. If the *Directive* argument is EP_CURRENT_FIELD or EP_NEXT_FIELD, on output this parameter is a pointer to a 16-byte buffer where the function stores the GUID. The GUID can be NULL if the GUID output is not desired.

pFieldData
Supplied and returned parameter. On input, a pointer to a buffer where the function should store the extension field data. On input, this parameter can be NULL if the data output is not desired. On output, a pointer to a buffer where the function stores the extension field data.

pdwDataLength
Supplied and returned parameter. On input, the length of the buffer for the data from the extension field. On output, the actual length of the data. If the buffer is too short or NULL, the data is not read but *pdwDataLength* is reset to the required buffer length.

Values for the *Directive* parameter

Directive	Description
EP_CURRENT_FIELD	Retrieves the extension field pointed to by the *phCursor* parameter, which must be a valid non-NULL cursor handle.
EP_NEXT_FIELD	Advances the cursor and reads the next field. If there are no more fields, returns MQ_ERROR_EXTENSION_FIELD_NOT_FOUND and *phCursor* is set to NULL. If *phCursor* is NULL or **phCursor* is NULL, the cursor is positioned to the first field (sorted in ascending order of GUID) and this field is read. If *phCursor* is not NULL, **phCursor* is set to the extension field. If *phCursor* is not NULL and **phCursor* is not NULL, the cursor (*phCursor*) is positioned to the first field (sorted in ascending order of GUID) and this field's ID and data are read and returned.
EP_NEXT_KEY_FIELD	Advances the cursor and reads the next field having a GUID matching *pFieldID*. If there are no more matching fields, returns MQ_ERROR_EXTENSION_FIELD_NOT_FOUND and sets *phCursor* to the first field having the next higher GUID, or to NULL if there are no more fields. If *phCursor* is NULL or **phCursor* is NULL, then the first field having a GUID matching *pFieldID* is read, and the cursor is positioned to this field. If the field is found it's field ID and data are returned and if *phCursor* is not NULL, **phCursor* is set to the field.

Return Codes

MQ_OK
The function executed successfully.
MQ_ERROR_ALLOC_FAIL
The function failed because memory could not be allocated for the internal data buffers used for the EP object.
MQ_ERROR_EXTENSION_FIELD_NOT_FOUND
The function failed because the extension field matching the specified GUID could not be found.
MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.
MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.
MQ_ERROR_USER_BUFFER_TOO_SMALL
The function failed because the length of the buffer passed was too small for the data.

Remarks

In an EP object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the EPDeleteAll function is called with a *pFieldID* of NULL.

The following example illustrates how to use this function.

```
HANDLE hExt;
HANDLE hCursor;
GUID guid;
void *pBuffer;
DWORD dwSize, dwCount;
DWORD dwTotalSize = 0;
...

/* Retrieve one field by GUID */
dwSize = 1024;
EPGet(hExt, EP_NEXT_KEY_FIELD, NULL, &guid, pBuffer, &dwSize);

/* Count the fields in a message extension */
for (hCursor = NULL, dwCount = 0;
     EPGet(hExt, EP_NEXT_FIELD, &hCursor, NULL, NULL, NULL)==MQ_OK;
     dwCount++);

/* Compute the total length of all extension fields
   having a given GUID */
for (hCursor = NULL, dwCount = 0;
          EPGet(hExt, EP_NEXT_KEY_FIELD, &hCursor, &guid, NULL,
              &dwSize) == MQ_OK;
     dwTotalSize += dwSize);
```

See Also

EPDelete, EPDeleteAll

EPGetBuffer

The **EPGetBuffer** function converts an EP object to a message extension (PROPID_M_EXTENSION format) that can be sent in a message and packs the message extension into the supplied buffer.

```
HRESULT EPGetBuffer(
    HANDLE hExtension,
    void *pBuf,
    PDWORD pdwBufLength,
    );
```

Parameters

hExtension
Supplied parameter. The EP object handle.
pBuf
Supplied parameter. A pointer to the buffer where this function will store the PROPID_M_EXTENSION message extension.
pdwBufLength
Supplied and returned parameter. On input, the length of the buffer for the message extension. On output, the actual length of the stored data. If the buffer is too short or NULL, the data is not converted but *pdwBufLength* is reset to the required buffer length.

Return Codes

MQ_OK
The function executed successfully.
MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.
MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.
MQ_ERROR_USER_BUFFER_TOO_SMALL
The function failed because the length of the buffer passed was too small for the data.

Remarks

If this function executed successfully, the *pdwBufLength* parameter contains the actual length of the packed extension buffer. If MQ_ERROR_USER_BUFFER_TOO_SMALL is returned, *pdwBufLength* contains the required buffer length.

The following example illustrates how to use this function.

```
HANDLE hExt;
void *pBuffer;
DWORD dwSize;

/* Read the required buffer length */
dwSize = 0;
EPGetBuffer(hExt, NULL, &dwSize);

/* Allocate the buffer */
pBuffer = malloc(dwSize);

/* Write the message extension to the buffer */
EPGetBuffer(hExt, pBuffer, &dwSize);
```

See Also

EPAdd, EPOpen

EPOpen

The **EPOpen** function creates an EP object and optionally unpacks the supplied message extension buffer into it.

```
HRESULT EPOpen(
    PHANDLE phExtension,
    void *pExtBuffer,
    DWORD dwExtBufLength
    );
```

Parameters

phExtension
Returned parameter. A pointer to an EP object handle of the EP object that is created.

pExtBuffer
Supplied parameter. The pointer to a buffer containing the message extension data in the sequence GUID (16 bytes), length of data (4 bytes), data, GUID, length of data, data, etc.

dwExtBufLength
Supplied parameter. The length of the buffer containing the message extension data.

Return Codes

MQ_OK
The function executed successfully.

MQ_ERROR_ALLOC_FAIL
The function failed because memory could not be allocated for the EP object handle and internal data buffers.

MQ_ERROR_CORRUPTED_EXTENSION_BUFFER
The function failed because the buffer containing the message extension data was corrupted.

MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.

Remarks

If a NULL pointer is passed for *pExtBuffer* or *dwExtBufLength* is zero, an EP object with no extension fields is created.

The following example illustrates how to use this function.

```
HANDLE hExt1, hExt2;
void *pBuffer;
DWORD dwBufLength;
...
/* Create an empty EP object */
EPOpen(&hExt1, NULL, 0);
/* Create an EP object, copying data from a message extension */
EPOpen(&hExt2, pBuffer, dwBufLength);
```

See Also

EPClose

EPUpdate

The **EPUpdate** function updates (replaces) the data and length subfields of an existing extension field in an EP object.

```
HRESULT EPUpdate(
    HANDLE hExtension,
    HANDLE hCursor
    void *pFieldData,
    DWORD dwDataLength,
    );
```

Parameters

hExtension
Supplied parameter. The EP object handle to the EP object that is to have data updated.
hCursor
Supplied parameter. The cursor pointing to the extension field to be updated which must not be NULL.
pFieldData
Supplied parameter. A pointer to the buffer containing the new data for the extension field. This parameter may be NULL for an empty data subfield.
dwDataLength
Supplied parameter. The length of the buffer containing the new data for the extension field.

Return Codes

MQ_OK
The function executed successfully.
MQ_ERROR_ALLOC_FAIL
The function failed because memory could not be allocated for the internal data buffers used to update the EP object.
MQ_ERROR_INVALID_HANDLE
The function failed because the EP object handle passed to the function is invalid.
MQ_ERROR_INVALID_PARAMETER
The function failed because one or more of the parameters passed to this function are invalid.

Remarks

The following example illustrates how to use this function.

```
HANDLE hExt;
HANDLE hCursor;
GUID guid;
...
/* Find an extension field containing a specified GUID */
EPGet (hExt, EP_NEXT_KEY_FIELD, &hCursor, &guid, NULL, 0)
/* Change the length and data subfields of the extension field */
EPUpdate(hExt, hCursor, "newdata", 8);
```

SDK Components for MSMQ-MQSeries Bridge Extensions

The Microsoft® Host Integration Server 2000 SDK contains software components used for application integration using messaging and the MSMQ-MQSeries Bridge. The components used for application integration using the MSMQ-MQSeries Bridge are described in the following topics.

This section contains:

Program and DLL Files for MSMQ-MQSeries Bridge

The following executable system files, DLL library files, and other files are included with the Host Integration Server 2000 SDK for use with the MSMQ-MQSeries Bridge:

File name	Description
BCluster.exe	A program used to create or remove the MSMQ-MQSeries Bridge Service resource in a cluster.
explres.dll	The resource file for Q2QEXPL.exe, the MSMQ-MQSeries Bridge explorer program.
MQBInst.dll	The COM component used to create, delete, or modify MSMQ-MQSeries Bridge objects in Active Directory.
mqfrgnky.dll	A library to provide a function for the MSMQ-MQSeries Bridge to store a public key in a foreign computer object (i.e. MQFrgn_StorePubKeysInDS).
MQSRRecv.exe	A sample program that uses the MQSeries API to receive messages from a specified MQSeries queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MQSRSend.exe	A sample program that uses the MQSeries API to send 10 test messages to a specified MQSeries queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MSMQRecv.exe	A sample program that uses the MSMQ API to receive messages from a specified MSMQ queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MSMQSend.exe	A sample program that uses the MSMQ API to sends 10 test messages to a specified MSMQ local or foreign queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
Q2QCLDLL.dll	A helper DLL (now obsolete) that contains functions to work with a cluster.
Q2QEXPL.exe	The MSMQ-MQSeries Bridge explorer program.
Q2QGW.exe	The MSMQ-MQSeries Bridge service program.
q2qmsg.dll	The Event Log message file.
q2qperf.ini	The performance counter definition file for the MSMQ-MQSeries Bridge.
q2qprfdl.dll	The performance counter implementation DLL for the MSMQ-MQSeries Bridge extension.
q2qprfsm.def	Defines the performance counter object in q2qperf.ini.
Q2QSHDLL.dll	A helper DLL (now obsolete) that contains functions for installing and uninstalling the MSMQ-MQSeries Bridge.
SHDLLRes.dll	The resource DLL (now obsolete) for Q2QSHDLL.DLL for installing and uninstalling the MSMQ-MQSeries Bridge.
wmiMQBridge.dll	The MSMQ-MQSeries Bridge WMI Provider.
wmimqbridge.mof	The WMI Managed Object File (MOF) for the MSMQ-MQSeries Bridge.

The following executable system files, DLL library files, and other files are included with SNA Server 4.0 Service Pack 4 for use with the MSMQ-MQSeries Bridge:

File name	Description
EPRECV.EXE	A sample program that uses the MSMQ-MQSeries Bridge Extensions API to display the MQMD structure in the MSMQ extension property.
EPSEND.EXE	A sample program uses the MSMQ-MQSeries Bridge Extensions API to override the default MSMQ-MQseries Bridge message property mapping MsgType, ReplyToQMgr, and ReplyToQ in the MQSeries MQMD structure.
explres.dll	The resource file for Q2QExpl.exe, the MSMQ-MQSeries Bridge explorer program.
Inetwh32.dll	A support DLL for online help.
MQBridge.chm	The MSMQ-MQSeries Bridge online help file.

MQSRRecv.exe	A sample program that uses the MQSeries API to receive messages from a specified MQSeries queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MQSRSend.exe	A sample program that uses the MQSeries API to send 10 test messages to a specified MQSeries queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MSMQRecv.exe	A sample program that uses the MSMQ API to receive messages from a specified MSMQ queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MSMQSend.exe	A sample program that uses the MSMQ API to sends 10 test messages to a specified MSMQ local or foreign queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
q2qcldll.dll	A helper DLL that contains functions to work with a cluster.
Q2QCIlns.exe	A helper program for the MSMQ-MQSeries Bridge cluster installation.
Q2QClUni.exe	A helper program for the MSMQ-MQSeries Bridge cluster uninstallation.
Q2QExpl.exe	The MSMQ-MQSeries Bridge explorer program.
q2qgw.exe	The MSMQ-MQSeries Bridge service program.
Q2Qgwy.CNT	The online help index file for the MSMQ-MQSeries Bridge service program.
Q2Qgwy.hlp	The online help file for the MSMQ-MQSeries Bridge service program.
Q2QInsSt.exe	A program used to launch Q2QCIlIns.exe, the MSMQ-MQSeries Bridge cluster installation program.
Q2QMSG.dll	The Event Log message file.
Q2qperf.ini	The performance counter definition file for the MSMQ-MQSeries Bridge.
q2qprfdl.dll	The performance counter implementation DLL for the MSMQ-MQSeries Bridge extension.
Q2QSHDLL.dll	A helper DLL (now obsolete) that contains functions for installing and uninstalling the MSMQ-MQSeries Bridge.
SHDLLRes.dll	The resource DLL (now obsolete) for Q2QSHDLL.DLL for installing and uninstalling the MSMQ-MQSeries Bridge.
SNAVER.exe	A utility program to retrieve the SNA Server program version.

Symbol Files for MSMQ-MQSeries Bridge

The following symbol files for use when debugging are included with Host Integration Server 2000 for use with the MSMQ-MQSeries Bridge. These files are installed as part of the Host Integration Server package and a copy of these files are also located on the Host Integration Server CD-ROM under the Support\Symbols folder:

File name	Description
EXE\BCluster.dbg	Symbols from BCluster.exe
DLL\explres.dbg	Symbols from Explres.dll
DLL\MQBInst.dbg	Symbols from MQBInst.dll
EXE\MQSRRecv.dbg	Symbols from MQSRRecv.exe
EXE\MQSRSend.dbg	Symbols from MQSRSend.exe
EXE\MSMQRecv.dbg	Symbols from MSMQRecv.exe
EXE\MSMQSend.dbg	Symbols from MSMQSend.exe
DLL\Q2QCLDLL.dbg	Symbols from Q2QCLDLL.dll.
EXE\Q2QCIIns.dbg	Symbols from Q2QCIIns.exe.
EXE\Q2QClUni.dbg	Symbols from Q2QClUni.exe.
EXE\Q2QEXPL.dbg	Symbols from Q2QEXPL.exe.
EXE\Q2QGW.dbg	Symbols from Q2QGW.exe.
EXE\Q2QInst.dbg	Symbols from Q2QInst.exe.
DLL\q2qmsg.dbg	Symbols from q2qmsg.dll.
DLL\q2qprfdl.dbg	Symbols from q2qprfdl.dll.
DLL\Q2QSHDLL.dbg	Symbols from Q2QSHDLL.dll.
DLL\SHDLLRes.dbg	Symbols from SHDLLRes.dll.
DLL\wmiMQBridge.dbg	Symbols from wmiMQBridge.dll.

The following symbol files for use when debugging are included with SNA Server 4.0 Service Pack 4 for use with the MSMQ-MQSeries Bridge. These files are located on the SNA Server CD-ROM under the mqbridge folder:

File name	Description
EPRECV.DBG	Symbols from EPRECV.EXE
EPSEND.DBG	Symbols from EPSEND.EXE
eplres.dbg	Symbols from explres.dll
MQSRRecv.dbg	Symbols from MQSRRecv.exe
MQSRSend.dbg	Symbols from MQSRSend.exe
MSMQRecv.dbg	Symbols from MSMQRecv.exe
MSMQSend.dbg	Symbols from MSMQSend.exe
Q2QCLDLL.dbg	Symbols from q2qcldll.dll
Q2QCIIns.dbg	Symbols from Q2QCIIns.exe
Q2QClUni.dbg	Symbols from Q2QClUni.exe
Q2QEXPL.dbg	Symbols from Q2QExpl.exe
Q2QGW.dbg	Symbols from q2qgw.exe
Q2QInsSt.dbg	Symbols from Q2QInsSt.exe
q2qmsg.dbg	Symbols from Q2QMSG.dll
q2qprfdl.dbg	Symbols from q2qprfdl.dll
Q2QSHDLL.dbg	Symbols from Q2QSHDLL.dll
SHDLLRes.dbg	Symbols from SHDLLRes.dll
SNAVER.dbg	Symbols from SNAVER.EXE

Header Files for MSMQ-MQSeries Bridge

Provider-specific header files needed to build the MSMQ-MQSeries Bridge sample applications are included with Host Integration Server 2000. These files are installed as part of the Host Integration Server package and a copy of these files are also located on the Host Integration Server CD-ROM under the SDK\Include folder:

The following provider-specific files are provided with Host Integration Server for developing applications using the MSMQ-MQSeries Bridge:

File name	Description
msmqep.h	GUID definitions, enumeration constants, and error codes for use with the MSMQ-MQSeries Bridge.

Provider-specific header files needed to build the MSMQ-MQSeries Bridge sample applications are included with SNA Server 4.0 Service Pack 4. These files are installed as part of the MSMQ-MQSeries Bridge with SNA Server and a copy of these files are also located on the SNA Server 4.0 CD-ROM under the mqbridge folder:

The following provider-specific files are provided with SNA Server 4.0 Service Pack 4 for developing applications using the MSMQ-MQSeries Bridge:

File name	Description
mqsrext.h	GUID definitions, enumeration constants, and error codes for use with the MSMQ-MQSeries Bridge.
MSMQExt.h	Function prototypes and enumeration constants for use with MSMQ-MQSeries Bridge extended functions.
Q2qprfsm.h	Definitions for the Performance counter object in q2qperf.ini.

Import Library Files for MSMQ-MQSeries Bridge

Provider-specific import library files needed to build the MSMQ-MQSeries Bridge extension sample applications are included with Host Integration Server 2000. These files are installed as part of the Host Integration Server package and a copy of these files are also located on the Host Integration Server CD-ROM under the SDK\Lib folder:

The following provider-specific files are provided with Host Integration Server for developing applications using the MSMQ-MQSeries Bridge:

File name	Description
msmqep.lib	Import library of functions for use with the MSMQ-MQSeries Bridge extension.

Provider-specific import library files needed to build the MSMQ-MQSeries Bridge extension sample applications are included with SNA Server 4.0 Service Pack 4. These files are installed as part of the MSMQ-MQSeries Bridge with SNA Server and a copy of these files are also located on the SNA Server CD-ROM under the mqbridge folder:

The following provider-specific files are provided with SNA Server 4.0 Service Pack 4 for developing applications using the MSMQ-MQSeries Bridge:

File name	Description
MSMQEP.lib	Import library of functions for use with the MSMQ-MQSeries Bridge extensions.

Application Integration Samples

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information about the sample applications that implement the MSMQ-MQSeries bridge and the COM Transaction Integrator (COMTI).

This section contains:

Sample Programs for MSMQ-MQSeries Bridge

The source code for several sample programs that illustrate using MSMQ-MQSeries Bridge are included on the Microsoft® Host Integration Server 2000 CD-ROM and as part of the Microsoft Developer Network (MSDN) Platform SDK. These sample programs are located in the \SDK\Samples\Bridge subdirectory on the Host Integration Server 2000 CD-ROM. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\Bridge subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Host Integration Server SDK, by default).

When installed as part of the MSDN Platform SDK, these samples are located under the Samples\NetDS\HIS\Bridge subdirectory below where the MSDN Platform SDK has been installed (C:\Program Files\Microsoft SDK, by default).

These sample programs include the files in the following subdirectories:

Subdirectory	Description
EPRecv	A sample program in C that uses the MSMQ-MQSeries Bridge Extensions API to display the MQMD structure in the MSMQ extension property.
EPSend	A sample program in C that uses the MSMQ-MQSeries Bridge Extensions API to override the default MSMQ-MQseries Bridge message property mapping MsgType, ReplyToQMgr, and ReplyToQ in the MQSeries MQMD structure.
MQSRRecv	A sample program in C that uses the MQSeries API to receive messages from a specified MQSeries queue.
MQSRSend	A sample program in C that uses the MQSeries API to send 10 test messages to a specified MQSeries queue.
MSMQRecv	A sample program in C that uses the MSMQ API to receive messages from a specified MSMQ queue.
MSMQSend	A sample program in C that uses the MSMQ API to sends 10 test messages to a specified MSMQ local or foreign queue.
WMI	A collection of WMI sample scripts written in Microsoft® Active Server Pages (ASP) that show how to use WMI to configure the MSMQ-MQSeries Bridge.

Several sample programs with source code are provided with Host Integration Server 2000 that illustrate how to use the MSMQ-MQSeries Bridge and Bridge Extensions.

The MSMQ-MQSeries Bridge samples are designed to be built using Microsoft® Visual C/C++ 6.0 or later using the command-line compiler or using the Microsoft® Visual Studio .NET interactive development environment (IDE). Most of these samples also require that the IBM MQSeries Client toolkit has been installed, providing access to several MQSeries include and lib files.

To build the MSMQ-MQSeries Bridge samples using the command-line compiler, set up your build environment as follows:

- Run VCVARS32.bat (for VS6) or VSVARS32.bat (for VS.NET) from the Visual Studio bin directory(by default, C:\Program Files\Microsoft Visual Studio\VC98\Bin for VS6 or C:\Program Files\Microsoft Visual Studio .NET\Common7\Tools for VS.NET))
- Set the MQS_INC environment variable so it points to the INCLUDE directory where MQSeries was installed. The default location for this variable is normally C:\Program Files\MQSeries Client\tools\c\include.
- Set the MQS_LIB environment variable so it points to the LIB directory where MQSeries was installed. The default location for this variable is normally C:\Program Files\MQSeries Client\tools\lib.

For example, set the following environment variables for building the MQS samples:

```
set MQS_INC=C:\Program Files\MQSeries Client\tools\c\include
set MQS_LIB=C:\Program Files\MQSeries Client\tools\lib
```

To build all the C/C++ samples (EPSend, EPRecv, MQSRRecv, MQSRSend, MSMQSend and MSMQRecv), open an MS-DOS Command Prompt window, navigate to Bridge subdirectory, and invoke NMAKE. This will recursively invoke NMAKE and build all of the Bridge samples.

To build a specific sample (EPSend, for example) using the command-line compiler, open an MS-DOS Command Prompt window, navigate to the appropriate subdirectory (Bridge\EPSend, for example), and invoke NMAKE.

To build a specific sample (EPSend, for example) using the Visual Studio .NET IDE, start Microsoft Visual Studio .NET 7.0 and open the appropriate Visual C++ 7.0 project file (epsend.vcproj, for example) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each VC7 project file has two configurations, one for a DEBUG build and one for a RETAIL build. Note that several of the MSMQ-MQSeries Bridge samples require access to the IBM MQSeries Client toolkit include and lib files.

The VC7 project files for these samples assume that the IBM MQSeries Client toolkit is installed in the default location at C:\Program Files\MQSeries Client\tools. If the IBM MQSeries Client toolkit is installed in a different location, the VC7 project files will need to be modified. For each C source file, the **Additional Include Directories** property under **C/C++/General** will need to be changed. For the target, the **Additional Dependencies** property under **Linker/Input** will need to be changed.

This section contains:

- EPRecv sample program
- EPSend sample program
- MQSRRecv sample program
- MQSRSend sample program
- MSMQRecv sample program
- MSMQSend sample program.
- WMI MSMQ-MQSeries Bridge sample programs

EPRecv Sample

The MSMQ-MQSeries Bridge Extension API can be used to obtain the original MQSeries message properties for an MQSeries message sent using the MSMQ-MQSeries Bridge to MSMQ. The Bridge\EPRecv folder contains a sample program written in C that receives messages from an MSMQ queue using the MSMQ APIs and prints the original MQSeries message MQMD properties in the PROPID_M_EXTENSION if they exist. The sample illustrates how to use MSMQ-MQSeries Bridge Extensions and can be used for testing or troubleshooting the MSMQ-MQSeries Bridge and Bridge Extensions.

The usage for this command-line tool is as follows:

```
EPRecv <computer name>\<queue name>
```

The only parameter. <computer name>\<queue name> is the path name of the specified MSMQ queue name where messages are received. This MSMQ queue name can be specified in UNC or DNS format.

Sample program usage and sample output are listed below.

```
eprecv MSBRIDGE\QUEUE

Queue opened.
Waiting for messages to arrive.
Use CTLR-C to stop.
-------> Message arrived:
Label = ''
Body (256) = 'Test Message 0 - 19:41:26'
Body Type (4113)
Extension property found.  Dumping values:
    MQMD1 Extension Field found.  Dumping values:
        MQMD1.Report = 00000000   MQMD1.MsgType = 00000008
        MQMD1.Feedback = 00000000   MQMD1.Priority = 0
        MQMD1.Version = 00000001  MQMD1.Expiry = -1
        MQMD1.ReplyToQMgr = 'BRIDGE2K_QM                                    '
        MQMD1.ReplyToQ    = '                                               '
        MQMD1.UserIdentifier = 'testuser     '
        MQMD1.ApplIdentityData = '            '
        MQMD1.PutApplName = 'n Server\sys'
        MQMD1.PutDate = '20000628'
        MQMD1.PutTime = '02530720'
        MQMD1.MsgId = '414D512053544152 5741525F514D2020 9197523913300000'
        MQMD1.CorrelId = '0000000000000000 0000000000000000 0000000000000000'
```

EPSend Sample

The MSMQ-MQSeries Bridge Extension API can be used to override the default MSMQ-MQSeries Bridge message property mapping. The Bridge\EPSend folder contains a sample written in C that illustrates how to use the MSMQ-MQSeries Bridge Extension API to override the default MSMQ-MQSeries Bridge message propery mapping for MsgType, ReplyToQMgr, and ReplyToQ in the MQSeries MQMD structure. This sample sends messages to MSMQ queue, overiding the default values for these MQMD extension fields. The sample illustrates how to use MSMQ-MQSeries Bridge Extensions and can be used for testing or troubleshooting the MSMQ-MQSeries Bridge and Bridge Extensions.

The usage for this command-line tool is as follows:

```
EPSend <computer name>\<queue name>
```

The only parameter <computer name>\<queue name> is the path name of the specified MSMQ queue name where messages are to be sent. This MSMQ queue name can be specified in UNC or DNS format.

Sample program usage and sample output are listed below.

```
epsend IBMNT_QM\QUEUE

Queue opened.
Reply Q Manager Name : MSBRIDGE1
Reply Q Name : QUEUE
------> Sending message (Use CTRL-C to stop).Label: ABC
Body: ABC
```

MQSRRecv Sample

The Bridge\MQSRRecv folder contains a sample program written in C that uses the MQSeries API to receive messages from a specified MQSeries queue. This sample can be used to receive messages sent from MQSeries or sent from MSMQ using the MSMQ-MQSeries Bridge. The sample can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MQSRRecv <QM name> <queue name>
```

The first parameter, QM name, is the name of the MQSeries Queue Manager. The second parameter, queue name, is the queue name from which to receive the messages. Note that the program assumes that queue name is located on the QM name computer.

You can run the MQSRRecv program on a computer where the MQSeries Client is installed and configured. The environment variables used by the MQSeries client should point to the appropriate channel table file. The computer running the MSMQ-MQSeries Bridge is a good choice because it should already be properly configured.

MQSRSend Sample

The Bridge\MQSRSend folder contains a sample written in C that uses the MQSeries API to send 10 test messages to a specified MQSeries queue. This sample can be used to send messages to a specified MQSeries queue or to a specified MSMQ queue using the MSMQ-MQSeries Bridge. The sample can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MQSRSend <local QM name> <destination QM name>
        <queue name>
```

The first parameter, local QM name, is the name of the immediate MQSeries Queue Manager to connect to (the server side of the MQI channel). MQSRSend needs this information to establish the MQI channel connection.

The second parameter, the destination QM name, is the destination queue manager for the messages. To send messages to MSMQ, specify the queue manager alias for the destination QM name representing the MSMQ queue.

The third parameter, queue name, is the name of the queue where the messages should be sent.

You can send MQSeries message to an MSMQ queue with one of the following methods.

1. Specify the MSMQ-MQSeries Bridge machine name in the destination QM name and the MSMQ format name in the queue name.
2. Define QREMOTE for the MSMQ destination QM name in MQSeries.

You can run the MQSRSend program on a computer where the MQSeries Client is installed and configured. The environment variables used by the MQSeries client should point to the appropriate channel table file. The computer running the MSMQ-MQSeries Bridge is a good choice because it should already be properly configured.

MSMQRecv Sample

The Bridge\MSMQRecv folder contains a sample written in C that uses the MSMQ API to receive messages from a specified MSMQ queue. This sample can be used to receive messages sent from MSMQ or receive messages sent from MQSeries using the MSMQ-MQSeries Bridge. The sample illustrates how to receive messages using MSMQ and can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MSMQRecv <computer name>\<queue name>
```

The only parameter. <computer name>\<queue name> is the path name of the specified MSMQ queue name where messages are received. This MSMQ queue name can be specified in UNC or DNS format.

You can run the MSMQRecv program on any computer where MSMQ is installed, not necessarily the computer running the MSMQ-MQSeries Bridge.

MSMQSend Sample

The SDK\Samples\Bridge\MSMQSend folder contains a sample written in C that sends 10 test messages using the MSMQ APIs. This sample can be used to send messages to a specified MSMQ queue or a foreign MQSeries queue through the MSMQ-MQSeries Bridge. The sample illustrates how to send messages using MSMQ and can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MSMQSend <computer name>\<queue name>
```

The only parameter. <computer name>\<queue name> is the path name of the specified MSMQ queue name where messages are to be sent. This MSMQ queue name can be specified in UNC or DNS format.

You can run the MSMQSend program on any computer where MSMQ is installed, not necessarily the computer running the MSMQ-MQSeries Bridge.

WMI MSMQ-MQSeries Bridge Sample

The Bridge\WMI folder contains a collection of Active Server Pages (ASP) for use with a Web server application that allow you to view and make changes to the MSMQ-MQSeries Bridge configuration using WMI. These sample applications require Microsoft Internet Information Server version 3.0 or higher with Active Server Pages be installed. Host Integration Server 2000 and Internet Information Server must be installed and running on the same computer.

The WMI ASP samples must be installed into the Web server's public directories below WWWRoot. Copy the contents of the entire WMI directory from the SDK\Samples\Bridge\WMI subdirectory to your WWWROOT directory on the Web server. After these files have been copied you should have a WWWROOT\WMI folder containing a number of ASP and GIF files.

The samples may then be run by opening Internet Explorer or some other Web browser on the same computer or a different computer and entering the following URL in the address line:

```
http://<computer name>/WMI/WMI_Test_Main.asp
```

Substitute the network name of the computer hosting the Web server and the MSMQ-MQSeries Bridge for the computer name (in angle brackets in the URL above). This will open the main page of the Bridge WMI ASP application and allow you to select any of the other sample ASP pages. Information about each sample is provided on this web page.

These ASP pages illustrate using WMI to view and make changes to the MSMQ-MQSeries Bridge configuration. The management functions supported by this application allow you to create a new instance, move to other instances (previous and next), delete an instance, and save an instance.

The WMI subdirectory below WWWROOT needs to have IIS security enabled (no anonymous access). Otherwise the scripts in these subdirectories will fail since the anonymous user account by default does not have access rights that would allow it to start or stop services on Windows NT or Windows 2000 or make changes to the MSMQ-MQSeries Bridge on the Host Integration Server system.

It is possible to host these ASP pages on a computer running the Web server that is different from the computer running the MSMQ-MQSeries Bridge and Host Integration Server. However, this requires some changes to the ASP pages to handle connections to a different computer, security, and authentication issues.

Sample Programs for COMTI

The source code for several sample programs that illustrate using features of the COM Transaction Integrator (COMTI) for CICS and IMS is included on the Microsoft® Host Integration Server 2000 CD-ROM as a part of the Host Integration Server Software Development Kit (SDK). COMTI allows developers to integrate component-based Windows® applications using COM, distributed COM, and COM+ with CICS and IMS transactions on IBM mainframes.

In addition to the COMTI samples included in the Host Integration Server SDK, there is a basic COMTI sample entitled CedarBank that is installed with COMTI when the COMTI feature option is selected during setup. The CedarBank sample is installed under the system\Tutorials\CedarBank subdirectory below where Host Integration Server is installed (the default location is C:\Program Files\Host Integration Server\system\Tutorials\CedarBank).

Note that documentation on COMTI is not included with the Host Integration Server SDK. Documentation on COMTI is included under Application Integration Services as part of the Host Integration Server 2000 user documentation. The documentation is also available in printable format on the Host Integration Server CD-ROM under the Documentation\Printable Books folder in the Application Integration Services.pdf file.

The COMTI sample programs are located in the \SDK\Samples\COMTI subdirectory on the Host Integration Server 2000 CD-ROM. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\COMTI subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Host Integration Server SDK, by default).

When installed as part of the MSDN® Platform SDK, these samples are located under the Samples\NetDS\HIS\COMTI subdirectory below where the MSDN Platform SDK has been installed (C:\Program Files\Microsoft SDK, by default).

These sample programs include the files in the following subdirectories:

Subdirectory	Description
BoundedRecordsets\COBOL-CICS	A sample program in COBOL using COMTI that illustrates the use of bounded recordsets. This subdirectory also contains a sample TLB file created using the COMTI Component Builder for this COBOL sample.
BoundedRecordsets\VB	A sample class defined in Microsoft Visual Basic® using COMTI that illustrates the use of bounded recordsets.
ProgrammingSpecifics	This folder contains a comprehensive sample that include Visual Basic client code as well as mainframe COBOL code and sample COMTI type libraries. This sample is intended to be a complete end-to-end sample demonstrating features of COMTI.
ProgrammingSpecifics\CICSNonlink	A sample program in COBOL using COMTI that demonstrates how to receive a COMTI fixed-sized data area greater than 32767. This sample is not intended to be a complete end-to-end program, but it demonstrates the receiving-side logic of a CICS Non-Link server application program using COMTI.
ProgrammingSpecifics\TCP	A set of several sample programs in COBOL using COMTI that demonstrate how to use a CICS TCP server application.
SyncLev2	A sample program in COBOL using COMTI that demonstrates how to use Sync Level 2.

These samples primarily use a remote environment of CICS using LU 6.2. These COMTI samples are designed to assist developers in creating code for specific COMTI features.

In order to first start working with COMTI, it is recommended that developers use the CedarBank tutorial that comes with the COMTI installation. The CedarBank tutorial illustrates how to use of all of the COMTI Remote Environments and includes the COMTI Type libraries and the COBOL code for the mainframe for all of the environments (IMS, CICS, APPC and TCP/IP). The CedarBank sample also includes sample programs for the client-side code written in Microsoft Visual Basic and Microsoft Visual C++®.

Once connectivity has been established by working with the CedarBank tutorial, then the COMTI samples included with the Host Integration Server SDK can be used to gain an understanding of more advanced COMTI features not covered by the CedarBank tutorial.

This section contains:

- Sync Level 2 Sample

Bounded Recordsets Sample

The COM Transaction Integrator (COMTI) for CICS and IMS can be used with Microsoft Visual Basic bounded recordsets. This sample includes Visual Basic code and CICS COBOL code showing how to use bounded recordsets by calling into a CICS transaction program via LU 6.2 (Remote Environment CICS using LU 6.2).

The Visual Basic code is in the COMTI\BoundedRecorsdsets\VB folder and defines a Visual Basic class file that illustrates the use of bounded recordsets. Note that additional Visual Code would need to be written to use this Visual Basic class file in a project. The Visual Basic code in the class file demonstrates how to create a recordset and populate it with data to send to the mainframe. Note that there is no code that actually displays the data that comes back from the mainframe. A developer can put in a breakpoint in the Visual Basic code using the debugger and use the immediate window to look at the data or insert further code to examine the data that is returned.

In the COMTI\BoundedRecorsdsets\COBOL-CICS folder, there is a COMTI type library (TLB file) that can be used with this sample. The type library is set up for accessing a transaction named GETI on the host. There is also sample COBOL code that can be compiled and linked on the mainframe side. The compiled code should be set up to run on the host as a transaction named GETI or the COMTI type library must be changed to reflect the name of the transaction if it is different.

Programming Specifics Sample

The COM Transaction Integrator (COMTI) for CICS and IMS supports a number of powerful features that are illustrated by this sample. In the COMTI\ProgrammingSpecifics folder, there is a complete Microsoft Visual Basic project that demonstrates the following features of COMTI:

- Returning a Recordset
- Variable Length Tables
- Handling REDEFINES Clauses
- Variably Sized Strings
- Handling FILLER
- Unbounded Recordsets
- In/Out Variable Length Table

The Visual Basic project contains comments with the Visual Basic source code that indicates which COBOL (*.cbl) file contains the associated COBOL code for the mainframe side. The sample type library is included for CICS using LU 6.2. There are seven methods defined in the type library. Check on the properties for each method and look at the Host Names tab to see what the Mainframe TP name is. The value of the mainframe TP name property can be changed to the name used when compiling the sample COBOL programs.

Programming Specifics CICSNonlink Sample

In the COMTI\ProgrammingSpecifics\CICSNonlink folder there is sample COBOL code showing how to receive more than 32K bytes of data in a single method call. This sample includes only the mainframe code (COBOL), and does not include the corresponding Visual Basic or Visual C++ code for the PC side. It is intended to demonstrate the receiving side logic of a COMTI Non-link server application. This COBOL program contains comments explaining what is being done in the code.

Programming Specifics TCP Sample

In the COMTI\ProgrammingSpecifics\TCP folder, there are sample COBOL Child Server programs that can be used for TCP/IP connections. The Cicscs.cbl code is a sample program for TCP using CICS with Concurrent Server (analogous to CICS using LU 6.2). The Mscmtics.clb code is a sample program for CICS calling a Link-to program (using CICS DPL). The Imsexpl.cbl code is a sample program for using IMS in the Explicit mode. The Imsimpl.cbl code is a sample program for using IMS in the Implicit mode. There are similar sample programs included with the CedarBank tutorial which directly reflect the CedarBank data being passed.

Sync Level 2 Sample

The COM Transaction Integrator (COMTI) for CICS and IMS supports the use of Sync Level 2 transactions. This sample includes COBOL source code illustrating transactional support (Sync Level 2) on the mainframe with CICS using LU 6.2. This sample only includes COBOL source code which contains comments describing each of the code sections. The sample code demonstrates executing a Commit and identifying that a Rollback has been requested from COMTI. Please note that there is also related documentation in Knowledge Base article Q220967 available at http://go.microsoft.com/fwlink/?LinkId=14803. This article explains COMTI Metadata elements so that developers can better understand how to use Metadata to allow the COBOL program to initiate a Rollback of a transaction.

Data Integration

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information required to develop applications to access data in an environment using Microsoft Host Integration Server 2000. This section provides documentation for developers on data access, data replication, and data tools.

This section contains:

Introduction to Data Integration

This section of the *Microsoft Host Integration Server 2000 Developer's Guide* provides information required to develop applications to access data in an environment using Microsoft® Host Integration Server 2000. This section provides documentation for developers on data access, data replication, and data tools.

Applications for data integration used in a Host Integration Server 2000 environment can be developed using several different development tools and application programming interfaces including:

- C or C++ applications that use OLE DB to access AS/400 and VSAM files.
- C or C++ applications that use OLE DB to access IBM Data Base 2 (DB2).
- C, C++, or Microsoft Visual Basic® applications that use Open Database Connectivity (ODBC) drivers to access IBM DB2.
- Microsoft Visual Basic applications that use ActiveX® Data Objects (ADO) to access AS/400 and VSAM files.
- Microsoft Visual Basic applications that use ActiveX Data Objects (ADO) to access IBM DB2 using OLE DB.
- Microsoft Visual Basic applications that use ActiveX Data Objects (ADO) to access IBM DB2 using ODBC.
- C, C++, or Microsoft Visual Basic applications that use the Host File Transfer ActiveX control to transfer files to and from MVS, OS/390, AS/400, and AS/36.
- C, C++, or Microsoft Visual Basic applications that use the Data Queue ActiveX control to access AS/400 data queues.

To use this guide effectively, you should be familiar with:

- Microsoft Host Integration Server 2000
- One of the following operating environments:
    - Microsoft Windows® 2000
    - Microsoft Windows NT®
    - Microsoft Windows 98
    - Microsoft Windows 95
- SNA concepts

Depending on the application programming interface and development tools used, you should be familiar with:

- Microsoft COM objects
- Microsoft OLE DB
- Microsoft ADO
- Microsoft ODBC

This section contains:

Additional Resources

This guide does not describe the products, architectures, or standards developed by other companies or organizations. For information about Microsoft Windows NT and other operating systems, consult your product documentation.

For information about SNA architecture, refer to your system network documentation.

The following documents provide additional information about the OLE DB application programming interfaces (APIs):

- Microsoft Data Access Components (MDAC) Software Development Kit 2.5

The following documents provide additional information about ActiveX Data Objects:

- Microsoft Data Access Components (MDAC) Software Development Kit 2.5

The following documents and publications provide additional information about the Open Database Connectivity (ODBC) standard and ODBC programming:

- *Microsoft Data Access Components (MDAC) Software Development Kit 2.5*
- *Microsoft ODBC 3.0 Software Development Kit and Programmer's Reference*
- *Inside ODBC*, written by Kyle Geiger and published by Microsoft Press

For more information about SNA and the Distributed Data Manager (DDM), see the following manuals:

- *IBM Systems Network Architecture: Introduction to APPC*
- IBM Systems Network Architecture: Transaction Programmer's Reference Manual for LU Type 6.2

OLE DB Providers

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information on using the OLE DB providers for AS/400, VSAM, and DB2.

This section contains:

Using the OLE DB Provider for AS/400 and VSAM

The Microsoft® OLE DB Provider for AS/400 and VSAM enables you to directly access record-level data in mainframe VSAM, Partitioned Data Sets (PDS), and midrange OS/400 files from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provide heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for AS/400 and VSAM combines the universal data access of OLE DB with the record-level input/output (RLIO) protocol of IBM's Distributed Data Management (DDM) architecture.

DDM is a set of rules for distributing or extending the data management from one computer to another, such as from a mainframe to an AS/400 computer, or from one of these host computers to a server computer. By combining the OLE DB and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal data access to all enterprise-wide data sources.

This section contains:

Goals of the OLE DB Provider for AS/400 and VSAM

For the majority of enterprises today, the bulk of mission-critical information resides on IBM mainframe and AS/400 computers. This information is stored in records on the OS/400 and VSAM file systems. This information is created, owned, and often accessible by only host-based applications. In the mainframe world, these applications include CICS and DB2; other commercial applications; and a large number of custom applications written in COBOL, PL/I, and other languages. In the AS/400 world, these applications include primarily DB2 and commercial applications, plus a large number of custom RPG applications. A key point to make is that not all of these data sources are SQL-accessible. Many of the host data stores contain non-SQL-accessible data that is owned by something other than a traditional relational database management system (RDBMS).

These same enterprises rely on vast networks of personal computers to enable their users to achieve business goals. End users invariably rely on network e-mail, Microsoft® Windows® productivity applications such as Microsoft Office, and personal database programs such as Microsoft Access, to accomplish their daily tasks. It is essential for these same users to incorporate data stored on host systems into their regular correspondence, analysis, and reports.

Available methods of accessing host data do not provide the granular, "record-level" access required for cost-effective, secure, and meaningful integration of host and personal computer systems. In many cases, end users employ outright antiquated means of data integration. These methods include copying and pasting data from a terminal emulation screen, retyping information taken off printouts from host application reports, and importing text files containing comma-delimited values that use host EBCDIC-to-computer ASCII file transfer. These methods are not efficient although widely used and are not supported by products from independent software vendors (ISVs).

The challenge faced by IS professionals is how to provide direct record-level access to this valuable data without going through the host application. Much of the renewed interest in improved access to host data sources is a result of the burgeoning growth of local intranets, the use of the Internet, and Web technology as a mechanism for delivering information. Fast and inexpensive methods of record-level access are needed to deliver modern, three-tiered information systems during this era of cost-cutting and IS budget belt-tightening. Additional uses of this direct data access are ad hoc queries and Web-based reporting.

It is common for corporate management to rethink host data storage and the appropriate software used to provide data access. For many organizations, the answer to these issues is in rewriting the arguably outdated and certainly "misdated" host-based business rules with server-based, or even client-based, business logic.

The goal of the OLE DB Provider for AS/400 and VSAM is to provide customers and solution providers with the means to integrate desktop applications with this wealth of data residing on host computers.

The OLE DB Environment

Three main roles are performed by software applications in an OLE DB environment:

- **OLE DB Consumer**—The end-user or server-based program that uses (consumes) the OLE DB interfaces. An example is a Web-based component that makes OLE DB calls to integrate host records with a Web-based report.
- **OLE DB Data Provider**—A driver or other program that exposes OLE DB interfaces for use by consumer applications. Data providers translate OLE DB interfaces to a language or commands understood by the target data source. An example is the Microsoft® OLE DB Provider for AS/400 and VSAM, which translates OLE DB interfaces to DDM commands.
- **OLE DB Service Provider**—An application that both uses (consumes) and exposes OLE DB interfaces. Service providers typically act as proxies for the consumer, retrieving the data through the data provider and offering services to the consumer by manipulating the target data. An example is a query-processing engine.

DDM Record-Level Access

The Microsoft® OLE DB Provider for AS/400 and VSAM provides record-oriented access to host files. There is no need to perform bandwidth-intensive file transfers of entire host files to access data on the host.

The OLE DB interface provided by the OLE DB Provider for AS/400 and VSAM supports the following features:

- Set attributes and a record description of a host file (column information).
- Lock files and records.
- Position to the first record or the last record in a file.
- Navigate to the previous or next record in a file.
- Seek to a record, based on an index.
- Change records in a file.
- Insert new records and delete records in a file.
- Preserve file and record attributes.

The OLE DB Provider for AS/400 and VSAM is a "source" Distributed Data Management (DDM) requester implementation that can initiate DDM commands to be serviced by a remote host-based "target" DDM server. On the Microsoft Windows NT® operating system, the Microsoft DDM requester can run as a Windows NT service. This enables the DDM service to integrate with other host applications using the IBM DDM protocol and DDM servers resident on the host. Microsoft-based host software is not required (see Platforms Supported by the OLE DB Provider for AS/400 and VSAM). IBM offers DDM servers for the most popular host environments.

Providing users with direct record-level access reduces the development time to build and deploy new data integration solutions. Accessing only the target records, as opposed to entire host files, helps ensure data integrity.

Platforms Supported by the OLE DB Provider for AS/400 and VSAM

On the mainframe platform, IBM offers a target DDM server implementation in IBM Distributed File Manager (DFM), a component of IBM Data Facility Storage Management Subsystem (DFSMS). The Microsoft® OLE DB Provider for AS/400 and VSAM requires DFSMS version 1 release 2 or later for MVS/ESA and OS/390 to support an SNA LU6.2 connection.

On midrange AS/400 computers, IBM has implemented target DDM servers directly in OS/400. The Microsoft OLE DB Provider for AS/400 and VSAM requires OS/400 Version 3 Release 2 or later to support an SNA LU6.2 connection. The Microsoft OLE DB Provider for AS/400 and VSAM requires OS/400 Version 4 Release 2 or later to support a TCP/IP connection.

On the AS/400 platform, the OLE DB Provider for AS/400 and VSAM supports physical and logical files with an associated external record description file. For specific limitations, please see the *AS/400 DDM User's Guide*.

On the mainframe platform, the OLE DB Provider for AS/400 and VSAM supports the following data set types:

Sequential Access Method (SAM) data sets

- Basic Sequential Access Method data sets (BSAM)
- Queued Sequential Access Method data sets (QSAM)

Virtual Storage Access Method (VSAM) data sets

- Entry-Sequenced Data Sets (ESDS)
- Key-Sequenced Data Sets (KSDS)
- Fixed-Length Relative Record Data Sets (RRDS)
- Variable-Length Relative Record Data Sets (VRRDS)
- Relative Record Data Set (RRDS)
- VSAM Alternate Indexes for ESDS and KSDS data sets

Basic Partitioned Access Method (PDS) data sets

- Partitioned Data Set Extended members (PDSE)
- Partitioned Data Set members (PDS)
- Read-only support for PDSE directories
- Read-only support for PDS directories

The preceding data set types are supported by IBM DFM/MVS.

The following data set types are not supported by DFM/MVS and cannot be accessed using the OLE DB Provider for AS/400 and VSAM.

- VSAM Linear Data Sets (LDS)
- Generation Data Groups (GDG)
- Generation Data Sets (GDS)
- Basic Direct Access Method data sets (BDAM)
- Indexed Sequential Access Method data sets (ISAM)
- Sequential Data Striping data sets
- OpenEdition MVS Hierarchical File System (HFS) files
- Tape Media

All mainframe data sets accessible through IBM Distributed File Manager must be cataloged in an Intersystem communications function (ICF) catalog and reside on direct access storage devices (DASD).

The OLE DB Provider for AS/400 and VSAM supplied with Host Integration Server 2000 supports the following operating systems:

- Microsoft Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Professional

- Microsoft Windows NT® Server 4.0 with Service Pack 5 or later
- Microsoft Windows NT Server 4.0, Enterprise Edition with Service Pack 5 or later
- Microsoft Windows NT Server 4.0, Terminal Server Edition with Service Pack 5 or later
- Microsoft Windows NT Workstation 4.0 with Service Pack 5 or later
- Microsoft Windows 98, Second Edition

The OLE DB Provider for AS/400 and VSAM supplied with Host Integration Server 2000 Service Pack 1 adds support for the following additional operating systems:

- Microsoft Windows XP Professional
- Microsoft Windows XP Home Edition
- Microsoft Windows Millennium Edition

The OLE DB Provider for AS/400 and VSAM supplied with Host Integration Server 2000 supports only the Intel Windows 2000 and Windows NT platforms. Older versions of the OLE DB Provider for AS/400 and VSAM that shipped with SNA Server 4.0 Service Pack 1 and later supported Windows NT on the Alpha architecture.

The OLE DB Provider for AS/400 and VSAM requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2000
- Microsoft Host Integration Server End-User Client
- Microsoft Host Integration Server Administrator Client

Microsoft Host Integration Server 2000 can be installed on Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, Windows NT 4.0 Server, Windows NT 4.0 Server Enterprise Edition, or Windows NT 4.0 Server Terminal Server Edition.

The Microsoft Host Integration Server Administrator Client can be installed on Windows 2000 Professional or Windows NT 4.0 Workstation. The Microsoft Host Integration Server Administrator Client with Service Pack 1 can also be installed on Windows XP Professional. The Administrator Client cannot be installed on Windows 98 or Windows 95.

The Microsoft Host Integration Server End-User Client can be installed on Windows 2000 Professional, Windows NT 4.0 Workstation, or Windows 98. The Microsoft Host Integration Server End-User Client with Service Pack 1 can also be installed on Windows XP Professional, Windows XP Home Edition, or Windows Millennium Edition.

The OLE DB Provider for AS/400 and VSAM supplied with Microsoft Host Integration Server 2000 supports the following OLE DB and ADO versions:

- OLE DB version 2.5. The Host Integration Server 2000 data access features require the runtime libraries for OLE DB version 2.5. These libraries must be installed prior to installing the OLE DB Provider for AS/400 and VSAM. On Windows 2000, these OLE DB libraries are installed as part of the Windows 2000 operating system. On Windows NT 4.0, Windows 98, and Windows 95, these library files must be installed by running the Microsoft Data Access Components (MDAC) version 2.5 runtime package available as downloadable software from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.
  A version of OLE DB version 2.5 SDK is included in the Microsoft Data Access SDK which is available as a part of the Windows 2000 Platform SDK. These downloadable SDKs are available from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.
- ADO version 2.5. The Microsoft Host Integration Server 2000 data access features require the runtime libraries for ADO version 2.5. These libraries must be installed prior to installing the OLE DB Provider for AS/400 and VSAM. On Windows 2000, these ADO libraries are installed as part of the Windows 2000 operating system. On Windows NT 4.0, Windows 98, and Windows 95, these library files must be installed by running the Microsoft Data Access Components (MDAC) version 2.5 runtime package available as downloadable software from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.
  A version of the ADO 2.5 SDK is included in the Microsoft Data Access SDK which is available as a part of the Windows 2000 Platform SDK. These downloadable SDKs are available from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.

OLE DB version 2.0 or later and ADO version 2.0 or later are required to support indexed record access from an ADO consumer application using the OLE DB Provider for AS/400 and VSAM. Indexed support through OLE DB is supported with OLE DB versions 2.0 and later.

Indexed File Access

The OLE DB Provider for AS/400 and VSAM provides both sequential and indexed file access. Sequential file access is provided for all supported file types on the Platforms Supported by the OLE DB Provider for AS/400 and VSAM.

Indexed file access is provided for the following host file types only:

- Mainframe Virtual Storage Access Method (VSAM) data sets.
    - Key-Sequenced Data Sets (KSDS) only when the keys are unique.
    - Fixed-length Relative Record Data Sets (RRDS) only when the keys are unique.
    - Variable-length Relative Record Data Sets (VRRDS) only when the keys are unique.
- AS/400 files.
    - Logical files.
    - Keyed physical files (externally described to the system).

OLE DB and ADO offer several interfaces that enable indexed file access.

The OLE DB Provider for AS/400 and VSAM supports integrated indexes based on the underlying rowset. OLE DB support for indexed file access using the OLE DB Provider for AS/400 and VSAM is available using the **IRowsetIndex**, **IViewFilter**, and **IViewRowset** interfaces.

For more information on indexes, see Chapter 8, "Indexes" and Chapter 16, "Integrated Indexes" in the *OLE DB Programmer's Reference*. To obtain a list of available indexes in a target AS/400 library, a program can call the OLE DB Session object's **IDBSchemaRowset::GetRowset** function requesting a query type of DBSCHEMA_INDEXES.

ADO support for indexed file access using the OLE DB Provider for AS/400 and VSAM is available using the Find method, Filter property, and Sort property on the ADO **Recordset** object. To obtain a list of available indexes in a target AS/400 library using ADO, a program can call the OpenSchema method on the **Connection** object specifying a *QueryType* of **adSchemaIndexes**.

By default, the OLE DB Provider for AS/400 and VSAM uses a server-based cursor. This means that all indexed file access is based on the cursor located over the host file, and not a local computer copy of the host file. If you want to use the many client-based cursor service providers available with the Microsoft® Data Access Components, then you must configure the provider to use a client-based cursor. For example, a client-based cursor is required when using Remote Data Service (RDS) and the Microsoft Visual Studio® ADO data-bound controls. However, using these controls, an application can access the host files for read-only purposes. If your application needs to access host files with an intent of both reading and writing and you require indexed file access, then your application should use the OLE DB Provider for AS/400 and VSAM's own server-based cursor.

File and Record Attributes

By definition, the record description is not part of the record I/O architecture in Distributed Data Management (DDM). Traditionally, applications must embed the record format as part of the application program. This creates a tremendous burden on the application and is very inconsistent with the existing computer-based data access standards, such as OLE DB and ODBC.

To solve this problem, the Microsoft® OLE DB Provider for AS/400 and VSAM uses an external Host Column Description (HCD) file stored on the computer that allows administrators to describe the host record format. At run time, the OLE DB Provider for AS/400 and VSAM transparently converts the host data to computer data using the local HCD information. Before a user program can view or open a VSAM file using the OLE DB Provider for AS/400 and VSAM, the user program must create a valid record description file or entry for the target VSAM file.

The OLE DB Provider for AS/400 and VSAM includes a Microsoft Management Console (MMC) application designed to enable administrators and developers to easily create these local record description files and the necessary registry settings for data sources. The OLE DB DDM Management application makes it relatively easy to create HCD files without ever knowing the HCD file format. The Host Column Description file format is documented in the Data Integration Reference.

The conversion process occurs in two steps. The host data is converted from host EBCDIC to ASCII data by the DDM DLL. The HCD file is used during this step to convert host data types to C data types, which are defined in ODBC and based on the SQL data types defined in the ANSI/ISO SQL-92 standard. The second phase of this conversion occurs in the SNAOLEDB DLL where these SQL C data types are converted to the defined OLE DB data types.

The use of an HCD file is not necessary to describe the record format for data stored in the AS/400 because the OLE DB Provider for AS/400 and VSAM automatically detects that the target host system is an AS/400 and uses the appropriate DDM commands to retrieve the record description. If the system administrator or the OLE DB application developer wants to use an HCD file instead of retrieving the AS/400 record description, this behavior can be forced by setting the configuration of the **Host Column Description File** property using Data Links. This parameter is described in the next section.

Configuring the OLE DB Provider for AS/400 and VSAM

Microsoft® Data Access Components 2.0 and later includes Data Links, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Links, a core element of the Microsoft Data Access Components (MDAC), provide a uniform method of creating persistent OLE DB data source object definitions stored in the form of universal data link (.udl) files. The OLE DB Provider for AS/400 and VSAM normally uses Data Links and UDL files for loading and configuring data sources.

Applications, such as the RowsetViewer sample from the Microsoft Data Access SDK, can open a UDL file that was previously created and pass the stored initialization string to the OLE DB Provider for AS/400 and VSAM at run time. Data Links provide a flexible method for finding and saving connection information to OLE DB data sources.

In order to use Microsoft OLE DB Provider for AS/400 and VSAM with an OLE DB consumer application, the user must either (1) create a Microsoft data link (UDL) file and call this from the application; or (2) call the OLE DB provider from within the application using a connection string that includes the provider name and other necessary parameters. If an application will be accessing VSAM data sets, then after configuring a data link, a host data description must also be configured using the Data Descriptions tool.

Microsoft Management Console (MMC) and MMC snap-ins are the current method of exposing administrative tasks and options in server-based Microsoft products. An MMC snap-in for the OLE DB Provider for AS/400 and VSAM is installed with the Host Integration Client 2000, which enables you to configure settings for accessing data files on AS/400 systems and mainframes. This OLE DB Management Console snap-in enables you to configure data descriptions used by the OLE DB Provider for AS/400 and VSAM.

The **OLE DB Provider for AS/400 and VSAM** console contains one high-level object:

- **Data Descriptions**—Stored in Host Column Description (HCD) files that contain the information required to convert host data types to computer data types.

The **OLE DB Provider for AS/400 and VSAM** console is designed to run on Microsoft Windows® 2000, Windows NT®, Microsoft Windows 98, and Microsoft Windows 95. On Windows 2000 and Windows NT, the console respects the Windows 2000 and Windows NT security hierarchy, where only privileged users can read and write to some areas of the system registry. To prevent general users from modifying the data sources and HCD files on Windows 2000 and Windows NT, the OLE DB Data Descriptions tool can only be run by users that have administrative privileges on the local computer.

Configuring Data Sources for the OLE DB Provider for AS/400 and VSAM

Data source information must be configured for each AS/400 or mainframe system data source object that is to be accessed using the OLE DB Provider. The default parameters for the OLE DB Provider are used as the default values for data sources and when these parameters are not configured for each data source.

Microsoft Data Links, a core element of the Microsoft Data Access Components, provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of Universal Data Link (UDL) files. Applications, such as the RowsetViewer sample included with the Microsoft Data Access SDK and the MSDN Platform SDK, can open created UDL files and pass the stored initialization string to the OLE DB Provider for AS/400 and VSAM at run time.

Creating New Data Links for the OLE DB Provider for AS/400 and VSAM

UDL files are normally stored in a special folder located at:

C:\Programs Files\Common Files\System\Ole DB\data links

Microsoft Data Access Components 2.5 introduced a set of new OLE DB interfaces and functions to enumerate, create, and modify data link UDL files for configuring data sources. The NewSnaDS.exe utility provided as part of the OLE DB Provider for AS/400 and VSAM enables users to create and modify data links. This tool makes calls to the OLE DB Service Component Manager that provides these functions.

To create a new UDL file, run the NewSnaDS tool. This tool is installed in the System folder below the subdirectory where Microsoft Host Integration Server 2000 was installed. The default location where this tool is installed is the following:

C:\Program FilesHost Integration Server\System\NewSnaDS.exe

A shortcut for this tool is added to the **Programs** menu under the **Host Integration Server\Data Integration** folder with a name of OLE DB Data Sources. This shortcut is created when Host Integration Server 2000 or the Host Integration 2000 Client are first installed and support for data access is selected.

A shortcut entitled the **OLE DB Data Sources Browser** is also added to the **Programs** menu under the **Host Integration Server\Data Integration** folder. This shortcut opens Windows Explorer to the default directory where UDL files are stored:

C:\Programs Files\Common Files\System\Ole DB\data links

Using SNA Server 4.0 and older versions of the Microsoft Data Access Components (MDAC 2.1), it was possible to create a new UDL file by navigating to this folder using Windows Explorer. In the right pane of the Windows Explorer, a right-click would open a shortcut menu and enable you to create a **New Microsoft Data Link**.

In the past, a data link file could also be created using SNA Server 4.0 with a shortcut in the SNA Server 4.0 program folder. And the properties of a data link file could be edited by opening the file from Windows Explorer. The procedures used with SNA Server 4.0 to create a new UDL file have been deprecated and will not work with Microsoft Host Integration Server 2000, Windows 2000, and MDAC 2.5 or later.

Once a UDL file is created using the NewSnaDS tool, the file can be changed to a more appropriate name and copied to other client computers for use with the OLE DB Provider for AS/400 and VSAM.

A new data link file can be created with the NewSnaDS utility using the following procedure:

1. Click **Start**, point to **Programs**, and then point to **Host Integration Server**.
2. Point to **Data Integration**, and then click **OLE DB Data Sources** to run the NewSnaDS tool.

   A UDL file is created, and the **Data Link Properties** dialog box is displayed.
3. Select **Microsoft OLE DB Provider for AS/400 and VSAM** from the list of providers, and then configure the data source information as needed.
4. Click **OK** to save the data link.

By default, data links are created in the following folder:

C:\Program Files\Common Files\System\Ole DB\data links

However, a data link can be created in this location and moved to other client computers or folder, as needed.

Note that on Windows XP, Windows 2000, and Windows NT 4.0 using an NTFS partition, the file access permissions for this default folder are inherited from the System\Ole DB folder. The default file permissions allow full control by all members of the Users and Power Users groups in a Windows domain. Data link files may contain connection properties and configuration information that should be accessible only to specific users. For security reasons it is recommended that data link files be protected with an Access Control List (ACL) that restricts access to only appropriate users.

Windows 95, Windows 98, and Windows Millennium Edition do not include file systems that offer support for ACLs. Windows XP, Windows 2000, and Windows NT 4.0 can also be installed on FAT or FAT32 file systems lacking support for access control. In these cases, there is not protection available to protect any sensitive information stored in UDL files.

Browsing Data Sources for the OLE DB Provider for AS/400 and VSAM

By default, data links are created in the Program Files\Common Files\System\OLE DB\Data Links folder. A shortcut is provided in the Microsoft Host Integration Server 2000 program group.

1. Click the **Start** button, point to **Programs**, and then point to **Host Integration Server**.
2. Point to **Data Integration**, and then click **OLE DB Data Source Browser**.

   Windows Explorer opens to the default location where UDL files are stored. The list of data links saved in the default location appears.

Configuring Data Links for the OLE DB Provider for AS/400 and VSAM

To edit the properties of a Data Link file, right-click the file using Windows Explorer and click **Data Link Properties**. The **Data Link Properties** dialog box appears with several property tabs:

- General
- Security
- Summary
- Provider
- Connection
- Advanced
- All

The **General**, **Security**, and **Summary** tabs provide access to general file information for the UDL file that is available for other files and is not related to the Data Link properties. This information includes file location, file type, file size, file dates, file security permissions for access, and descriptive summary information (description and origin properties and values such title, subject, author, etc.) for the UDL file. The **General** tab has a text box with the name of the Data Link. This filename must end with the .UDL extension if the file is to be recognized as a Data Link file. Note that the **Security** and **Summary** tabs are available on NTFS files systems, not on the older FAT file systems.

The `NewSnaDS` tool can also be used to open and modify an existing UDL file. The **Data Link Properties** dialog box appears with several property tabs:

Provider

Connection

Advanced

All

Provider

The **Provider** tab enables you to select the OLE DB Provider (the provider name string) to be used in this UDL file from a list of possible OLE DB providers. Select the Microsoft OLE DB Provider for AS/400 and VSAM. The parameters and fields displayed by the remaining tabs (**Connection**, **Advanced**, and **All**) are determined by the OLE DB Provider that is selected.

Connection

The **Connection** tab enables you to configure the basic properties required to connect to a data source. For the Microsoft OLE DB Provider for AS/400 and VSAM, the connection properties include the following values.

Property	Description
Data Source	The data source is an optional parameter that can be used to describe the data source. When the NewSnaDS configuration program is loaded from the Host Integration Server 2000 program folder, th e Data Source field is required. This field is used to name the UDL file, which is stored in the Program Files\Comm on Files\System\OLE DB\Data Links folder.
Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RD BNAM. This parameter is not used when connecting to mainframe systems.
Use Windows NT Integrate d security	This radio button enables using the Host Integration Security features providing a single-sign on to access this OL E DB data source. When this radio button is selected, the **User name** and **Password** fields are grayed out and become inaccessible. The user name and password fields are set based on the Windows 2000 logon values. When this radio button is not selected, the **User name** and **Password** fields must normally contain appropriate v alues to access data sources on hosts.
Use a specific user name an d password	This radio button disables using the Host Integration 2000 security features. When this radio button is selected, the user name and password fields are accessible and must normally contain a ppropriate values to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on hosts. These values are case sen sitive. The user must click the radio button that requires a specific user name and password to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case sen sitive. The **Blank password** checkbox is only applicable for a Test Connection. In order to enter a password, the user will need to clear the **Blank password** check box if it is checked. If **Blank password** is checked, then a Test Connectio n with a blank password will not cause the OLE DB Provider to prompt for a password. Optionally, the user can choose to save the password in the UDL file by clicking the **Allow saving password** chec k box. Users and administrators should be warned that this option saves the authentication information (passwor d) in plain text within the UDL file.

It is possible to connect using a specific User name and Password defined on the host system or use the single sign-on feature (often referred to as Windows NT integrated security). If a specific User name and Password is to be used, this information may need to be saved into the UDL file. The User name and Password are saved in clear text in the UDL file. For security reasons in these cases, it is imperative that the UDL file be protected with an Access Control List (ACL) that restricts access to only authorized users. Saving the User name and Password in the data link also forces this UDL file to be updated whenever the Password associated with the User name is changed. So for a variety of reasons, specifying a User name and Password is not the preferred authentication option. Using the Windows NT integrated security option is the preferred method for authentication.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection parameters. The connection can only be tested after all of the required parameters are entered. When you click this button, an APPC session or a TCP/IP session attempts to be established to the host using the OLE DB Provider for AS/400 and VSAM.

Advanced

The **Advanced** tab enables you to set the network protection level and access permissions. You can set the protection level from the list box of allowable values. Access permissions are set by clicking the appropriate check boxes. For the Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the following values:

Property	Description
Impersonation level	The level of impersonation that the server is allowed to use when impersonating the client. This property applies only to network connections other than Remote Procedure Call (RPC) connections. These impersonation levels are similar to those provided by RPC. The values of this property correspond directly to the levels of impersonation that can be specified for authenticated RPC connections, but can be applied to connections other than authenticated RPC. This parameter can be set to one of the following values: **Anonymous**—The client is anonymous to the server. The server process cannot obtain identification information about the client and cannot impersonate the client. **Delegate**—The process can impersonate the client's security context while acting on behalf of the client. The server process can also make outgoing calls to other servers while acting on behalf of the client. **Identity**—The server can obtain the client's identity. The server can impersonate the client for access control list (ACL) checking, but cannot access system objects as the client. **Impersonate**—The server process can impersonate the client's security context while acting on behalf of the client. This information is obtained when the connection is established, not for every call. This parameter defaults to **Impersonate**. The impersonation level parameter can also be set using the **All** tab.
Protection level	The level of protection of data sent between client and server. The values of this property correspond directly to the levels of protection that can be specified for authenticated RPC connections. This parameter can be set to one of the following values: **Call**—Authenticates the source of the data at the beginning of each request from the client to the server. **Connect**—Authenticates only when the client establishes the connection with the server. **None**—Performs no authentication of data sent to the server. **Pkt**—Authenticates that all data received is from the client. **Pkt Integrity**—Authenticates that all data received is from the client and that it has not been changed in transit. **Pkt Privacy**—Authenticates that all data received is from the client, that it has not been changed in transit, and protects the privacy of the data by encrypting it. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to connect-level protection. The protection level parameter can also be set using the **All** tab.
Connection timeout	The amount of time (in seconds) to wait for initialization to complete. This parameter is not currently supported by the OLE DB Provider for AS/400 and VSAM and defaults to 0. This parameter is equivalent to the DBPROP_INIT_TIMEOUT OLE DB property ID.
Access permissions	Once a connection is established, this parameter represents a bit mask of the access permissions that will be applied to the data file. As implemented by the OLE DB Provider for AS/400 and VSAM, access permissions apply to host file locks and do not apply to record locks. The allowable values include the following: Read, ReadWrite, Share Deny None, Share Deny Read, Share Deny Write, Share Exclusive, and Write. The default value for the **Access permissions** parameter for the OLE DB Provider for AS/400 and VSAM is ReadWrite. This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID. These access permissions can also be set using the **All** tab.

All

The **All** tab allows users to configure essentially all of the properties for the data source except for the OLE DB Provider. The properties available in the **All** tab include properties that can be configured using the **Connection** and **Advanced** tabs as well as optional detailed properties used to connect to a data source. Some of the properties in the **All** tab are required.

These properties on the **All** tab may be edited by selecting a property from the list displayed and selecting **Edit Value**. This button will invoke dialog box for the specific property containing a Property Description describing the property and a Property Value box for making changes.

For the Microsoft OLE DB Provider for AS/400 and VSAM, these properties include the following values:

Property	Description
APPC Local LU Alias	The name of the local LU alias configured in the Host Integration Server 2000 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server 2000 computer configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
APPC Remote LU Alias	When LU 6.2 (SNA) is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the Host Integration Server 2000 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_REMOTELU OLE DB property ID.
Cache Authentication	This parameter determines whether the OLE DB Provider caches authentication information such as a password in an internal cache. The value of this property (true or false) is selected from the drop-down list box. This parameter is not currently supported by the OLE DB Provider and defaults to false. This parameter is equivalent to the DBPROP_AUTH_CACHE_AUTHINFO OLE DB property ID.
Connect Timeout	The amount of time (in seconds) to wait for initialization to complete. This parameter is not currently supported by the OLE DB Provider and defaults to 0. This parameter is equivalent to the DBPROP_INIT_TIMEOUT OLE DB property ID.
Data Source	The data source is an optional parameter that can be used to describe the data source. This parameter is equivalent to the DBPROP_INIT_DATASOURCE OLE DB property ID.
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
Encrypt Password	This parameter determines whether special security mechanisms are used to ensure password privacy. The value of this property (true or false) is selected from the drop-down list box. This parameter is not currently supported by the OLE DB Provider and defaults to false. This parameter is equivalent to the DBPROP_AUTH_ENCRYPT_PASSWORD OLE DB property ID.

Extended Properties	This parameter is a string containing provider-specific, extended connection information. Properties passed through this parameter should be delimited by semicolons and will be interpreted by the provider's underlying network client. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property parameters. This parameter is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the data as represented on the host. The CCSID property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the host column CCSID and default ANSI code page. This parameter defaults to U.S./Canada (37). This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Host Column Description File	The fully qualified filename of the DDM Host Column Description (HCD) file. This parameter can be a UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the system directory below where the Host Integration Server or Client software was installed. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
Impersonation Level	The level of impersonation that the server is allowed to use when impersonating the client. This property applies only to network connections other than Remote Procedure Call (RPC) connections; these impersonation levels are similar to those provided by RPC. The values of this property correspond directly to the levels of impersonation that can be specified for authenticated RPC connections, but can be applied to connections other than authenticated RPC. This parameter can be set to one of the following values: Anonymous—The client is anonymous to the server. The server process cannot obtain identification information about the client and cannot impersonate the client. Delegate—The process can impersonate the client's security context while acting on behalf of the client. The server process can also make outgoing calls to other servers while acting on behalf of the client. Identity—The server can obtain the client's identity. The server can impersonate the client for access control list (ACL) checking, but cannot access system objects as the client. Impersonate—The server process can impersonate the client's security context while acting on behalf of the client. This information is obtained when the connection is established, not on every call. The value of this property is selected from the drop-down list box. This parameter defaults to Impersonate. This parameter is equivalent to the DBPROP_INIT_IMPERSONATION_LEVEL OLE DB property ID.
Integrated Security	This parameter is a string containing the name of the authentication service used by the server to identify the user using the identity provided by an authentication domain. For example, for Microsoft® Windows 2000 Integrated Security, this is "SSPI" (for Security Support Provider Interface). If this parameter is a null pointer, the default authentication service should be used. When this property is used, no other DBPROP_AUTH* properties are needed and, if provided, their values are ignored. This parameter is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Locale Identifier	This parameter specifies the locale to be used. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to 437. This parameter is equivalent to the DBPROP_INIT_LCID OLE DB property ID.
Location	The remote database name used for connecting to OS/400 systems. In DB2/400, this property is referred to as RDBNAM. This parameter is not used when connecting to mainframe systems. This parameter is equivalent to the DBPROP_INIT_LOCATION OLE DB property ID.

Mask Password	This parameter indicates whether the password should be sent to the data source or enumerator in a masked form. The value of this property (true or false) is selected from the drop-down list box. This parameter is not supported by the OLE DB Provider and defaults to false. This parameter is equivalent to the DBPROP_AUTH_MASK_PASSWORD OLE DB property ID.
Mode	Once a connection is established, this parameter represents a bit mask of the access permissions that will be applied to the data file. As implemented by the OLE DB Provider for AS/400 and VSAM, access permissions apply to host file locks and do not apply to record locks. The allowable values include the following: Read, ReadWrite, Share Deny None, Share Deny Read, Share Deny Write, Share Exclusive, and Write. This parameter can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_WRITE—Write-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. This parameter is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this parameter is used to locate the target DDM service access port when connecting through TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.
Network Transport Library	This parameter, which represents the dynamic-link library used for transport, designates whether the provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCPIP, or SNA. If TCPIP is selected, then values for Network Address and Network Port are required. TCP/IP connectivity to the mainframe is not supported by the OLE DB Provider for AS/400 and VSAM. If SNA is selected, then values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. The value of this property (SNA or TCPIP) is selected from the drop-down list box. This value defaults to SNA. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case sensitive and is shown as asterisks in this dialog box for security purposes. Optionally, you can choose to save the password in the UDL file by clicking the **Allow saving password** checkbox. Users and administrators should be warned that this option persists the authentication information in plain text within the UDL file. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.

PC Code Page	Indicates the code page used for character code conversion. This property is required when processing binary data as character data. Unless the **Process Binary as Character** value is set, character data is converted based on the default ANSI code page configured in the Windows operating system. If this parameter is set to **Binary** or **65535**, then no character code conversions will take place. This parameter defaults to Latin 1 (1252). This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
Persist Security Info	This parameter indicates whether the data source object is allowed to persist sensitive authentication information such as a password along with other authentication information. Optionally, a user can choose to save the password in the UDL file by clicking the **Allow saving password** checkbox. Users and administrators should be warned that this option persists the authentication information in plain text within the UDL file. The value of this property (true or false) is selected from the drop-down list box. This parameter defaults to false. This parameter is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	This parameter indicates whether to process binary fields (CCSID of 65535) as character data type fields on a per data source basis. The **Host CCSID** and **PC Code Page** values are required input parameters when this parameter is true. The value of this property (true or false) is selected from the drop-down list box. The default for this parameter is false, don't process binary fields as character fields. This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.
Protection Level	The level of protection of data sent between client and server. The values of this property correspond directly to the levels of protection that can be specified for authenticated RPC connections. This parameter can be set to one of the following values: DB_PROT_LEVEL_NONE—Performs no authentication of data sent to the server. DB_PROT_LEVEL_CONNECT—Authenticates only when the client establishes the connection with the server. DB_PROT_LEVEL_CALL—Authenticates the source of the data at the beginning of each request from the client to the server. DB_PROT_LEVEL_PKT—Authenticates that all data received is from the client. DB_PROT_LEVEL_PKT_INTEGRITY—Authenticates all data received is from the client and that it has not been changed in transit. DB_PROT_LEVEL_PKT_PRIVACY—Authenticates all data received is from the client, that it has not been changed in transit, and protects the privacy of the data by encrypting it. The value of this property is selected from the drop-down list box. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM and defaults to the connect level of protection. This parameter is equivalent to the DBPROP_INIT_PROTECTION_LEVEL OLE DB property ID.
Repair Host Keys	This parameter provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This parameter defaults to false. The value of this property (true or false) is selected from the drop-down list box. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
Strict Validation	This parameter indicates whether strict validation should be used and defaults to false. The value of this property (true or false) is selected from the drop-down list box. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.

User ID	A valid user name is normally required to access data sources on hosts. This value is case sensitive. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

Configuring Data Descriptions

The OLE DB Data Descriptions tool is a Microsoft Management Console (MMC) console that is used to describe the host data file format for mainframe access. Use of the **OLE DB for AS/400 and VSAM** console and the Host Column Description files is not required for AS/400 files because by default, the data file format is retrieved automatically from the host.

The data descriptions are stored in a local Host Column Description (HCD) file for each data source.

The following table provides the general parameters or attributes that can be configured describing each column in a data description on the **General** property page:

General parameters	Description
Name	The character string that represents the name of the column. This parameter may be null.
Alias	An optional character string that represents an alias label for the column string name. This parameter may be null.
Comment	An optional character string that represents a comment about the column. This attribute may be null.

The following table provides the data type parameters or attributes that can be configured describing each column in a data description in the **Data Type** property page:

Host parameters	Description
Type	The data type on the host. The allowed data values for host data type are selected from a drop-down list box (see Host Data Types for allowed values).
Length	Length of the field in bytes. Depending on the selected Host Type, this parameter may not be editable.
Precision	Total number of decimal digits in the column containing numeric data on the host. Depending on the selected host type, this parameter may not be editable. The only numeric data types that require this information are the PACKED and ZONED data types. And for these types, this field cannot be null; it must contain a valid numeric value. For all other host types, this parameter is not editable.
Scale	Number of decimal digits to the right of any decimal point for numeric data on the host. Depending on the selected host type, this parameter may not be editable. The only numeric data types that require this information are the PACKED and ZONED host data types. And for these types, this field cannot be null; it must contain a valid numeric value. For all other host types, this parameter is not editable.
CCSID	The character code set identifier (CCSID) used on the host. The allowed data values for host CCSID are selected from a drop-down list box (see allowed values listed below). This parameter defaults to the host CCSID configured for the OLE DB Provider and is typically U.S./Canada (37).

The following table provides the local parameter that can be configured:

Local parameters	Description
Type	Indicates the OLE DB data type on the local computer. The allowed data values for the local data type are selected from a drop-down list box (see Local OLE DB Data Types for allowed values).

The OLE DB provider limits the maximum length character field that can be accessed on an AS/400 computer to 32,745. On mainframes, a limitation of the IBM DFM is that SAM data sets and PDSE members are inaccessible if the fixed record length is greater than 32,760 or variable record lengths are greater than 32,756. DFM also limits all VSAM data sets on a mainframe to have a maximum record length no greater than 32,760. Attempting to access a character field greater than these lengths on an AS/400 or a mainframe machine will fail and can have unpredictable results.

The CCSID setting used by the OLE DB Provider must be set to match the CCSID actually used on the host—otherwise, data loss will occur. Some AS/400 systems default to a CCSID of 937 for enabling double-byte character sets (DBCS).

Host Data Types

The **Host Type** parameter represents the data type used for this column on the host. The allowed values for **Host Type** that can be selected from the drop-down list box include the following:

Host Type	Description
Binary	Fixed-length binary data (no character conversion). The length must be specified for this data type.
Character	Fixed-length character data. The length must be specified for this data type.
Date	The date represented as character data in the format yyyy-mm-dd that fits into 10 bytes.
DBCS	Fixed-length character data that can contain only DBCS data. The length must be specified for this data type.
DCBS – Mixed Either	Fixed-length character data that can contain either DBCS or alphanumeric data. The length must be specified for this data type.
DCBS – Mixed Open	Fixed-length character data that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with shift-control characters. The length must be specified for this data type.
DBCS – Variable	Variable-length character data with a prefix of 2 bytes for length that contains only DBCS data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Either	Variable-length character data with a prefix of 2 bytes for length that can contain either DBCS or alphanumeric data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Open	Variable-length character data with a prefix of 2 bytes for length that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with shift-control characters. The maximum possible length for the column containing this data type must be specified.
Double	Floating-point data that fits in 8 bytes (64 bits).
Long	Integer data that fits in 4 bytes (32 bits).
Packed	Packed decimal numeric data where the precision and scale are exactly as specified.
Short	Integer data that fits in 2 bytes (16 bits).
Single	Floating-point data that fits in 4 bytes (32 bits).
Time	The time represented as character data in the format hh:mm:ss that fits into 8 bytes.
Time Stamp	Time stamp represented as characters in the format yyyy-mm-dd hh:mm:ss.ffffff that fits into 19 bytes.
Variable Binary	Variable-length binary data represented as an unsigned character array with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Variable Character	Variable-length character data with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Zoned	Zoned decimal numeric data where the precision and scale are exactly as specified.

The floating-point data format assumed by the OLE DB Provider for AS/400 and VSAM depends on the host. For AS/400, the host floating-point data format is assumed to be IEEE. On mainframe hosts, floating-point data types are assumed to be in IBM floating-point formats. Because OLE DB supports the IEEE floating-point format, data conversion errors can occur when converting the extreme values of VSAM floating-point data in IBM format to IEEE floating-point data by the OLE DB Provider. These conversion errors occur because the default IBM floating-point formats and the IEEE floating-point format use a different number of bits for the mantissa and exponent when representing a floating-point number.

Local OLE DB Data Types

The **Local Type** represents the OLE DB data type used for this column on the computer. The OLE DB data types are defined in the OLE DB specifications and **#defines** can be found in the Oledb.h file. The allowed values for **Local Type** that can be selected from the drop-down list box include the following:

Host Type	Description
DBTYPE_BYTES	Fixed-length binary data represented as an unsigned char array.
DBTYPE_DBDATE	The OLE DB DBDATE typedef struct as defined in the Oledb.h file.
DBTYPE_DBTIME	The OLE DB DBTIME typedef as defined in the Oledb.h file.
DBTYPE_DBTIMESTAMP	The OLE DB DBTIMESTAMP typedef struct as defined in the Oledb.h file.
DBTYPE_DECIMAL	The OLE DB DECIMAL typedef struct as defined in the Oledb.h file.
DBTYPE_I2	Integer data stored in 2 bytes (16 bits).
DBTYPE_I4	Integer data stored in 4 bytes (32 bits).
DBTYPE_NUMERIC	The OLE DB NUMERIC typedef struct as defined in the Oledb.h file.
DBTYPE_R4	Single precision IEEE floating-point data stored in 4 bytes (32 bits).
DBTYPE_R8	Double precision floating-point data stored in 8 bytes (64 bits).
DBTYPE_STR	Fixed and variable length character data.

Converting Existing Data Sources

The OLE DB Management console that was previously used in SNA 4.0 and SNA 4.0 with Service Pack 1 for configuring OLE DB Provider for AS/400 and VSAM data sources has been removed and replaced by Microsoft Data Links and the Data Description Utility. Microsoft Data Links is a component of Microsoft Data Access Components (MDAC) 2.5. The MDAC 2.5 runtime must be installed prior to installing Host Integration Server 2000 when the OLE DB Provider for AS/400 and VSAM is selected to be installed. On Windows 2000, MDAC 2.5 is installed as part of the Windows 2000 operating system. On Windows NT 4.0 and Windows 98, these files must be installed by running the Microsoft Data Access Components (MDAC) version 2.5 runtime package available as downloadable software from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.

Existing registry-based OLE DB Provider for AS/400 and VSAM data sources that were created in SNA Server 4.0 and SNA 4.0 SP1 can be converted to UDL files using the Reg2udl tool supplied with Host Integration Server. The Reg2Udl tool is not installed as part of Host Integration Server, but is located on the Host Integration Server 2000 CD-ROM in the \Options\Maintenance folder. Any UDL files that are converted should be moved to the following subdirectory:

C:\Program files\Common files\System\Ole db\data links folder.

When a duplicate UDL file is present in the destination folder, the Reg2udl tool will increment the file name by 1 (Data.udl will become Datat1.udl, for example). This may cause existing applications to fail because the OLE DB Provider for AS/400 and VSAM will be looking for the existing name (Data.udl).

Manual conversion of registry-based data sources to UDL files may be necessary in some cases when Setup for Host Integration Server 2000 is used (Web Setup for Windows 98 or Windows 95 is used, for example). A version of the Reg2udl tool (for Intel) can be found in the \Options\Maintenance folder on the Host Integration Server 2000 CD-ROM.

To convert data sources manually on SNA Server 4.0, use the appropriate Ireg2udl.exe (for Intel) or Areg2udl.exe (for Alpha) tool on the SNA Server 4.0 Service Pack 2 CD-ROM. On the SNA Server 4.0 Service Pack 3 CD-ROM, an Intel version of this tool for use on Windows NT 4.0, Windows, 98, and Windows 95 is located in the \Reg2Udl folder.

This Reg2Udl tool can also be used in a Microsoft Systems Management Server (SMS) package for rapid deployment of many client conversions at once.

Registry Settings Used by the OLE DB Provider for AS/400 and VSAM

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a number of registry settings for configuration and proper operation. These registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA OLE DB** key. These registry settings include the following subkeys:

Subkey Name	Description
Client	Stores the path to the directory where the Host Column Description (HCD) files are stored on the computer by the **OLE DB for AS/400 or VSAM** console.
Locale	Lists the conversions supported by the computer and the hosts.

The registry keys located under the client subkey include the following:

Value Name	Description
Path	Stores the path to the directory where Host Column Description (HCD) files are stored by the **OLE DB for AS/400 or VSAM**. This value defaults to the System directory below where Host Integration Server 2000 or SNA Server 4.0 was installed. On computers using Host Integration Server 2000 this value defaults to C:\Program Files\Host Integration Server\System. On computers using SNA Server 4.0, this value defaults to C:\SNA95\System on Microsoft Windows® 95 and Windows 98 and C:\SNA\System on Microsoft Windows NT®.

Registry subkeys located under the locale subkey indicate the character code conversions supported by the computer and the hosts and include the following:

Subkey	Descriptions
Host	Listed under this subkey are the possible CCSIDs for hosts when using custom code page conversion.
HostNLS	Listed under this subkey are the CCSIDs supported for hosts using SNA NLS.
PC	Listed under this subkey are the possible code pages when using custom code page conversions.

Programming Considerations Using the OLE DB Provider for AS/400 and VSAM

All the Microsoft® OLE DB objects exposed by the OLE DB Provider for AS/400 and VSAM support aggregation. Each OLE DB object has two classes, one that delegates its **IUnknown** calls and one that controls the object as a whole.

The apartment-threading model is supported, allowing multiple threads to access the objects safely. This is the only threading model supported.

When working with the Data Environment (DE) commands within Microsoft Visual Studio® 6.0, you must use a period (.) as a delimiter when specifying the AS/400 Library/File path. For example, the following is valid syntax when opening the AUTHORS physical file in the PUBS library on an AS/400:

```
EXEC OPEN PUBS.AUTHORS
```

In order to use the ADO Recordset Find method or the ADO Filter property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this method is used on an AS/400 non-keyed physical file or any other mainframe file type, then this method fails.

When using RRDS files, the **Find** method fails when a search is executed using a column name. For example, the following Visual Basic code will fail on an RRDS file with a column called Area:

```
RecordSet.Find "Area > '1111'", 0, adSearchForward, adBookmarkFirst
```

The error description will indicate that a Bookmark is invalid.

RRDS files don't not have an index based on a column name and the value of the column data, so the syntax to the above ADO **Find** method call doesn't make sense for RRDS files. In a COBOL program designed to dynamically find a record in an RRDS file, the record position would be passed. So for the 75th record in the file, a COBOL program would pass a value of 75. The COBOL program would then use the returned record number and the record length to calculate the position of the first byte of the record in the file.

The Data Environment's SQL command parser does not accept the forward slash (/) character. The OLE DB Provider for AS/400 and VSAM automatically substitutes a forward slash in place of the period and passes the correctly formatted path to your AS/400.

When using the Data Environment with Microsoft Visual Basic® 6.0, it is possible to get the following error when accessing the OLE DB Provider for AS/400 and VSAM:

```
"File is in use by another process. Unspecified error"
```

This error can occur once a data source has been configured for the OLE DB Provider for AS/400 and VSAM using the Data Links property page and a command is added using the Data Environment where the command added is the following:

```
"EXEC OPEN filename"
```

Using the Data Environment and selecting Run for this command can result in the above error. The Data Environment is opening the file and then trying to opening it a second time based on the command to execute without closing the first copy. Depending upon the share options of the dataset and the DBPROP_INIT_MODE property set for this data source, this error can occur and the user can be locked out of the AS/400 or VSAM file.

The OLE DB Provider for AS/400 and VSAM does not support the following SQL Server features:

- Data Transformation Services (DTS),
- Replication
- Distributed queries as a linked server.

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

The syntax supported by the OLE DB Provider for AS/400 and VSAM for command text is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a rowset (table) using command text is as follows:

```
EXEC OPEN FileName
```

where *FileName* represents one of the following host file naming conventions:

Host file type	**File naming convention**
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILENAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY.FILENAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

The distributed queries feature of SQL Server is sometimes referred to as the Distributed Query Processor (DQP).

Record Access and Data Conversion

The design of the OLE DB APIs is similar to the APIs provided by ODBC and other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default C data types as defined in ODBC, illustrated in the following table:

Host data type	**Default C data type**
Binary	unsigned char binary[]
Character	char string[]
Date (in character format)	date struct
Double	double
Long	int
Packed	unsigned char number[]
Short	short
Single	float
Time (in character format)	time struct
Time Stamp (in character format)	timestamp struct
Variable Binary	unsigned char binary[]
Variable Character	char string[]
Zoned	unsigned char number[]

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the OLE DB Provider for AS/400 and VSAM.

The OLE DB Provider for AS/400 and VSAM has a number of other limitations:

- Positive signed floating-point values cannot be read from ZONED DECIMAL fields.
- No floating point values can be inserted into ZONED DECIMAL fields.
- No values can be inserted into single-precision FLOATING POINT fields.
- Positive signed floating-point values cannot be inserted into PACKED DECIMAL fields.
- The ADO Find method fails to locate the first record when the key is multiple columns and the first column is a VARCHAR or TIME data type.

Record Locking

DDM supports record locks so that a requester can perform intended operations on a record without interference from concurrent users. Record locks are used only when the requester opens a file with an intent to update the file and specifies that the file is to be shared with another user. Two types of record locks are supported. Record locks are handled automatically by the Microsoft OLE DB Provider for AS/400 and VSAM whenever users call **IRowsetChange::SetData** (in immediate mode) or **IRowsetUpdate** (in the delayed mode). The OLE DB Provider for AS/400 and VSAM locks the record, updates the record, and then releases the lock.

Client Cursor Engines Using the OLE DB Provider for AS/400 and VSAM

The Microsoft Data Access Components (MDAC) supports the option of a client cursor engine. This feature is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the **CursorLocation** property on the recordset to **adUseClient**.

The OLE DB Provider for AS/400 and VSAM does not support any updating capabilities when used with a client cursor engine. In other words, if a client cursor engine is enabled using RDS or ADO, the OLE DB Provider cannot be used to update data on the host. The ADO recordset is treated as if it were read-only.

Single Sign-On

An Integrated Security (single sign-on) feature is supported by Microsoft Host Integration Server 2000 to automate the overall logon process. When configured for this feature, Host Integration Server 2000 automatically replaces special keywords in the data stream with the actual host user name and password at appropriate points in the session. This feature must be enabled by the administrator within a Host Integration Server 2000 subdomain and special strings must be entered for the user name (MS$SAME) and password (MS$SAME) that will be replaced.

When using this single sign-on feature with the OLE DB Provider for AS/400 and VSAM, the account in which the SNA DDM Service is running is used as the sign-on account. Thus, if the SNA DDM Service is running in the system account, single sign-on will always fail because the user name and password of the system account will be used rather than the actual user's name and password.

This feature can be exploited under certain circumstances when using the OLE DB Provider in combination with active server pages or other Web access schemes. If you want to use a single user account (UID) and password without revealing it through the Web page, the single sign-on provisions can be used so that the system service account UID and password are used.

Error Codes Returned by the OLE DB Provider for AS/400 and VSAM

The Microsoft OLE DB Provider for AS/400 and VSAM supports the following ranges of error codes:

Error code range	Source	Definition
1–100	Ddmapi.dll	OLE DB error codes (see the OLE DB Provider for AS/400 and VSAM help file).
256–511	Ddm.dll	IBM DDM documentation.
512–higher	Ddmwappc.dll	Errors specific to the OLE DB Provider for AS/400 and VSAM.

When using Host Integration Server 2000, passing an incorrect password at connect time yields "General Error" instead of "Authentication Error" (User does not have authority to access the host resource) on DB2/400 V4R4. An invalid local LU alias at connect time yields "Network Error" instead of "Invalid Local LU Alias" error. No error is reported when connecting using a non-existent default library value.

Using the OLE DB Provider for DB2

The Microsoft® OLE DB Provider for DB2 allows users to access IBM Data Base 2 (DB2) from within an OLE-aware application. The object linking and embedding database (OLE DB) is a standard set of interfaces that provides heterogeneous access to disparate sources of information located anywhere—file systems, e-mail folders, and databases. The OLE DB Provider for DB2 combines the universal data access of OLE DB with the IBM Distributed Relational Database Architecture (DRDA).

Organizations have invested in secure, robust, enterprise-wide data storage and management systems. DRDA is a set of rules for distributing or extending relational data from one computer to another, such as from a PC server to an IBM DB2 database server running on a mainframe or an AS/400 computer. By combining the OLE DB and DRDA architectures, Microsoft allows organizations to preserve their investments in existing data management infrastructure, while extending universal data access to all enterprise-wide data sources.

This section contains:

Goals of the OLE DB Provider for DB2

Relational database management systems (RDBMS) are one of the major sources of mission-critical information in today's enterprise organizations. Relational database technology enables departments and individual users to save their information in centrally-managed database stores that can be easily maintained by the organization's information systems group. Ad-hoc query tools designed for accessing relational database systems have added greater flexibility and ease of access to this information.

These same enterprises rely on vast networks of personal computers to enable their users to achieve business goals. End users invariably rely on network e-mail; Microsoft® Windows® productivity applications, such as Microsoft Office; and personal database programs, such as Microsoft Access, to accomplish their daily tasks. It is essential for these same users to incorporate data stored in relational database systems into their regular correspondence, analysis, and reports.

The challenge faced by IS professionals is how to provide access to this valuable data without the effort involved in developing traditional database applications. Much of the renewed interest in improved access to data sources is a result of the burgeoning growth in the use of Internet and Web technology as mechanisms for delivering information. Fast and inexpensive methods of accessing data stored in RDBMS systems are needed to deliver modern, three-tiered information systems during this era of cost cutting and IS budget belt-tightening. Additional uses of this relational database access include ad hoc queries and Web-based reporting.

IBM DB2 is a popular RDBMS for a significant number of enterprise customers. Customers need a cost-effective and manageable means to integrate DB2 with Microsoft SQL Server™, Microsoft Internet Information Services (IIS), and Microsoft Office applications. The goal of the OLE DB Provider for DB2 is to provide customers and solution providers with the means to integrate desktop applications with this wealth of data residing on DB2 database systems.

Distributed Relational Database Architecture

Database technology has allowed departments and even individual users to save their information locally—as opposed to centrally-managed stores owned by the organization's information systems group. Along with local storage and database query tools comes greater flexibility and ease of access to information. Yet, as more databases became distributed, a need emerged for users to access data stored remotely. IBM devised the Distributed Relational Database Architecture (DRDA) to enable their customers to access remote, distributed database systems across hardware platforms.

DRDA supports most dialects of the Structured Query Language (SQL) for access to relational database management systems (RDBMS). SQL is an international standard that defines a standardized language for accessing database management systems (DBMS). DRDA implementations generally support SQL in two ways: static (embedded) SQL, where the SQL commands are embedded directly in the application program and prepared as an extra step in the process of compiling the application; and dynamic or interactive (callable) SQL, where the user passes SQL commands as function calls at run time. One popular IBM implementation of dynamic SQL is the Call Level Interface (CLI). With dynamic SQL or CLI, SQL preparation is not required.

Clients that comply with DRDA are referred to as Application Requesters (AR) because they request data from the DRDA server. Servers that comply with DRDA are referred to as application servers (AS). Typically, application servers are implemented as the backend driver link to the RDBMS. In some cases, products are implemented as both application requesters and application servers.

DRDA supports access to stored procedures on DB2. SQL applications can invoke stored procedures or user-written programs on DB2 using the SQL CALL statement.

The OLE DB Provider for DB2 is an Application Requester implementation that can initiate DRDA commands to be serviced by a remote *target* DRDA application server represented by IBM DB2. On the Microsoft® Windows NT® operating system, the Microsoft DRDA application requester can run as a Windows NT service. This enables the integration of the DRDA service with other host applications using the IBM DRDA protocols and DRDA servers resident on the host. Microsoft host software is not required (see Platforms Supported by the OLE DB Provider for DB2). IBM offers Data Base 2 servers for most popular environments.

Platforms Supported by the OLE DB Provider for DB2

IBM and other software vendors have implemented DRDA support into database systems, such as IBM DB2, and database tools on a wide range of operating systems. DRDA is an open, published, and widely-supported protocol, which requires no additional license for development. This makes DRDA appealing to independent software vendors (ISVs), solution providers, large corporate development groups, as well as their customers.

The Microsoft® OLE DB Provider for DB2 is implemented as an IBM Distributed Relational Database Architecture (DRDA) application requester, which means it connects to popular DRDA-compliant DB2 systems.

The Microsoft OLE DB Provider for DB2 can access the following DB2 systems through SNA LU6.2 using Microsoft Host Integration Server 2000:

- DB2 for MVS Version 4 Release 1 (V4R1) or later
- DB2 for OS/390 Version 5 Release 1 (V5R1) or later
- DB2 for OS/400 (DB2/400) Version 3 Release 2 (V3R2) or later

The Microsoft OLE DB Provider for DB2 can access the following DB2 systems directly using TCP/IP:

- DB2 for OS/390 Version 5 Release 1 (V5R1) or later
- DB2 for OS/400 (DB2/400) Version 4 Release 2 (V4R2) or later
- DB2 Universal Database for Windows NT Version 5 Release 2 (V5R2) or later
- DB2 Universal Database for AIX Version 5 Release 2 (V5R2) or later

Note that DB2 for OS/400 (DB2/400) Version 4 Release 3 (V4R3) requires that PTF SF99103 be applied. DB2 for OS/400 (DB2/400) Version 4 Release 4 (V4R4) requires that PTF SF99104 be applied.

IBM DB2 with DRDA support is available on a variety of other platforms. The OLE DB Provider for DB2 has not been tested with these other implementations.

IBM DB2 for MVS Support

DB2 for MVS/ESA implements DRDA support in a component called Distributed Database Facility (DDF), which is an integral part of DB2 for MVS/ESA. IBM suggests that DDF provides optimal online transaction processing (OLTP) performance because of the close integration of DDF with the DB2 database engine. DB2 for MVS V4R1 and later includes a version of DDF that implements advanced DRDA features, such as stored procedures and distributed unit of work, including two-phase commit.

IBM DB2 for OS/400 Support

DB2 for OS/400 is built into OS/400 with no additional installation required. DB2 for OS/400 is a DRDA Application Requester supporting stored procedures and full distributed unit of work (two phase commit).

The Microsoft OLE DB Provider for DB2 can access the following DB2/400 systems through SNA LU6.2 using Microsoft Host Integration Server 2000:

- DB2 for OS/400 (DB2/400) Version 3 Release 2 (V3R2) or later

The Microsoft OLE DB Provider for DB2 can access the following DB2/400 systems directly using TCP/IP:

- DB2 for OS/400 (DB2/400) Version 4 Release 2 (V4R2) or later

Note that DB2 for OS/400 (DB2/400) Version 4 Release 3 (V4R3) requires that PTF SF99103 be applied. DB2 for OS/400 (DB2/400) Version 4 Release 4 (V4R4) requires that PTF SF99104 be applied.

IBM DB2 Universal Database Support

IBM DB2 Universal Database (UDB) is available on a variety of platforms. These implementations are also referred to as DB2 Common Server. The OLE DB Provider for DB2 supports accessing DB2 Universal Database V5R2 or later on Windows 2000, Windows NT, and IBM AIX directly using TCP/IP.

DB2 Common Server is also available for OS/2 and other versions of UNIX (HP HP-UX, Sun Solaris, Siemens-Nixdorf, and Bull). All of these DB2 Common Server implementations support DRDA Application Server capabilities, such as stored procedures and distributed unit of work.

Host Integration Server 2000 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the OLE DB Provider for DB2. These ISO code pages can be used when accessing DB2 Universal Database on AIX. For more information, see
Code Page Support Using the OLE DB Provider for DB2.

OLE DB Provider for DB2 Requirements

The OLE DB Provider for DB2 supplied with Host Integration Server 2000 supports the following operating systems:

- Microsoft® Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Professional
- Microsoft Windows NT® Server 4.0 with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Enterprise Edition with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Terminal Server Edition with Service Pack 6a or later
- Microsoft Windows NT Workstation 4.0 with Service Pack 6a or later
- Microsoft Windows 98, Second Edition

The OLE DB Provider for DB2 supplied with Host Integration Server 2000 Service Pack 1 adds support for the following additional operating systems:

- Microsoft Windows XP Professional
- Microsoft Windows XP Home Edition
- Microsoft Windows Millennium Edition

The OLE DB Provider for DB2 supplied with Host Integration Server 2000 supports only the Intel Windows 2000 and Windows NT platforms. Versions of the OLE DB Provider for DB2 that shipped with SNA Server 4.0 Service Pack 1 and later supported Windows NT on the Alpha architecture.

The OLE DB Provider for DB2 requires the following computer-to-host connectivity software when connecting over SNA using LU 6.2:

- Microsoft Host Integration Server 2000
- Microsoft Host Integration Server End User Client
- Microsoft Host Integration Server Administrator Client

Microsoft Host Integration Server 2000 can be installed on Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, Windows NT 4.0 Server, Windows NT 4.0 Server Enterprise Edition, or Windows NT 4.0 Server Terminal Server Edition.

The Microsoft Host Integration Server Administrator Client can be installed on Windows 2000 Professional or Windows NT 4.0 Workstation. The Microsoft Host Integration Server Administrator Client with Service Pack 1 can also be installed on Windows XP Professional. The Administrator Client cannot be installed on Windows 98 or Windows 95.

The Microsoft Host Integration Server End-User Client can be installed on Windows 2000 Professional, Windows NT 4.0 Workstation, or Windows 98. The Microsoft Host Integration Server End-User Client with Service Pack 1 can also be installed on Windows XP Professional, Windows XP Home Edition, or Windows Millennium Edition.

Note that the OLE Provider for DB2 does not require any special host connectivity software when connecting directly to a host system using TCP/IP.

The OLE DB Provider for DB2 supplied with Microsoft Host Integration Server 2000 supports the following OLE DB and ADO versions:

- OLE DB version 2.5. The Host Integration Server 2000 data access features require the runtime libraries for OLE DB version 2.5. These libraries must be installed prior to installing the OLE DB Provider for DB2. On Windows 2000, these OLE DB libraries are installed as part of the Windows 2000 operating system. On Windows NT 4.0, Windows 98, and Windows 95, these library files must be installed by running the Microsoft Data Access Components (MDAC) version 2.5 runtime package available as downloadable software from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.
  A version of OLE DB version 2.5 SDK is included in the Microsoft Data Access SDK which is available as a part of the Windows 2000 Platform SDK. These downloadable SDKs are available from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749, ADO version 2.5. The Microsoft Host Integration Server 2000 data access features require the runtime libraries for ADO version 2.5. These libraries must be installed prior to installing the OLE DB Provider for DB2. On Windows 2000, these ADO libraries are installed as part of the Windows 2000 operating system. On Windows NT 4.0, Windows 98, and Windows 95, these library files must be installed by running the Microsoft Data Access

Components (MDAC) version 2.5 runtime package available as downloadable software from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749. A version of the ADO 2.5 SDK is included in the Microsoft Data Access SDK which is available as a part of the Windows 2000 Platform SDK. These downloadable SDKs are available from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749. The OLE DB Provider for DB2 has been tested with MDAC 2.6 runtime as it is shipped with Microsoft SQL Server 2000.

Configuring the OLE DB Provider for DB2

Microsoft® Data Access Components 2.0 and later includes Data Links, a generic method for managing and loading connections to OLE DB data sources. Microsoft Data Links, a core element of the Microsoft Data Access Components (MDAC), provide a uniform method of creating persistent OLE DB data source object definitions stored in the form of universal data link (UDL) files. The OLE DB Provider for DB2 normally uses Data Links and UDL files for loading and configuring data sources.

Applications, such as the RowsetViewer sample from the Microsoft Data Access SDK, can open created UDL files and pass the stored initialization string to the OLE DB Provider for DB2 at run time. Data Links provide a flexible method for finding and saving connection information to OLE DB data sources.

In order to use Microsoft OLE DB Provider for DB2 with an OLE DB consumer application, the user must either (1) create a Microsoft data link (UDL) file and call this from the application, or (2) call the OLE DB provider from within the application using a connection string that includes the provider name and any other needed parameters.

Configuring Data Sources for the OLE DB Provider for DB2

Data source information must be configured for each DB2 system data source object that is to be accessed using the OLE DB Provider for DB2. The default parameters for the OLE DB Provider for DB2 are used as the default values for data sources and when these parameters are not configured for each data source.

The Microsoft Data Links, a core element of the Microsoft Data Access Components, provides a uniform method for creating file-persistent OLE DB data source object definitions in the form of Universal Data Link (UDL) files. Applications, such as the RowsetViewer sample included with the Microsoft Data Access and the MSDN Platform SDK, can open created UDL files and pass the stored initialization string to the OLE DB Provider for DB2 at run time.

Creating New Data Links for the OLE DB Provider for DB2

UDL files are normally stored in a special folder located at:

C:\Programs Files\Common Files\System\Ole DB\data links

Microsoft Data Access Components 2.5 introduced a set of new OLE DB interfaces and functions to enumerate, create, and modify data link UDL files for configuring data sources. The NewSnaDS.exe utility provided as part of the OLE DB Provider for DB2 enables users to create and modify data links. This tool makes calls to the OLE DB Service Component Manager that provides these functions.

To create a new UDL file, run the NewSnaDS tool. This tool is installed in the **system** folder below the subdirectory where Microsoft Host Integration Server 2000 is installed. The default location where this tool is installed is the following:

C:\Program Files\Host Integration Server\system\NewSnaDS.exe

A shortcut for this tool is added to the **Programs** menu under the **Host Integration Server\Data Integration** folder with a name of **OLE DB Data Sources**. This shortcut is created when the Microsoft Host Integration Server 2000 or the Host Integration Client 2000 are first installed and support for data access is selected.

A shortcut entitled the **OLE DB Data Source Browser** is also added to the **Programs** menu in the **Host Integration Server\Data Integration** folder. This shortcut opens Windows Explorer to the default directory where UDL files are stored:

C:\Programs Files\Common Files\System\Ole DB\data links

Using SNA Server 4.0 and older versions of the Microsoft Data Access Components (MDAC 2.1), it was possible to create a new UDL file by navigating to this folder using Windows Explorer. In the right pane of the Windows Explorer, a right-click would open a shortcut menu and enable you to create a **New Microsoft Data Link**.

In the past, a data link file could also be created using SNA Server 4.0 with a shortcut in the SNA Server 4.0 program folder. And the properties of a data link file could be edited by opening the file from Windows Explorer. The procedures used with SNA Server 4.0 to create a new UDL file have been deprecated and will not work with Microsoft Host Integration Server 2000, Windows 2000, and MDAC 2.5 or later.

Once a UDL file has been created using the NewSnaDS tool, the file can be changed to a more appropriate name and copied to other client computers for use with the OLE DB Provider for DB2.

A new data link file can be created with the NewSnaDS utility using the following procedure:

1. Click the **Start** button, point to **Programs**, and then point to **Host Integration Server**.
2. Point to **Data Integration**, and then click **OLE DB Data Sources** to run the NewSnaDS tool.

   A UDL file is created, and the **Data Link Properties** dialog box is displayed.
3. Select **Microsoft OLE DB Provider for DB2** from the list of providers, and then configure the data source information as needed.
4. Click **OK** to save the data link.

By default, data links are created in the following folder:

C:\Program Files\Common Files\System\Ole DB\data links

However, a data link can be created in this location and moved to other client computers or folder, as needed.

Note that on Windows XP, Windows 2000, and Windows NT 4.0 using an NTFS partition, the file access permissions for this default folder are inherited from the System\Ole DB folder. The default file permissions allow full control by all members of the Users and Power Users groups in a Windows domain. Data link files may contain connection properties and configuration information that should be accessible only to specific users. For security reasons it is recommended that data link files be protected with an Access Control List (ACL) that restricts access to only appropriate users.

Windows 95, Windows 98, and Windows Millennium Edition do not include file systems that offer support for ACLs. Windows XP, Windows 2000, and Windows NT 4.0 can also be installed on FAT or FAT32 file systems lacking support for access control. In these cases, there is not protection available to protect any sensitive information stored in UDL files.

Browsing Data Sources for the OLE DB Provider for DB2

By default, data links are created in following folder:

C:\Program Files\Common Files\System\Ole DB\data links

A shortcut is provided in the Microsoft Host Integration Server 2000 program group.

1. Click the **Start** button, point to **Programs**, and then point to **Host Integration Server**.
2. Point to the Data Integration, and then click OLE DB Data Source Browser.

   Windows Explorer opens in the default location where UDL files are stored. The list of data links saved in the default location appears.

Configuring Data Links for the OLE DB Provider for DB2

To edit the properties of a Data Link file, right-click the file using Windows Explorer and click **Properties**. The **Properties** dialog box appears with several property tabs:

- **General**
- **Security**
- **Summary**
- Provider
- Connection
- Advanced
- All

The **General**, **Security**, and **Summary** tabs provide access to general file information for the UDL file that is available for other files and is not related to the Data Link properties. This information includes file location, file type, file size, file dates, file security permissions for access, and descriptive summary information (description and origin properties and values such title, subject, author, etc.) for the UDL file. The **General** tab has a text box with the name of the Data Link. This filename must end with the .UDL extension if the file is to be recognized as a Data Link file. Note that the **Security** and **Summary** tabs are available on NTFS files systems, not on the older FAT file systems.

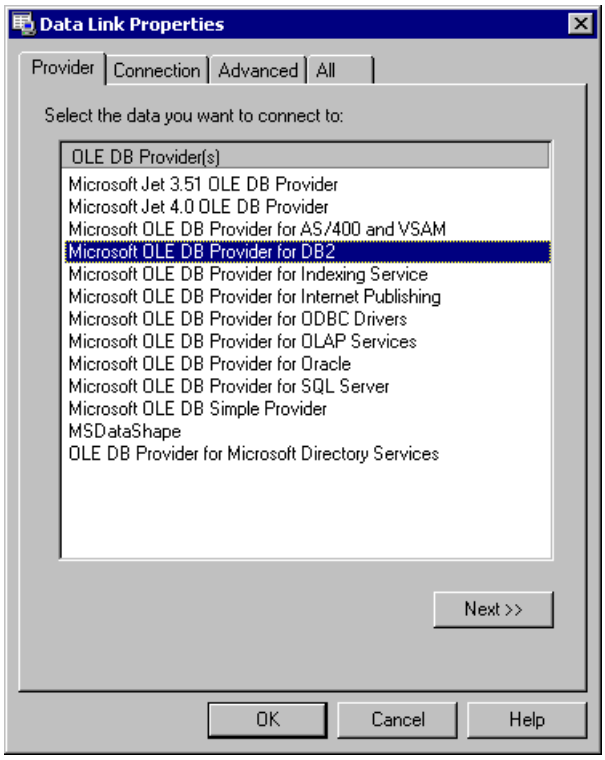
The **Provider**, **Connection**, **Advanced**, and **All** tabs provide access to the Data Link properties that need to be configured to connect to the DB2 system.

The `NewSnaDS` tool can also be used to open and modify an existing UDL file. In this tool, the **Data Link Properties** dialog box appears with the following property tabs:

- Provider
- Connection
- Advanced
- All

Provider

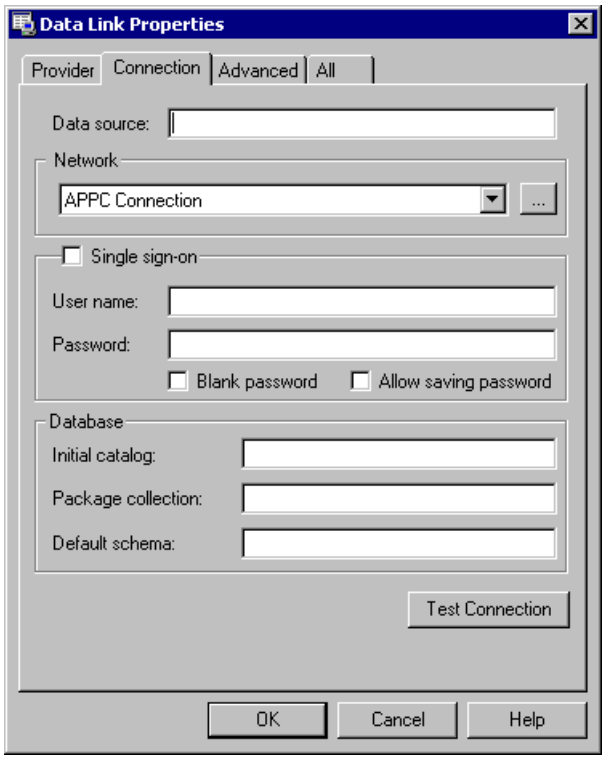
The **Provider** tab enables you to select the OLE DB provider (the provider name string) to use in the UDL file from a list of possible OLE DB providers. Select the Microsoft OLE DB Provider for DB2. The parameters and fields displayed in the remaining tabs (**Connection**, **Advanced**, and **All**) are determined by the OLE DB Provider that is selected.



Connection

The **Connection** tab enables you to configure the basic properties required to connect to a data source. The **Connection** tab dialog contains several sections:

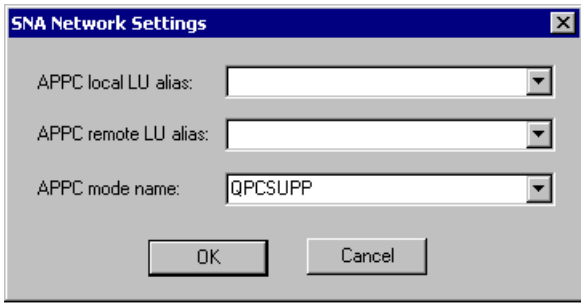
- Data source and Network connectivity
- Authentication
- Database Properties

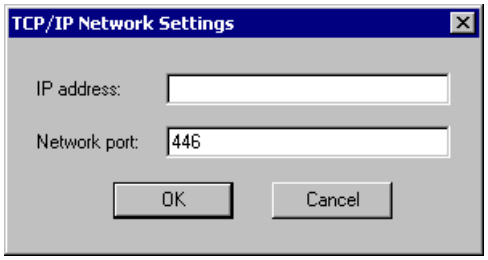


For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for Data source and Network connectivity values:

Property	Description
Data source	The data source is an optional property that can be used to describe the data source. When the NewSnaDS configuration program is loaded from the Host Integration Server 2000 program folder, the Data source field is required. This field is used to name the UDL file, which is stored in the following default folder: C:\Program Files\Common Files\System\Ole DB\data links.
Network	This drop-down list box allows selecting the type of network connection to be used. The allowable options are **TCP/IP Connection** or **APPC Connection**. If **TCP/IP Connection** is selected, click the **More Options** (...) button, to open a dialog box for configuring TCP/IP network settings. The properties you can configure include the IP address of the DB2 host (or a hostname alias for this computer) and the Network Port (TCP/IP port) used for communication with the host. The default value for the Network Port is 446. The IP address of the host has no default value. If **APPC Connection** is selected (using SNA LU 6.2), click the **More Options** (...) button to open a dialog box for configuring APPC network settings. The properties you can configure include: the APPC local LU alias, the APPC remote LU alias, and the APPC mode name used for communication with the host. The default value for the APPC mode normally defaults to QPCSUPP. The local and remote LU alias fields do not have default values. The default value for the APPC mode name normally defaults to QPCSUPP. The APPC mode name can be selected from the drop-down list box.

The **Data source** in OLE DB is similar to a Data Source Name (DSN) in ODBC. The data source information is stored in a Microsoft Data Links file and contains the connection information required for the OLE DB Provider for DB2 to access IBM Data Base 2.





For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for authentication information:

Property	Description
Single sign-on	Click this checkbox to enable using the Host Integration Security features providing a single-sign on to access this OLE DB data source. Note that single sign-on is only supported using the APPC Connection option (SNA LU 6.2). When this checkbox is selected, the User name and Password fields are grayed out and become inaccessible. The user name and password fields are set based on the login name used for the Windows 2000 or Windows NT 4.0 domain login. When this checkbox is not selected, the User name and Password fields must normally contain appropriate values in order to access data sources on hosts.
User name	A valid user name and password are normally required to access data sources on a host. These values are case-sensitive. Users must not check the Single sign-on option button if a specific user name and password are to be entered.
Password	A valid user name and password are normally required to access data sources on hosts. These values are case-sensitive. The **Blank password** checkbox is only applicable for a Test Connection. In order to enter a password, the user will need to clear the **Blank password** check box if it is checked. If **Blank password** is checked, then a Test Connection with a blank password will not cause the OLE DB Provider to prompt for a password. Optionally, users can choose to save the password in the UDL file by clicking the **Allow saving password** check box. Users and administrators should be warned that this option saves the authentication information (password) in plain text within the UDL file.

The AS/400 requires that the **User name** and **Password** properties be in uppercase. When connecting to DB2/400, these parameters must be passed as uppercase strings. When connecting to DB2 on IBM mainframes, the **User name** and **Password** parameters can be in mixed case.

It is possible to connect using a specific User name and Password defined in DB2 on the host system or use the Single sign-on feature (often referred to as integrated Windows security). If a specific DB2 user name and Password is to be used, this information may need to be saved into the UDL file. The User name and Password are saved in clear text in the UDL file. For security reasons in these cases, it is imperative that the UDL file be protected with an Access Control List (ACL) that restricts access to only authorized users. Saving the User name and Password in the data link also forces this UDL file to be updated whenever the Password associated with the User name is changed. So for a variety of reasons, specifying a User name and Password is not the preferred authentication option. Using the Single sign-on option is the preferred method for authentication.

For the Microsoft OLE DB Provider for DB2, the **Connection** tab includes the following properties for database property values:

Property	Description

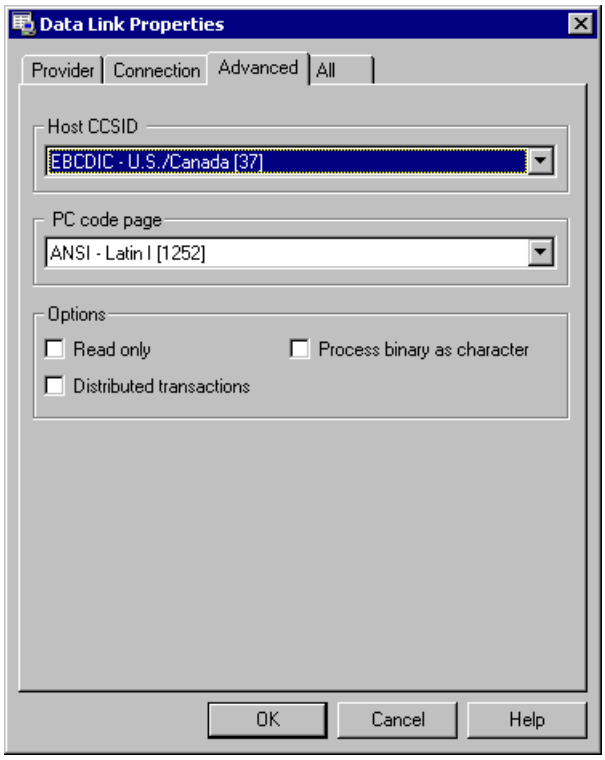
Initial catalog	This field is the first entry in the Database section of the Connection properties. This OLE DB property is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required property. This property is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.
Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be upper case, lower case, or mixed case. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection property. By default, the OLE DB Provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level specified when calling the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as when setting the ADO **IsolationLevel** property on the Connection object. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), then the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users (see Creating Packages for Use with the OLE DB Provider for DB2). The OLE DB Provider for DB2 ships with a tool program for use by administrators to create packages. The crtpkg.exe tool is a Windows GUI application for use by the administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This utility will create a set of packages and grant EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system . The packages (see descriptions under the isoLevel parameter of the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as the ADO IsolationLevel property) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000. The package names changed from SNA Server 4.0. This property is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.

Default schema	The name of the Collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the OLE DB Provider uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined. This property is equivalent to the DBPROP_DB2OLEDB_CATALOGCOL OLE DB property ID.

The **Connection** tab also includes a **Test Connection** button that can be used to test the connection properties. The connection can only be tested after all of the required parameters are entered. When this button is pressed, an APPC session or a TCP/IP session will attempt to be established with the host using the OLE DB Provider for DB2.

Advanced

The **Advanced** tab allows users to select the character code set identifier used by the host, the PC code page used on the client, and select some specific options when using the OLE DB Provider for DB2.



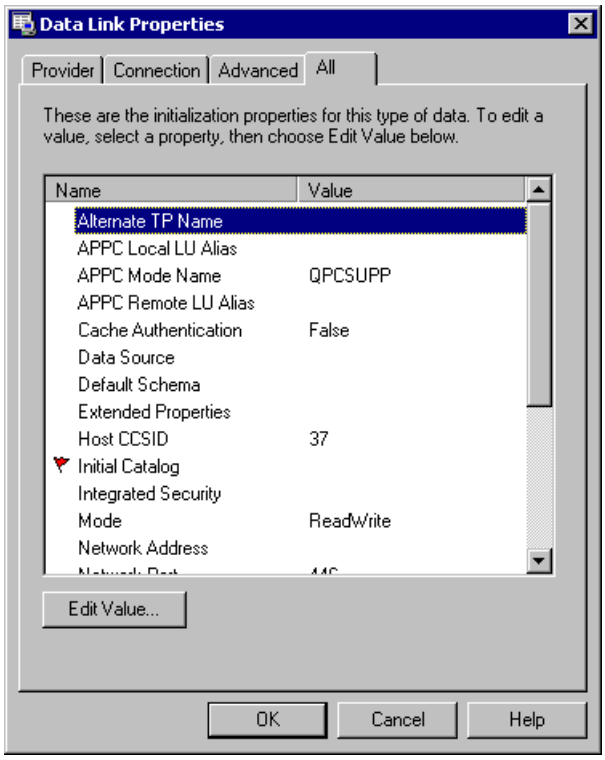
For the Microsoft OLE DB Provider for DB2, these properties include the following values:

Property	Description
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. Note that Host CCSID 37 is not supported by the OLE DB Provider for DB2 when connecting to DB2 UDB for Windows NT or DB2 UDB for AIX. This property defaults to U.S./Canada (37). This property is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.
PC code page	The PC code page property indicates the code page to be used on the PC for character code conversion. This property is required when processing binary data as character data. Unless the Process binary as character checkbox is selected (value is set to true), character data is converted based on the default ANSI code page configured in Windows. This property defaults to Latin 1 (1252). This property is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.
Read only	When this option is checked, the OLE DB Provider for DB2 creates a read-only data source by setting the Mode property to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This property defaults to a Mode property of Read/Write (DB_MODE_READ/WRITE). This property is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Process binary as character	When this option is checked (property is set to true), the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This property defaults to false. This property is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.

Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. Th is option works only with DB2 for OS/390 V5R1 or later. This option also requires that an **APPC Connection** (the SNA LU 6.2 service) is selected as the network transport in the **Connection** tab and Microsoft Transaction Server (MTS) is installe d. This property is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.

All

The **All** tab allows users to configure essentially all of the properties for the data source except for the OLE DB Provider. The properties available in the **All** tab include properties that can be configured using the **Connection** and **Advanced** tabs as well as optional detailed properties used to connect to a data source.



For the Microsoft OLE DB Provider for DB2, these properties include the following values:

Property	Description
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, the Alternative TP Name is set to 0X07F9F9F9. This property is equivalent to the DBPROP_DB2OLEDB_TPNAME OLE DB property ID.
APPC Local LU Alias	When an APPC Connection using SNA LU 6.2 is selected for the Network Transport Library, this field is the name of the local LU alias configured in the SNA server. This property is equivalent to the DBPROP_DB2OLEDB_LOCALLU OLE DB property ID.
APPC Mode Name	When an APPC Connection using SNA LU 6.2 is selected for the Network Transport Library, this field is the APPC mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property normally defaults to QPCSUPP. This property is equivalent to the DBPROP_DB2OLEDB_APPCMODE OLE DB property ID.

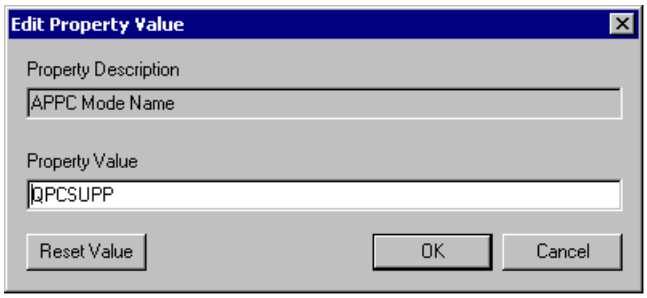
APPC Remote LU Alias	When an APPC Connection using SNA LU 6.2 is selected for the Network Transport Library, this field is the name of the remote LU alias configured in the SNA server. This property is equivalent to the DBPROP_DB2OLEDB_REMOTELU OLE DB property ID.
Cache Authentication	This property determines whether the OLE DB Provider caches authentication information. This property defaults to false. The value of this property (true or false) is selected from the drop-down list box. This property is equivalent to the DBPROP_AUTH_CACHE_AUTHINFO OLE DB property ID.
Data Source	The data source is an optional property that can be used to describe the data source. This property does not have a default value.
Default Schema	The name of the Collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the OLE DB Provider uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined. This property is equivalent to the DBPROP_DB2OLEDB_CATALOGCOL OLE DB property ID.
Extended Properties	This property is a string containing provider-specific, extended connection information. The use of this property implies that the OLE DB consumer knows how this string will be interpreted and used by the OLE DB provider. This parameter should be used only for provider-specific connection information that cannot be explicitly described through the other property values. This property is equivalent to the DBPROP_INIT_PROVIDERSTRING OLE DB property ID.
Host CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote host computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the DB2 column CCSID and default ANSI code page. Note that Host CCSID 37 is not supported by the OLE DB Provider for DB2 when connecting to DB2 UDB for Windows NT or DB2 UDB for AIX. This property defaults to U.S./Canada (37). This property is equivalent to the DBPROP_DB2OLEDB_HOSTCCSID OLE DB property ID.

Initial Catalog	This OLE DB property is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. If the provider supports changing the catalog for an initialized data source, the consumer can specify a different catalog name through the DBPROP_CURRENTCATALOG property in the DBPROPSET_DATASOURCE property set after initialization. This is a required property. This property is equivalent to the DBPROP_INIT_CATALOG OLE DB property ID.
Integrated Security	This property determines whether the OLE DB Provider uses Host Security Integration (single sign-on). When this property is set to SSPI, single sign-on is enabled and separate user id and password parameters are not required. The user name and password fields are set based on the login name used for the Windows 2000 or Windows NT 4.0 domain login. When this property is null, this single sign-on feature is disabled. This property defaults to null (host security integration is disabled) and a user id and password are required. This property is equivalent to the DBPROP_AUTH_INTEGRATED OLE DB property ID.
Mode	A Mode property is a bit mask specifying access permissions. This bit mask can be a combination of zero or more of the following: DB_MODE_READ—Read-only. DB_MODE_READWRITE—Read/write (DB_MODE_READ | DB_MODE_WRITE). DB_MODE_SHARE_DENY_NONE—Neither read nor write access can be denied to others. DB_MODE_SHARE_DENY_READ—Prevents others from opening in read mode. DB_MODE_SHARE_DENY_WRITE—Prevents others from opening in write mode. DB_MODE_SHARE_EXCLUSIVE—Prevents others from opening in read/write mode (DB_MODE_SHARE_DENY_READ | DB_MODE_SHARE_DENY_WRITE). DB_MODE_WRITE—Write-only. The following values for mode are supported by the OLE DB Provider for DB2: Read (DB_MODE_READ) and Read/Write (DB_MODE_READ/WRITE). This property defaults to Read/Write. When the Read Only property is checked in the Advanced tab, the OLE DB Provider for DB2 creates a read-only data source by setting the Mode property to Read (DB_MODE_READ). A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This property is equivalent to the DBPROP_INIT_MODE OLE DB property ID.
Network Address	When TCP/IP has been selected for the Network Transport Library, this property indicates the IP address of the DB2 host or a hostname alias for this computer. This property is equivalent to the DBPROP_DB2OLEDB_NETADDRESS OLE DB property ID.
Network Port	When TCP/IP has been selected for the Network Transport Library, this property is the TCP/IP port used for communication with the DB2 host. The default value is TCP/IP port 446. This property is equivalent to the DBPROP_DB2OLEDB_NETPORT OLE DB property ID.

Network Transport Library	The network transport dynamic link library property designates whether the OLE DB Provider for DB2 connects via an APPC Connection using SNA LU6.2 or a TCP/IP Connection. The possible values for this property are TCPIP, or SNA. The default value for this property is SNA. If the default SNA is selected, then values for APPC Local LU Alias, APPC Mode Name, and APPC Remote LU Alias are required. If TCPIP is selected, then values for Network Address and Network Port are required. This property is equivalent to the DBPROP_DB2OLEDB_NETTYPE OLE DB property ID.
Package Collection	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. Package names are not restricted and can be upper case, lower case, or mixed case. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection property. By default, the OLE DB Provider will automatically create one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the User ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level specified when calling the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as when setting the ADO **IsolationLevel** property on the Connection object. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), then the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users (see Creating Packages for Use with the OLE DB Provider for DB2). The OLE DB Provider for DB2 ships with a tool program for use by administrators to create packages. The crtpkg.exe tool is a Windows GUI application for use by the administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This utility will create a set of packages and grant EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system . The packages (see descriptions under the isoLevel parameter of the OLE DB **ITransactionLocal::StartTransaction** or **ITransactionJoin::JoinTransaction** methods, as well as the ADO IsolationLevel property) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000. The package names changed from SNA Server 4.0. This property is equivalent to the DBPROP_DB2OLEDB_PACKAGECOL OLE DB property ID.
Password	A valid user name and password are normally required to access data sources on hosts. The password is case-sensitive and is displayed as asterisks in this dialog box for security purposes. This property is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
PC Code Page	The PC Code Page property indicates the code page to be used on the PC for character code conversion. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set to true, character data is converted based on the default ANSI code page configured in Windows. This property defaults to Latin 1 (1252). This property is equivalent to the DBPROP_DB2OLEDB_PCCODEPAGE OLE DB property ID.

Persist Security Info	This property indicates whether the data source object is allowed to persist sensitive authentication information, such as a password along with other authentication information. This property defaults to false. The value of this property (true or false) is selected from the drop-down list box. This property is equivalent to the DBPROP_AUTH_PERSIST_SENSITIVE_AUTHINFO OLE DB property ID.
Process Binary as Character	When this property is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This property defaults to false. The value of this property (true or false) is selected from the drop-down list box. This property is equivalent to the DBPROP_DB2OLEDB_BINASCHAR OLE DB property ID.
Units of Work	This property indicates whether two-phase commit (distributed unit of work) used for transactions is supported for this data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. The following values for this property are supported by the OLE DB Provider for DB2: RUW (remote unit of work) DUW (distributed unit of work) This property defaults to RUW. Distributed unit of work (two-phase commit) works only with DB2 for OS/390 V5R1 or later. This option also requires that an APPC Connection using SNA LU 6.2 is selected as the network transport and Microsoft Transaction Server (MTS) is installed. This property is equivalent to the DBPROP_DB2OLEDB_UNITSOFWORK OLE DB property ID.
User ID	A valid User name is normally required to access data sources on hosts. This value is case-sensitive. This property is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

These properties on the **All** tab may be edited by selecting a property from the list displayed and selecting **Edit Value**. This button will invoke dialog box for the specific property containing a Property Description describing the property and a Property Value box for making changes.



Creating Packages for Use With the OLE DB Provider for DB2

The Microsoft® OLE DB Provider for DB2, which is implemented as an IBM Distributed Relational Database Architecture (DRDA) Application Requester, uses packages to issue SQL statements and call DB2 stored procedures. There is a provider-specific property that the OLE DB Provider for DB2 uses to identify a location in which to create and store DB2 packages. The OLE DB Provider for DB2 will create packages dynamically in the location to which the user points using the Package Collection property corresponding to the DBPROP_DB2OLEDB_PACKAGECOL property ID of OLE DB. This location may be configured using the Connection and Advanced tabs using Microsoft Data Links or can be passed as part of the connection string as an attribute keyword and argument. This attribute keyword can be either pkgcol or the long form of this attribute, Package Collection.

There are two package creation options:

1. The ODBC Provider for DB2 will auto-create one package for the currently-used isolation level at run-time if no package already exists. This auto-create process may fail if the user account does not have authority to create packages.
2. An administrator or user can manually creates all four packages (five packages on DB2/400) for use with all isolation levels and for use by all users (the PUBLIC group on DB2 representing all users) or a specific set of users. The OLE DB Provider for DB2 includes a utility program for use by users with appropriate administrative privilege that will create these packages and grant access to the PUBLIC group for this purpose.

However, some users may not have the security level when manually creating packages to GRANT authority to the packages to other users (grant authority to the DB2 PUBLIC group representing all users, for example). This can be a problem if two or more users with different user IDs try to access a single collection of packages. The first user that created the packages will have access to the packages, but the second user likely will not. The Microsoft® Host Integration Server 2000 CD-ROM includes a program for use by an administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. The Create Packages for DB2 utility, CrtPkg.exe, is a GUI-based tool included with Host Integration Server 2000 for creating packages for use with DB2. This tool is installed in the System folder below the subdirectory where the Microsoft Host Integration Server 2000 has been installed. The default location where this tool is installed is the following:

C:\Program Files\Host Integration Server\system\CrtPkg.exe

A shortcut for this tool is added to the **Programs** menu off the **Start** button on the Windows Taskbar under the **Host Integration Server\Data Integration** folder with a name of **Packages for DB2**. This shortcut is created when the Microsoft Host Integration Server or the Host Integration Client are first installed and support for Data Access is checked.

This tool will create a set of packages and grant EXECUTE privileges on these packages to the PUBLIC group. The PUBLIC group on DB2 systems is a default group that represents all DB2 users. The following packages are created:

- AUTOCOMMITTED package (MSNC001) is only applicable on DB2/400)
- READ UNCOMMITTED package (MSUR001)
- READ COMMITTED package (MSCS001)
- REPEATABLE READ package (MSRS001)
- SERIALIZABLE package (MSRR001)

Note that the AUTOCOMMITTED package (MSNNC001) is only created on DB2 for OS/400.

The descriptive process name used by the CrtPkg utility of each package corresponds with the isolation levels defined in the ANSI SQL standard. The table below indicates how these packages correspond with the terms used by IBM for isolation levels in DB2 documentation.

Package Description	**Package Name**	**IBM Documentation**
AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level	MSNC001	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 auto-commit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.
READ UNCOMMITTED	MSUR001	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.

READ COMMITTED	MSCS001	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
REPEATABLE READ	MSRS001	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.
SERIALIZABLE	MSRR001	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000. The package names used by the OLE DB Provider for DB2 on SNA Server 4.0 are not compatible with the OLE DB Provider for DB2 included with Host Integration Server. On SNA Server 4.0, these packages used different names as follows:

```
AUTOCOMMITTED package (SNANC001) only applicable on DB2/400
READ UNCOMMITTED package (SNACH001)
READ COMMITTED package, (SNACS001)
REPEATABLE READ package, (SNARR001)
SERIALIZABLE package (SNAAL001)
```

These Isolation Levels are described in detail under Support for Isolations Level using the OLE DB Provider for DB2. These Isolation Levels are also described under the OLE DB isoLevel parameter and ADO IsolationLevel property. Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

Note that the CrtPkg tool creates this set of packages and grants EXECUTE privileges to the PUBLIC group. There may be cases for security reasons where EXECUTE privileges to this set of packages on the DB2 system should be restricted to a different group of users or specific users. In these cases, execution privileges on these created packages will need to be modified on the host system.

The CrtPkg utility will create all of these packages inside the Collection that is specified in the Package Collection property in the datalink file, or in the connection string. If the user does not have the appropriate authority to create packages in the specified Collection, or if the specified Collection does not exist, the OLE DB Provider for DB2 will return an error.

In the case of DB2 on MVS or OS/390, the normal error text returned if the user does not the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -567.
```

In the case of DB2/400, the normal error text returned if the user does not the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -805.
```

In the case of DB2/400, the normal error returned if the collection does not exist would be as follows:

```
Failed to create AUTOCOMMITTED (NC) package.  RETCODE=-99.
SQL Error: Code=-204, State=42704, Error Text= A SQL error has occurred.  Please consult the
documentation for your specific DB2 version for a description of the associated Native Error
and SQL State. SQLSTATE: 42704, SQLCODE: -204
```

There are two authorities required to execute the create package process on MVS using the CrtPkg utility:

```
GRANT BINDADD TO <authorization ID>
GRANT CREATE IN COLLECTION <collection ID> TO <authorization ID>
```

The "authorization ID" is the user who needs the permission to create the packages. The "collection ID" is the name of the Collection, which the user specifies in the datalink file for the Package Collection property. This Collection should be a valid Collection within the DB2.
If an administrator executes the above statements on behalf a non-privileged user, then this non-privileged user can then run the CrtPkg utility. Once run, the CrtPkg process will create four sets of packages (one for each of the four isolation levels supported

on DB2 for MVS or OS/390) for use by "all" (PUBLIC) users of the Microsoft data access features.

The example below illustrates this process on DB2 for MVS or DB2 for OS/390.

Grant rights to run the CrtPkg utility to authorization ID WNW999

```
GRANT BINDADD TO WNW999
GRANT CREATE IN COLLECTION MSPKG TO WNW999
```

Run the CrtPkg utility using authorization ID WNW999 (see output from CrtPkg below)

```
Beginning creation process
Initializing environment...
Connecting to the host...
Connection established.
Start package creation process...
Creating READ UNCOMMITTED package...
READ UNCOMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSUR001            granted to PUBLIC
Creating READ COMMITTED package...
READ COMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSCS001            granted to PUBLIC
Creating REPEATABLE READ package...
REPEATABLE READ package created.
Package creation succeeded.
EXECUTE privilege on MSRS001            granted to PUBLIC
Creating SERIALIZABLE package...
SERIALIZABLE package created.
Package creation succeeded.
EXECUTE privilege on MSRR001            granted to PUBLIC
Free statement handles...
Disconnecting...
Disconnected
End of package creation.
Creation process has completed
```

In order to execute the CrtPkg utility on DB2/400, a user ID must have one of the following authorities:

- *CHANGE authority on the DB2 collection
- *ALL authority on the DB2 collection

If the user merely has *USE authority or if the user has *EXCLUDE authority, the Create Package process will fail.

There are several steps required to change user authority on a DB2/400 collection (AS/400 library): From interactive SQL (STRSQL command) while logged in as user with administrative privileges, create a new collection. This command can also be issued using ADO, OLE DB, and ODBC. However, most administrators typically create collections from the AS/400 console since the administrator must be logged in at the console to issue the Command Language (CL) command with which to change the user authority on the collection.

```
CREATE COLLECTION <collection ID>
```

From the AS/400 command console, issue the CL WRKOBJ command with the <collection ID> as a parameter.

```
WRKOBJ <collection ID>
```

The "collection ID" is the name of the Collection, which the user specifies in the datalink file for the Package Collection property. This Collection should be a valid Collection within DB2. The Work with objects screen appears. Place the cursor on the *PUBLIC Object Authority line and change the authority from *USE to *ALL.

If an administrator executes the above statements on behalf a non-privileged user, then this non-privileged user can then run the CrtPkg utility. Once run, the CrtPkg process will create five sets of packages (one for each of the five isolation levels supported on DB2/400) for use by "all" (PUBLIC) users of the Microsoft data access features. On DB2/400, five packages are created including

the AUTOCOMMITTED packages.

The example below illustrates this process on DB2/400.

Grant rights to run the CrtPkg utility to authorization ID WNW999

```
CREATE COLLECTION MSPKG
WRKOBJ MSPKG
```

Run the CrtPkg utility (see the output from CrtPkg for DB2/400 below)

```
Beginning creation process
Initializing environment...
Connecting to the host...
Connection established.
Start package creation process...
Creating AUTOCOMMITTED (NC) package...
AUTOCOMMITTED (NC) package created.
Package creation succeeded.
EXECUTE privilege on MSNC001            granted to PUBLIC
Creating READ UNCOMMITTED package...
READ UNCOMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSUR001            granted to PUBLIC
Creating READ COMMITTED package...
READ COMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSCS001            granted to PUBLIC
Creating REPEATABLE READ package...
REPEATABLE READ package created.
Package creation succeeded.
EXECUTE privilege on MSRS001            granted to PUBLIC
Creating SERIALIZABLE package...
SERIALIZABLE package created.
Package creation succeeded.
EXECUTE privilege on MSRR001            granted to PUBLIC
Free statement handles...
Disconnecting...
Disconnected
End of package creation.
Creation process has completed
```

CrtPkg allows a user to create a new UDL file or load a data source and modify an existing UDL file for connection configuration information. The File menu of CrtPkg has a New option used for creating a new OLE DB UDL File and a Load Data Source option to load an existing UDL file. The File menu Edit Data Source option allows a user to access and modify the properties for a data source similar to using the NewSnaDS.exe tool. The Run menu option is used to create packages.

When using the create package tool, if the package collection specified does not exist, then DB2 returns SQLCODE -805.

When using auto-create packages, if a package collection is not specified or the package collection does not exist, then during the "auto-create" package process, the consumer application will receive SQLSTATE HY000 and SQLCODE -385. The SQLSTATE HY000 is defined as a provider-specific error. The -385 Error Return Code is not a SQLCODE but rather a DDM DRDA AR (DB2 client) return code. This error code is defined as DDM_VALNSPRM with the following associated text string:

```
"The parameter value is not supported by the target system."
```

The OLE DB Provider for DB2 client error codes are defined in the db2oledb.h file located on the Host Integration Server 2000 CD-ROM.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000.

SNA Server 4.0 with Service Pack 3 came with two similar utilities for creating packages: CRTPKG.EXE (a command-line tool) and CRTPKGW.EXE (a GUI-based tool).

Registry Settings Used By the OLE DB Provider for DB2

The Microsoft® OLE DB Provider for DB2 uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup** key. These registry settings include the following subkeys:

Subkey	Comment
RootDir	Stores the path to the root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the OLE DB Provider for DB2 DLLs and other support DLLs are installed.

Programming Considerations Using the OLE DB Provider for DB2

The Microsoft® OLE DB Provider for DB2 provides passthrough support for SQL statements. No SQL parsing is provided. The user must know what SQL syntax is supported for the target DB2 implementation. For information on what SQL syntax is supported, see the specific DB2 SQL Reference and DB2 Application Programming and SQL Guide for the DB2-specific platform.

The OLE DB Provider for DB2 does not parse the SQL statements to qualify table names. Consequently, users of the OLE DB Provider for DB2 must use either two-part or three-part (fully-qualified) object names when naming tables, views, and stored procedures in DB2. A two-part table name would consist of the user ID and table, <UserID>.<Table>. One-part names (just the table name) will not succeed unless the combination of the DB2 collection and schema name correspond directly to the OLE DB User ID (the OLE DB DBPROPSET_DBINIT property is equal to the OLE DB DBPROP_AUTH_USERID property).

All the OLE DB objects exposed by the OLE DB Provider for DB2 support aggregation. Each OLE DB object has two classes, one that delegates its **IUnknown** calls and one that controls the object as a whole.

The free-threading model is supported, allowing multiple threads to access the objects safely.

The current implementation of the OLE DB Provider for DB2 services all OLE DB Session, Command, and Rowset objects present in a given instance of the DataSource object through a single APPC conversation or TCP/IP connection. One implication of this design is that if two Rowset objects, each created from a different OLE DB Session object, use explicit commitment control through the **ITransaction** interface, they will interfere with each other. When a Commit or Abort for one instance is invoked, all work for the DataSource object will be either committed or aborted. This may yield undesirable results. The work around to this problem is to instantiate two instances of the DataSource object.

The OLE DB Provider for DB2 does not work with OLE DB Session Pooling.

The OLE DB Provider for DB2 in Microsoft Host Integration Server 2000 supports distributed transactions, DRDA Distributed Unit of Work, and can participate in a distributed transaction coordinated by Microsoft Distributed Transaction Coordinator. This feature is only available when connecting to one of the following across an LU 6.2 network connection:

- DB2 for OS/390 V5R1 or later
- DB2/400 V4R3 or later

This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed. The Microsoft OLE DB Provider for DB2 does not support OLE DB automatic transaction enlistment under Microsoft Transaction Server. Note that the OLE DB Provider for DB2 supplied with SNA Server 4.0 does not support distributed transactions.

The Microsoft Data Access Components (MDAC) support the option of using a client cursor engine. This service component is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the CursorLocation property on the recordset to adUseClient. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must set the OLE DB Provider for DB2 Auto Commit Mode property in the data link or connection string to FALSE. This is not required when connecting to DB2 for OS/400.

The OLE DB Provider for DB2 included with Host Integration Server 2000 supports updating capabilities when used with a client cursor engine when the following requirements are met:

- To support updates (UPDATE, INSERT, and DELETE) using a client cursor engine, the values in at least one column in the target table must be unique.

When used with the version of the OLE DB Provider for DB2 provided with SNA Server 4.0 Service Pack 3 or later, the OLE DB Provider supports updating capabilities when used with a client cursor engine when the following requirements are met:

- To support updates (UPDATE, INSERT, and DELETE) using a client cursor engine, the values in at least one column in the target table must be unique.
- The Commit parameter must be set to FALSE (auto commit is off) when configuring the data source or when this parameter is passed as part of a connection string.

Previous versions of the OLE DB Provider for DB2 prior to SNA Server 4.0 Service Pack 3 do not support any updating capabilities when used with a client cursor engine. In other words, if a client cursor engine is enabled using RDS or ADO, the OLE DB Provider for DB2 cannot be used to update data on the host. The ADO recordset is treated as if it were read-only.

When the intent is to update records, DB2 requires that the SQL SELECT statement also include the FOR UPDATE option. For

example, to select all records from the AUTHORS table in the DB2 collection called PUBS with an intent to update requires the following SQL syntax:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE
```

When using DB2 for MVS V4R1 and DB2 for OS/400 V3R2, there are further requirements to indicate the columns that you intend to update. For example, to update the AU_LNAME and AU_FNAME columns in the PUBS.AUTHORS table, the following SQL syntax must be used:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE OF AU_LNAME, AU_FNAME
```

Microsoft Visual Studio® 6.0 offers a number of ADO data-bound controls, including a datagrid and the ADO Data Control. When using these ADO data controls, the developer must set the CursorLocation property on the recordset to adUseClient. Additionally, when using these ADO data controls with DB2 for OS/390, the developer must set the OLE DB Provider for DB2 Auto Commit Mode property in the data link or connection string to FALSE.

Support for Isolation Levels Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 provides flexibility in dealing with issues of isolation levels and transaction state. The isolation level for a session can be set using the DBPROP_SESS_AUTOCOMMITISOLEVELS property on a session.

The OLE DB Provider for DB2 supports the following values for the DBPROP_SESS_AUTOCOMMITISOLEVELS and DBPROP_SUPPORTEDTXNISOLEVELS property.

OLE DB Property Value	Description
DBPROPVAL_TI_BROWSE	This isolation level is the same as DBPROPVAL_TI_READUNCOMMITTED. Note that the OLE DB specification and the OLEDB.H include file defines two macros with the same value.
DBPROPVAL_TI_CHAOS	An undefined value for isolation level. This value is not supported using the OLE DB Provider for DB2.
DBPROPVAL_TI_CURSORSTABILITY	This isolation level is the same as DBPROPVAL_TI_READCOMMITTED. Note that the OLE DB specification and the OLEDB.H include file defines two macros with the same value.
DBPROPVAL_TI_ISOLATED	This isolation level is the same as DBPROPVAL_TI_SERIALIZABLE. Note that the OLE DB specification and the OLEDB.H include file defines two macros with the same value.
DBPROPVAL_TI_READCOMMITTED	When this property is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This is the default value for isolation level. This isolation level is also called Cursor Stability (CS) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to adXactReadCommitted.
DBPROPVAL_TI_READUNCOMMITTED	When this property is set, it does not isolate data read from changes by others and changes made by others by others can be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This isolation level is called Uncommitted Read (UR) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to adXactReadUncommitted.
DBPROPVAL_TI_REPEATABLEREAD	When this property is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the read statement is affected by others. This supports a repeatable read. This isolation level is called Read Stability (RS) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to adXactRepeatableRead.
DBPROPVAL_TI_SERIALIZABLE	When this property is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is not affected by others. This supports a repeatable read. This isolation level is called Repeatable Read (RR) in IBM DB2 documentation. This isolation level corresponds with the ADO property set to adXactSerializable.

The isolation level can also be set by calling **ITransactionLocal::StartTransaction** with the appropriate value for the IsoLevel parameter to start a new transaction. Note that the same integer values used for the DBPROP_SESS_AUTOCOMMITISOLEVELS and DBPROP_SUPPORTEDTXNISOLEVELS property values are also used for the IsoLevel parameter passed to the **ITransactionLocal::StartTransaction** method. The legal values for the IsoLevel parameter are defined in TRANSACT.H while the OLE DB property values for isolation level are defined in OLEDB.h. While the #define macro strings used for the OLE DB property values and the IsoLevel parameter values differ, the integer values of these macros are the same.

The following table shows the OLE DB property values for isolation level and the equivalent IsoLevel parameter passed to **ITransactionLocal::StartTransaction**.

OLE DB Isolation Level Property	OLE DB IsoLevel Parameter
DBPROPVAL_TI_BROWSE	ISOLATIONLEVEL_BROWSE
DBPROPVAL_TI_CURSORSTABILITY	ISOLATIONLEVEL_CURSORSTABILITY
DBPROPVAL_TI_ISOLATED	ISOLATIONLEVEL_ISOLATED
DBPROPVAL_TI_READCOMMITTED	ISOLATIONLEVEL_READCOMMITTED
DBPROPVAL_TI_READUNCOMMITTED	ISOLATIONLEVEL_READUNCOMMITTED
DBPROPVAL_TI_REPEATABLEREAD	ISOLATIONLEVEL_REPEATABLEREAD
DBPROPVAL_TI_SERIALIZABLE	ISOLATIONLEVEL_SERIALIZABLE

Nested transactions are not supported by the OLE DB Provider for DB2. If there is already an active transaction on the session (that is, **StartTransaction** has been called with no matching **ITransaction::Commit** or **ITransaction::Abort**), it is not possible to start a new transaction below the current transaction. Calling **ITransactionLocal::StartTransaction** when there is already an active transaction on the session returns XACT_E_XTIONEXISTS.

IBM documents isolation level in DB2 documentation using somewhat different terms. The following table shows how the OLE DB values for isolation level are mapped to the terms used by IBM DB2 for isolation level.

OLE DB Isolation Level	IBM DB2 Isolation Level
DBPROPVAL_TI_BROWSE	Uncommitted Read (UR)
DBPROPVAL_TI_CURSORSTABILITY	Cursor Stability (CS)
DBPROPVAL_TI_ISOLATED	Repeatable Read (RR)
DBPROPVAL_TI_READCOMMITTED	Cursor Stability (CS)
DBPROPVAL_TI_READUNCOMMITTED	Uncommitted Read (UR)
DBPROPVAL_TI_REPEATABLEREAD	Read Stability (RS)
DBPROPVAL_TI_SERIALIZABLE	Repeatable Read (RR)

Transaction Support Using the OLE DB Provider for DB2

In earlier versions of the OLE DB provider for DB2 supplied with Microsoft SNA Server 4.0, the Auto commit property, an OLE DB provider-specific property, controlled whether work done through the provider (i.e. ICommand->Execute) was committed to the database as the work was done. This property defeated the intention of the OLE DB specification. Work done through the provider should be auto committed unless a request by the consumer is made to explicitly control when commits or aborts occur through the **ITransactionLocal**-object and the **StartTransaction** interface.

The OLE DB Provider for DB2 included with Microsoft Host Integration Server 2000 supports distributed transactions. This support is enabled by setting the provider specific property "UNITS OF WORK" to "DUW" (or checking the Distributed transactions option when configuring a UDL or DSN). The current DUW implementation does not have a notion of auto committing transactions so it is recommended to join the transaction through **ITransactionJoin**->**JoinTransaction** prior to performing work through **ICommandExecute** (or other interfaces). ADO applications do not generally join before starting their work, rather, they rely upon automatic transaction enlistment to enlist in the distributed transaction.

Using the earlier OLE DB Provider for DB2 supplied with SNA Server 4.0 Service Pack 3, RUW transaction state could cross OLE DB sessions on a single data source object. Because of this limitation, it was recommended that programmers utilize separate data source objects for each session object. To reduce the number of concurrent active sessions, then DBPROP_MULTIPLECONNECTIONS is set to VARIANT_FALSE.

The OLE DB Provider for DB2 included with Host Integration Server 2000 supports DBPROP_MULTIPLECONNECTIONS (the default value is VARIANT_TRUE) for remote unit of work (RUW) connections. This ensures that no transaction state conflicts across OLE DB session objects (ADO commands or recordsets on a single connection). This feature is a property of DBPROPSET_DATASOURCE. Therefore, you can only set this property after the OLE DB data source or ADO connection objects are created.

If the transaction has been auto enlisted, the default Transaction Isolation level is used (NC for the AS/400, CS for all other host platforms). If a join is requested (not applicable to ADO applications) after auto enlistment and work, then the Isolation Level specified on the join may differ from the default. This appears to be acceptable except in the case that a statement was prepared using one Isolation Level, the Isolation Level is then changed via **ITransactionJoin**, and then the prepared statement is executed again.

Stored Procedure Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 supports calling DB2 stored procedures. An application must use the CALL keyword before the SQL statement in order to execute a stored procedure. When using ADO, a CommandType property of adCmdStoredProc cannot be used for executing a stored procedure since ADO inserts an EXEC not CALL keyword before the command text. In order to execute a stored procedure using ADO, the **CommandType** property should be set to adCmdText and the CALL keyword should be used before the SQL statement containing the stored procedure to be executed.

When calling DB2 stored procedures, the following limitations apply when using the Microsoft OLE DB Provider for DB2:

- Binding output parameters of type REAL or DOUBLE is not supported.
- Calling stored procedures when the parameter values contain CHAR Mixed or GRAPHIC (DBCS) data types are not supported.
- Calling a non-existent procedure causes error.
- The OLE DB Provider for DB2 does not return single or multiple result sets.

Distributed Query Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 supports remote database access when configured as a linked server to Microsoft SQL Server™ using distributed queries. The distributed queries feature of SQL Server is sometimes referred to as the Distributed Query Processor (DQP). Microsoft SQL Server 2000 supports distributed queries to the OLE DB Provider for DB2 supplied with Microsoft Host Integration Server 2000 or Microsoft SNA Server 4.0 Service Pack 3 or later.

When using Microsoft SQL Server 2000 distributed queries and the OLE DB Provider for DB2 supplied with Host Integration Server or SNA Server 4.0, the following OLE DB provider options (displayed in the same order as in the SQL Server Enterprise Manager) are supported:

Provider Options in SQL Server 2000	**Comments**
Dynamic parameter	SQL Server will generate parameterized queries as an optimization for providers that support the '?' parameter marker syntax for parameterized queries in dynamic SQL. This option should not be enabled for the OLE DB Provider for DB2. .
Nested queries	SQL Server will generate nested queries for providers that support nested SELECT queries in the FROM clause. Some versions of DB2 have support for nested queries. This option should not be enabled for OLE DB Provider for DB2.
Level zero only	A level zero OLE DB provider is a very basic provider that does not support commands, and only level zero OLE DB interfaces are invoked against the provider. The Microsoft OLE DB Provider for DB2 is not a basic provider and uses commands. This option should not be enabled for the OLE DB Provider for DB2.
Allow InProcess	SQL Server allows the OLE DB provider to be instantiated as an in-process server. The default behavior is to instantiate the OLE DB provider outside the SQL Server process. Instantiating the provider outside the SQL Server process protects the SQL Server process from errors in the OLE DB provider. SQL Server requires an in-process server for handling specific types of data including long columns, text, and image data. The OLE DB Provider for DB2 does not currently support the DB2 Large Object (LOB) types. This option may be enabled or disabled for the OLE DB Provider for DB2, but this option is normally unnecessary when using SQL Server 2000.
Non transacted updates	SQL Server will disable support for transacted updates if this option is enabled. The Microsoft OLE DB Provider supports transactions, so this option is not appropriate. This option should not be enabled for the OLE DB Provider for DB2.
Index as access path	SQL Server will use the OLE DB Index object with OLE DB providers that support this feature. The OLE DB Provider for DB2 does not currently support the Index object, so this option is not appropriate. This option should not be enabled for the OLE DB Provider for DB2. .
Disallow adhoc accesses	SQL Server will use this option when only an ODBC driver is available. This option should not be enabled for the OLE DB Provider for DB2. .

The OLE DB provider options for managing distributed queries can be set using SQL Server Enterprise Manager. In the left pane of SQL Server Enterprise Manager, right-click a SQL Server instance and then select the **Security** tree to define a new linked server or change the properties of an existing linked server. Right click an existing linked server or create a new linked server. On the **General** tab, select the **Other data source** radio button and select the OLE DB Provider for DB2 for the **Provider name** from the dropdown listbox. Click the **Provider Options** button below the selected OLE DB provider to set the options for distributed queries. Check the appropriate checkboxes to enable an option for this linked server. Note that these options operate at the provider level. When the appropriate options are set for the OLE DB Provider for DB2, these settings apply to all linked server definitions using the same OLE DB Provider for DB2.

When using Microsoft SQL Server 7.0 and distributed queries with the OLE DB Provider for DB2 supplied with Host Integration Server 2000 or SNA Server 4.0, the **Allow InProcess** option must be enabled. This option is needed because SQL Server 7.0 will pass the proper authentication across the remote procedure call only when the OLE DB Provider for DB2 is configured for **Allow InProcess**. When creating a linked server for use with the OLE DB Provider for DB2 using SQL Server 7.0, you can use the

Microsoft SQL Server Enterprise Manager to configure the OLE DB options for linked servers. Configure the OLE DB Provider for DB2 to be loaded in-process (click the options button and check **Allow InProcess**). This will enable SQL Server 7.0 to initialize an instance of the OLE DB Provider for DB2 for distributed queries. Without the **Allow InProcess** option enabled, the user will receive the following error:

```
Server: Msg 7302, Level 16, State 1, Line 12; Could not create an instance of OLE DB provider
'DB2OLEDB'
```

The OLE DB Provider for DB2 performs data type and code page conversions on behalf of the OLE DB consumer application, in this case SQL Server's Distributed Query Processor. First, the provider will convert DB2 numeric and datetime data types to OLE DB numeric and datetime data types. The provider will do this on a best-match basis using information provided by DB2 in the DRDA SQL reply data structure for the result set. Second, the provider will convert the character data from the DB2 Coded Character Set Identifier (CCSID) to the Windows ANSI code page. For example in the case of an SQL SELECT fetch of data from DB2 for OS/400, the provider converts character data from EBCDIC to UNICODE and UNICODE to ANSI. The source EBCDIC CCSID value comes from the table column descriptor or from the DB2 database if the column CCSID is undefined. The target ANSI code page value comes from the value of the PC Code Page data source property. For example, to convert character data from CCSID 1026, IBM EBCDIC Turkish (Latin-5), to ANSI code page 1254, Turkish, then the PC CodePage would need to be set to 1254. OLE DB consumers may convert the data once again from OLE DB to some native data type. In this case, the OLE DB consumer application is distributed query processor. When using distributed queries, SQL Server does perform numeric and datetime conversions from OLE DB to SQL Server data types.

UNIONs in SELECT statements are not supported by the current version of the OLE DB Provider for DB2 when used with distributed queries. For example, the following SELECT statement will fail:

```
SELECT * FROM ( SELECT TITLE_ID FROM SNA.TITLE )
```

The SQL parser built into the OLE DB Provider for DB2 does not properly parse these UNION statements in a way compatible with DB2. The above statement will generate a type 199 error "Keyword FROM not expected. Valid Tokens: LEFT CROSS INNER EXCEPTION." When performing the same query with correlation names added, the error becomes a type 104 error "Token was not valid. Valid tokens: LEFT CROSS INNER EXCEPTION."

Linked server definitions can also be created or deleted using stored procedures as well as through the SQL Server Enterprise Manager.

When creating linked server definitions, the @catalog parameter of the sp_addlinkedserver procedure corresponds to the OLE DB provider-specific Initial Catalog property. Additionally, when creating linked server definitions, one can use the contents of a UDL for the @provstr parameter value or enter the short provider string keyword arguments (see the ADO ConnectionString property for details), which are consumed via the OLE DB DBPROP_INIT_PROVIDERSTRING (Extended Properties) property.

The sample below illustrates how to create a linked server for DB2/MVS using an SNA Connection.

```
USE master
GO
EXEC sp_dropserver 'DB2MVS_SNA', 'droplogins'
GO
EXEC sp_addlinkedserver
    @server = 'DB2MVS_SNA',
    @srvproduct = 'Microsoft OLE DB Provider for DB2',
    @provider = 'DB2OLEDB',
    @catalog = 'P390D37',
    @provstr='InitCat=P390D37;NetLib=SNA;LOCALLU=MVSRUS;
       REMOTELU=P390L37;MODENAME=IBMRDB;PkgCol=MSPKG;DefSch=DB2DEMO'
GO
EXEC sp_addlinkedsrvlogin
    @rmtsrvname='DB2MVS_SNA',
    @useself=false,
    @locallogin=NULL,
    @rmtuser='wnw999',
    @rmtpassword='wnw999'
GO
```

The sample below illustrates how to create a linked server for DB2/MVS using a TCP/IP Connection.

```
USE master
GO
EXEC sp_dropserver 'DB2MVS_IP', 'droplogins'
GO
EXEC sp_addlinkedserver
    @server = 'DB2MVS_IP',
    @srvproduct = 'Microsoft OLE DB Provider for DB2',
    @provider = 'DB2OLEDB',
    @catalog = 'P390D37',
    @provstr='InitCat=P390D37;NetLib=TCPIP;NetAddr=MVSrUS;
        NetPort=446;PkgCol=MSPKG;DefSch=DB2DEMO'
GO
EXEC sp_addlinkedsrvlogin
    @rmtsrvname='DB2MVS_IP',
    @useself=false,
    @locallogin=NULL,
    @rmtuser='wnw999',
    @rmtpassword='wnw999'
GO
```

The sample below illustrates several DB2 linked server queries using a TCP/IP Connection.

```
/* SELECT using four-part linked server query:   */
/*    <Linked Server>.<Catalog>.<Schema>.<Table> */
SELECT * FROM DB2MVS_IP.P390D37.DB2DEMO.DEPARTMENT
SELECT DEPTNAME FROM DB2MVS_IP.P390D37.DB2DEMO.DEPARTMENT WHERE DEPTNO = 'A00'

/* SELECT using pass-through OPENQUERY with      */
/*     three-part naming convention              */
SELECT * FROM OPENQUERY(DB2MVS_IP,"SELECT * FROM P390D37.DB2DEMO.EMP_ACT")

/* SELECT using pass-through OPENROWSET with     */
/*     two-part naming convention                */
SELECT * FROM OPENROWSET
    (
    'DB2OLEDB',
    'InitCat=P390D37;NetLib=TCPIP;NetAddr=MVSrUS;NetPort=446;
         PkgCol=MSPKG;DefSch=DB2DEMO;User ID=WNW999;Password=WNW999',
    'SELECT * FROM DB2DEMO.EMPLOYEE'
    )
```

The sample below illustrates several SQL Server Views to access a DB2 linked server using a TCP/IP Connection.

```
/* Create SQL Server View using DB2 linked server query */
USE DB2Demo
GO
DROP VIEW DB2VIEW
GO
CREATE VIEW DB2View
AS
SELECT ORD_ID, ORDERDATE, ORDERSTATUS
    FROM DB2MVS_IP.P390D37.DB2DEMO.ORDERS
GO

/* Access Db2 data using SQL Server View */
SELECT * FROM DB2Demo.dbo.DB2View
```

The sample below illustrates the SQL SELECT, UPDATE, and DELETE commands using four-part linked server queries to DB2 over a TCP/IP Connection.

```
SELECT * FROM DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS
INSERT INTO DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS VALUES (1002,
    'password', 'User', 'DB2Demo', 'One Microsoft Way', 'Redmond',
    '425-882-8080', 'WA', '98052', 'mssna@microsoft.com')
```

```
UPDATE DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS  SET PHONE = '206-882-8080'
    WHERE CUST_ID = 1002
DELETE FROM DB2MVS_IP.P390D37.DB2DEMO.CUSTOMERS WHERE CUST_ID = '1002'
```

The sample below illustrates invoking DB2 linked server queries from SQL Server stored procedure.

```
USE DB2Demo
DROP PROCEDURE spGetOrderDetails_DB2MVS_IP

CREATE PROCEDURE spGetOrderDetails_DB2MVS_IP
    @ORDER_ID INT
AS
BEGIN
    SELECT a.*, b.Title, b.SubTitle, b.Author, b.ISBN, b.Weight
        FROM DB2MVS_IP.P390D37.DB2DEMO.ORDERDETAILS AS a
    INNER JOIN Titles AS b
        ON a.Prod_Id = b.TitleId
        WHERE a.Ord_Id >= @ORDER_ID
END

EXEC spGetOrderDetails_DB2MVS_IP 1001
```

Note: for more information on the above stored procedures, see the Microsoft SQL Server books online.

INSERT, UPDATE and DELETE statements when using four-part linked server queries will invoke the client cursor engine (CCE). This means that some statements may fail or update incorrect columns. For example, if there is not a unique key column on the target tables or there are not enough unique values for the CCE to accurately guess which columns to update. For INSERT, UPDATE and DELETE linked server queries, there must be either a unique index or unique values.

Using distributed queries, SQL Server will return all rows for the target table locally, then sort through results using the client cursor engine to find a unique value (composed of all columns if need be). If the CCE can't find a unique value, then the distributed query will fail to perform the INSERT, UPDATE, or DELETE statement.

Using the OLE DB Provider for DB2, SQL Server distributed queries return the incorrect precision for DECIMAL data types when run OPENQUERY. The correct precision is returned for DECIMAL data types with using a linked server query.

Query Designer Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 supports using the Query Designer that is included with Microsoft SQL Server. When Query Designer is launched from products such as SQL Server Data Transformation Services (DTS), the OLE DB Provider for DB2 is initialized with no provider-specific properties and an invalid property error may be generated.

To work around this problem, create a data link with the provider-specific properties required to connect to the host. These properties are specified in the Extended Properties field on the All tab when configuring a data source. Typically, the remote LU Alias, the local LU Alias, and the Default Schema should be specified using either the full property name (APPC Remote LU Alias=REMLU;APPC Local LU Alias;Default Schema=MYLIB) or the short names (RLU=REMLU;LLU;DEFSCH=MYLIB).

Other properties, such as APPC Mode Name, may need to be specified if the default values for that property are not acceptable. You should also specify a Default Schema. If a Default Schema is not specified, Query Designer will display all schemas on the remote system (including libraries, collections, etc.), which can result in slow performance.

Data Transformation Services Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 supports using the Data Transformation Services (DTS) facility provided with Microsoft SQL Server. DTS can be used for file transfer between DB2 and Microsoft SQL Server. There are some special considerations necessary when using DTS and the OLE DB Provider for DB2.

A DB2/400 database member can only be accessed in a SQL statement by using an ALIAS or SYNONYM. For example, if you have several members of a SALES.REVENUE database file, each member storing monthly sales information, then you would access one month's data member by using an ALIAS. First, you must create the ALIAS.

```
CREATE ALIAS SALES.REVENUE_JANUARY FOR SALES.REVENUE(JANUARY)
```

Second, you must use this alias when issuing a SQL statement. You can access individual members using an ALIAS in the following SQL statements: SELECT, SELECT INTO, INSERT, UPDATE, and DELETE.

```
SELECT * FROM SALES.REVENUE_JANUARY
```

Once the alias is created, you should be able to see the table listed in the systables by issuing the following SQL statement:

```
SELECT * FROM QSYS2.SYSTABLES WHERE TABLE_SCHEMA = 'SALES'
```

The REVENUE_JANUARY table type is "ALIAS". Many OLE DB providers and ODBC drivers do not list ALIASes as TABLEs when returning catalog schema. Note that DTS will not list the table when using the Microsoft OLE DB Provider for DB2 or the Microsoft ODBC Driver for DB2. If the ALIAS is not listed, then simply utilize the Query option in DTS to specify a SELECT * FROM SALES.REVENUE_JANUARY statement.

Note that it is possible to use the OVRDBF CL command. However, using an override database file has significant overhead, whereas ALIASes are less demanding on DB2 server resources. Additionally, the OVRDBF command must be issued each time (likely as part of a stored procedure), whereas an ALIAS is persistent.

For more information, see the DB2/400 IBM SQL Reference Version 4, Document Number SC41-5612-02.

Microsoft SQL Server's Data Transformation Services will not automatically create target DB2 tables that can store DBCS or mixed DBCS-SBCS data. When using DTS to move DBCS or mixed data to DB2 as a source, then one of the following techniques are recommended:

- Create the target DB2 table ahead of time.
- Edit the CREATE TABLE script within the DTS package to include the required CCSID and FOR MIXED clauses as appropriate for the target DB2 platform and version.

Exporting DBCS VARCHAR data from SQL Server using DTS is not currently supported by the Microsoft OLE DB Provider for DB2.

When importing TIME data fields into Microsoft SQL Server using DTS and the OLE DB Provider for DB2, the second field is incorrectly set to a value of '00'. This behavior occurs when the field data type in SQL Server is Smalldatetime.

SQL Server Replication Using the OLE DB Provider for DB2

Host Integration Server 2000 supports using the Microsoft OLE DB Provider for DB2 and Microsoft SQL Server 7.0 Replication.

In order to use the Microsoft OLE DB Provider for DB2 with Microsoft SQL Server 7.0 Replication, the following software must the installed:

- Microsoft Host Integration Server 2000
- Microsoft SQL Server 7.0 with Service Pack 2 or later
- Microsoft SQL Server 7.0 with Service Pack 1 with the appropriate hotfix

When using transactional replication, object names, such as tables and constraints, can be longer in Microsoft SQL Server than in DB2. Therefore, when moving data from Microsoft SQL Server to DB2, one of the following strategies should be used for compatibility:

- Create the Microsoft SQL Server tables and constraints so that the names do not exceed the limits of DB2 (see the DB2 SQL Reference for the target platform and version of DB2).
- Create the Microsoft SQL Server tables and constraints with names up to the maximum supported by Microsoft SQL Server, then run ALTER TABLE SQL scripts against the Microsoft SQL Server distribution database after replication has created the publication, but before creating the subscriptions.

In order for replication to work properly, SQL Server-to-DB2 data type mapping entries must be provided for several data types. These data type mappings must be stored in the Microsoft SQL Server MSdatatype_mappings table in the msdb database. Data type mapping entries must be provided to properly support the CHAR and VARCHAR data types when used to store SBCS character strings or binary data (BINARY and VARBINARY) with replication. The mappings for CHAR and VARCHAR are needed due to the limits for the boundary values using the OLE DB Provider for DB2. The mappings for binary data types are required since binary data is stored as character data using the OLE DB Provider for DB2.

This SQL Server msdb.MSdatatype_mappings table can be updated using a stored procedure that comes with SQL Server. The exec sp_add_datatype_mapping command is a stored procedure that comes with the SQL Server. Users should run these data mappings in the SQL Query Analyzer (isqlw.exe). Each line of the exec sp_add_datatype_mapping procedure will add one data mapping to msdb.Msdatatype_mappings.

The Microsoft OLE DB Provider for DB2 when accessing DB2 on all platforms and versions does not support the following Microsoft SQL Server data types with direct mappings. The following is a summary of the limitations.

Microsoft OLE DB Provider for DB2 does not support DB2 GRAPHIC, VARGRAPHIC and LONG VARGRAPHIC data types. Mappings to these DB2 types should be avoided.

Microsoft OLE DB Provider for DB2 does not support DB2 Large Object data types, such as CLOB, DBCLOB, and BLOB, which are used in DB2 Universal Database. Microsoft OLE DB Provider for DB2 does not support the DB2 BIGINT data types, which is used in DB2 Universal Database for Windows NT.

Microsoft SQL Server NCHAR, NVARCHAR, NTEXT, and SYSNAME data types do not map well to supported DB2 data types. The Microsoft SQL Server TIMESTAMP data type should be mapped to a DB2 CHAR FOR BIT DATA data type. The TIMESTAMP data type in SQL Server is used only for the purposes of table logging and not for end user data. Therefore, you should not map the SQL Server TIMESTAMP data type to the DB2 TIMESTAMP.

The sample mapping table entries map Microsoft SQL Server TEXT and IMAGE to DB2 VARCHAR and DB2 VARCHAR FOR BIT DATA respectively. These Microsoft SQL Server data types can represent up to 2GB of data. In contrast, the DB2 VARCHAR data types can hold at most approximately 32k of data. As such, data truncation may occur.

For Microsoft SQL Server data types, MONEY, SMALLMONEY, DECIMAL, NUMERIC, data values can be replicated to DB2 correctly, but these floating-point data types are mapped to STRING instead of FLOAT. Once these data values are replicated to DB2, the string values should be converted back to float before performing calculations. An alternative is to do the calculations and update using SQL Server before replicating these data values over to DB2.

The following commands will create the appropriate data type mapping entries.

SQL Replication with DB2 for OS/400

When used with DB2 for OS/400, run the following commands in a stored procedure:

```
exec dbo.sp_add_datatype_mapping 'DB2/400', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'char', 'CHAR', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'float', 'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'int', 'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'smallmoney',
    'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'text',
    'VARCHAR', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'varchar',
    'VARCHAR', 8000, 4, 1
```

When using Microsoft SQL Server 7.0 (including SQL Server 7.0 with Service Pack 1 or Service Pack 2), replication does not support the following data conversions:

```
exec dbo.sp_add_datatype_mapping 'DB2/400', 'binary',
    'CHAR () FOR BIT DATA', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'image',
    'VARCHAR () FOR BIT DATA', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'timestamp',
    'CHAR () FOR BIT DATA', 8, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/400', 'varbinary',
    'VARCHAR () FOR BIT DATA', 8000, 4, 1
```

Microsoft SQL Server 7.0 with Service Pack 3 is required to support replication with these data conversions.

SQL Replication with DB2 for MVS

When used with DB2 for MVS , run the following commands:

```
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'char', 'CHAR', 254, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'float', 'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'int',
    'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'smallmoney',
   'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'text',
   'VARCHAR', 4045, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'varchar',
    'VARCHAR', 4045, 4, 1
```

When using Microsoft SQL Server 7.0 (including SQL Server 7.0 with Service Pack 1 or Service Pack 2), replication does not support the following data conversions:

```
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'binary',
    'CHAR () FOR BIT DATA', 254, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'image',
   'VARCHAR () FOR BIT DATA', 4045, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'timestamp',
   'CHAR () FOR BIT DATA', 8, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/MVS', 'varbinary',
    'VARCHAR () FOR BIT DATA', 4045, 4, 1
```

Microsoft SQL Server 7.0 with Service Pack 3 is required to support replication with these data conversions.

SQL Replication with DB2 UDB for AIX

When used with DB2 Universal Database for AIX, run the following commands:

```
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'char',
    'CHAR', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'float',
    'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'int', 'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'smallmoney',
    'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'text',
    'VARCHAR', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'varchar',
    'VARCHAR', 8000, 4, 1
```

When using Microsoft SQL Server 7.0 (including SQL Server 7.0 with Service Pack 1 or Service Pack 2), replication does not support the following data conversions:

```
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'binary',
    'CHAR () FOR BIT DATA', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'image',
    'VARCHAR () FOR BIT DATA', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'timestamp',
    'CHAR () FOR BIT DATA', 8, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/6000', 'varbinary',
    'VARCHAR () FOR BIT DATA', 8000, 4, 1
```

Microsoft SQL Server 7.0 with Service Pack 3 is required to support replication with these data conversions.

SQL Replication with DB2 UDB for NT

When used with DB2 Universal Database for NT, run the following commands:

```
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'bit',
    'SMALLINT', 1,  0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'char', 'CHAR', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'datetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'decimal',
    'DECIMAL', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'double precision',
    'DOUBLE', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'float', 'FLOAT', 53, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'int', 'INT', 10, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'money',
    'DECIMAL', 19, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'numeric',
    'NUMERIC', 31, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'real', 'REAL', 24, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'smalldatetime',
    'TIMESTAMP', 26, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'smallint',
    'SMALLINT', 5, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'smallmoney',
    'DECIMAL', 10, 3, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'text',
    'VARCHAR', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'tinyint',
    'SMALLINT', 1, 0, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'uniqueidentifier',
    'CHAR', 38, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'varchar',
    'VARCHAR', 8000, 4, 1
```

When using Microsoft SQL Server 7.0 (including SQL Server 7.0 with Service Pack 1 or Service Pack 2), replication does not support the following data conversions:

```
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'binary',
    'CHAR () FOR BIT DATA', 8000, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'image',
    'VARCHAR () FOR BIT DATA', 32739, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'timestamp',
    'CHAR () FOR BIT DATA', 8, 4, 1
exec dbo.sp_add_datatype_mapping 'DB2/NT', 'varbinary',
    'VARCHAR () FOR BIT DATA', 8000, 4, 1
```

Microsoft SQL Server 7.0 with Service Pack 3 is required to support replication with these data conversions.

Code Page Support Using the OLE DB Provider for DB2

When creating data links for use with the OLE DB Provider for DB2, the Host CCSID (character code set identifier) should be configured in the data source to match the DB2 data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the OLE DB Provider for DB2.

Depending on the version of Windows being used, to support specific code page conversions, you may need to install the appropriate National Language Support (NLS) file for your locale.

On Windows 2000, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows 2000.

On Windows NT 4.0, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows NT or when you install the Windows NT Language Pack on a non-localized version of Windows NT. The Windows NT Language Pack is available on the Windows NT 4.0 CD-ROM in the LANGPACK directory. You install the locale components of the language pack as needed by either making a change in the Control Panel Locales applet or by installing one of the locale-specific INF files.

On Windows 98 and Windows 95, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows 98 or Windows 95.

The following sections discuss the character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2000.The The tables in these sections list the INF files by name that are required under Windows NT 4.0 for a specific codepage (european.inf, for example). Typically you would install locales one at a time as needed.

ANSI Code Page Support Using the OLE DB Provider for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured to use ANSI code pages, for example ANSI 1253 (Greek). Host Integration Server 2000 includes support for some ANSI code pages for purposes of ANSI-to-UNICODE-to-ANSI conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ANSI code pages can be used when accessing IBM DB2 Universal Database on Windows NT and IBM DB2 ON AIX (not all of these ANSI code pages are supported on IBM DB2 Universal Database for AIX).

The following table shows the ANSI character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ANSI - Arabic	1256	1256	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
ANSI - Baltic	1257	1257	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ANSI - Cyrillic	1251	1251	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
ANSI - Central Europe	1250	1250	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ANSI - Greek	1253	1253	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
ANSI - Hebrew	1255	1255	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
ANSI - Latin I	1252	1252	Support for this codepage is normally installed as part of the operating system on Windows 2000, Windows NT, Windows 98, and Windows 95. On Windows NT 4.0, support for this NLS Code Page is installed using the us_eng.inf file from the Language Pack.
ANSI - Turkish	1254	1254	On Windows NT 4.0, support for this NLS Code Page is installed using the turkish.inf file from the Language Pack.
ANSI/OEM - Japanese Shift JIS	932	932	On Windows NT 4.0, support for this NLS Code Page is installed using the japanese.inf file from the Language Pack.
ANSI/OEM - Korean	949	949	On Windows NT 4.0, support for this NLS Code Page is installed using the korean.inf file from the Language Pack.
ANSI/OEM - Simplified Chinese GBK	936	936	On Windows NT 4.0, support for this NLS Code Page is installed using the exchsrvr.inf file from the Language Pack.
ANSI/OEM - Thai	874	874	On Windows NT 4.0, support for this NLS Code Page is installed using the thai.inf file from the Language Pack.
ANSI/OEM - Traditional Chinese Big5	950	950	On Windows NT 4.0, support for this NLS Code Page is installed using the tchinese.inf file from the Language Pack.
ANSI/OEM - Viet Nam	1258	1258	On Windows NT 4.0, support for this NLS Code Page is installed using the vietnam.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows 2000 or Windows NT definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ANSI-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the OLE DB Provider for DB2. When setting the Host CCSID or PC Code Page attribute/property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ANSI code page in IBM publications, which for these supported ANSI CCSIDs are the same as the Microsoft CCSID values. IBM lists their ANSI support in publications by referencing the display name which for these ANSI code pages is the same as the Microsoft display name. The OLE DB Provider for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The OLE DB Provider for DB2 maps the Microsoft NLS numbers to ANSI NLS files which correspond with the appropriate IBM CCSID numbers. The OLE DB Provider for DB2, as well as Microsoft ODBC Driver for DB2, pass the corresponding IBM CCSID to the DB2 system at run time even though you configure the provider or driver to use the Microsoft NLS number.

These are the only ANSI pages currently supported by the OLE DB Provider for DB2 in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional ANSI pages, however, the ANSI code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM ANSI code pages (CCSIDs) match.

EBCDIC Code Page Support Using the OLE DB Provider for DB2

IBM DB2 for MVS, IBM DB2 for OS/390, and IBM DB2 for OS/400 are frequently configured to use EBCDIC code pages, for example EBCDIC 875 (Greek Modern). Host Integration Server 2000 includes support for most EBCDIC code pages for purposes of EBCDIC-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-EBCDIC, and EBCDIC-to-UNICODE-to-EBCDIC conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These EBCDIC code pages can be used when accessing IBM DB2 on a variety of platforms (not all of these EBCDIC code pages are supported on all versions of IBM DB2).

The following table shows the EBCDIC character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
IBM EBCDIC - Arabic	20420	420	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
IBM EBCDIC - Cyrillic (Russian)	20880	880	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
IBM EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
IBM EBCDIC - Denmark/Norway	20277	277	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Denmark/Norway (Euro)	1142	1142	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Finland/Sweden	20278	278	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Finland/Sweden (Euro)	1143	1143	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - France	20297	297	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - France (Euro)	1147	1147	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Germany	20273	273	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Germany (Euro)	1141	1141	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Greek	20423	423	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
IBM EBCDIC - Greek (Modern)	875	875	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
IBM EBCDIC - Hebrew	20424	424	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
IBM EBCDIC - Icelandic	20871	871	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Icelandic (Euro)	1149	1149	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - International	500	500	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - International (Euro)	1148	1148	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Italy	20280	280	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Italy (Euro)	1144	1144	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Japan English/Kanji (Extended)	939	939	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan English/Kanji (Extended)	5035	5035	Support for this double-byte character set is supplied using TRNSDT.

IBM EBCDIC - Japan Katakana/Kanji (Extended)	930	930	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	5026	5026	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japanese	931	931	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Korea (Extended)	933	933	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Latin America/Spain	20284	284	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Latin America/Spain (Euro)	1145	1145	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Multilingual/ROECE (Latin-2)	870	870	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Simplified Chinese (Extended)	935	935	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Thai	20838	838	On Windows NT 4.0, support for this NLS Code Page is installed using the thai.inf file from the Language Pack.
IBM EBCDIC - Traditional Chinese (Extended)	937	937	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Turkish (Latin-3)	20905	905	On Windows NT 4.0, support for this NLS Code Page is installed using the turkish.inf file from the Language Pack.
IBM EBCDIC - Turkish (Latin-5)	1026	1026	On Windows NT 4.0, support for this NLS Code Page is installed using the turkish.inf file from the Language Pack.
IBM EBCDIC - U.S./Canada	037	37	On Windows NT 4.0, support for this NLS Code Page is installed using the us_eng.inf file from the Language Pack.
IBM EBCDIC - U.S./Canada (Euro)	1140	1140	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - United Kingdom	20285	285	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - United Kingdom (Euro)	1146	1146	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows 2000 or Windows NT definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an EBCDIC-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the OLE DB Provider for DB2. When setting the Host CCSID or PC Code Page attribute/property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the EBCDIC code page in IBM publications. IBM lists their EBCDIC support in publications by referencing the display name which for these EBCDIC code pages is the same as the Microsoft display name. The OLE DB Provider for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The OLE DB Provider for DB2 maps the Microsoft NLS numbers to EBCDIC NLS files which correspond with the appropriate IBM CCSID numbers. The OLE DB Provider for DB2, as well as Microsoft ODBC Driver for DB2, pass the corresponding IBM CCSID to the DB2 system at run time even though you configure the provider or driver to use the Microsoft NLS number.

These are the only EBCDIC pages currently supported by the OLE DB Provider for DB2 in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional EBCDIC pages, however, the EBCDIC code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM EBCDIC code pages (CCSIDs) match.

ISO Code Page Support Using the OLE DB Provider for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured for an ISO code page, for example ISO 819 (Latin I). Host Integration Server 2000 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ISO code pages can be used when accessing IBM DB2 Universal

The following table shows the ISO character code set identifiers (CCSIDs) supported by OLE DB Provider for DB2 in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 8859-2 Central Europe	28592	912	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 8859-5 Cyrillic	28595	915	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
ISO 8859-6 Arabic	28596	1089	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
ISO 8859-7 Greek	28597	813	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
ISO 8859-8 Hebrew	28598	916	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
ISO 8859-9 Turkish	28599	920	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the OLE DB Provider for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (Euro)	20865	923	NLS Code Page 819 with support for the Euro. On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows NT Language Pack definitions for these NLS files.

The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the OLE DB Provider for DB2. When setting the Host CCSID or PC Code Page attribute/property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The OLE DB Provider for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The OLE DB Provider for DB2 maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The OLE DB Provider for DB2, as well as Microsoft ODBC Driver for DB2, pass the corresponding IBM CCSID to the DB2 system at run time even though you configure the provider or driver to use the Microsoft NLS number.

Note that IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269. Note that ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the OLE DB Provider for DB2, but is displayed in the configuration options when creating or modifying data sources.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000. The OLE DB Provider for DB2 has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

DBCS Code Page Support Using the OLE DB Provider for DB2

Support for Double-Byte Character String (DBCS) data is limited using the OLE DB Provider for DB2. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported. Positioned updates against DBCS EBCDIC implementations of DB2 are not supported.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are not supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

Parameterized SQL statements or calling stored procedures when the parameter values contain Mixed or DBCS characters are not supported.

Data Conversion Using the OLE DB Provider for DB2

The design of the OLE DB APIs is similar to the APIs provided by ODBC and other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default C data types as defined in ODBC and OLE DB illustrated in the following table:

DB2 data type	Default C data type	Comments
BIGINT		An eight-byte integer. This data type is converted to DBTYPE_I8 for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
BLOB		A Binary Large Object (BLOB) is a varying-length string that can be up to 2 gigabytes in length. A BLOB is primarily intended to hold binary data. This data type is converted to a DBTYPE_STR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
CHAR (Bit)	char string[]	A fixed length string. This data type is converted to a DBTYPE_BSTR for use by OLE DB.
CHAR (SBCS)	char string[]	A fixed-length SBCS character string. This data type is converted to a DBTYPE_BSTR for use by OLE DB.
CHAR (Mixed Data)	char string[]	A fixed-length mixed character string. This data type is converted to a DBTYPE_BSTR for use by OLE DB.
CLOB		A Character Large Object (CLOB) is a varying-length string that can be up to 2 gigabytes in length. A CLOB is used to store large single-byte character set data. A CLOB is considered to be a character string. This data type is converted to a DBTYPE_STR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
DATE	date struct	A ten byte date string. This data type is converted to a DBTYPE_DATE for use by OLE DB.
DEC	unsigned char number[]	A packed decimal number. This data type is converted to a DBTYPE_DECIMAL for use by OLE DB.
DOUBLE	double	An 8-byte double-precision floating point number. This data type is converted to a DBTYPE_R8 for use by OLE DB.
FLOAT	double	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE. This data type is converted to a DBTYPE_R8 for use by OLE DB.
GRAPHIC (DBCS)	unsigned char binary[]	A fixed-length graphic string consisting of a sequence of double byte character string (DBCS) data. This data type is converted to a DBTYPE_WSTR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
INTEGER	int	A four-byte integer ranging in value from -2,147,463,648 to +2,147,483,647. This data type is converted to a DBTYPE_I4 for use by OLE DB.

LONG VARCHAR (Bit)	char string[]	A varying-length character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARCHAR (SBCS)	char string[]	A varying-length SBCS character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARCHAR (Mixed)	char string[]	A varying-length mixed-character string. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARGRAPHIC (DBCS)	unsigned char binary[]	A varying-length graphic string consisting of a sequence of double byte character string (DBCS) data ranging up to 16,383 DBCS characters in length. This data type is converted to a DBTYPE_WSTR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.
SMALLINT	short	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767. This data type is converted to a DBTYPE_I2 for use by OLE DB.
REAL	float	A 4-byte single-precision floating point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
TIME	time struct	An 8-byte time string. This data type is converted to a DBTYPE_TIME for use by OLE DB. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.
TIMESTAMP	timestamp struct	A 26-byte string representing the date, time, and microseconds. This data type is converted to a DBTYPE_DBTIMESTAMP for use by OLE DB.
VARCHAR (Bit)	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR (SBCS)	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR (Mixed)	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARGRAPHIC (DBCS)	unsigned char binary[]	A varying-length graphic string consisting of a sequence of double byte character string (DBCS) data. The maximum length of the string is dependent on the version and the platform that DB2 is running on. This data type is converted to a DBTYPE_WSTR for use by OLE DB. This data type is not supported by the OLE DB Provider for DB2.

Note that the maximum length of fixed-length CHAR, fixed-length GRAPHIC, VARCHAR, and VARGRAPHIC data types is dependent on the version of DB2 that is being accessed. For example, the maximum length of the CHAR data type on DB2 for OS/390 is 254 characters, while the maximum length of this same host data type is 32,765 on DB2/400.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the OLE DB Provider for DB2.

Note that the OLE DB Provider for DB2 does not support mapping DB2 bit strings and graphic data types to binary data types. The OLE DB Provider for DB2 does not support a binary-to-binary conversion. Consequently, CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, and LONGVARCHAR FOR BIT DATA can only be supported when the Process Binary As Character property is set to true

when configuring the OLE DB data source or passed as part of the connection string. In this way, the OLE DB client would actually bind the column as an OLE DB character type, not as a binary type.

Using the OLE DB Provider for DB2, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The OLE DB Provider for DB2 translates all such undefined characters to the question mark character ("?"). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters will be replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The ANSI to EBCDIC character conversions affected include the following:

Character Value (Decimal)	**Character Value (Hexadecimal)**	**ANSI Code Page 1252**	**EBCDIC Character After Conversion to CCSID 37**
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Floating Point Considerations Using the OLE DB Provider for DB2

When real or double (synonymous with float) data is inserted into a DB2 table as a floating point data type, it is stored in scientific notation. For example, FLOAT(1.1) would be stored as +1.10000E+000.

Care must be taken when executing SQL statements to make sure that the proper data type specified in the SQL statement matches the values stored in DB2. For example, the following select statement would match values in DB2 stored as decimal 1.1.

```
SELECT * FROM TEST WHERE C1 = 1.1
```

If the data in DB2 was stored as real numbers, there would not be a match since decimal 1.1 is stored as 1.1, not the representation of +1.10000E+000. When DB2 parses and executes the SQL select statement, it interprets 1.1 as a decimal type. When doing the select query, DB2 does not implicitly do the conversion to floating point. In this case, the SQL statement should explicitly typecast the 1.1 so that DB2 looks for the correct format (the scientific notation format). The select query would look like the following:

```
SELECT * FROM TEST WHERE C1 = REAL(1.1)
```

This will give the results expected. The SQL REAL function will convert the decimal 1.1 to the proper format before DB2 executes the actual select.

Usernames and Passwords Using the OLE DB Provider for DB2

When connecting to remote DB2 systems, most users must be authenticated by the remote system by passing a valid User ID and Password.

The AS/400 computer is case-sensitive with regard to User ID and Password. The AS/400 only accepts a User ID and Password in uppercase. The Microsoft OLE DB Provider for DB2 will force the User ID and Password into uppercase when it knows that it is connecting to a DB2/400 system.

The mainframe is not case-sensitive. This means that on mainframe computers, one can enter the User ID and Password in any case.

DB2 Universal Database (UDB) for Windows NT is case-sensitive. UDB supports mixed case Passwords. The user must enter the Password in the correct mixed case. When entering a User ID, use only the Windows NT user name and do not include the Windows NT Domain Name.

Troubleshooting the OLE DB Provider for DB2

The Windows 2000 and Windows NT Event Viewer can be a useful tool for troubleshooting data access in some cases. The OLE DB Provider for DB2 does not issue events. However, when SNA (APPC/LU 6.2) is used for the network transport for the OLE DB Provider for DB2, the low-level SNA APPC transport issues events on the SNA connection.

The Microsoft OLE DB Provider for DB2 supplied with Host Integration Server 2000 has the ability to trace DRDA data flows when used over TCP/IP.

This DB2 tracing capability is accessible from the SNADB2 Service tracing inside the Trace utility. This facility will show the same data as an APPC trace but without the control indicators (For example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Platform SDK.

The OLE DB Provider for DB2 can return the following types of errors:

- DB2 SQL errors from the remote database
- Microsoft OLE DB Provider-specific errors
- Errors from the underlying DRDA Application Requester network client

When the OLE DB Provider for DB2 passes an error code, the best source in which to look-up the meaning of the return code is often the SQL Reference or SQL Messages and Codes Reference for the target SQL database. In this case, the target database would be one of the DB2 platforms supported by the Microsoft OLE DB Provider for DB2.

The OLE DB Provider for DB2 maintains an internal integer variable named SQLCODE and an internal 5-byte character string variable named SQLSTATE used to check the execution of SQL statements on DB2. SQLCODE is set by DB2 after each SQL statement is executed. DB2 returns the following values for SQLCODE:

- If SQLCODE = 0, execution was successful.
- If SQLCODE > 0, execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.
- SQLCODE = 100, "no data" was found. For example, a FETCH statement returned no data because the cursor was positioned after the last row of the result table.

SQLSTATE is also set by DB2 after the execution of each SQL statement. Application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE. SQLSTATE provides application programs with common codes for common error conditions (the values of SQLSTATE are product-specific only if the error or warning is product-specific). Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors.

SQLSTATE values consist of a two-character class code value, followed by a three-character subclass code value. The first character of an SQLSTATE value indicates whether the SQL statement was executed successfully or unsuccessfully (equal to or not equal to zero, respectively). Class code values represent classes of successful and unsuccessful execution conditions. The following SQLSTATE class codes are used by DB2:

Class Code	Description of Error Class
00	Successful completion. Execution of the SQL statement was successful and did not result in any type of warning or exception condition.
01	Warning
02	No data
07	Dynamic SQL error
08	Connection exception
0A	Feature not supported
0F	Invalid token
21	Cardinality violation
22	Data exception
23	Constraint violation
24	Invalid cursor state
25	Invalid Transaction State
26	Invalid SQL statement identifier
2D	Invalid transaction termination
34	Invalid cursor name

39	External function call exception
40	Transaction rollback
42	Syntax error or access rule violation
44	WITH CHECK OPTION violation
51	Invalid application state
53	Invalid operand or inconsistent specification
54	SQL or product limit exceeded
55	Object not in prerequisite state
56	Miscellaneous SQL or product error
57	Resource not available or operator intervention
58	System error

The SQLSTATE value of HY000 is defined as a provider-specific error. An SQLSTATE of 08S01 (connection exception with a subclass code of S01) also indicates a provider-specific error. This means the SQLCODE should be looked up in the driver-specific documentation included with the OLE DB Provider for DB2.

If the SQLSTATE does not indicate a driver-specific error when the OLE DB Provider for DB2 passes back an SQLSTATE of 08S01, it indicates a network error. For example, an SQLCODE of -603 is a provider-specific error that is mapped to DB2OLEDB_COMM_HOST_CONNECT_FAILED in the db2oledb.h include file supplied with the OLE DB Provider for DB2. Errors with an SQLSTATE of 08S01 are documented in the db2oledb.h include file (the SQLCODE value) which is located on the Host Integration Server 2000 CD-ROM in the SDK\Include subdirectory.

The following steps are useful in researching an error. Start by reading the provided error text returned by the OLE DB Provider for DB2. In some cases, the error text provides very limited useful information. For example, error text from an SQLCODE of -603 states the following:

```
Test connection failed because of an error in initializing provider.
Could not connect to specified host.
```

The next step is to lookup the SQLSTATE to determine the source of the error. Is the error a DB2 error, a network client error, or an OLE DB Provider error? An SQLSTATE of 08S01 is defined as follows:

```
Communication link failure.
```

This definition is intended to inform the user, administrator, or developer that the error is one related to the OLE DB Provider's underlying network client.

Unfortunately, many of the SQLSTATE codes returned by the OLE DB Provider for DB2 are DB2 errors and are not documented in the OLE DB Provider for DB2 on-line help.

The SQLSTATE of HY000 is defined as a provider-specific error. An SQLSTATE of 08S01 also indicates a provider-specific error. This means the SQLCODE should be looked up in the provider-specific documentation included with the OLE DB Provider for DB2.

If the SQLSTATE does not indicate a driver-specific error, then the SQLCODE should be looked up in the appropriate DB2 manual for the target platform. For example, an SQLCODE of -603 is documented in Appendix B, SQLCODEs and SQLSTATEs, in the *AS/400 Advanced Series DB2 for AS/400 SQL Programming, Version 4*, Document Number SC41-5611-00 published by IBM. An SQLCODE of -603 corresponds to SQLSTATE 23515 in the DB2 for OS/400 error code list. For example, the explanation for this SQLCODE is as follows:

```
Unique index cannot be created because of duplicate keys.
```

When the SQLSTATE and the SQLCODE definitions documented in these appendices create a mismatch with the actual errors returned, this usually indicates a provider-specific error condition.

A final step to understand an error is to check the db2oledb.h file. This file is not installed by the Host Integration Server or Host Integration Client setup program, but can be found on the Host Integration Server 2000 product CD ROM in the SDK\Include subdirectory. An SQLCODE (for example, -603) can be looked up by searching the right-most column of the db2oledb.h file for a value near to 603. In this case, one will see a comment "/* -600 */" and can then count down three additional lines to line number 603. The internal error code -603 is defined as follows:

```
DB2OLEDB_COMM_HOST_CONNECT_FAILED
```

Unfortunately, this error text is not further defined anywhere in the software or documentation provided to the customer. This particular error usually indicates a problem with the configuration parameters or the connection string passed.

ODBC Drivers

The Microsoft® ODBC Driver for DB2 enables users to access IBM Data Base 2 (DB2) from within an ODBC-aware application. ODBC defines a standard set of interfaces that provide access to disparate databases. The ODBC Driver for DB2 combines the data access of ODBC with the underlying Microsoft Distributed Relational Database Architecture (DRDA) Application Requester also used by the Microsoft OLE DB Provider for DB2. Using this combination of technologies, the ODBC Driver for DB2 can provide database access to IBM's Distributed Relational Database Architecture and IBM DB2.

Organizations have invested in secure, robust, enterprise-wide data storage and management systems. DRDA is a set of rules for distributing or extending relational data from one computer to another, such as a server computer to an IBM DB2 database server running on a mainframe or an AS/400 computer. By combining the ODBC and DRDA architectures, Microsoft allows organizations to preserve their investments in an existing data management infrastructure, while extending data access to all enterprise-wide DB2 data sources.

The ODBC Driver for DB2 can be used interactively or from an application program to issue SQL statements and execute DB2 stored procedures. From Microsoft Excel, users can import DB2 tables into worksheets and use Excel graphing tools to analyze the data. From Microsoft Access, users can import from and export to DB2. With Microsoft Internet Information Server (IIS), developers can publish DB2-stored information to users through a Web browser.

This section contains:

Goals of the ODBC Driver for DB2

Relational database management systems (RDBMS) are one of the major sources of mission-critical information in today's enterprise organizations. Relational database technology enables departments and individual users to save their information in centrally-managed database stores that can be easily maintained by the organization's information systems group.

IBM DB2 is a popular RDBMS for a significant number of enterprise customers. Customers need a cost-effective and manageable means to integrate DB2 with Microsoft SQL Server, Microsoft Internet Information Server (IIS), and Microsoft Office applications. The goal of Microsoft ODBC Driver for DB2 is to provide customers and solution providers with the means to integrate desktop database applications with this wealth of data residing on IBM DB2 database systems.

ODBC Driver for DB2 Architecture

The Microsoft® ODBC Driver for DB2 is an ODBC-compliant database driver for Windows 95, Windows 98, and Windows NT that lets your existing ODBC applications access data residing in IBM DB2 database servers without changing any code. The ODBC Driver for DB2 can connect ODBC-compliant applications with DB2 data sources using the underlying Microsoft Distributed Relational Database Architecture (DRDA) Application Requester. The ODBC application connects to the ODBC Driver for DB2. These ODBC requests are processed by the underlying Microsoft DRDA Application Requester. The data is then passed by an SQL interface to the DB2 data store.

The ODBC Driver for DB2 shares the same DRDA Application Requester that is used by the Microsoft OLE DB Provider for DB2. The DRDA Application Requester is the network client that provides remote database access to DB2 across an SNA LU6.2 and TCP/IP network.

The ODBC Driver for DB2 is compliant with the Microsoft Open Database Connectivity (ODBC) specification. ODBC is a specification for an application program interface (API) that enables applications to access multiple database systems using SQL.

Platforms Supported by the ODBC Driver for DB2

The Microsoft® ODBC Driver for DB2 supports popular DB2 platforms supported by the Microsoft OLE DB Provider for DB2 because both use the same underlying DRDA Application Requester (see Platforms Supported by the OLE DB Provider for DB2).

The ODBC Driver for DB2 offers network connectivity using SNA APPC LU6.2 connectivity, as well as native TCP/IP (not reliant on any special IBM or third-party routers).

ODBC Driver for DB2 Requirements

The ODBC Driver for DB2 supplied with Host Integration Server 2000 supports the following operating systems:

- Microsoft Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Professional
- Microsoft Windows NT® Server 4.0 with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Enterprise Edition with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Terminal Server Edition with Service Pack 6a or later
- Microsoft Windows NT Workstation 4.0 with Service Pack 6a or later
- Microsoft Windows 98, Second Edition

The ODBC Driver for DB2 supplied with Host Integration Server 2000 Service Pack 1 adds support for the following additional operating systems:

- Microsoft Windows XP Professional
- Microsoft Windows XP Home Edition
- Microsoft Windows Millennium Edition

The ODBC Driver for DB2 supplied with Host Integration Server 2000 supports only the Windows 2000 and Windows NT (Intel version) platforms. Older versions of the ODBC Driver for DB2 that shipped with SNA Server 4.0 Service Pack 1 and later supported Windows NT on the Alpha architecture.

The ODBC Driver for DB2 requires the following PC-to-host connectivity software when connecting over SNA using LU 6.2:

- Microsoft Host Integration Server 2000
- Microsoft Host Integration Server End-User Client
- Microsoft Host Integration Server Administrator Client

Microsoft Host Integration Server 2000 can be installed on Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, Windows NT 4.0 Server, Windows NT 4.0 Server Enterprise Edition, or Windows NT 4.0 Server Terminal Server Edition.

The Microsoft Host Integration Server Administrator Client can be installed on Windows 2000 Professional or Windows NT 4.0 Workstation. The Microsoft Host Integration Server Administrator Client with Service Pack 1 can also be installed on Windows XP Professional. The Administrator Client cannot be installed on Windows 98 or Windows 95.

The Microsoft Host Integration Server End-User Client can be installed on Windows 2000 Professional, Windows NT 4.0 Workstation, or Windows 98. The Microsoft Host Integration Server End-User Client with Service Pack 1 can also be installed on Windows XP Professional, Windows XP Home Edition, or Windows Millennium Edition.

Note that the ODBC Driver for DB2 does not require any special host connectivity software when connecting directly to a host system using TCP/IP.

The ODBC Driver for DB2 supplied with Microsoft Host Integration Server 2000 supports the following ADO versions:

- ADO version 2.5. The Microsoft Host Integration Server 2000 data access features require the runtime libraries for ADO version 2.5. These libraries must be installed prior to installing the ODBC Driver for DB2. On Windows 2000, these ADO libraries are installed as part of the Windows 2000 operating system. On Windows NT 4.0 and Windows 98, these library files must be installed by running the Microsoft Data Access Components (MDAC) version 2.5 runtime package available as downloadable software from the Microsoft Universal Data Access Web site at http://go.microsoft.com/fwlink/?LinkId=12749.
  A version of the ADO 2.5 SDK is included in the Microsoft Data Access SDK which is available as a part of the Windows 2000 Platform SDK. These downloadable SDKs are available from the Microsoft Windows 2000 Web site at http://go.microsoft.com/fwlink/?LinkId=12752.

Configuring ODBC Data Sources

A data source associates a particular ODBC driver with the data to be accessed through that driver. Data source information must be configured for each DB2 system that is to be accessed using the ODBC Driver for DB2. The default parameters for the ODBC Driver for DB2 are used for the data source only when these parameters are not configured for each data source.

An ODBC data source name (DSN) can be one of the following types:

- User - A data source local to a computer and accessible only by the current user that created the data source.
- System - A data source local to a computer but not dedicated to a specific user, so any user with appropriate privileges can access a system DSN. A System data source is visible to all users on a computer, including Windows NT services.
- File - A data source stored in a file that can be shared among all users who have the same ODBC drivers installed. These data sources need not be dedicated to a specific user or local to a computer.

User and System data sources are stored in the registry. File data sources are stored as files with a file extension of dsn. File DSNs can be stored in any location on the file system including remotely-mounted shares. By default, File DSNs are stored in the following location:

C:\Program Files\Common Files\ODBC\Data Sources

ODBC data sources can be configured using the **ODBC Data Source Administrator**. On Windows 2000, a shortcut to the **ODBC Data Source Administrator** is located in the Control Panel under **Administrative Tools** as **Data Sources (ODBC)**. On Windows NT 4.0, a shortcut to the **ODBC Data Source Administrator** is located in the Control Panel as **Data Sources (ODBC)**. On Windows 98, a shortcut to the **ODBC Data Source Administrator** is located in the Control Panel as **ODBC Data Sources (32bit)**.

The NewSnaDS.exe utility provided as part of the ODBC Driver for DB2 enables users to create and modify ODBC data sources. This tool makes calls to the ODBC Data Source Administrator application to provide these functions.

The NewSnaDS tool is installed in the system folder below the subdirectory where Microsoft Host Integration Server 2000 is installed. The default location where this tool is installed is the following:

C:\Program Files\Host Integration Server\system\NewSnaDS.exe

A shortcut for using this tool to create or modify ODBC data sources is added to the **Programs** menu under **Host Integration Server\Data Integration** with a name of **ODBC Data Sources**. This shortcut is created when the Microsoft Host Integration Server 2000 or the Host Integration Client 2000 are first installed and support for data access is selected.

Several options are available for creating new data sources or modifying existing data sources for use with the ODBC Driver for DB2:

- Select the **ODBC Data Sources** shortcut under the **Programs\Host Integration Server\Data Integration** menu to start the NewSnaDS tool.
- Run the ODBC Data Source Administrator directly from the Control Panel.

The following steps describe how to configure a data source for use with the ODBC Driver for DB2 using the NewSnaDS tool:

1. Click the **Start** button, point to **Programs**, and then point to **Host Integration Server**.
2. Point to Data Integration, and then click ODBC Data Sources to run the NewSnaDS tool.
3. Select the tab for the ODBC data source type to be created or modified: User DSN, System DSN, or File DSN.
4. If you are modifying an existing data source for the ODBC Driver for DB2, select the data source from the list box and click the Configure button.
   If you are creating a new data source, click the Add button, select the Microsoft ODBC Driver for DB2 from the list of drivers, and click the Finish button.
5. Data source information specific to the ODBC Driver for DB2 is configured using the Microsoft ODBC Driver for DB2 Configuration dialogs. Type the appropriate information into the various fields in the tabbed dialog box and clicking the OK button to return to the main ODBC Data Source Administrator application.
6. Configure other ODBC parameters not specific to the ODBC Driver for DB2 in the ODBC Data Source Administrator and click the OK button to save the data source.

The **Microsoft ODBC Driver for DB2 Configuration** dialog box contains five tabs, which are described in the following topics.

This section contains:

- General
- Connection
- Security
- Target Database
- Locale
- Configuration Property Mappings Between the ODBC Driver for DB2 and the OLE DB Provider for DB2

General

The **General** tab allows the user to configure the data source name required to connect to DB2. For the Microsoft ODBC Driver for DB2 supplied with Host Integration Server 2000, the **General** tab contains the following fields:

Parameter	Comments
Data Source Name	A blank field for specifying the name of the data source. Enter a string that identifies this ODBC data source. The data source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file, which is stored in C:\Program Files\Common Files\ODBC\Data Sources.
Description	A blank field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

Connection

The **Connection** tab allows the user to configure the basic attributes required to connect to a data source. For the Microsoft ODBC Driver for DB2, the **Connection** tab has the following fields:

Parameter	Comments
Network transport	An option button (radio button) is used to select the network transport. Valid options are APPC Connection (SNA LU 6.2) or TCP/IP Connection. For the default, APPC Connection, the values for APPC local LU alias, APPC remote LU alias, and APPC Mode Name are required. For TCP/IP Connection, the values for IP address and Network port are required.
APPC local LU alias	When APPC Connection is selected, this field is the name of the local LU alias configured in Host Integration Server.
APPC remote LU alias	When APPC Connection is selected, this field is the name of the remote LU alias configured in Host Integration Server.
APPC mode name	When APPC Connection is selected, this field is the APPC mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). The default is typically QPCSUPP.
IP address	When TCP/IP Connection is selected as the network transport, this field indicates the IP address of the host DB2 server.
Network port	When TCP/IP Connection is selected as the network transport, this field indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default is IP port 446.

The **Connection** tab also includes a **Test connection** button that may be used to test the connection parameters. A connection can only be tested after all of the required parameters for the **Connection** tab and other ODBC data source parameters are configured properly. When this button is clicked, a session is established with the remote DB2 system using ODBC Driver for DB2

Security

The **Security** tab allows the user to configure optional attributes used to restrict connections to a data source.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2000, the Security tab has the following fields:

Parameter	Comments
Authentication	An option button (radio button) is used to select the type of authentication. Valid options are **Use this username** or **Use single signon**. For the default Use this username option, the value for the username is required.
Use this username	When this option is selected, authentication is based on the username entered in the textbox. A valid user name is normally required to access data on DB2. A user name can remain optionally in the DSN. The ODBC Driver for DB2 will prompt the user at run time to enter a valid password. Additionally, the prompt dialog will enable the user to override the user name that is stored in the DSN.
Use single signon	An option button to select whether single sign-on or a specific user name should be used. Single sign-on is an optional Host Security feature. Single sign on enables the administrator to create data source definitions that isolate the logon process from the end user. The user context for single sign on is the user context associated with the SNA DB2 Service. When running on Windows 95 or Windows 98, the user context is associated with the currently logged-on user.

For the ODBC Driver for DB2 in SNA Server 4.0, the **Security** tab has the following fields:

Parameter	Comments
Use single sign on	An option button to select whether single sign-on or a specific user name should be used. Single sign-on is an optional SNA Server Host Security feature. Single sign on enables the administrator to create data source definitions that isolate the logon process from the end user. The user context for single sign on is the user context associated with the SNA DB2 Service. When running on Windows 95 or Windows 98, the user context is associated with the currently logged-on user.
User Name	The user name to use if the **Use single sign-on** option button is not selected. A valid user name is normally required to access data on DB2. A user name can remain optionally in the DSN. The ODBC Driver for DB2 will prompt the user at run time to enter a valid password. Additionally, the prompt dialog will enable the user to override the user name that is stored in the DSN.
Database is Read-only	This option creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example).

The AS/400 computer is case sensitive with regard to user IDs and passwords. When connecting to DB2 for OS/400, user names and passwords must be in uppercase. The AS/400 only accepts a DB2 for OS/400 user ID and password in uppercase. If a DB2 for OS/400 connection fails due to incorrect authentication, the ODBC driver resends the authentication, forcing the user ID and password into uppercase.

When connecting to DB2 on IBM mainframes, user names and passwords can be of mixed case; the mainframe is not case sensitive. The ODBC driver sends these values in uppercase.

DB2 Universal Database (UDB) for Windows NT is case sensitive. The user ID is stored in uppercase. The password is stored in mixed case and users must enter the password in the correct case. The ODBC driver sends the password exactly in the case entered by the user. The user ID should contain only the user name, not a combination of the Windows NT domain name and user name.

It is possible to connect using a specific User name and Password defined in DB2 on the host system or use the single sign-on feature (often referred to as integrated Windows security). If a specific DB2 User name and Password is to be used, this information may need to be saved to a data source name (DSN) file. The User name and Password are saved in clear text in the DSN file or to registry keys if a System or User DSN is selected. For security reasons when using file DSNs, it is imperative that the DSN file be protected with an Access Control List (ACL) that restricts access to only authorized users. System and User DSNs are preferred for security reasons as long as the locations where these ODBC DSNs are stored in the registry have appropriate

security protections. Saving the User name and Password in the DSN also forces this DSN to be updated whenever the Password associated with the User name is changed. So for a variety of reasons, specifying a User name and Password is not the preferred authentication option. Using the Single sign-on option is the preferred method for authentication.

Target Database

The **Target Database** tab allows the user to configure required, as well as optional, attributes used to define the target DB2 system.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2000, the Target Database tab has the following fields:

Parameter	Comments
Initial catalog	This parameter is used as the first part of a three-part fully qualified DB2 table name. It is referred to by different names depending on the DB2 platform. In DB2 for OS/390 and DB2 for MVS, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 that you need to connect to on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
Package collection	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This can be the same as the default schema. The ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver creates packages dynamically in the location that the user points to using the Package Collection parameter. By default, the ODBC Driver for DB2 automatically creates one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single <AUTH_ID> only, where AUTH_ID is based on the user ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value specified in the connection. Problems can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), then the package is created only for use by this user. This means that other users may be unable to access the required package. The solution is for an administrative user with package administrative rights to create a set of packages for use by all users (see Creating Packages for Use with the ODBC Driver for DB2). The ODBC Driver for DB2 supplied with Host Integration Server 2000 includes a tool program for use by administrators to create packages. The crtpkg.exe tool is a Windows GUI application for use by the administrator to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. This utility will create a set of packages and grant EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system. The packages (see descriptions under the SQL_ATTR_TXN_ISOLATION connection attribute) created are as follows: AUTOCOMMITTED package (MSNC001 is only applicable on DB2/400) READ UNCOMMITTED package (MSUR001) READ COMMITTED package, (MSCS001) REPEATABLE READ package, (MSRS001) SERIALIZABLE package (MSRR001) Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400. Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE, the DB2 for OS/400 QSYS2.SYSPACKAGE, and the DB2 Universal Database (UDB) SYSIBM.SYSPACKAGE catalog tables. Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000. The package names changed from SNA Server 4.0.

Default schema	The name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses the Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at log on. For DB2/400, the driver uses QSYS2 if no collection is found matching the USER_ID value. This default is inappropriate in many cases so it is essential that the Default Schema value in the data source be defined.
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the Alternate TP Name in the off-line demo configuration (DRDADEMO.UDL). In that case, the Alternative TP Name is set to 0X07F9F9F9.
Distributed transactions	When this option is checked, two-phase commit (distributed unit of work) is enabled. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 V5R1 or later. This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.
Process binary as character	When this option is checked, it indicates that binary data fields should be processed as characters. This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. See the **Locale** tab.

For the ODBC Driver for DB2 in SNA Server 4.0, the **Target Database** tab has the following fields:

Parameter	Comments
Remote Database Name	This parameter is used as the first part of a three-part fully qualified DB2 table name. It is referred to by different names depending on the DB2 platform. In DB2 for OS/390 and DB2 for MVS, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 that you need to connect to on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.

Package Collection	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This can be the same as the default schema. The ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver creates packages dynamically in the location that the user points to using the Package Collection parameter. By default, the ODBC Driver for DB2 automatically creates one package in the target collection, if one does not exist, at the time the user issues their first SQL statement. The package is created with GRANT EXECUTE authority to a single < AUTH_ID> only, where AUTH_ID is based on the user ID value configured in the data source. The package is created for use by SQL statements issued under the same isolation level based on the Isolation Level value configured in the data source. A problem can arise in multi-user environments. For example, if a user specifies a Package Collection value that represents a DB2 collection used by multiple users, but this user does not have authority to GRANT execute rights to the packages to other users (the PUBLIC group on the DB2 system, for example), then the package is created for use only by this user. This means that other users may be unable to access the required package. The solution is for an administrative user, with package administrative rights (for example., PACKADM authority in DB2 for OS/390), to create a set of packages for use by all users. The ODBC Driver for DB2 supplied with SNA Server 4.0 includes two utility programs for use by administrators to create packages. The crtpkg.exe tool is a command line utility for the administrator to create packages. The crtpkgw.exe tool is a Windows GUI utility used for the same purpose. Either of these utilities can be run using a privileged user ID to create packages in collections accessed by multiple users. These utilities will create a sets of packages (see descriptions under the Default Isolation parameter) and grant EXECUTE privilege on these packages to the PUBLIC group representing all users on the DB2 system. The packages created are as follows: AUTOCOMMIT package (SNANC001) READ_UNCOMMITTED package (SNACH001) REPEATABLE_READ package, (SNARR001) READ_COMMITTED package, (SNACS001) SERIALIZABLE or REPEATABLE_READ package (SNAAL001) Once created, the packages are listed in the DB2 (mainframe) SYSIBM.SYSPACKAGE and DB2 for OS/400 QSYS.SYSPACKAGE.
Default Schema	The name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at log on. For DB2/400, the driver uses QSYS2 if no collection is found matching the USER_ID value. This default is inappropriate in many cases so it is essential that the Default Schema value in the data source be defined.

Default Isolation	This parameter determines the isolation level provided for the data source in cases of simultaneous access to DB2 objects by multiple applications. Valid settings for the default isolation level are: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2 for OS/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2 for OS/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2 for OS/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, this isolation level corresponds to Repeatable Read. RR—Repeatable Read. In DB2 for OS/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. Note that the ALL isolation level is not allowed. Users should set the isolation level to RS because it has the equivalent meaning and is defined in DB2 (ALL is not defined in any DB2 system).
Bind Type	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are: NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The NORM package binding option is designed to provide reasonable performance and maximum compatibility with different versions of DB2: DB2 for MVS, DB2 for OS/390, DB2 UDB, and DB2 for OS/400. Optionally, administrators can use the FAST method when running the Create Package utility and creating packages in many target collections. The FAST option should not be used with DB2 for MVS and DB2 UDB for Windows NT as a result of known incompatibilities. The default value for this parameter is NORM. This parameter is currently supported only by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2 or later and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
Alternate TP Name	The Alternate Transaction Program (TP) Name property represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.
Auto commit	A check box indicating whether auto commit mode is enabled. This parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. The default value for this parameter is true.
Convert all binary data types as character data types	This option treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. See the **Locale** tab.

Note that two-phase commit (distributed unit of work) and distributed transactions are not supported by the ODBC Driver for DB2 supplied with SNA Server 4.0.

Locale

The **Locale** tab allows the user to configure the parameters used for character conversion between the client and the DB2 server.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2000, the Locale tab has the following fields:

Parameter	Comments
Host CCSID	The coded character set identifier (CCSID) matching the DB2 data as represented on the remote computer. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the DB2 column CCSID and configured ANSI code page. This parameter defaults to U.S./Canada (37).
PC code page	This parameter indicates the personal computer code page to use. It is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

Two versions of the Locale tab are possible for the ODBC Driver for DB2 supplied with SNA Server 4.0 depending the Service Pack installed.

For the ODBC Driver for DB2 in SNA Server 4.0 Service Pack 2, the Locale tab has the following fields:

Parameter	Comments
Host Locale	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the Process Binary as Character value is configured, character data is converted based on the DB2 column CCSID and default ANSI code page. This parameter defaults to U.S./Canada (37).
Use default code page for locale	A checkbox indicating whether the default ANSI code page for Windows should be used for the personal computer locale. If this default setting is not selected, then the user may choose any supported personal computer Code Page
PC Locale	When the previous check box is not selected, this parameter indicates which personal computer Code Page to use. This parameter is required when processing binary data as character data. Unless the Process Binary as Character value is configured, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

For the ODBC Driver for DB2 included with the Japanese version of SNA Server 4.0 Service Pack 2 and for the ODBC Driver for DB2 included with all versions of the SNA Server 4.0 Service Pack 3 or later, the **Locale** tab has the following fields:

Parameter	Comments
Host CCSID	The character code set identifier (CCSID) group box allows you to select the appropriate CCSID values matching the DB2 data as represented on the remote computer.
Single CCSID	The coded character set identifier (CCSID) matching the DB2 data as represented on the remote computer. This property is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the DB2 column CCSID and configured ANSI code page. This parameter defaults to U.S./Canada (37).

Mixed CCSID	The mixed coded character set identifier (MCCSID) matching the DB2 data as represented on the remote computer. This property is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte character set (DBCS) data. When accessing DB2 for OS/390 or DB2 for MVS, a value must be specified for MCCSID if the "MIXED DATA" field (7) of the DB2 installation panel for Application Programming Defaults (DSNTIPF) is set to "YES." The following values for MCCSID are supported by the ODBC Driver for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is currently supported only by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2 or later and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
Graphics CCSID	The graphics coded character set identifier (GCCSID) matching the DB2 data represented on the remote computer. This property is required when accessing DB2 databases configured to support mixed single-byte and double-byte character set data. When accessing DB2 for OS/390 or DB2 for MVS, a value must be specified for MCCSID if the "MIXED DATA" field (7) of the DB2 installation panel for Application Programming Defaults (DSNTIPF) is set to "YES." The following values for GCCSID are supported by the ODBC Driver for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is currently supported only by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2 or later and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
PC Locale	This parameter indicates the personal computer Code Page to use. It is required when processing binary data as character data. Unless the Process Binary as Character value is set, character data is converted based on the default ANSI code page configured in Windows. The default value for this property is Latin 1 (1252).

Click the **OK** or **Cancel** button when data entry is finished. If you click the **OK** button, the values specified become the defaults when an application connects to this data source. These default values can be changed at any time using this procedure to reconfigure the data source. An ODBC application can override these defaults by connecting to the data source using a connection string with alternate values.

Configuration Property Mappings Between the ODBC Driver for DB2 and the OLE DB Provider for DB2

The following tables compare the configuration parameters used by the ODBC Driver for DB2 and the OLE DB Provider for DB2.

For the Microsoft ODBC Driver for DB2 in Host Integration Server 2000, the configuration parameters compare as follows:

Microsoft ODBC Driver for DB2	Microsoft OLE DB Provider for DB2
General	
Data Source Name	Data Source
Data Source Description	
Connection	
Connection	Network Transport Library
APPC Connection	SNA
TCP/IP Connection	TCPIP
APPC local LU Alias	APPC Local LU Alias
APPC remote LU Alias	APPC Remote LU Alias
APPC mode name	APPC Mode Name
IP address	Network Address
Network port	Network Port
Security	
Use this username	
User Name	User ID
Use Single Sign-on	Integrated Security.
Target Database	
Initial catalog	Initial Catalog
Package collection	Package Collection
Default schema	Default Schema
Alternate TP name	Alternate TP Name
Distributed transactions	Distributed transactions
Process binary as character	Process binary as character
Locale Tab	
Host CCSID	Host CCSID
PC code page	PC Code Page

For the Microsoft ODBC Driver for DB2 in SNA Server 4.0, the configuration parameters compare as follows:

Microsoft ODBC Driver for DB2	Microsoft OLE DB Provider for DB2
General	
Data Source Name	Data Source
Data Source Description	
Connection	
Connection	Network Transport Library
LU 6.2 Connection	SNA
TCP/IP Connection	TCPIP
Local APPC LU Alias	APPC Local LU Alias
Remote APPC LU Alias	APPC Remote LU Alias
APPC Mode Name	APPC Mode Name
IP Address	Network Address
Network Port	Network Port
Security	
Use this username	Persist Security Info
User Name	User ID
Password	Password

Use Single Sign-on	
Database is read-only	
Target Database	
Remote Database Name	Initial Catalog
Package Collection	Package Collection
Default Schema	Default Schema
Default Isolation	Default Isolation Level
Alternate TP Name	Alternate TP Name
BindType	BindType
Auto Commit	Auto Commit Mode
Convert Binary Data Types as Character Data Types	Process Binary as Character
Locale	
Host Locale	Host CCSID
Use default code page for locale	
PC Locale	PC Code Page
Locale (SNA Server 4.0 Service Pack 2 Japanese version and SNA Server 4.0 Service Pack 3 or later)	
System CCSID	Host CCSID
Mixed CCSID	Mixed CCSID
Graphics CCSID	Graphics CCSID
PC Locale	PC Code Page

ODBC Connection String Attributes

The ODBC **SQLBrowseConnect** and **SQLDriverConnect** functions allow passing in a connection string containing a series of attribute/value pairs to the ODBC Driver Manager to establish a connection with a data source. An example of a connection string :

```
"DSN=MYDATA;NTL=SNA;LLU=Local;RMU=Remote;RDB=BigData;PC=QSYS2;
DS=QSYS2;RO=false;UID=myname;PWD=Secret"
```

Some ODBC attributes are required as part of the connection string when used with the ODBC Driver for DB2.

The following tables compare the configuration parameters used by the ODBC Driver for DB2 and the ODBC attribute keywords that are supported by the OLE DB Driver for DB2 as part of the passed-in connection string.

For the ODBC Driver for DB2 in Host Integration Server 2000, these attribute keywords compare as follows:

Microsoft ODBC Driver for DB2	**ODBC Attribute Keyword**	**Comments**
General Tab		
Data Source Name	DSN	Required parameter.
Data Source Description	DESC	
Connection Tab		
Connection	NTL	Required parameter.
APPC connection	NTL=SNA	
TCP/IP connection	NTL=TCPIP	
APPC local LU alias	LLU	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC remote LU alias	RLU	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
APPC mode name	MN	Applicable only if SNA (an APPC connection) is used for the network transport library (NTL=SNA).
IP address	NA	Applicable only if TCPIP (a TCP/IP connection) is used for the network transport library (NTL=TCPIP).
Network port	NP	Applicable only if TCPIP (a TCP/IP connection) is used for the network transport library (NTL=TCPIP).
Security Tab		
Use this username		
User Name	UID	
	PWD	The Password parameter is not on the Security Tab and is not configurable from the ODBC Administrator tool used to configure ODBC data sources. This parameter can only be preset using the ODBC connection string. Most applications will prompt the user for this parameter.
Use single sign-on		Not applicable
Target Database Tab		
Initial Catalog	RDB	Required parameter.
Package Collection	PC	Required parameter.

Default Schema	DS	Required parameter.
Alternate TP Name	TPN	
Distributed transactions	RUW	
Process binary as character	BAC	
Locale Tab		
Host CCSID	CCSID	Required parameter.
PC code page	CP	Required parameter.

For the ODBC Driver for DB2 supplied with Host Integration Server 2000, these attribute keywords compare as follows:

Microsoft ODBC Driver for DB2	**ODBC Attribute Keyword**	**Comments**
General Tab		
Data Source Name	DSN	Required parameter.
Data Source Description	DESC	
Connection Tab		
Connection	NTL	Required parameter.
LU 6.2 Connection	NTL=SNA	
TCP/IP Connection	NTL=TCPIP	
Local APPC LU Alias	LLU	Applicable only if SNA is used for the network transport library.
Remote APPC LU Alias	RLU	Applicable only if SNA is used for the network transport library.
APPC Mode Name	MN	Applicable only if SNA is used for the network transport library.
IP Address	NA	Applicable only if TCPIP is used for the network transport library.
Network Port	NP	Applicable only if TCPIP is used for the network transport library.
Security Tab		
Use this username		
User Name	UID	
Password	PWD	
Use Single Sign-on		Not applicable
Database is read only	RO	
Target Database Tab		
Remote Database Name	RDB	Required parameter.
Package Collection	PC	Required parameter.
Default Schema	DS	Required parameter.
Default Isolation	DIL	
Alternate TP Name	TPN	
BindType	BT	This parameter is only supported by the ODBC Driver included with SNA Server 4.0 Service Pack 2 Japanese version and SNA Server 4.0 Service Pack 3 or later.
Auto Commit	ACM	
Convert Binary Data Types as Character Data Types	BAC	
Locale Tab		
Host Locale	CCSID	Required parameter.
Use default code page for locale		
PC Locale	CP	Required parameter.
Locale (SNA Server 4.0 Service Pack 2 Japanese version and SNA Server 4.0 Service Pack 3 and later)		
System CCSID	CCSID	Required parameter.

Mixed CCSID	MCCSID	Required parameter.
Graphics CCSID	GCCSID	Required parameter.
PC Locale	CP	Required parameter.

Creating Packages for Use with the ODBC Driver for DB2

The ODBC Driver for DB2, which is implemented as an IBM Distributed Relational Database Architecture (DRDA) Application Requester, uses packages to issue SQL statements and call DB2 stored procedures. There is a configuration parameter that the ODBC Driver for DB2 uses to identify a location in which to create and store DB2 packages. The ODBC Driver for DB2 will create packages dynamically in the location to which the user points using the Package Collection parameter. This location may be configured using the Target Database tab from the Microsoft ODBC Data Source Administrator tool or can be passed as part of the ODBC connection string as an attribute keyword and argument. The attribute keyword for Package Collection is PC.

There are two package creation options:

1. The ODBC Driver for DB2 will auto-create one package for the currently-used isolation level at run-time if no package already exists. This auto-create process may fail if the user account does not have authority to create packages.
2. An administrator or user can manually creates all four packages (five packages on DB2/400) for use with all isolation levels and for use by all users (the PUBLIC group on DB2 representing all users) or a specific set of users. The ODBC Driver for DB2 includes a utility program for use by users with appropriate administrative privilege that will create these packages and grant access to the PUBLIC group for this purpose.

However, some users may not have the security level when manually creating packages to GRANT authority to the packages to other users (grant authority to the DB2 PUBLIC group representing all users, for example). This can be a problem if two or more users with different user IDs try to access a single collection of packages. The first user that created the packages will have access to the packages, but the second user likely will not. The Host Integration Server 2000 CD-ROM includes a program for use by an administrator or a user with appropriate privileges to create packages. This tool can be run using a privileged User ID to create packages in collections accessed by multiple users. The Create Packages for DB2 utility, CrtPkg, is a GUI-based tool included with Host Integration Server 2000 for creating packages for use with DB2. This tool (CrtPkg.exe) is installed in the System folder below the subdirectory where the Microsoft Host Integration Server 2000 has been installed. The default location where this tool is installed is the following:

Program Files\Host Integration Server\system\CrtPkg.exe

A shortcut for this tool is added to the **Programs** Menu off the Start button on the Windows Taskbar under the **Host Integration Server\Data Integration** folder with a name of **Packages for DB2**. This shortcut is created when the Microsoft Host Integration Server or the Host Integration Client are first installed and support for Data Access is checked.

This tool will create a set of packages and grant EXECUTE privileges on these packages to the PUBLIC group. The PUBLIC group on DB2 systems is a default group that represents all DB2 users. The following packages are created:

- AUTOCOMMITTED package (MSNC001) is only applicable on DB2/400)
- READ UNCOMMITTED package (MSUR001)
- READ COMMITTED package (MSCS001)
- REPEATABLE READ package (MSRS001)
- SERIALIZABLE package (MSRR001)

Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

The descriptive process name used by the CrtPkg utility of each package corresponds with the isolation levels defined in the ANSI SQL standard. The table below indicates how these packages correspond with the terms used by IBM for isolation levels in DB2 documentation.

Package Description	**Package Name**	**IBM Documentation**
AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level	MSNC001	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 auto-commit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.
READ UNCOMMITTED	MSUR001	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.

READ COMMITTED	MSCS001	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
REPEATABLE READ	MSRS001	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.
SERIALIZABLE	MSRR001	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000. The package names used by the ODBC Driver for DB2 on SNA Server 4.0 are not compatible with the ODBC Driver for DB2 included with Host Integration Server. On SNA Server 4.0, these packages used different names as follows:

```
AUTOCOMMITTED package (SNANC001) only applicable on DB2/400
READ UNCOMMITTED package (SNACH001)
READ COMMITTED package, (SNACS001)
REPEATABLE READ package, (SNARR001)
SERIALIZABLE package (SNAAL001)
```

These Isolation Levels are described in detail under Support for Isolation Levels Using the ODBC Driver for DB2. These Isolation Levels are also described under the ADO IsolationLevel property. Note that the AUTOCOMMITTED package (MSNC001) is only created on DB2 for OS/400.

Note that the CrtPkg tool creates this set of packages and grants EXECUTE privileges to PUBLIC. There may be cases for security reasons where EXECUTE privileges to this set of packages should be restricted to a certain group of users or specific users. In these cases, execution privileges on these created packages will need to be modified on the host system.

The CrtPkg utility will create all of these packages inside the Collection that is specified in the Package Collection property in the datalink file, or in the connection string. If the user does not have the appropriate authority to create packages in the specified Collection, or if the specified Collection does not exist, the ODBC Driver for DB2 will return an error.

In the case of DB2 on MVS or OS/390, the normal error text returned if the user does not the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -567.
```

In the case of DB2/400, the normal error text returned if the user does not the appropriate authority would be as follows:

```
A SQL error has occurred. Please consult the documentation for your specific DB2 version for
a description of the associated Native Error and SQL State. SQLSTATE: 51002, SQLCODE: -805.
```

In the case of DB2/400, the normal error returned if the collection does not exist would be as follows:

```
Failed to create AUTOCOMMITTED (NC) package.  RETCODE=-99.
SQL Error: Code=-204, State=42704, Error Text= A SQL error has occurred.  Please consult the
documentation for your specific DB2 version for a description of the associated Native Error
and SQL State. SQLSTATE: 42704, SQLCODE: -204
```

There are two authorities required to execute the create package process on OS/390 or MVS using the CrtPkg utility:

```
GRANT BINDADD TO <authorization ID>
GRANT CREATE IN COLLECTION <collection ID> TO <authorization ID>
```

The "authorization ID" is the user who needs the permission to create the packages. The "collection ID" is the name of the Collection, which the user specifies in the datalink file for the Package Collection property. This Collection should be a valid Collection within the DB2.
If an administrator executes the above statements on behalf a non-privileged user, then this non-privileged user can then run the CrtPkg utility. Once run, the CrtPkg process will create four sets of packages (one for each of the four isolation levels supported on DB2 for MVS or OS/390) for use by "all" (PUBLIC) users of the Microsoft data access features.

The example below illustrates this process on DB2 for MVS or DB2 for OS/390.

Grant rights to run the CrtPkg utility to authorization ID WNW999

```
GRANT BINDADD TO WNW999
GRANT CREATE IN COLLECTION MSPKG TO WNW999
```

Run the CrtPkg utility using authorization ID WNW999 (see the output from CrtPkg below)

```
Beginning creation process
Initializing environment...
Connecting to the host...
Connection established.
Start package creation process...
Creating READ UNCOMMITTED package...
READ UNCOMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSUR001            granted to PUBLIC
Creating READ COMMITTED package...
READ COMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSCS001            granted to PUBLIC
Creating REPEATABLE READ package...
REPEATABLE READ package created.
Package creation succeeded.
EXECUTE privilege on MSRS001            granted to PUBLIC
Creating SERIALIZABLE package...
SERIALIZABLE package created.
Package creation succeeded.
EXECUTE privilege on MSRR001            granted to PUBLIC
Free statement handles...
Disconnecting...
Disconnected
End of package creation.
Creation process has completed
```

In order to execute the CrtPkg utility on DB2/400, a user ID must have one of the following authorities:

- *CHANGE authority on the DB2 collection
- *ALL authority on the DB2 collection

If the user merely has *USE authority or if the user has *EXCLUDE authority, the Create Package process will fail.

There are several steps required to change user authority on a DB2/400 collection (AS/400 library): From interactive SQL (STRSQL command) while logged in as user with administrative privileges, create a new collection. This command can also be issued using ADO, OLE DB, and ODBC. However, most administrators typically create collections from the AS/400 console since the administrator must be logged in at the console to issue the Command Language (CL) command with which to change the user authority on the collection.

```
CREATE COLLECTION <collection ID>
```

From the AS/400 command console, issue the CL WRKOBJ command with the <collection ID> as a parameter.

```
WRKOBJ <collection ID>
```

The "collection ID" is the name of the Collection, which the user specifies in the datalink file for the Package Collection property. This Collection should be a valid Collection within DB2. The Work with objects screen appears. Place the cursor on the *PUBLIC Object Authority line and change the authority from *USE to *ALL.

If an administrator executes the above statements on behalf a non-privileged user, then this non-privileged user can then run the CrtPkg utility. Once run, the CrtPkg process will create five sets of packages (one for each of the five isolation levels supported on DB2/400) for use by "all" (PUBLIC) users of the Microsoft data access features. On DB2/400, five packages are created including the AUTOCOMMITTED packages.

The example below illustrates this process on DB2/400.

Grant rights to run the CrtPkg utility to authorization ID WNW999

```
CREATE COLLECTION MSPKG
WRKOBJ MSPKG
```

Run the CrtPkg utility (see the output from CrtPkg for DB2/400 below)

```
Beginning creation process
Initializing environment...
Connecting to the host...
Connection established.
Start package creation process...
Creating AUTOCOMMITTED (NC) package...
AUTOCOMMITTED (NC) package created.
Package creation succeeded.
EXECUTE privilege on MSNC001            granted to PUBLIC
Creating READ UNCOMMITTED package...
READ UNCOMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSUR001            granted to PUBLIC
Creating READ COMMITTED package...
READ COMMITTED package created.
Package creation succeeded.
EXECUTE privilege on MSCS001            granted to PUBLIC
Creating REPEATABLE READ package...
REPEATABLE READ package created.
Package creation succeeded.
EXECUTE privilege on MSRS001            granted to PUBLIC
Creating SERIALIZABLE package...
SERIALIZABLE package created.
Package creation succeeded.
EXECUTE privilege on MSRR001            granted to PUBLIC
Free statement handles...
Disconnecting...
Disconnected
End of package creation.
Creation process has completed
```

CrtPkg allows a user to create a new DSN file or load a data source and modify an existing DSN file for connection configuration information. The File menu of CrtPkg has a New option used for creating a new ODBC DSN file or UDL File and a Load Data Source option to load an existing DSN or UDL file. The File menu Edit Data Source option allows a user to access and modify the parameters for a data source similar to using the NewSnaDS.exe tool. The Run menu option is used to create packages.

When using the create package tool, if the package collection specified does not exist, then DB2 returns SQLCODE -805.

When using auto-create packages, if a package collection is not specified or the package collection does not exist, then during the "auto-create" package process, the consumer application will receive SQLSTATE HY000 and SQLCODE -385. The SQLSTATE HY000 is defined as a driver-specific error. The -385 Error Return Code is not a SQLCODE but rather a DDM DRDA AR (DB2 client) return code. This error code is defined as DDM_VALNSPRM with the following associated text string:

```
"The parameter value is not supported by the target system."
```

The ODBC Driver for DB2 client error codes are defined in the db2oledb.h file located on the Host Integration Server 2000 CD-ROM.

Note that when upgrading from SNA Server 4.0, any existing SNA 4.0 packages must be recreated using the Host Integration Server CrtPkg utility to make them compatible with Host Integration Server 2000.

SNA Server 4.0 with Service Pack 3 came with two similar utilities for creating packages: CRTPKGW.EXE (a command-line tool) and CRTPKGW.EXE (a GUI-based tool).

ODBC Conformance

The Microsoft® ODBC Driver for DB2 supports ODBC 2.*x* and ODBC 3.*x* functions. SQL grammar conformance varies, depending on the version of the DB2 database that is accessed. The following sections list the ODBC functions and attributes supported by the Microsoft ODBC Driver for DB2.

This section contains:

Support for ODBC 2 Core Functions

The following table lists the ODBC 2.*x* Core functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* Core Functions	**Functions Supported by the Microsoft ODBC Driver for DB2**
SQLAllocConnect	Yes
SQLAllocEnv	Yes
SQLAllocStmt	Yes
SQLBindCol	Yes
SQLCancel	Yes
SQLColAttributes	Yes
SQLConnect	Yes
SQLDescribeCol	Yes
SQLDisconnect	Yes
SQLError	Yes
SQLExecDirect	Yes
SQLExecute	Yes
SQLFetch	Yes
SQLFreeConnect	Yes
SQLFreeEnv	Yes
SQLFreeStmt	Yes
SQLGetCursorName	Yes
SQLNumResultCols	Yes
SQLPrepare	Yes
SQLRowCount	Yes
SQLSetCursorName	Yes
SQLSetParam	In ODBC 2.0, the ODBC 1.0 SQLSetparam function was replaced by SQLBindParameter.
SQLTransact	Yes

Support for ODBC 2 Level 1 Functions

The following table lists the ODBC 2.*x* level 1 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* Level 1 Functions	**Functions Supported by the Microsoft ODBC Driver for DB2**
SQLBindParameter	Yes
SQLColumns	Yes
SQLDriverConnect	Yes
SQLGetConnectOption	Yes
SQLGetData	Yes
SQLGetFunctions	Yes
SQLGetInfo	Yes
SQLGetStmtOption	Yes
SQLGetTypeInfo	Yes
SQLParamData	Yes
SQLPutData	Yes
SQLSetConnectOption	Yes
SQLSetStmtOption	Yes
SQLSpecialColumns	Yes
SQLStatistics	Yes
SQLTables	Yes

Support for ODBC 2 Level 2 Functions

The following table lists the ODBC 2.*x* level 2 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* Level 2 Functions Supported	**Functions Supported by the Microsoft ODBC Driver for DB2**
SQLBrowseConnect	No
SQLColumnPrivileges	No
SQLDataSources	Yes. This function is actually supported by the ODBC Driver Manager.
SQLDescribeParam	No
SQLDrivers	Yes. This function is actually supported by the ODBC Driver Manager.
SQLExtendedFetch	Yes, but supports forward scrolling only.
SQLForeignKeys	No
SQLMoreResults	Yes
SQLNativeSQL	Yes
SQLNumParams	Yes
SQLParamOptions	Yes
SQLPrimaryKeys	Yes, but SQL grammar conformance varies depending on the version of the DB2 database being accessed.
SQLProcedureColumns	No
SQLProcedures	Yes.
SetPos	Yes
SQLSetScrollOptions	Yes
SQLTablePrivileges	No

Support for ODBC 3 Functions

The following table lists the ODBC 3.0 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 3.0 Functions	Functions Supported by the Microsoft ODBC Driver for DB2
SQLAllocHandle	Yes
SQLBulkOperations	No
SQLCloseCursor	Yes
SQLColAttribute	Yes
SQLCopyDesc	Yes
SQLEndTran	Yes
SQLFetchScroll	Yes, but supports forward scrolling only.
SQLFreeHandle	Yes
SQLGetConnectAttr	Yes
SQLGetDescField	Yes
SQLDescRec	Yes
SQLGetDiagField	Yes
SQLGetDiagRec	Yes
SQLGetEnvAttr	Yes
SQLGetStmtAttr	Yes
SQLRowCount	Yes.
SQLSetConnectAttr	Yes
SQLSetDescField	Yes
SQLSetDescRec	Yes
SQLSetEnvAttr	Yes
SQLSetStmtAttr	Yes

Support for ODBC Connection Attributes

The following table lists the ODBC connection attribute support using the Microsoft ODBC Driver for DB2. Note that the connection attributes in this list use the ODBC Version 3.0 attribute names, rather than the older ODBC 1.0 names.

ODBC Connection Attribute	ODBC Version	Attribute Supported by the Microsoft ODBC Driver for DB2
SQL_ATTR_ACCESS_MODE	1.0	Yes
SQL_ATTR_ASYNC_ENABLE	3.0	No
SQL_ATTR_AUTO_IPD	3.0	No
SQL_ATTR_AUTOCOMMIT	1.0	Yes
SQL_ATTR_CONNECTION_DEAD	3.5	No
SQL_ATTR_CONNECTION_TIMEOUT	3.0	No
SQL_ATTR_CURRENT_CATALOG	2.0	Yes
SQL_ATTR_ENLIST_IN_DTC	3.0	Yes
SQL_ATTR_ENLIST_IN_XA	3.0	No
SQL_ATTR_LOGIN_TIMEOUT	1.0	No
SQL_ATTR_METADATA_ID	3.0	No
SQL_ATTR_ODBC_CURSORS	2.0	Yes, handled by ODBC Driver Manager.
SQL_ATTR_PACKET_SIZE	2.0	No
SQL_ATTR_QUIET_MODE	2.0	Yes
SQL_ATTR_TRACE	1.0	Yes, handled by ODBC Driver Manager.
SQL_ATTR_TRACEFILE	1.0	Yes, handled by ODBC Driver Manager.
SQL_ATTR_TRANSLATE_LIB	1.0	No
SQL_ATTR_TRANSLATE_DLL	1.0	No
SQL_ATTR_TRANSLATE_OPTION	1.0	No
SQL_ATTR_TXN_ISOLATION	1.0	Yes

Support for ODBC Statement Attributes

The following table lists the ODBC statement attribute support using the Microsoft ODBC Driver for DB2. Note that the statement attributes in this list use the ODBC Version 3.0 attribute names, rather than the older ODBC 1.0 names.

ODBC Statement Attribute	ODBC Version	Attribute Supported by the Microsoft ODBC Driver for DB2
SQL_ATTR_APP_PARAM_DESC	3.0	Yes
SQL_ATTR_APP_ROW_DESC	3.0	Yes
SQL_ATTR_ASYNC_ENABLE	1.0	No
SQL_ATTR_CONCURRENCY		No
SQL_ATTR_CURSOR_SCROLLABLE	3.0	No
SQL_ATTR_CURSOR_SENSITIVITY	3.0	No
SQL_ATTR_CURSOR_TYPE	1.0	Yes, but the ODBC Driver for DB2 supports a forward only cursor type.
SQL_ATTR_ENABLE_AUTO_IPD	3.0	No
SQL_ATTR_FETCH_BOOKMARK_PTR	3.0	No
SQL_ATTR_IMP_PARAM_DESC		Yes, handled by ODBC Driver Manager.
SQL_ATTR_IMP_ROW_DESC		Yes, handled by ODBC Driver Manager.
SQL_ATTR_KEYSET_SIZE	1.0	No
SQL_ATTR_MAX_LENGTH	1.0	No
SQL_ATTR_MAX_ROWS	1.0	No
SQL_ATTR_METADATA_ID	3.0	Yes
SQL_ATTR_NOSCAN	1.0	Yes
SQL_ATTR_PARAM_BIND_OFFSET_PTR	3.0	Yes
SQL_ATTR_PARAM_BIND_TYPE	3.0	Yes
SQL_ATTR_PARAM_OPERATION_PTR	3.0	Yes
SQL_ATTR_PARAM_STATUS_PTR	3.0	Yes
SQL_ATTR_PARAMS_PROCESSED_PTR	3.0	Yes
SQL_ATTR_PARAMSET_SIZE	3.0	Yes
SQL_ATTR_QUERY_TIMEOUT	1.0	No
SQL_ATTR_RETRIEVE_DATA	1.0	No
SQL_ATTR_ROW_ARRAY_SIZE	3.0	Yes
SQL_ATTR_ROW_BIND_OFFSET_PTR	3.0	Yes
SQL_ATTR_ROW_BIND_TYPE	1.0	Yes
SQL_ATTR_ROW_NUMBER	1.0	No
SQL_ATTR_ROW_OPERATION_PTR	3.0	No
SQL_ATTR_ROW_STATUS_PTR	3.0	Yes
SQL_ATTR_ROWS_FETCHED_PTR	3.0	Yes
SQL_ATTR_SIMULATE_CURSOR	1.0	No
SQL_ATTR_USE_BOOKMARKS	1.0	No

Programming Considerations Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 provides pass through support for SQL statements. No SQL parsing is provided. The user must know what SQL syntax is supported for the target DB2 implementation. For information on what SQL syntax is supported, see the specific DB2 SQL Reference and DB2 Application Programming and SQL Guide for the DB2-specific platform.

The ODBC Driver for DB2 does not parse the SQL statements to qualify table names. Consequently, users of the ODBC Driver for DB2 must use either two-part or three-part (fully-qualified) object names when naming tables, views, and stored procedures in DB2. A two-part table name would consist of the user ID and table, <UserID>.<Table>. One-part names (just the table name) will not succeed unless the combination of the DB2 collection and schema name correspond directly to the ODBC User ID

The Microsoft ODBC Driver for DB2 does not insert the correct value for the fraction when using a parameterized insert with the TIMESTAMP data type.

The Microsoft Data Access Components (MDAC) support the option of using a client cursor engine. This service component is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the CursorLocation property on the recordset to adUseClient. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must configure the ODBC Driver for DB2 Auto Commit Mode property in the DSN or connection string to FALSE. This is not required when connecting to DB2 for OS/400.

The ODBC Driver for DB2 included with Host Integration Server 2000 supports updating capabilities when used with a client cursor engine and the following requirements are met:

- To support updates (UPDATE, INSERT, and DELETE) , the values in at least one column in the target table must be unique.
- The Auto Commit parameter must be set to FALSE when configuring the data source or when this parameter is passed as part of a connection string.

Previous versions of the ODBC Driver for DB2 do not support any updating capabilities when used with a client cursor engine. In other words, if a client cursor engine is enabled using RDS or ADO, the ODBC Driver for DB2 cannot be used to update data on the host. The ADO recordset is treated as if it were read-only. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must configure the ODBC Driver for DB2 Auto Commit parameter in the data source or connection string to FALSE. This is not required when connecting to DB2 for OS/400.

When the intent is to update records with a server-side cursor, DB2 requires that the SQL SELECT statement also include the FOR UPDATE option. For example, to select all records from the AUTHORS table in the DB2 collection called PUBS with an intent to update requires the following SQL syntax:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE
```

When using DB2 for MVS V4R1 and DB2 for OS/400 V3R2, there are further requirements to indicate the columns that you intend to update. For example, to update the AU_LNAME and AU_FNAME columns in the PUBS.AUTHORS table, the following SQL syntax must be used:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE OF AU_LNAME, AU_FNAME
```

The Microsoft ODBC Driver for DB2 provides support for distributed transactions and DRDA Distributed Unit of Work, and can participate in a distributed transaction coordinated by Microsoft Distributed Transaction Coordinator. This feature is only available when connecting to one of the following across an LU 6.2 network connection:

- DB2 for OS/390 V5R1 or later.
- DB2 for DB2/400 V4R3 or later.

This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed. The Microsoft ODBC Driver for DB2 does not support automatic transaction enlistment under Microsoft Transaction Server.

Applications should not commit or roll back transactions by executing COMMIT or ROLLBACK statements using the SQLExecute or SQLExecDirect ODBC functions. The effects of doing this are undefined and the ODBC Driver for DB2 no longer knows when a transaction is active. Applications should call the SQLEndTran ODBC function instead.

Microsoft Visual Studio 6.0 offers a number of ADO data-bound controls, including a datagrid and the ADO Data Control. When

using these ADO data controls, the developer must set the CursorLocation property on the recordset to adUseClient. Additionally, when using these ADO data controls with DB2 for OS/390, the developer must set the ODBC Driver for DB2 Auto Commit parameter in the data source or connection string to FALSE.

The Microsoft ODBC Driver for DB2 is not supported when used in conjunction with the Microsoft SQL Server 7.0 Replication feature. In place of the ODBC driver, use the Microsoft OLE DB Provider for DB2.

Microsoft Query (MSQUERY) supplied with Excel and Office can be used to access ODBC data sources using the ODBC Driver for DB2. When a data of a column defined with TIMESTAMP data type is updated using Microsoft Query, the microseconds portion of the TIMESTAMP is not updated properly. The net result is that updating any TIMESTAMP value using Microsoft Query will cause the loss of fractional seconds.

The Microsoft ODBC Driver for DB2 is not supported for use with the Microsoft ODBC .NET Data Provider. When accessing DB2 from ADO.NET, use the Microsoft OLE DB Provider for DB2 in conjunction with the Microsoft OLE DB .NET Data Provider.

This section contains:

Stored Procedure Support Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 supports calling DB2 stored procedures. An application must use the CALL keyword before the SQL statement in order to execute a stored procedure. When using ADO, a CommandType property of adCmdStoredProc cannot be used for executing a stored procedure since ADO inserts an EXEC not CALL keyword before the command text. In order to execute a stored procedure using ADO, the **CommandType** property should be set to adCmdText and the CALL keyword should be used before the SQL statement containing the stored procedure to be executed.

When calling DB2 stored procedures using the ODBC Driver for DB2, the following limitations apply:

- Binding output parameters of types REAL or DOUBLE are not supported.
- Calling stored procedures when the parameter values contain CHAR Mixed or GRAPHIC (DBCS) data types are not supported.
- Calling a non-existent procedure causes error.
- The ODBC Driver for DB2 does not return single or multiple result sets.

Support for Isolation Levels Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 provides flexibility in dealing with issues of isolation levels and transaction state. The ODBC **SQLSetConnectAttr** function is used to set the isolation level that is to be used for a connection. This function would be called with the attribute parameter set to SQL_ATTR_TXN_ISOLATION and the ValuePtr parameter pointing to an integer value indicating the isolation level requested. This integer value is a 32-bit bitmask that sets the transaction isolation level for the current connection.

The allowable values for isolation level (the ValuePtr parameter when calling SQLSetConnectAttr) can be determined by calling SQLGetInfo with InfoType equal to SQL_TXN_ISOLATION_OPTION. The following table list the allowable values for isolation level using the ODBC Driver for DB2 supplied with Host Integration Server.

ODBC Isolation Level Attribute	**Description**
SQL_TXN_READ_COMMITTED	When this attribute value is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This is the default value for isolation level This isolation level is also called Cursor Stability (CS) in IBM DB2 documentation.
SQL_TXN_READ_UNCOMMITTED	When this attribute value is set, it does not isolate data read from changes by others and changes made by others by others can be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This isolation level is called Uncommitted Read (UR) in IBM DB2 documentation.
SQL_TXN_REPEATABLE_READ	When this attribute value is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the read statement is affected by others. This supports a repeatable read. This isolation level is called Read Stability (RS) in IBM DB2 documentation.
SQL_TXN_SERIALIZABLE	When this attribute value is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is not affected by others. This supports a repeatable read. This isolation level is called Repeatable Read (RR) in IBM DB2 documentation.

The SQL_ATTR_TXN_ISOLATION attribute can be set only if there are no open transactions on the connection. An application must call **SQLEndTran** to commit or roll back all open transactions on a connection, before calling **SQLSetConnectAttr** with this option.

Some connection attributes support substitution of a similar value if the data source does not support the value specified in *ValuePtr*. In such cases, the driver returns SQL_SUCCESS_WITH_INFO and SQLSTATE 01S02 (Option value changed). To determine the substituted value, an application calls SQLGetConnectAttr.

Code Page Support Using the ODBC Driver for DB2

When creating data sources or file DSNs for use with the ODBC Driver for DB2, the Host character code set identifier (CCSID) should be configured in the data source to match the DB2 data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37).

Depending on the version of Windows being used, to support specific code page conversions, you may need to install the appropriate National Language Support (NLS) file for your locale.

On Windows 2000, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows 2000.

On Windows NT 4.0, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows NT or when you install the Windows NT Language Pack on a non-localized version of Windows NT. The Windows NT Language Pack is available on the Windows NT 4.0 CD-ROM in the LANGPACK directory. You install the locale components of the language pack as needed by either making a change in the Control Panel Locales applet or by installing one of the locale-specific INF files.

On Windows 98 and Windows 95, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows 98 or Windows 95.

The following sections discuss the character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2000.The The tables in these sections list the INF files by name that are required under Windows NT 4.0 for a specific codepage (european.inf, for example). Typically you would install locales one at a time as needed.

This section contains:

ANSI Code Page Support Using the ODBC Driver for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured to use ANSI code pages, for example ANSI 1253 (Greek). Host Integration Server 2000 includes support for some ANSI code pages for purposes of ANSI-to-UNICODE-to-ANSI conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ANSI code pages can be used when accessing IBM DB2 Universal Database on Windows NT and IBM DB2 ON AIX (not all of these ANSI code pages are supported on IBM DB2 Universal Database for AIX).

The following table shows the ANSI character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ANSI - Arabic	1256	1256	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
ANSI - Baltic	1257	1257	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ANSI - Cyrillic	1251	1251	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
ANSI - Central Europe	1250	1250	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ANSI - Greek	1253	1253	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
ANSI - Hebrew	1255	1255	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
ANSI - Latin I	1252	1252	Support for this codepage is normally installed as part of the operating system on Windows 2000, Windows NT, Windows 98, and Windows 95. On Windows NT 4.0, support for this NLS Code Page is installed using the us_eng.inf file from the Language Pack.
ANSI - Turkish	1254	1254	On Windows NT 4.0, support for this NLS Code Page is installed using the turkish.inf file from the Language Pack.
ANSI/OEM - Japanese Shift JIS	932	932	On Windows NT 4.0, support for this NLS Code Page is installed using the japanese.inf file from the Language Pack.
ANSI/OEM - Korean	949	949	On Windows NT 4.0, support for this NLS Code Page is installed using the korean.inf file from the Language Pack.
ANSI/OEM - Simplified Chinese GBK	936	936	On Windows NT 4.0, support for this NLS Code Page is installed using the exchsrvr.inf file from the Language Pack.
ANSI/OEM - Thai	874	874	On Windows NT 4.0, support for this NLS Code Page is installed using the thai.inf file from the Language Pack.
ANSI/OEM - Traditional Chinese Big5	950	950	On Windows NT 4.0, support for this NLS Code Page is installed using the tchinese.inf file from the Language Pack.
ANSI/OEM - Viet Nam	1258	1258	On Windows NT 4.0, support for this NLS Code Page is installed using the vietnam.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows 2000 or Windows NT definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ANSI-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page parameter using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ANSI code page in IBM publications, which for these supported ANSI CCSIDs are the same as the Microsoft CCSID values. IBM lists their ANSI support in publications by referencing the display name which for these ANSI code pages is the same as the Microsoft display name. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources. The ODBC Driver for DB2 maps the Microsoft NLS numbers to ANSI NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

These are the only ANSI pages currently supported by the ODBC Driver for DB2 in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional ANSI pages, however, the ANSI code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM ANSI code pages (CCSIDs) match.

EBCDIC Code Page Support Using the ODBC Driver for DB2

IBM DB2 for MVS, IBM DB2 for OS/390, and IBM DB2 for OS/400 are frequently configured to use EBCDIC code pages, for example EBCDIC 875 (Greek Modern). Host Integration Server 2000 includes support for most EBCDIC code pages for purposes of EBCDIC-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-EBCDIC, and EBCDIC-to-UNICODE-to-EBCDIC conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These EBCDIC code pages can be used when accessing IBM DB2 on a variety of platforms (not all of these EBCDIC code pages are supported on all versions of IBM DB2).

The following table shows the EBCDIC character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
IBM EBCDIC - Arabic	20420	420	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
IBM EBCDIC - Cyrillic (Russian)	20880	880	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
IBM EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
IBM EBCDIC - Denmark/Norway	20277	277	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Denmark/Norway (Euro)	1142	1142	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Finland/Sweden	20278	278	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Finland/Sweden (Euro)	1143	1143	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - France	20297	297	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - France (Euro)	1147	1147	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Germany	20273	273	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Germany (Euro)	1141	1141	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Greek	20423	423	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
IBM EBCDIC - Greek (Modern)	875	875	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
IBM EBCDIC - Hebrew	20424	424	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
IBM EBCDIC - Icelandic	20871	871	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Icelandic (Euro)	1149	1149	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - International	500	500	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - International (Euro)	1148	1148	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Italy	20280	280	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Italy (Euro)	1144	1144	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Japan English/Kanji (Extended)	939	939	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan English/Kanji (Extended)	5035	5035	Support for this double-byte character set is supplied using TRNSDT.

IBM EBCDIC - Japan Katakana/Kanji (Extended)	930	930	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	5026	5026	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japanese	931	931	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Korea (Extended)	933	933	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Latin America/Spain	20284	284	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Latin America/Spain (Euro)	1145	1145	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - Multilingual/ROECE (Latin-2)	870	870	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - Simplified Chinese (Extended)	935	935	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Thai	20838	838	On Windows NT 4.0, support for this NLS Code Page is installed using the thai.inf file from the Language Pack.
IBM EBCDIC - Traditional Chinese (Extended)	937	937	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Turkish (Latin-3)	20905	905	On Windows NT 4.0, support for this NLS Code Page is installed using the turkish.inf file from the Language Pack.
IBM EBCDIC - Turkish (Latin-5)	1026	1026	On Windows NT 4.0, support for this NLS Code Page is installed using the turkish.inf file from the Language Pack.
IBM EBCDIC - U.S./Canada	037	37	On Windows NT 4.0, support for this NLS Code Page is installed using the us_eng.inf file from the Language Pack.
IBM EBCDIC - U.S./Canada (Euro)	1140	1140	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.
IBM EBCDIC - United Kingdom	20285	285	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
IBM EBCDIC - United Kingdom (Euro)	1146	1146	On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows 2000 or Windows NT definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an EBCDIC-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page parameter using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the EBCDIC code page in IBM publications. IBM lists their EBCDIC support in publications by referencing the display name which for these EBCDIC code pages is the same as the Microsoft display name. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The ODBC Driver for DB2 maps the Microsoft NLS numbers to EBCDIC NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

These are the only EBCDIC pages currently supported by the ODBC Driver for DB2 in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional EBCDIC pages, however, the EBCDIC code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM EBCDIC code pages (CCSIDs) match.

ISO Code Page Support Using the ODBC Driver for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured for an ISO code page, for example ISO 819 (Latin I). Host Integration Server 2000 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ISO code pages can be used when accessing IBM DB2 Universal

The following table shows the ISO character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 8859-2 Central Europe	28592	912	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 8859-5 Cyrillic	28595	915	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
ISO 8859-6 Arabic	28596	1089	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
ISO 8859-7 Greek	28597	813	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
ISO 8859-8 Hebrew	28598	916	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
ISO 8859-9 Turkish	28599	920	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the ODBC Driver for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (Euro)	20865	923	NLS Code Page 819 with support for the Euro. On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows NT Language Pack definitions for these NLS files.

The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page attribute/property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources. The ODBC Driver for DB2 maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

Note that IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269. Note that ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the ODBC Driver for DB2, but is displayed in the configuration options when creating or modifying data sources.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000. The ODBC Driver for DB2 has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

DBCS Code Page Support Using the ODBC Driver for DB2

Support for Double-Byte Character String (DBCS) data is limited using the ODBC Driver for DB2. Conversions between DBCS and ANSI code pages are not supported and conversions between DBCS and ISO code pages are not supported. Positioned updates against DBCS EBCDIC implementations of DB2 are not supported.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are not supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

Parameterized SQL statements or calling stored procedures when the parameter values contain Mixed or DBCS characters are not supported.

Data Conversion Using the ODBC Driver for DB2

The design of ODBC APIs are similar to other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default SQL data types, as defined in ODBC, and listed in the following table:

DB2 data type	Default SQL Data Type	Exposed as Native Type in SQLGetTypeInfo	Comments
BIGINT			An eight-byte integer. This data type is not supported by the ODBC Driver for DB2.
BLOB			A Binary Large Object (BLOB) is a varying-length string that can be up to 2 gigabytes in length. A BLOB is primarily intended to hold binary data. This data type is not supported by the ODBC Driver for DB2.
CHAR (BIT)	SQL_BINARY	No	A fixed length (double-byte only) character string.
CHAR (SBCS)	SQL_CHAR	Yes	A fixed-length SBCS character string.
CHAR (MIXED)	SQL_CHAR	No	A fixed-length mixed (single and double-byte) character string.
CLOB			A Character Large Object (CLOB) is a varying-length string that can be up to 2 gigabytes in length. A CLOB is used to store large single-byte character set data. A CLOB is considered to be a character string. It is not supported by the ODBC Driver for DB2.
DATE	SQL_TYPE_DATE	Yes	A ten byte date string. This data type is converted to an SQL_DATE for use by ODBC.
DBCLOB			A Double-Byte Character Large Object (DBCLOB) is a varying-length string of double-byte characters that can be up to 2 gigabytes in length (1,073,741,823 double-byte characters). A DBCLOB is used to store large double-byte character set data. A DBCLOB is considered to be a graphic string. It is not supported by the ODBC Driver for DB2.
DECIMAL	SQL_DECIMAL	Yes	A packed decimal number.
DOUBLE	SQL_DOUBLE	Yes	An 8-byte double-precision floating point number.
FLOAT	SQL_FLOAT	Yes	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE.
GRAPHIC (DBCS)	SQL_CHAR	No	A fixed-length graphic string consisting of a sequence of double byte (DBCS only) character string data.
INTEGER	SQL_INTEGER	Yes	A four-byte integer with a precision of 10 digits ranging in value from -2,147,463,648 to +2,147,483,647.
LONG VARCHAR (BIT)	SQL_BINARY	No	A varying-length (double-byte only) character string.
LONG VARCHAR (SBCS)	SQL_CHAR	No	A varying-length SBCS character string.
LONG VARCHAR (MIXED)	SQL_CHAR	No	A varying-length mixed-character (single and double-byte) string.

LONG VARGRAPHIC (DBCS)	SQL_LONGVARCHAR	No	A varying-length graphic string consisting of a sequence of double byte (DBCS only) character string data.
SMALLINT	SQL_SMALLINT	Yes	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767.
REAL	SQL_REAL	Yes	A 4-byte single-precision floating point number.
TIME	SQL_TYPE_TIME	Yes	An 8-byte time string. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.
TIMESTAMP	SQL_TYPE_TIMESTAMP	Yes	A 26-byte string representing the date, time, and microseconds.
VARCHAR (BIT)	SQL_BINARY	No	A varying-length (double-byte only) character string.
VARCHAR (SBCS)	SQL_CHAR	Yes	A varying-length character string.
VARCHAR (MIXED)	SQL_CHAR	No	A varying-length mixed (single and double-bye) character string.
VARGRAPHIC (DBCS)	SQL_VARCHAR	No	A varying-length graphic string consisting of a sequence of double byte (DBCS only) character string data.

Not all platforms and versions of DB2 support all of the above-referenced data types. Consult your IBM SQL Reference for the specific target and platform and version of DB2.

The ODBC Driver for DB2 exposes only selected DB2 data types as native types in the ODBC catalog function GetTypeInfo. For example, the driver does not expose LONG CHARACTER or VARYING LONG CHARACTER types. Rather these types are exposed as CHARACTER and VARYING CHARACTER respectively. Also, the driver exposes CHARACTER FOR SBCS DATA, CHARACTER FOR MIXED DATA, and CHARACTER FOR BIT DATA as CHARACTER. The driver exposes VARYING CHARACTER FOR SBCS DATA, VARYING CHARACTER FOR MIXED DATA, and VARYING CHARACTER FOR BIT DATA as VARYING CHARACTER. However, the ODBC Driver for DB2 we will return these LONG and VARYING LONG data types if one reads a table with these data types. For example, when reading a table with a variable character string of length greater than 254 bytes, the ODBC Driver for DB2 will return a LONG VARCHAR.

The ODBC Driver for DB2 can read but not write to columns containing DB2 GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC data types. These types are not exposed as native data types in the ODBC Catalog function GetTypeInfo.

The maximum length of the DB2 character and graphic string data types is dependent on the DB2 platform and version. For example, a CHAR type on DB2 for OS/390 V5R1 has a maximum length of 254 bytes, whereas a CHAR type on DB2/400 V4R4 has a maximum length of 32,766 bytes.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the ODBC Driver for DB2.

See the section on Code Page Support Using the ODBC Driver for DB2 for limitations on the support for the DB2 character data types of subtype MIXED using the ODBC Driver for DB2.

Note that the ODBC Driver for DB2 does not support mapping DB2 bit strings and graphic data types to SQL_BINARY. The ODBC Driver for DB2 does not support a binary-to-binary conversion. Consequently, CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, and LONGVARCHAR FOR BIT DATA can only be supported when the Process Binary As Character property is set to true when configuring the ODBC data source or passed as part of the connection string. In this way, the ODBC client actually binds the column as an ODBC character type, not as a binary type.

Using the ODBC Driver for DB2, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The ODBC Driver for DB2 translates all such undefined characters to the question mark character ("?"). So when

ASCII strings containing these characters are converted back to EBCDIC, these undefined characters will be replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The ANSI to EBCDIC character conversions affected include the following:

Character Value (Decimal)	Character Value (Hexadecimal)	ANSI Code Page 1252	EBCDIC Character After Conversion to CCSID 37
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Floating Point Considerations Using the ODBC Driver for DB2

When real or double (synonymous with float) data is inserted into a DB2 table as a floating point data type, it is stored in scientific notation. For example, FLOAT(1.1) would be stored as +1.10000E+000.

Care must be taken when executing SQL statements to make sure that the proper data type specified in the SQL statement matches the values stored in DB2. For example, the following select statement would match values in DB2 stored as decimal 1.1

```
SELECT * FROM TEST WHERE C1 = 1.1
```

If the data in DB2 was stored as real numbers, there would not be a match since decimal 1.1 is stored as 1.1, not the representation of +1.10000E+000. When DB2 parses and executes the SQL select statement, it interprets 1.1 as a decimal type. When doing the select query, DB2 does not implicitly do the conversion to floating point. In this case, the SQL statement should explicitly typecast the 1.1 so that DB2 looks for the correct format (the scientific notation format). The select query would look like the following:

```
SELECT * FROM TEST WHERE C1 = REAL(1.1)
```

This will give the results expected. The SQL REAL function will convert the decimal 1.1 to the proper format before DB2 executes the actual select.

Usernames and Passwords Using the ODBC Driver for DB2

When connecting to remote DB2 systems, most users must be authenticated by the remote system by passing a valid user ID and password.

The AS/400 computer is case sensitive with regard to user ID and password; it accepts them only in uppercase. The ODBC Driver for DB2 automatically converts the user ID and password into uppercase when connecting to a DB2 for OS/400 system.

The mainframe is not case sensitive; the user ID and password is acceptable in lowercase or uppercase.

DB2 Universal Database (UDB) for Windows NT is case sensitive; it supports mixed case passwords. Users must enter a password in the correct mixed case. When entering a user ID, use only the Windows NT user name and not the Windows NT domain name.

Errors Returned by the ODBC Driver for DB2

The ODBC Driver for DB2 generates errors in these areas:

- ODBC Driver Manager
- Microsoft ODBC Driver for DB2
- DRDA Application Requester network client

The ODBC Driver Manager is a shared library that establishes connections with ODBC drivers, submits requests to ODBC drivers, and returns results to applications. An ODBC Driver Manager error has the following format:

```
[vendor] [ODBC DLL] message
```

For example:

```
[Microsoft] [ODBC DLL] Driver does not support this function.
```

If you encounter this type of error, check the last ODBC call the application made for possible problems. For further information on ODBC Driver Manager errors, contact your ODBC application vendor, or refer to the ODBC documentation available from Microsoft Press.

An error reported by the Microsoft ODBC Driver for DB2 has the following format:

```
[Microsoft] [ODBC Driver for DB2] message
```

For example:

```
[Microsoft] [ODBC Driver for DB2] Invalid precision specified.
```

If you encounter this type of error is, check the last ODBC call the application made for possible problems. For further information on ODBC Driver errors, contact your ODBC application vendor, or refer to the ODBC documentation available from Microsoft Press.

When using the Microsoft ODBC Driver for DB2, data source refers to the target database. An error that occurs in the data source is returned with the data source name and in the following format:

```
[Microsoft] [ODBC Driver for DB2] [data_source] message
```

For example, an ODBC application may receive the following message from a DB2 data source running on an IBM mainframe:

```
[Microsoft] [ODBC Driver for DB2] [DB2] DB2-0919: specified length too long for CHAR column
```

If you encounter this type of error, the application attempted to perform an operation not supported by the DB2 database system. Check the DB2 database system documentation for more information, or consult your database administrator.

Troubleshooting the ODBC Driver for DB2

The Windows 2000 and Windows NT Event Viewer can be a useful tool for troubleshooting data access in some cases. The ODBC Driver for DB2 does not issue events. However, when SNA (APPC/LU 6.2) is used for the network transport for the ODBC Driver for DB2, the low-level SNA APPC transport issues events on the SNA connection.

The ODBC Driver for DB2 supplied with Host Integration Server 2000 has the ability to trace DRDA data flows when used over TCP/IP. This capability is accessible from the SNADB2 Service tracing inside the Trace utility shipped with Host Integration Server 2000.

This facility shows the same data as an APPC trace but without the control indicators (for example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Win32 SDK.

When the ODBC Driver for DB2 passes an error code, the best source in which to look-up the meaning of the return code is often the SQL Reference or SQL Messages and Codes Reference for the target SQL database. In this case, the target database is one of the DB2 platforms supported by the ODBC Driver for DB2.

The ODBC Driver for DB2 maintains an internal integer variable named SQLCODE and an internal 5-byte character string variable named SQLSTATE used to check the execution of SQL statements on DB2. SQLCODE is set by DB2 after each SQL statement is executed. DB2 returns the following values for SQLCODE:

- If SQLCODE = 0, execution was successful.
- If SQLCODE > 0, execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.
- SQLCODE = 100, "no data" was found. For example, a FETCH statement returned no data because the cursor was positioned after the last row of the result table.

SQLSTATE is also set by DB2 after the execution of each SQL statement. Application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE. SQLSTATE provides application programs with common codes for common error conditions (the values of SQLSTATE are product-specific only if the error or warning is product-specific). Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors.

SQLSTATE values consist of a two-character class code value, followed by a three-character subclass code value. The first character of an SQLSTATE value indicates whether the SQL statement was executed successfully or unsuccessfully (equal to or not equal to zero, respectively). Class code values represent classes of successful and unsuccessful execution conditions. The following SQLSTATE class codes are used by DB2:

Class Code	Description of Error Class
00	Successful completion. Execution of the SQL statement was successful and did not result in any type of warning or exception condition.
01	Warning
02	No data
07	Dynamic SQL error
08	Connection exception
0A	Feature not supported
0F	Invalid token
21	Cardinality violation
22	Data exception
23	Constraint violation
24	Invalid cursor state
25	Invalid Transaction State
26	Invalid SQL statement identifier
2D	Invalid transaction termination
34	Invalid cursor name
39	External function call exception
40	Transaction rollback
42	Syntax error or access rule violation
44	WITH CHECK OPTION violation
51	Invalid application state

53	Invalid operand or inconsistent specification
54	SQL or product limit exceeded
55	Object not in prerequisite state
56	Miscellaneous SQL or product error
57	Resource not available or operator intervention
58	System error

The SQLSTATE value of HY000 is defined as a driver-specific error. An SQLSTATE of 08S01 (connection exception with a subclass code of S01) also indicates a driver-specific error. This means the SQLCODE should be looked up in the driver-specific documentation included with the ODBC Driver for DB2.

If the SQLSTATE does not indicate a driver-specific error when the ODBC Driver for DB2 passes back an SQLSTATE of 08S01, it indicates a network error. For example, an SQLCODE of -603 is a driver-specific error that is mapped to DB2OLEDB_COMM_HOST_CONNECT_FAILED in the db2oledb.h include file supplied with the ODBC Driver for DB2. Errors with an SQLSTATE of 08S01 are documented in the db2oledb.h include file (the SQLCODE value) which is located on the Host Integration Server 2000 CD-ROM in the SDK\Include subdirectory.

The following steps are useful in researching an error. Start by reading the provided error text returned by the ODBC Driver for DB2. In some cases, the error text may provide limited information. For example, error text from an SQLCODE of -603 reads:

```
Test connection failed because of an error in initializing driver.
Could not connect to specified host.
```

The next step is to lookup the SQLSTATE to determine the source of the error. Is the error a DB2 error, a network client error, or an ODBC Driver error? An SQLSTATE of 08S01 is defined as follows:

```
Communication link failure.
```

This definition is intended to inform the user, administrator, or developer that the error is one related to the ODBC driver's underlying network client.

Unfortunately, many of the SQLSTATE codes returned by the ODBC Driver for DB2 are DB2 errors and are not documented in the ODBC Driver for DB2 online Help.

The SQLSTATE of HY000 is defined as a driver-specific error. An SQLSTATE of 08S01 also indicates a driver-specific error. In this case, you should look up the SQLCODE in the driver-specific documentation included with the ODBC Driver for DB2.

If the SQLSTATE does not indicate a driver-specific error, you should look up the SQLCODE in the appropriate DB2 manual for the target platform. For example, an SQLCODE of -603 is documented in Appendix B, "SQLCODEs and SQLSTATEs," in the *AS/400 Advanced Series DB2 for AS/400 SQL Programming, Version 4*, document number SC41-5611-00 published by IBM. An SQLCODE of -603 corresponds to SQLSTATE 23515 in the DB2 for OS/400 error code list. For example, the explanation for this SQLCODE is:

```
Unique index cannot be created because of duplicate keys.
```

When the SQLSTATE and the SQLCODE definitions documented in these appendixes create a mismatch with the actual errors returned, it usually indicates a driver-specific error condition.

A final step in understanding an error is to check the db2oledb.h file. This file is not installed by Setup for the Host Integration Client 2000, but is located on the CD-ROM for in the SDK\Include folder. An SQLCODE (for example, -603) can be found by searching the rightmost column of the db2oledb.h file for a value near to 603. For instance, locate the comment "/* -600 */" and then count down three additional lines to line number 603. The internal error code -603 is defined as follows:

```
DB2OLEDB_COMM_HOST_CONNECT_FAILED.
```

Unfortunately, this error text is not further defined anywhere in the software or documentation provided to the customer. This particular error usually indicates a problem with the configuration parameters or the connection string passed.

ActiveX Controls

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information about how to integrate your applications using the Data Queue and Host File Transfer ActiveX® controls.

This section contains:

Using the Data Queue ActiveX Control

A data queue is an AS/400 system object that is used for inter-process communications between multiple programs or jobs. Data queues allow multiple programs to send and receive shared messages via a central repository without first writing the message data to a physical database file. Typically, when a data record is read from the queue, the record is erased from the queue. The advantage of using data queues to share data in comparison with using database files is that data queues require much less file I/O and therefore improve overall system performance.

The Microsoft® Data Queue ActiveX® Control provides the ability to access AS/400 data queues. Host Integration Server 2000 provides this service via a single ActiveX Control that depends on other core Host Integration Server DLLs. Developers can move part or all of their AS/400 applications from an AS/400 computer to a PC platform, while retaining access in the program running on the PC to a remote data queue on the AS/400.

The Microsoft Data Queue ActiveX Control is implemented as a Distributed Data Management (DDM) Application Requester. The Data Queue ActiveX Control uses the Data Queue interfaces in the DDM Level 4 architecture, which are extensions to the record-level input/output (RLIO) protocol of IBM's Distributed Data Management architecture.

DDM is a set of rules for distributing or extending data management from one computer to another, such as from a mainframe to an AS/400 computer, or from one of these host computers to a server computer. By combining the Microsoft Data Queue ActiveX Control and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal file and data transfer to all enterprise-wide data sources.

The information in this section is required to develop applications with Host Integration Server 2000 that use ActiveX or COM objects to transfer data from local machines to AS/400 Data Queues in a Systems Network Architecture (SNA) environment or over TCP/IP using RLIO and DDM.

This section contains:

Advantages of Data Queues

Data queues provide a fast means of inter-process communication, requiring low system overhead and minimal setup. AS/400 Data Queues are designed to provide a flexible, highly efficient, yet temporary means of inter-process communication. Data queues are familiar to most AS/400 programmers as a simply method of passing information to another program.

Data queues provide considerable flexibility to the application programmer. The data queues interfaces require no communications programming and can be used either for connected or disconnected communication. AS/400 and PC applications can be developed using any supported language, yet still communicate with each other. PC programs can communicate with AS/400 programs via a common AS/400 data queue. The use of data queues requires little knowledge of communication and no knowledge of APPC if the programmer utilizes the Microsoft® Data Queue ActiveX® control. The data queue messages are merely described at the record-level, allowing the application programmer to define the field-level structure as required.

By default, when one program reads an entry in the queue, the entry is then deleted. Pointers to the queue entries are then updated to reflect the change in the record stack. A data queue can exist with no entries, a single entry, or multiple entries. Multiple concurrent jobs and programs can access data queues.

When receiving data, the requesting application can set a timeout value to wait for data to arrive in the queue. Waits can be applied based on entry of the data record or for a time period (zero seconds to many days in length). A program that reads from a queue need not be running when the queue is created or when records are inserted. A single data queue can support many separate interactive jobs. At regular intervals or at the end of the day, records in the data queue can be persisted to a file by a single automated batch process.

Platforms Supported by the Data Queue ActiveX Control

AS/400 Data Queue support in Host Integration Server 2000 is implemented by extending the features of the existing Distributed Data Management (DDM) Application Requester and by the creation of an ActiveX control. To support data queues via DDM, a large number of DDM commands are implemented. DDM Data Queue support requires a DDM Architecture Level 4 implementation for both source and target.

The Data Queue ActiveX® Control requires the following system software on the AS/400:

- OS/400 V3R7 or higher.
- OS/400 V3R2 or higher.
- OS/400 V3R0M5 with the following program technical fixes applied: SF21521, SF21498, SF21500, and SF21254.
- OS/400 V3R1M0 with the following program technical fixes applied: SF21555, SF21499, SF21501, and SF21266.
- OS/400 V2R3 with the following program technical fixes applied: SF21522, SF19749, SF19748, and SF19122.

The Data Queue ActiveX Control supplied with Host Integration Server 2000 supports the following operating systems:

- Microsoft® Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Data Center
- Microsoft Windows 2000 Professional
- Microsoft Windows NT® Server 4.0 with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Enterprise Edition with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Terminal Server Edition with Service Pack 6a or later
- Microsoft Windows NT Workstation 4.0 with Service Pack 6a or later
- Microsoft Windows 98, Second Edition

The Data Queue ActiveX Control supplied with Host Integration Server 2000 Service Pack 1 adds support for the following additional operating systems:

- Microsoft Windows XP Professional
- Microsoft Windows XP Home Edition
- Microsoft Windows Millennium Edition

The Data Queue ActiveX Control requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2000
- Microsoft Host Integration Server 2000 Administrator Client
- Microsoft Host Integration Server 2000 End-User Client

Registry Settings Used by Data Queues

The Microsoft® Data Queue ActiveX® Control uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup** key. These registry settings include the following subkeys:

Subkey	Comment
RootDir	Stores the path to root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the Data Queue ActiveX Control DLL and other support DLLs are installed.

Object Support Using Data Queues

The Microsoft® Data Queue ActiveX® Control supports a number of standard COM interfaces as well some custom objects and interfaces.

COM Interface Support Using Data Queues

The Microsoft Data Queue ActiveX Control supports a number of standard COM interfaces as well as several custom interface, **IEIGDataQueueCtl**, **IEIGDataQueue**, and **IEIGDataQueueItem**. The ActiveX Control object has the ability to register and de-register itself via standard control mechanisms. Support for a number of standard COM interfaces makes it easy to develop applications using the Data Queue ActiveX Control with Microsoft Visual Basic® and Microsoft Visual C++® as well as from Microsoft Internet Explorer and Microsoft Access. Supporting a variety of standard COM interfaces also provides different ways for a client to save information.

The following table summarizes the standard COM interfaces supported by the Data Queue ActiveX Control.

COM Interface	Comments
ICategorizeProperties	This interface divides up the properties into an intelligent presentation to the client.
IConnectionPointContainer	
IDispatch	A dual interface deriving from **IDispatch** is exposed to provide support and flexibility to clients. Clients that provide support for automation interfaces will utilize the **IDispatch** interface, while more robust clients may use the custom interface. Using the custom interface provides for the greatest execution speed.
IPerPropertyBrowsing	This interface provides support for client browsing of properties in an intelligent manner. This interface exposes to the client property lists used in the population of a dropdown list. This interface is required for the control to be hosted by Microsoft Access.
IPropertyNotifySink	The interface is implemented by a sink object to receive notifications about property changes from an object that supports **IPropertyNotifySink** as an outgoing interface. The client that needs to receive the notifications in this interface (from a supporting connectable object) creates a sink with this interface and connects it to the connectable object through the connection point mechanism.
IPersist	
IPersistPropertyBag	This interface is the preferred method of property persisting for Internet Explorer and Visual Basic. Using this interface persisted properties are stored as a set of name/VARIANT value pairs.
IPersistStorage	This interface stores persistent properties into a structured storage object.
IPersistStreamInit	This interface is responsible for saving the persisted properties in binary form using a stream interface. This is the method used by the Microsoft Visual C/C++ compiler to persist properties.
ISupportErrorInfo	This interface is the preferred method to return error indications to scripting clients. Using this interface, error codes and explanation text are returned to the client. This information may be used in order to provide diagnostic information to the user and in cases of failure.

The IEIGDataQueueCtl Object

The **IEIGDataQueueCtl** object supports a number of properties and methods that provide the ability to connect with a host and communicate with OS/400 Data Queues. The **IEIGDataQueueCtl** also supports a set of events notifying a client application of connection status and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the **IConnectionPointContainer**.

The following **IEIGDataQueueCtl** object methods are supported by the Microsoft Data Queue ActiveX Control.

Method Name	Comment
Connect method	Establishes a connection to the configured host and reports to the user an indication of the success or failure of the action.
CreateQueueContainer method	Create an instance of a IEIGDataQueue container object and optionally initialize the QueueName property. The created queue object is assumed to be associated with the connection object that created it for the life of the connection or the life of the queue object.
Disconnect method	Terminates an existing connection to a host machine.

The following **IEIGDataQueueCtl** object properties are supported by the Microsoft Data Queue ActiveX Control.

Property Name	Comment
CCSID property	Sets or returns the character code set identifier (CCSID) that must match the data in the AS/400 data queue as represented on the remote host computer. This property defaults to U.S./Canada (37).
ConnectionState property	Returns the current state of the connection. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting.
ConnectionType property	Sets or returns the network transport used for this connection. The **ConnectionType** property designates whether the Data Queue ActiveX Control connects via APPC (SNA LU6.2) or TCP/IP. The possible values for this parameter are TCPIP or APPC. The default value for this parameter is SNA. If APPC is selected, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required. If TCPIP is selected, then values for **NetAddr** and **NetPort** properties are required. Note that a TCP/IP connection is not currently supported when connecting to an AS/400 using the Data Queue ActiveX Control, since TCP/IP is not supported by the AS/400 DDM implementation.
LocalLU property	Sets or returns the Local LU Alias. When APPC (SNA LU 6.2) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager. This property defaults to the string value of "LOCAL" represented as a BSTR.
ModeName property	Sets or returns the APPC mode. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this field must be set to the APPC mode that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property defaults to the string value of "QPCSUPP" represented as a BSTR.
NetAddr property	Sets or returns the IP address of the host computer. When TCPIP (a TCP/IP connection) has been selected for the **ConnectionType** property, this property indicates the IP address of the host. This property can be an IP address or the name representing the host IP address using the Domain Name System (sna.microsoft.com, for example). This property is a string (BSTR) and has no default value. Note that a TCP/IP connection is not currently supported when connecting to an AS/400 using the Data Queue ActiveX Control, since TCP/IP is not supported by the AS/400 DDM implementation.

NetPort property	Sets or returns the TCP/IP port used for communication with the host. When TCPIP (a TCP/IP connection) has been selected for the **ConnectionType** property, this parameter is the TCP/IP port used for communication with the host. The default value for this property is the string (BSTR) "446" representing TCP/IP port 446. Note that a TCP/IP connection is not currently supported when connecting to an AS/400 using the Data Queue ActiveX Control, since TCP/IP is not supported by the AS/400 DDM implementation.
Password property	Sets or returns the password used for authentication. A valid user name and password are normally required to access data on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes. This property is a string (BSTR) and has no default value.
PCCodePage property	Sets or returns the PC code page The PC Code Page property indicates the code page to be used on the PC for character code conversion. This property defaults to Latin 1 (1252).
RemoteLU property	Sets or returns the Remote LU Alias. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this property is the name of the remote LU alias configured using SNA Manager. This property is a string (BSTR) and has no default value.
UserID property	Sets or returns the username used for authentication. A valid user name and password are normally required to access data on a host computer. This value is case sensitive. This property is a string (BSTR) and has no default value.

The IEIGDataQueue Object

The **IEIGDataQueue** object represents a logical queue and supports a number of properties and methods that provide the ability to communicate with a specific data queue. The QueueName property is the name of the physical queue. All methods and events are related to the queue that is represented by the individual instance of the object. The Data Queue ActiveX Control also supports a set of events notifying a client application of connection status, data transfer status, and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the **IConnectionPointContainer**.

The following **IEIGDataQueue** object methods are supported by the Microsoft Data Queue ActiveX Control.

Method Name	**Comment**
AddQueueItem method	Adds a record to the current queue.
Cancel method	Terminates a request to receive information from the queue that is already in progress.
CancelQueue method	Indicates that an application no longer wants to be notified of an incoming queue data item. This can be used to stop pending notifications that were queued as a result of calling **GetQueueItem**.
ClearAll method	Removes all items from the queue.
CreateQueue method	Creates a data queue.
DeleteQueue method	Clears all messages from the queue and then deletes the queue.
Get_QueueName method	Retrieves the queue name from a data queue.
GetQueueItem method	Retrieves an item from the queue.
QueryAttribute method	Requests information on one of the queue's attributes
SetAttribute method	Changes the attributes associated with a data queue.
StopQueue method	Stops the queue from responding to client requests.

The following **IEIGDataQueue** object property is supported by the Microsoft Data Queue ActiveX Control.

Property Name	**Comment**
QueueName property	This is the name of the data queue this object is associated with.

The IEIGDataQueueItem Object

The **IEIGDataQueueItem** object represents a specific queue item and supports a number of properties and methods.

The following **IEIGDataQueueItem** object method is supported by the Microsoft Data Queue ActiveX Control.

Method Name	Comment
Reset method	Resets the queue item properties to default values.

The following **IEIGDataQueueItem** object properties are supported by the Microsoft Data Queue ActiveX Control.

Property Name	Comment
ExtUser property	The external job user name.
ExtJobName property	The external job name.
ExtJobNumber property	The external job number.
InactiveRec property	Indicates an Inactive record.
Keyval property	The key value.
Message property	The queue message.
QItemType property	The type of queue item this represents.
Record property	The entire queue data.
RecordAttribute property	The list of record attributes.
RecCount property	The record count.
RecNumber property	The record number.
ReplyRequest property	Indicates if the reply message should be returned.
UsrProf property	The user profile.

IEIGDataQueueCtlEvents Notifications

The **IEIGDataQueueCtl** object of the Microsoft Data Queue ActiveX Control also supports a set of events notifying a client application of connection status and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGDataQueueCtlEvents** notification interface methods are supported by the Data Queue ActiveX Control:

Event Notifications	Comment
ConnectionStateChange	This event is fired when the state of a connection has changed. A ConnectionState parameter is passed to the client callback function that receives this event method call. This parameter is an eigConnectionStateEnum value representing the new state of the ConnectionState property.
ReportError	This event is fired when an error condition needs to be reported during non-blocking (asynchronous) functions. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.

IEIGDataQueueEvents Notifications

The **IEIGDataQueue** object of the Microsoft Data Queue ActiveX Control also supports a set of events notifying a client application of when transfers are completed, requests are received, and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGDataQueueEvents** notification interface methods are supported by the Data Queue ActiveX Control:

Event Notifications	Comment
ReportError2	This event is fired when an error condition needs to be reported during non-blocking (asynchronous) functions. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.
RequestReceived	This event is fired when a request is received.
SendComplete	This event is fired as an indication to the client that the requested transfer operation has completed.

Programming Considerations Using the Data Queue ActiveX Control

The Microsoft® Data Queue ActiveX® Control exposes a dual interface deriving from **IDispatch**. This provides support and flexibility to clients wishing to use the object. Clients that provide support for automation interfaces can use the **IDispatch** interface while more robust clients may use the custom interface. Using the custom interface offers the greatest execution speed.

The single-threading model is supported, allowing only single threads to access the objects safely.

Asynchronous read operations are not currently supported. The BlockComplete parameter of the **GetQueueItem** method must be set to a value of 0 (eigAnswerYes), indicating that the **GetQueueItem** operation should block until the completion status is known.

Code Page Support Using Data Queues

When using the Data Queue ActiveX Control, the Host CCSID (character code set identifier) property should be configured to match the data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the Data Queue ActiveX Control.

DBCS Code Page Support Using Data Queues

Support for Double-Byte Character String (DBCS) data is limited using the Data Queue ActiveX Control. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are not supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

Usernames and Passwords Using Data Queues

When connecting to host systems, most users must be authenticated by the remote system by passing a valid User ID and Password.

The AS/400 computer is case sensitive with regard to User ID and Password. The AS/400 only accepts a User ID and Password in uppercase. The Microsoft Data Queue ActiveX Control will force the User ID and Password into uppercase when it knows that it is connecting to an AS/400 system.

Troubleshooting the Data Queue ActiveX Control

The Microsoft Data Queue ActiveX Control supplied with Host Integration Server 2000 has the ability to trace DRDA data flows when used over TCP/IP.

This tracing capability is accessible from the SNADB2 Service tracing inside the Trace tool. This facility will show the same data as an APPC trace but without the control indicators (For example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Platform SDK.

The Data Queue ActiveX Control can return the following types of errors:

- Errors from the remote hosts
- Microsoft Data Queue-specific errors
- Errors from the underlying DDM Application Requester network client

Using the Host File Transfer ActiveX Control

The Microsoft® Host File Transfer ActiveX Control provides the ability to transfer files between a local machine and an MVS, OS/390, AS/400, or AS/36 host system. Host Integration Server 2000 provides this service via a single ActiveX Control that depends on other core Host Integration Server DLLs. This extends the ability for a client application to perform file transfer operations from a large number of client development environments.

The Microsoft Host File Transfer ActiveX Control uses the record-level input/output (RLIO) protocol of IBM's Distributed Data Management (DDM) architecture to transfer files. The Host File Transfer ActiveX Control is implemented as a Distributed Data Management (DDM) source requester, which communicates via APPC LU6.2 or TCP/IP to a DDM target server.

DDM is a set of rules for distributing or extending data management from one computer to another, such as from a mainframe to an AS/400 computer, or from one of these host computers to a server computer. By combining the Microsoft File Transfer ActiveX Control and DDM architectures, Microsoft enables organizations to preserve their investments in existing data management infrastructure, while extending universal file transfer to all enterprise-wide data sources.

The information in this section is required to develop applications with Host Integration Server that use ActiveX or COM objects to transfer files from local machines to hosts in a Systems Network Architecture (SNA) environment or over TCP/IP using RLIO and DDM.

This section covers the following topics about the Microsoft Host File Transfer ActiveX Control:

This section contains:

Platforms Supported by the Host File Transfer ActiveX Control

On the mainframe platform, IBM offers a target DDM server implementation in IBM Distributed File Manager (DFM), a component of IBM Data Facility Storage Management Subsystem (DFSMS). The Microsoft® Host File Transfer ActiveX Control requires DFSMS version 1 release 2 or later for MVS/ESA and OS/390 to support an SNA LU6.2 connection.

On midrange AS/400 computers, IBM has implemented target DDM servers directly in OS/400. The Microsoft Host File Transfer ActiveX Control requires OS/400 Version 3 Release 2 or later to support an SNA LU6.2 connection. The Microsoft Host File Transfer ActiveX Control requires OS/400 Version 4 Release 2 or later to support a TCP/IP connection.

On the AS/400 platform, the Host File Transfer ActiveX Control supports physical and logical files with an associated external record description file. For specific limitations, please see the *AS/400 DDM User's Guide*.

On the mainframe platform, the Host File Transfer ActiveX Control supports the following data set types:

Sequential Access Method (SAM) data sets

- Basic Sequential Access Method data sets (BSAM)
- Queued Sequential Access Method data sets (QSAM)

Basic Partitioned Access Method (PDS) data sets

- Partitioned Data Set Extended members (PDSE)
- Partitioned Data Set members (PDS)

Virtual Storage Access Method (VSAM) data sets

- Entry-Sequenced Data Sets (ESDS)
- Key-Sequenced Data Sets (KSDS)
- Fixed-Length Relative Record Data Sets (RRDS)
- Variable-Length Relative Record Data Sets (VRRDS)
- Relative Record Data Set (RRDS)
- VSAM Alternate Indexes for ESDS and KSDS data sets

The preceding data set types are supported by IBM DFM/MVS. The following data set types are not supported by DFM/MVS and cannot be accessed using the Host File Transfer ActiveX Control.

- VSAM Linear Data Sets (LDS)
- Generation Data Groups (GDG)
- Generation Data Sets (GDS)
- Basic Direct Access Method data sets (BDAM)
- Indexed Sequential Access Method data sets (ISAM)
- Sequential Data Striping data sets
- OpenEdition MVS Hierarchical File System (HFS) files
- Tape Media

All mainframe data sets accessible through IBM Distributed File Manager must be cataloged in an Intersystem communications function (ICF) catalog and reside on direct access storage devices (DASD).

The Host File Transfer ActiveX Control supplied with Host Integration Server 2000 supports the following operating systems:

- Microsoft® Windows® 2000 Server
- Microsoft Windows 2000 Advanced Server
- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Professional
- Microsoft Windows NT® Server 4.0 with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Enterprise Edition with Service Pack 6a or later
- Microsoft Windows NT Server 4.0, Terminal Server Edition with Service Pack 6a or later
- Microsoft Windows NT Workstation 4.0 with Service Pack 6a or later
- Microsoft Windows 98, Second Edition

The Host File Transfer ActiveX Control supplied with Host Integration Server 2000 Service Pack 1 adds support for the following additional operating systems:

- Microsoft Windows XP Professional
- Microsoft Windows XP Home Edition
- Microsoft® Windows® Millennium Edition

The Host File Transfer ActiveX Control requires the following computer-to-host connectivity software:

- Microsoft Host Integration Server 2000
- Microsoft Host Integration Server 2000 Administrator Client
- Microsoft Host Integration Server 2000 End-User Client

Configuring Data Descriptions for Host File Transfer

In order to use the Microsoft Host File Transfer ActiveX Control to transfer files, a user or client application must describe the data format of the host file to transfer. A host data description is normally configured using the Data Descriptions tool.

Microsoft® Management Console (MMC) and MMC snap-ins are the current method of exposing administrative tasks and options in server-based Microsoft products. An MMC snap-in for Data Integration is installed with the Host Integration Client 2000, which enables you to configure data descriptions for transferring files on OS/390, OS/400, MVS/ESA, and AS/36systems. The Data Integration Management Console snap-in enables you to configure data descriptions used by the Host File Transfer ActiveX Control.

The **Data Integration** console contains one high-level object:

- **Data Descriptions**—Stored in Host Column Description (HCD) files that contain the information required to convert host data types to PC computer data types.

When creating a Data Description for use with the Host File Transfer ActiveX Control, the **Use Table for File Transfer** checkbox must be checked and values must be entered for the following additional parameters:

Parameter	Comment
FieldDelimiter	This value represents the delimiter used to mark the end of one field and the beginning of another within a single record. The position of the field elements within a record is assumed to be absolute as configured and variable length fields are not supported. This element is used in order to inform the conversion routine to remove this character if it is found at the position within the record as indicated by the Data Description. This parameter is required and has no default value. The comma character "," or tab character "\t" is commonly used with desktop applications as a field separator.
RecordDelimiter	This value represents the character or characters that appear at the ending of a record. This element is used in order to inform the conversion routine to remove this character if it is found in the last position of the record as indicated by the Data Description. This parameter is required and has no default value. The end-of-line character sequence is commonly used as a record delimiter. The carriage return and linefeed character sequence "\n\r" is commonly used with desktop applications. The newline character "\n" is standard for use on UNIX systems and with some desktop applications.
TextQualifier	This value is used in order to allow elements that may contain the **FieldDelimiter** character to be properly parsed by the parsing engine. If this element is enabled on a particular field, then the inclusion of this character at the beginning of the field is an indication to the parsing engine that all characters up to the next instance of the **TextQualifier** should be treated as part of the current field being processed. This parameter has no default value. The single quote or double quote character is sometimes used as a text qualifier to protect a comma character included in a field from being misinterpreted as a field delimiter.

The **Data Integration** console and the **Data Descriptions** tool is designed to run on Microsoft® Windows 2000, Windows NT®, Microsoft® Windows® 98, and Microsoft® Windows® 95. On Windows 2000 and Windows NT, the console respects the Windows 2000 and Windows NT security hierarchy, where only privileged users can read and write to some areas of the system registry and the file system. To prevent general users from modifying the HCD files on Windows 2000 and Windows NT, the Data Descriptions tool can only be run by users that have administrative privileges on the local computer.

Registry Settings Used By Host File Transfer

The Microsoft® Host File Transfer ActiveX Control uses a number of registry settings for configuration and proper operation. The configuration registry settings are located under the **HKEY_LOCAL_MACHINE\Software\Microsoft\SNA Server\CurrentVersion\Setup** key. These registry settings include the following subkey:

Subkey	Comment
RootDir	Stores the path to root directory where the Host Integration Server was installed. The system directory below this root directory is the location where the Host File Transfer ActiveX Control DLL and other support DLLs are installed.

Object Support Using Host File Transfer

The Microsoft® Host File Transfer ActiveX Control supports a number of standard COM interfaces as well some custom objects and interfaces.

COM Interface Support Using Host File Transfer

The Microsoft® Host File Transfer ActiveX Control supports a number of standard COM interfaces as well as a single custom interface, **IEIGFileTransferCtl**. The ActiveX Control object has the ability to register and de-register itself via standard control mechanisms. Support for a number of standard COM interfaces makes it easy to develop applications using the Host File Transfer ActiveX Control with Visual Basic and Visual C++ as well as from Microsoft Internet Explorer and Microsoft Access. Supporting a variety of standard COM interfaces also provides different ways for a client to save information.

The following table summarizes the standard COM interfaces supported by the Host File Transfer ActiveX Control.

COM Interface	Comments
ICategorizeProperties	This interface divides up the properties into an intelligent presentation to the client.
IConnectionPointContainer	
IDispatch	A dual interface deriving from **IDispatch** is exposed to provide support and flexibility to clients. Clients that provide support for automation interfaces will utilize the **IDispatch** interface, while more robust clients may use the custom interface. Using the custom interface provides for the greatest execution speed.
IOleControl	
IOleInPlaceActiveObject	
IOleInPlaceObject	
IOleInPlaceObjectWindowless	
IOleObject	
IOleWindow	
IPerPropertyBrowsing	This interface provides support for client browsing of properties in an intelligent manner. This interface exposes to the client property lists used in the population of a dropdown list. This interface is required for the control to be hosted by Microsoft Access.
IPropertyNotifySink	The interface is implemented by a sink object to receive notifications about property changes from an object that supports **IPropertyNotifySink** as an outgoing interface. The client that needs to receive the notifications in this interface (from a supporting connectable object) creates a sink with this interface and connects it to the connectable object through the connection point mechanism.
IPersist	
IPersistPropertyBag	This interface is the preferred method of property persisting for Internet Explorer and Visual Basic. Using this interface, persisted properties are stored as a set of name/VARIANT value pairs.
IPersistStorage	This interface stores persistent properties into a structured storage object.
IPersistStreamInit	This interface is responsible for saving the persisted properties in binary form using a stream interface. This is the method used by the Microsoft Visual C/C++ compiler to persist properties.
IProvideClassInfo	

IProvideClassInfo2	
IQuickActivate	
ISupportErrorInfo	This interface is the preferred method to return error indications to scripting clients. Using this interface, error codes and explanation text are returned to the client. This information may be used in order to provide diagnostic information to the user and in cases of failure.
IViewObject	
IViewObject2	
IViewObjectEx	

The IEIGFileTransferCtl Object

The Microsoft® Host File Transfer ActiveX Control supports a number of standard COM interfaces as well as a single custom interface. The **IEIGFileTransferCtl** object supports a number or properties and methods that provide the ability to transfer files to and from MVS, OS/390, AS/400, or AS/36 hosts. The Host File Transfer ActiveX Control also supports a set of events notifying a client application of connection status, file transfer status, and error reporting. These events are handled by the client supporting several callback functions and setting these callbacks using the IConnectionPointContainer.

The following **IEIGFileTransferCtl** object methods are supported by the Microsoft Host File Transfer ActiveX Control:

Method Name	Comment
Cancel method	Terminate a file transfer operation that is already in progress.
Connect method	Establishes a connection to the configured host and reports to the user an indication of the success or failure of the action.
Disconnect method	Terminates an existing connection to a host machine.
GetFile method	Copy a file from host storage to local storage. This method requires the two file names as parameters.
PutFile method	Copy a file from local storage to host storage. This method requires the two file names as parameters.

The following **IEIGFileTransferCtl** object properties are supported by the Microsoft Host File Transfer ActiveX Control:

Property Name	Comment
AppendToEnd property	Sets or returns whether a file transfer should append to the end of a file (eigAnswerYes) if the file exists, or should it overwrite the existing contents replacing the data with the new information (eigAnswerNo). This property defaults to eigAnswerYes (0).
CCSID property	Sets or returns the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer. This property defaults to U.S./Canada (37).
ConnectionState property	Returns the current state of the connection. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting.
ConnectionType property	Sets or returns the network transport used for this connection. The **ConnectionType** property designates whether the Host File Transfer ActiveX Control connects via APPC (SNA LU6.2) or TCP/IP. The possible values for this parameter are a TCP/IP or an APPC connection using an enumerated value. The default value for this parameter is an APPC (SNA) connection type. If APPC is selected, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required. If TCP/IP is selected, then values for **NetAddr** and **NetPort** properties are required.
CreateIfNonExisting property	Sets or returns whether a file operation should create a new destination file if one does not already exist (eigAnswerYes). This property defaults to eigAnswerNo (1)
LocalLU property	Sets or returns the Local LU Alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager. This property defaults to the string value of "LOCAL" represented as a BSTR.
ModeName property	Sets or returns the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This property defaults to the string value of "QPCSUPP" represented as a BSTR.

NetAddr property	Sets or returns the IP address of the host computer. When TCP/IP has been selected for the **ConnectionType** property, this property indicates the IP address of the host. This property can be an IP address or the name representing the host IP address using the Domain Name System (sna.microsoft.com, for example). This property is a string (BSTR) and has no default value.
NetPort property	Sets or returns the TCP/IP port used for communication with the host. When TCP/IP has been selected for the ConnectionType property, this parameter is the TCP/IP port used for communication with the host. The default value for this property is the string (BSTR) "446" representing TCP/IP port 446.
OverwriteHostFile property	Sets or returns whether a file operation request to copy a file that will write over an existing file will fail. When this property is set to eigAnswerNo, a request to write a file over an existing file will fail. This property defaults to eigAnswerNo (1)
Password property	Sets or returns the password used for authentication. A valid user name and password are normally required to access files on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes. This property is a string (BSTR) and has no default value.
PCCodePage property	Sets or returns the PC codepage The PC Code Page property indicates the code page to be used on the PC for character code conversion. This property defaults to Latin 1 (1252).
RDBName property	Sets or returns the name of the remote database name and the Host Column Description (HCD) file that describes the data types and data conversions used to transfer this file. The HCD file describing the data should be located in the system subdirectory below the root directory where Host Integration Server was installed. Setup defaults to the following location: C:\Program Files\Host Integration Server When TCP/IP is selected for the **ConnectionType** property, the **RDBName** must also match the name of the remote database system.
RemoteLU property	Sets or returns the Remote LU Alias. When APPC (LU 6.2 SNA) is selected for the **ConnectionType** property, this property is the name of the local LU alias configured using SNA Manager. This property is a string (BSTR) has no default value.
UserID property	Sets or returns the username used for authentication. A valid user name and password are normally required to access files on a host computer. This value is case sensitive. This property is a string (BSTR) and has no default value.

IEIGFileTransferCtlEvents Notification

The Microsoft® Host File Transfer ActiveX Control also supports a set of events notifying a client application of connection status, file transfer status, and error reporting. These events are handled by the client supporting several callback interfaces and setting these callbacks derived from the standard **IConnectionPointContainer** COM object.

The following **IEIGFileTransferCtlEvents** notification interface methods are supported by the Microsoft Host File Transfer ActiveX Control:

Event Notifications	Comment
ConnectionStateChange	This event is fired when the state of a connection has changed. A ConnectionState parameter is passed to the client callback function that receives this event method call. This parameter is an eigConnectionStateEnum value representing the new state of the ConnectionState property.
ReportError	This event is used in order to return error conditions that occur during the synchronous processing of methods. This event passes two parameters to the client callback function that receives this event method call. The first parameter is a long value representing an error code. The second parameter is a BSTR string containing a brief text description of the error.
TransferComplete	This event is an indication to the client that the requested transfer operation has completed.
TransferProgress	This event will be fired periodically in order to inform the client of the progress of an unattended file transfer. A PercentageDone parameter is passed to the client callback function that receives this event method call. This parameter is a short value representing the percentage complete of the requested operation ranging from 0 to 100. A client application has the option to terminate a file transfer when this event is fired.

Programming Considerations Using Host File Transfer

The Host File Transfer ActiveX Control exposes a dual interface deriving from **IDispatch**. This provides support and flexibility to clients wishing to use the object. Clients that provide support automation interfaces can use the **IDispatch** interface while more robust clients may use the custom interface. Using the custom interface offers the greatest execution speed.

The single-threading model is supported, allowing only single threads to access the objects safely.

The Host File Transfer ActiveX Control does not support uploading Direct Relative Record Data Set (RRDS) files on System/36. An error (381) will occur and the following error message will be received.

```
"Target Not Supported"
```

The Host File Transfer ActiveX Control also does not support uploading RRDS files with the CreateIfNonExisting property option set to yes on System/36. An error will occur (381) and the following message will be received.

```
"Target Not Supported"
```

If there is existing data in a file on OS/390, setting the OverwriteHostFile and AppendToEnd properties to "no" should cause an error (58) to occur and the following error message should be received.

```
"File contains existing data. Upload not configured to append data - upload aborted"
```

On OS/390, this error is not triggered for sequential or KSDS files. Instead the data is appended to the existing data in the file for sequential files and duplicate records are not appended to KSDS files.

The **AppendToEnd** property and the **OverwriteHostFile** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd**defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order that these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until **AppendToEnd** property is set to no (disabled).

Using the Data Descriptions tool, setting the Ascending/Descending option on an OS/390 or MVS/ESA key sequenced file has no effect. Using the Host File Transfer ActiveX Control, data is always uploaded and downloaded in the ascending key order.

If the **Cancel** method is executed while uploading a file with the **AppendToEnd** property set to yes, this will result in no change to the host file. However, if the **Cancel** method is executed while uploading a file with the **OverwriteHostFile** property set to yes, this will result in an empty host file. The **Cancel** method implies the transfer has been stopped and all the files are at their original values but this is not really the case when the **OverwriteHostFile** property is set to yes.

Code Page Support Using Host File Transfer

When using the Host File Transfer ActiveX Control, the Host CCSID (character code set identifier) property should be configured to match the data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37) when using the Host File Transfer ActiveX Control.

ISO Code Page Support Using Host File Transfer

Host Integration Server 2000 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the Host File Transfer ActiveX Control. These ISO code pages can be used when accessing host files containing ISO code pages.

Depending on the version of Windows being used, to support ISO-to-UNICODE-to-ANSI (Windows), ANSI-to-UNCODE-to-ISO, and ISO-to-UNICODE-to-ISO code page conversions, you may need to install the appropriate ISO National Language Support (NLS) file for your locale.

On Windows 2000, the appropriate ISO NLS file for your locale is installed automatically when you install a localized version of Windows 2000.

On Windows NT 4.0, the appropriate ISO NLS file for your locale is installed automatically when you install a localized version of Windows NT or when you install the Windows NT Language Pack on a non-localized version of Windows NT.

On Windows 98 and Windows 95, the appropriate ISO NLS file for your locale is installed automatically when you install a localized version of Windows 98 or Windows 95.

The following table shows the ISO character code set identifiers (CCSIDs) supported by Host File Transfer ActiveX Control in Host Integration Server 2000.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 8859-2 Central Europe	28592	912	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 8859-5 Cyrillic	28595	915	On Windows NT 4.0, support for this NLS Code Page is installed using the cyrillic.inf file from the Language Pack.
ISO 8859-6 Arabic	28596	1089	On Windows NT 4.0, support for this NLS Code Page is installed using the arabic.inf file from the Language Pack.
ISO 8859-7 Greek	28597	813	On Windows NT 4.0, support for this NLS Code Page is installed using the greek.inf file from the Language Pack.
ISO 8859-8 Hebrew	28598	916	On Windows NT 4.0, support for this NLS Code Page is installed using the hebrew.inf file from the Language Pack.
ISO 8859-9 Turkish	28599	920	On Windows NT 4.0, support for this NLS Code Page is installed using the european.inf file from the Language Pack.
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the OLE DB Provider for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (Euro)	20865	923	NLS Code Page 819 with support for the Euro. On Windows NT 4.0, support for this NLS Code Page is installed using the ibm_euro.inf file from the Language Pack.

The Microsoft Display Name is the name found in the Windows NT Language Pack definitions for these NLS files.

The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when using the Host File Transfer ActiveX Control. When setting the Host CCSID or PC Code Page property, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The Host File Transfer ActiveX Control does not recognize or display the IBM CCSID values. The Host File Transfer ActiveX Control maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The Host File Transfer ActiveX Control passes the corresponding IBM CCSID to the host system at run time even though you configure this property using the Microsoft NLS number.

Note that IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269. Note that ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the Host File Transfer ActiveX Control.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000. The Host File Transfer ActiveX Control has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server 2000 and in SNA Server 4.0 with Service Pack 3 or later. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

DBCS Code Page Support Using Host File Transfer

Support for Double-Byte Character String (DBCS) data is limited using the Host File Transfer ActiveX Control. Conversions between DBCS and ANSI code pages are not supported. Conversions between DBCS and ISO code pages are not supported.

Data Conversion Using Host File Transfer

Using the Host File Transfer ActiveX Control, host data is converted to default C data types as defined in ODBC and OLE DB and illustrated in the following table:

Host Data Type (description in HCD file)	**Default C data type**	**Comments**
BINARY		A free form binary data type of specified length. This data type is transferred without being converted.
CHAR	char string[]	A fixed length string. This data type is converted to a DBTYPE_BSTR for use by Host File Transfer ActiveX Control.
DATE	date struct	A 10-byte date string. This data type is converted to a DBTYPE_DATE for use by OLE DB.
DOUBLE	double	An 8-byte double-precision floating point number. This data type is converted to a DBTYPE_R8 for use by OLE DB.
FLOAT	double	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE. This data type is converted to a DBTYPE_R8 for use by OLE DB.
LONG	int	A 4-byte integer ranging in value from -2,147,463,648 to +2,147,483,647. This data type is converted to a DBTYPE_I4 for use by OLE DB.
LONG VARBINARY	char string[]	A varying-length binary string up to 32,740 bytes in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
LONG VARCHAR	char string[]	A varying-length character string up to 32,740 characters in length. This data type is converted to a DBTYPE_STR for use by OLE DB.
PACKED	unsigned char number[]	A packed decimal number. This data type is converted to a DBTYPE_DECIMAL for use by OLE DB
REAL	float	A 4-byte single-precision floating point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
SHORT	short	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767. This data type is converted to a DBTYPE_I2 for use by OLE DB.
SINGLE	float	A 4-byte single-precision floating point number. This data type is converted to a DBTYPE_R4 for use by OLE DB.
TIME	time struct	An 8-byte time string. This data type is converted to a DBTYPE_TIME for use by OLE DB. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.

TIMESTAMP	timestamp struct	A 26-byte string representing the date, time, and microseconds. This data type is converted to a DBTYPE_DBTIMESTAMP for use by OLE DB.
VARBINARY	char string[]	A varying-length binary field. The maximum length of the binary is dependent on the version and the host platform. This data type is transferred without being converted. This data type is converted to a DBTYPE_STR for use by OLE DB.
VARCHAR	char string[]	A varying-length character string. The maximum length of the string is dependent on the version and the host platform. This data type is converted to a DBTYPE_STR for use by OLE DB.
ZONED	unsigned char number[]	A zoned numeric number. This data type is converted to a DBTYPE_NUMERIC for use by OLE DB

Note that the maximum length of fixed-length BINARY, fixed-length CHAR, VARBINARY, and VARCHAR data types is dependent on the version of the host software that is being accessed. For example, the maximum length of the CHAR data type on OS/390 is 254 characters, while the maximum length of this same host data type is 32,765 on OS/400.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the Host File Transfer ActiveX Control.

Using the Host File Transfer ActiveX Control, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The Host File Transfer ActiveX Control translates all such undefined characters to the question mark character ("?"). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters will be replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The ANSI to EBCDIC character conversions affected include the following:

Character Value (Decimal)	**Character Value (Hexadecimal)**	**ANSI Code Page 1252**	**EBCDIC Character After Conversion to CCSID 37**
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?
145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Usernames and Passwords Using Host File Transfer

When connecting to host systems, most users must be authenticated by the remote system by passing a valid User ID and Password.

The AS/400 computer is case sensitive with regard to User ID and Password. The AS/400 only accepts a User ID and Password in uppercase. The Microsoft Host File Transfer ActiveX Control will force the User ID and Password into uppercase when it knows that it is connecting to an AS/400 system.

The mainframe is not case sensitive. This means that on mainframe computers, one can enter the User ID and Password in any case.

Troubleshooting the Host File Transfer ActiveX Control

The Microsoft® Host File Transfer ActiveX Control supplied with Host Integration Server 2000 has the ability to trace DRDA data flows when used over TCP/IP.

This tracing capability is accessible from the SNADB2 Service tracing inside the Trace tool. This facility will show the same data as an APPC trace but without the control indicators (For example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Platform SDK.

The Host File Transfer ActiveX Control can return the following types of errors:

- Errors from the remote hosts
- Microsoft Host File Transfer-specific errors
- Errors from the underlying DDM Application Requester network client

Data Integration Reference

This section of the Microsoft® Host Integration Server 2000 Developer's Guide describes the objects, methods, properties, controls, and other interfaces that allow you to integrate data into your Host Integration Server application.

This section contains:

OLE DB Object and Interface Support

The OLE DB specification version 2.0 defines a number of objects and interfaces.

The Microsoft® OLE DB Provider for AS/400 and VSAM supports the OLE DB objects and interfaces appropriate for an OLE DB data provider accessing a non-SQL host file system. The following topics provide detailed information on OLE DB support:

- OLE DB Object Support in the OLE DB Provider for AS/400 and VSAM
- OLE DB Interface Support in the OLE DB Provider for AS/400 and VSAM
- OLE DB Property Support in the OLE DB Provider for AS/400 and VSAM

The Microsoft® OLE DB Provider for DB2 supports the OLE DB objects and interfaces appropriate for an OLE DB data provider accessing an SQL database. The following topics provide detailed information on OLE DB support:

- OLE DB Object Support in the OLE DB Provider for DB2
- OLE DB Interface Support in the OLE DB Provider for DB2
- OLE DB Property Support in the OLE DB Provider for DB2

In addition, the following topics provide a comparison of the objects and interfaces supported by the OLE DB Provider for AS/400 and VSAM and the OLE DB Provider for DB2:

- OLE DB Object Support Comparison
- OLE DB Interface Support Comparison

OLE DB Object Support Comparison

The following table compares the OLE DB version 2.0 objects that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft OLE DB Provider for DB2:

OLE DB object	OLE DB Provider for AS/400 and VSAM	OLE DB Provider for DB2
Command	Yes, most interfaces	Yes, most interfaces
CustomErrorObject	No	Yes, all interfaces
DataSource	Yes, most interfaces	Yes, some interfaces
Enumerator	No	No
ErrorObject	Yes, all interfaces	Yes, all interfaces
ErrorRecord	Yes, all interfaces	Yes, all interfaces
Index	Yes, all interfaces	No
MultipleResults	No	No
Rowset	Yes, most interfaces	Yes, some interfaces
Session	Yes, some interfaces	Yes, some interfaces
Transaction	No	Yes, some interfaces
TransactionOptions	No	Yes, all interfaces
View	Yes, all interfaces	No

OLE DB Interface Support Comparison

The following table compares the OLE DB version 2.0 interfaces that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM and the OLE DB Provider for DB2:

Object	Interface	OLE DB Provider for AS/400 and VSAM	OLE DB Provider for DB2
Command	**IAccessor**	Yes	Yes
	IColumnsInfo	Yes	Yes
	IColumnsRowset	No	No
	ICommand	Yes	Yes
	ICommandPersist	No	No
	ICommandPrepare	No	Yes
	ICommandProperties	Yes	Yes
	ICommandText	Yes	Yes
	ICommandWithParameters	No	Yes
	IConvertType	Yes	Yes
	ISupportErrorInfo	Yes	Yes
CustomErrorObject	**IErrorLookup**	No	Yes
	ISQLErrorInfo	No	Yes
DataSource	**IDBAsynchStatus**	No	No
	IConnectionPointContainer	No	No
	IDBCreateSession	Yes	Yes
	IDBDataSourceAdmin	No	No
	IDBInfo	No	Yes
	IDBInitialize	Yes	Yes
	IDBProperties	Yes	Yes
	IPersist	Yes	No
	IPersistFile	Yes	No
	ISupportErrorInfo	Yes	Yes
Enumerator	**IDBInitialize**	No	No
	IDBProperties	No	No
	IParseDisplayName	No	No
	ISourcesRowset	No	No
	ISupportErrorInfo	No	No
ErrorObject	**IErrorRecords**	Yes	Yes
ErrorRecord	**IErrorInfo**	Yes	Yes
Index	**IAccessor**	Yes	No
	IColumnsInfo	Yes	No
	IConvertType	Yes	No
	IRowset	Yes	No
	IRowsetChange	Yes	No
	IRowsetFind	Yes	No
	IRowsetIdentity	Yes	No
	IRowsetIndex	Yes	No
	IRowsetInfo	Yes	No
	IRowsetLocate	Yes	No
	IRowsetRefresh	Yes	No
	IRowsetScroll	Yes	No
	IRowsetUpdate	Yes	No
	IRowsetView	Yes	No
	ISupportErrorInfo	Yes	No
MultipleResults	**IMultipleResults**	No	No
	ISupportErrorInfo	No	No

Rowset	**IAccessor**	Yes	Yes
	IChapteredRowset	Yes	No
	IColumnsInfo	Yes	Yes
	IColumnsRowset	Yes	No
	IConnectionPointContainer	No	No
	IConvertType	Yes	Yes
	IDBAsynchStatus	No	No
	IRowset	Yes	Yes
	IRowsetChange	Yes	Yes
	IRowsetChapterMember	No	No
	IRowsetFind	Yes	No
	IRowsetIdentity	Yes	No
	IRowsetIndex	Yes	No
	IRowsetInfo	Yes	Yes
	IRowsetLocate	Yes	No
	IRowsetRefresh	Yes	No
	IRowsetScroll	No	No
	IRowsetUpdate	Yes	Yes
	IRowsetView	Yes	No
	ISupportErrorInfo	Yes	Yes
Session	**IAlterIndex**	No	No
	IAlterTable	No	No
	IDBCreateCommand	Yes	Yes
	IDBSchemaRowset	Yes	Yes
	IGetDataSource	Yes	Yes
	IIndexDefinition	No	No
	IOpenRowset	Yes	Yes
	ISessionProperties	Yes	Yes
	ISupportErrorInfo	Yes	Yes
	ITableDefinition	No	No
	ITransaction	No	Yes
	ITransactionJoin	No	No
	ITransactionLocal	No	Yes
	ITransactionObject	No	Yes
Transaction	**IConnectionPointContainer**	No	No
	ISupportErrorInfo	No	No
	ITransaction	No	No
TransactionOptions	**ISupportErrorInfo**	No	Yes
	ITransactionOptions	No	Yes
View	**IAccessor**	Yes	No
	IColumnsInfo	Yes	No
	ISupportErrorInfo	Yes	No
	IViewChapter	Yes	No
	IViewFilter	Yes	No
	IViewRowset	Yes	No
	IViewSort	Yes	No

OLE DB Object Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the OLE DB version 2.0 objects that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

OLE DB object	Support
Command	Yes, most interfaces
CustomErrorObject	No
DataSource	Yes, most interfaces
Enumerator	No
ErrorObject	Yes, all interfaces
ErrorRecord	Yes, all interfaces
Index	Yes, all interfaces
MultipleResults	No
Rowset	Yes, most interfaces
Session	Yes, some interfaces
Transaction	No
TransactionOptions	No
View	Yes, all interfaces

OLE DB Interface Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the OLE DB version 2.0 interfaces that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

Object	Interface	Support
Command	**IAccessor**	Yes
	IColumnsInfo	Yes
	IColumnsRowset	No
	ICommand	Yes
	ICommandPersist	No
	ICommandPrepare	No
	ICommandProperties	Yes
	ICommandText	Yes
	ICommandWithParameters	No
	IConvertType	Yes
	ISupportErrorInfo	Yes
CustomErrorObject	**IErrorLookup**	No
	ISQLErrorInfo	No
DataSource	**IDBAsynchStatus**	No
	IDBConnectionPointContainer	No
	IDBCreateSession	Yes
	IDBDataSourceAdmin	No
	IDBInfo	No
	IDBInitialize	Yes
	IDBProperties	Yes
	IPersist	Yes
	IPersistFile	Yes
	ISupportErrorInfo	Yes
Enumerator	**IDBInitialize**	No
	IDBProperties	No
	IParseDisplayName	No
	ISourcesRowset	No
	ISupportErrorInfo	No
ErrorObject	**IErrorRecords**	Yes
ErrorRecord	**IErrorInfo**	Yes
Index	**IAccessor**	Yes
	IColumnsInfo	Yes
	IConvertType	Yes
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetFind	Yes
	IRowsetIdentity	Yes
	IRowsetIndex	Yes
	IRowsetInfo	Yes
	IRowsetLocate	Yes
	IRowsetRefresh	Yes
	IRowsetScroll	Yes
	IRowsetUpdate	Yes
	IRowsetView	Yes
	ISupportErrorInfo	Yes
MultipleResults	**IMultipleResults**	No

	ISupportErrorInfo	No
Rowset	**IAccessor**	Yes
	IChapteredRowset	Yes
	IColumnsInfo	Yes
	IColumnsRowset	Yes
	IConnectionPointContainer	No
	IConvertType	Yes
	IDBAsynchStatus	No
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetChapterMember	No
	IRowsetFind	Yes
	IRowsetIdentity	Yes
	IRowsetIndex	Yes
	IRowsetInfo	Yes
	IRowsetLocate	Yes
	IRowsetRefresh	Yes
	IRowsetScroll	No
	IRowsetUpdate	Yes
	IRowsetView	Yes
	ISupportErrorInfo	Yes
Session	**IAlterIndex**	No
	IAlterTable	No
	IDBCreateCommand	Yes
	IDBSchemaRowset	Yes
	IGetDataSource	Yes
	IIndexDefinition	No
	IOpenRowset	Yes
	ISessionProperties	Yes
	ISupportErrorInfo	Yes
	ITableDefinition	No
	ITransaction	No
	ITransactionJoin	No
	ITransactionLocal	No
	ITransactionObject	No
Transaction	**IConnectionPointContainer**	No
	ISupportErrorInfo	No
	ITransaction	No
TransactionOptions	**ISupportErrorInfo**	No
	ITransactionOptions	No
View	**IAccessor**	Yes
	IColumnsInfo	Yes
	ISupportErrorInfo	Yes
	IViewChapter	Yes
	IViewFilter	Yes
	IViewRowset	Yes
	IViewSort	Yes

OLE DB Provider for AS/400 and VSAM Command Object

The **Command** object is created by an OLE DB consumer, or by a service provider on behalf of a consumer. A **Command** object is used to execute a DDM-specific command on a remote DDM server. The **Command** object currently supports executing Command Language commands on AS/400 DDM servers.

It is important not to confuse a command, which is an OLE COM object, and its command text, which is a string. Commands are generally used for data definition, such as creating a table or granting privileges, and data manipulation, such as updating or deleting rows. A special case of data manipulation using the **Command** object is opening a rowset (a table).

Before a consumer can use a command, it must determine if commands are supported. To do this, the consumer calls **QueryInterface** for **IDBCreateCommand** on a session. If this interface is exposed, the provider supports commands. To create a command, the consumer then calls **IDBCreateCommand::CreateCommand** on the session. A single session can be used to create multiple commands.

When the command is first created, it does not contain a command text. The consumer sets the command text with **ICommandText::SetCommandText**. Because the text command syntax is provider-specific, the consumer passes the GUID of the syntax to use. For use with Microsoft® OLE DB Provider for AS/400 and VSAM, the GUID is DBGUID_DBSQL. Please note that under the OLE DB Provider for AS/400 and VSAM, this GUID does not signify that the text command is a superset of ANSI SQL. The level at which the provider supports ANSI SQL is specified by the DBPROP_SQLSUPPORT property. This property is a bit mask specifying the level of support for SQL. The OLE DB Provider for AS/400 and VSAM sets this property to DBPROPVAL_SQL_NONE, indicating that SQL is not supported.

The syntax supported by the OLE DB Provider for AS/400 and VSAM for command text is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a rowset (table) using command text is as follows:

```
EXEC OPEN FileName
```

where *FileName* represents one of the following host file naming conventions:

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILENAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY.FILENAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

To execute the command, the consumer calls **ICommand::Execute**. If the command text specifies the command to open a rowset, (an **EXEC OPEN** command), **Execute** instantiates the rowset and returns an interface pointer to it.

The following interfaces of the **Command** object are supported by the current version of the OLE DB Provider for AS/400 and VSAM:

- **IAccessor**
- **IColumnsInfo**
- **ICommand**

- **ICommandProperties**
- **ICommandText**
- **IConvertType**
- **ISupportErrorInfo**

OLE DB Provider for AS/400 and VSAM DataSource Object

The **DataSource** object is created by an OLE DB consumer. The **DataSource** object contains the knowledge and ability to connect to an IBM mainframe or AS/400 over APPC and LU6.2 (through Microsoft® Host Integration Server 2000) or over TCP/IP. The **DataSource** object is used to create one or more **Session** objects.

The following interfaces of the **DataSource** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

- **IDBCreateSession**
- **IDBInitialize**
- **IDBProperties**
- **IPersist**
- **IPersistFile**
- **ISupportErrorInfo**

OLE DB Provider for AS/400 and VSAM ErrorObject Object

The **ErrorObject** object is created by any interface on any SNA OLE DB object. The **ErrorObject** object is used to retrieve additional information when an error occurs.

The following interfaces of the **ErrorObject** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

- **IErrorRecords**

The IErrorRecords interface returns **ErrorRecord** objects with detailed information on the error that occurred.

OLE DB Provider for AS/400 and VSAM ErrorRecord Object

The **ErrorRecord** object is created by calling the IErrorRecord interface on the **ErrorObject** object. An **ErrorObject** is created on any interface on any SNA OLE DB object when an error occurs. The **ErrorRecord** object is used to retrieve additional information when an error occurs.

The following interfaces of the **ErrorRecord** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

- **IErrorInfo**

OLE DB interface methods return error information in two ways. The error code returned by an interface method, known as the *return code*, indicates the overall success or failure of a method. Error records provide detailed information about the error, such as a text description of the error, the GUID of the interface that defined the error, and provider-specific error information. Error objects in OLE DB are an extension of the error objects in Automation, they use many of the same mechanisms, and can be used as Automation error objects.

OLE DB error return codes are of type HRESULT. There are two general classes of return codes: success and warning codes, and error codes.

Success and warning codes begin with S_ or DB_S_ and indicate that the method successfully completed. The standard OLE DB error codes are defined in the OLEDBERR.H include file.

If the return code is other than S_OK or S_FALSE, it is likely that an error occurred from which the method was able to recover. For example, **IRowset::GetNextRows** returns DB_S_ENDOFROWSET when it is unable to return the requested number of rows due to reaching the end of the rowset. If a single warning condition occurs, the method returns the code for that condition. If multiple warning conditions occur, the method describes the hierarchy of warning return codes indicating which warning code should be returned when given a choice between multiple warning return codes.

Error codes begin with E_ or DB_E_ and indicate that the method failed completely and was unable to do any useful work. For example, **GetNextRows** returns E_INVALIDARG when the pointer in which it is to return a pointer to an array of row handles (*prghRows*) is null. An exception to this is that some of the methods that return DB_E_ERRORSOCCURRED allocate memory in which to return additional information about these errors. Consumers must free this memory. For information about which methods allocate memory in this case, see the methods that return DB_E_ERRORSOCCURRED. Although error codes can indicate run-time errors, such as running out of memory, they generally indicate programming errors. If multiple errors occur, the code that is returned is provider-specific. If both errors and warnings occur, the method fails and returns an error code.

All methods can return S_OK, E_FAIL, and E_OUTOFMEMORY. The E_OUTOFMEMORY code applies only to those methods which allocate memory that is returned to the consumer. In some cases, the E_OUTOFMEMORY code might be eliminated by calling the method requesting fewer returned values, such as fewer rows from **GetNextRows**.

OLE DB Provider for AS/400 and VSAM Index Object

An OLE DB index, also known as an *index rowset*, is a rowset built over an index in a data source. It is generally used in conjunction with a rowset built over a base table in the same data source. Each row of the index rowset contains a bookmark that points to a row in the base-table rowset. Thus, an OLE DB consumer can traverse the index rowset and use it to access rows in the base-table rowset.

Indexes are created using the Index interfaces of the **Rowset** object. Index rowsets allow an application to read records efficiently by means of a key.

The following Index interfaces of the **Rowset** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys.

- **IAccessor**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetFind**
- **IRowsetIdentity**
- **IRowsetIndex**
- **IRowsetInfo**
- **IRowsetLocate**
- **IRowsetRefresh**
- **IRowsetScroll**
- **IRowsetUpdate**
- **IRowsetView**
- **ISupportErrorInfo**

The OLE DB Provider for AS/400 and VSAM supports integrated indexes using the **IRowsetIndex** interface based on the underlying rowset. For more information on indexes, see Chapter 8, "Indexes" and Chapter 16, "Integrated Indexes" in the *OLE DB Programmer's Reference*.

OLE DB Provider for AS/400 and VSAM Rowset Object

Rowset objects are created by **Session** objects. The **Rowset** object exposes data in tabular format.

The following interfaces of the **Rowset** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

- **IAccessor**
- **IChapteredRowset**
- **IColumnsInfo**
- **IColumnsRowset**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetFind**
- **IRowsetIdentity**
- **IRowsetIndex**
- **IRowsetInfo**
- **IRowsetLocate**
- **IRowsetRefresh**
- **IRowsetUpdate**
- **IRowsetView**
- **ISupportErrorInfo**

> **Note** The IRowsetFind interface is only supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys.

OLE DB Provider for AS/400 and VSAM Session Object

The **Session** object is created by a **DataSource** object. The **Session** object is used to create one or more **Rowset** objects.

The following interfaces of the **Session** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

- **IDBCreateCommand**
- **IDBSchemaRowset**
- **IGetDataSource**
- **IOpenRowset**
- **ISessionProperties**
- **ISupportErrorInfo**

Consumers can get information about a data store without knowing its structure by using the **IDBSchemaRowset** methods. The methods on this interface can be used to retrieve advanced schema information. The OLE DB Provider for AS/400 and VSAM represents organizes this information into a set of schemas that contain tables for each schema. These schema rowsets are identifed by GUIDs.

The following schema rowset GUIDs are supported by the OLE DB Provider for AS/400 and VSAM:

- DBSCHEMA_COLUMNS
- DBSCHEMA_INDEXES
- DBSCHEMA_PROVIDER_TYPES
- DBSCHEMA_TABLES

The following table lists these GUIDs and the columns for which restrictions can be specified on the schema rowset when using the OLE DB Provider for AS/400 and VSAM. The number of restriction columns for each schema rowset are defined as constants prefixed with CRESTRICTIONS_ in the OLEDB header files. Restriction values are treated as literals rather than as search patterns. For example, the restriction value "A_C" matches "A_C" but not "ABC".

GUID	Number of Restrictions	Restriction Columns
DBSCHEMA_COLUMNS	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME COLUMN_NAME
DBSCHEMA_INDEXES	5	TABLE_CATALOG TABLE_SCHEMA INDEX_NAME TYPE TABLE_NAME
DBSCHEMA_PROVIDER_TYPES	2	DATA_TYPE BEST_MATCH
DBSCHEMA_TABLES	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME TABLE_TYPE

The **IDBSchemaRowset** interface allows an application to pass at run time the target library of a Partioned Data Set (PDS/PDSE), a dataset, or a member name when using the IDBSchemaRowset:GetSchemas function to retrieve the schema.

This following sample illustrates using a target library to retrieve a table schema:

```
hr = pIDBSchemaRowset->GetRowset(
        NULL,                                   // punkOuter
        DBSCHEMA_TABLES,     // schema IID
         2L,                                       // # of restrictions
         rgRestrictions,                    // array of restrictions
         IID_IRowset,                       // rowset interface
         0L,                                        // # of properties
         NULL,                                   // properties
         (IUnknown**)&pIRowset);  // rowset pointer
```

The variable *rgRestrictions* is an array containing two restriction values. The first array entry is VT_EMPTY and the second array entry is the target library name.

OLE DB Provider for AS/400 and VSAM View Object

The **View** object is created on a **Rowset** object. The **View** object is used to expose simple operations, such as sorting and filtering a rowset by applying a view. Views can be applied when opening a **Rowset** object or applied to an existing **Rowset** object.

The following interfaces of the **View** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys.

- **IAccessor**
- **IColumnsInfo**
- **ISupportErrorInfo**
- **IViewChapter**
- **IViewFilter**
- **IViewRowset**
- **IViewSort**

OLE DB Property Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the provider-specific OLE DB version 2.0 properties in the SNAOLEDB_DBPROPSET_DBINIT property set that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM.

OLE DB Property ID	Description
DBPROP_SNAOLEDB_APPCMODE	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_SNAOLEDB_NETTYPE), this property is the APPC mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_SNAOLEDB_BINASCHAR	This property indicates whether to process binary fields (CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, don't process binary fields as character fields.
DBPROP_SNAOLEDB_HCDPATH	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This VT_BSTR type property is required when connecting to mainframe systems and is optional when connecting to OS/400.
DBPROP_SNAOLEDB_HOSTCCSID	The character code set identifier (CCSID) matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_SNAOLEDB_BINASCHAR property is set to true, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 property defaults to U.S./Canada (37).
DBPROP_SNAOLEDB_LIBRARY	The default AS/400 library to be accessed. This VT_BSTR property is not required for mainframe access and is optional when connecting to AS/400 files.
DBPROP_SNAOLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server.
DBPROP_SNAOLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting via TCP/IP.

DBPROP_SNAOLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting via TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value for the VT_BSTR type property is 446.
DBPROP_SNAOLEDB_NETTYPE	This property which represents the dynamic link library used for transport designates whether the provider connects via SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCP/IP or SNA. If TCPIP is selected, then values for Network Address (DBPROP_SNAOLEDB_NETADDRESS) and Network Port (DBPROP_SNAOLEDB_NETPORT) are required. TCP/IP connectivity to the mainframe is not supported by the OLE DB Provider for AS/400 and VSAM. If SNA is selected, then values for APPC Local LU Alias (DBPROP_SNAOLEDB_LOCALLU, APPC Mode Name (DBPROP_SNAOLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_SNAOLEDB_REMOTELU) are required. This value for this VT_BSTR property defaults to SNA.
DBPROP_SNAOLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the PC for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_SNAOLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, then no character code conversions will take place. The default value for this VT_I4 type property is 1252 (Latin-1).
DBPROP_SNAOLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_SNAOLEDB_NETTYPE), this property ID is the name of the remote LU alias configured in the SNA server.
DBPROP_SNAOLEDB_REPAIRKEY	This property ID provides for repair of invalid key offsets received from OS/400 when keys have been defined using the DDS "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This VT_BOOL type property defaults to VARIANT_FALSE.
DBPROP_SNAOLEDB_STRICTVAL	This property indicates whether strict validation should be used. This VT_BOOL type property defaults to VARIANT_FALSE.

OLE DB Object Support in the OLE DB Provider for DB2

The following table summarizes the OLE DB version 2.0 objects that are supported by the current version of the Microsoft® OLE DB Provider for DB2:

OLE DB object	Support
Command	Yes, most interfaces
CustomErrorObject	Yes, all interfaces
DataSource	Yes, some interfaces
Enumerator	No
ErrorObject	Yes, all interfaces
ErrorRecord	Yes, all interfaces
Index	No
MultipleResults	No
Rowset	Yes, some interfaces
Session	Yes, some interfaces
Transaction	Yes, some interfaces
TransactionOptions	Yes, all interfaces
View	No

OLE DB Interface Support in the OLE DB Provider for DB2

The following table summarizes the OLE DB version 2.0 interfaces that are supported by the current version of the Microsoft® OLE DB Provider for DB2:

Object	Interface	Support
Command	**IAccessor**	Yes
	IColumnsInfo	Yes
	IColumnsRowset	No
	ICommand	Yes
	ICommandPersist	No
	ICommandPrepare	Yes
	ICommandProperties	Yes
	ICommandText	Yes
	ICommandWithParameters	Yes
	IConvertType	Yes
	ISupportErrorInfo	Yes
CustomErrorObject	**IErrorLookup**	Yes
	ISQLErrorInfo	Yes
DataSource	**IDBAsynchStatus**	No
	IConnectionPointContainer	No
	IDBCreateSession	Yes
	IDBDataSourceAdmin	No
	IDBInfo	Yes
	IDBInitialize	Yes
	IDBProperties	Yes
	IPersist	Yes
	IPersistFile	Yes
	ISupportErrorInfo	Yes
Enumerator	**IDBInitialize**	No
	IDBProperties	No
	IParseDisplayName	No
	ISourcesRowset	No
	ISupportErrorInfo	No
ErrorObject	**IErrorRecords**	Yes
ErrorRecord	**IErrorInfo**	Yes
Index	**IAccessor**	No
	IColumnsInfo	No
	IConvertType	No
	IRowset	No
	IRowsetChange	No
	IRowsetFind	No
	IRowsetIdentity	No
	IRowsetIndex	No
	IRowsetInfo	No
	IRowsetLocate	No
	IRowsetRefresh	No
	IRowsetScroll	No
	IRowsetUpdate	No
	IRowsetView	No
	ISupportErrorInfo	No
MultipleResults	**IMultipleResults**	No
	ISupportErrorInfo	No
Rowset	**IAccessor**	Yes

	IChapteredRowset	No
	IColumnsInfo	Yes
	IColumnsRowset	No
	IConnectionPointContainer	No
	IConvertType	Yes
	IDBAsynchStatus	No
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetChapterMember	No
	IRowsetFind	No
	IRowsetIdentity	No
	IRowsetIndex	No
	IRowsetInfo	Yes
	IRowsetLocate	No
	IRowsetRefresh	No
	IRowsetScroll	No
	IRowsetUpdate	Yes
	IRowsetView	No
	ISupportErrorInfo	Yes
Session	**IAlterIndex**	No
	IAlterTable	No
	IDBCreateCommand	Yes
	IDBSchemaRowset	Yes
	IGetDataSource	Yes
	IIndexDefinition	No
	IOpenRowset	Yes
	ISessionProperties	Yes
	ISupportErrorInfo	Yes
	ITableDefinition	No
	ITransaction	Yes
	ITransactionJoin	No
	ITransactionLocal	Yes
	ITransactionObject	Yes
Transaction	**IConnectionPointContainer**	No
	ISupportErrorInfo	Yes
	ITransaction	Yes
TransactionOptions	**ISupportErrorInfo**	Yes
	ITransactionOptions	Yes
View	**IAccessor**	No
	IColumnsInfo	No
	ISupportErrorInfo	No
	IViewChapter	No
	IViewFilter	No
	IViewRowset	No
	IViewSort	No

OLE DB Provider for DB2 Command Object

The **Command** object is created by an OLE DB consumer, or by a service provider on behalf of a consumer. A **Command** object is used to execute a DDM-specific command on a remote DDM server. The **Command** object currently supports executing Command Language commands on AS/400 DDM servers.

It is important not to confuse a command, which is an OLE COM object, and its command text, which is a string. Commands are generally used for data definition, such as creating a table or granting privileges, and data manipulation, such as updating or deleting rows. A special case of data manipulation using the **Command** object is the creation of rowsets based on DB2 tables. When using the command text with DB2/400 on the AS/400, table names specified in a command are by default passed as uppercase. If a table name uses mixed case, then the table name must be passed in a quoted string.

Before a consumer can use a command, it must determine if commands are supported. To do this, the consumer calls **QueryInterface** for **IDBCreateCommand** on a session. If this interface is exposed, the provider supports commands. To create a command, the consumer then calls **IDBCreateCommand::CreateCommand** on the session. A single session can be used to create multiple commands.

When the command is first created, it does not contain a command text. The consumer sets the command text with **ICommandText::SetCommandText**. Because the text command syntax is provider-specific, the consumer passes the GUID of the syntax to use. For use with Microsoft® OLE DB Provider for DB2, the GUID is DBGUID_DBSQL. Please note that under the OLE DB Provider for DB2, this GUID signifies that the text command is a superset of ANSI SQL. The level at which the provider supports ANSI SQL is specified by the DBPROP_SQLSUPPORT property. This property is a bit mask specifying the level of support for SQL.

The syntax supported by the OLE DB Provider for DB2 for command text is as Entry-Level ANSI SQL 92 (with some exceptions based on the DB2 server host platform).

Legal SQL commands are documented in the following publications published by IBM:

- AS/400 Advanced Series: DB2 for AS/400 SQL Reference Version 4 (Document Number SC41-5612-00)
- DB2 for OS/390 Version 5: SQL Reference (Document Number SC26-8966)

To execute the command, the consumer calls **ICommand::Execute**. If the command text specifies the command to open a rowset, **Execute** instantiates the rowset and returns an interface pointer to it.

The following interfaces of the **Command** object are supported by the current version of the OLE DB Provider for DB2.

- **IAccessor**
- **IColumnsInfo**
- **ICommand**
- **ICommandPrepare**
- **ICommandProperties**
- **ICommandText**
- **ICommandWithParameters**
- **IConvertType**
- **ISupportErrorInfo**

When using the **ICommand** object, the Microsoft OLE DB Provider for DB2 cannot derive parameter type information from the data store. The OLE DB client application must supply the native parameter type information through **ICommandWithParameters::SetParameterInfo** function. The OLE DB provider uses the type information specified by **SetParameterInfo** to determine how to convert parameter data from the type supplied by the consumer (as indicated by the wType value in the binding structure) to the native type used by the data store. When the consumer specifies a data type with known precision, scale, and size values, any information supplied by the consumer for precision, scale, or size is ignored by the OLE DB Provider for DB2.

The information that the consumer supplies must be correct and must be supplied for all parameters. The OLE DB Provider for DB2 cannot verify the supplied information against the parameter metadata, although the OLE DB provider can determine that the specified values are legal values for the provider. The result of executing a command using incorrect parameter information or passing parameter information for the wrong number of parameters is undefined. For example, if the parameter type is LONG and the consumer specifies a type indicator of DBTYPE_STR in **ICommandWithParameters::SetParameterInfo**, the OLE DB Provider for DB2 converts the data to a string before sending it to the data store. Because the data store is unepecting a LONG, this will likely result in an error.

OLE DB Provider for DB2 CustomErrorObject Object

The **CustomErrorObject** object is created by a **Command** object when a command error occurs. The **CustomErrorObject** object is used to retrieve additional information when an error occurs.

The following interfaces of the **CustomErrorObject** object are supported by the current version of the Microsoft® OLE DB Provider for DB2:

- **IErrorLookup**
- **ISQLErrorInfo**

OLE DB Provider for DB2 DataSource Object

The **DataSource** object is created by an OLE DB consumer. The **DataSource** object contains the knowledge and ability to connect to DB2 over APPC and LU6.2 (through Microsoft® Host Integration Server 2000) or over TCP/IP. The **DataSource** object is used to create one or more **Session** objects.

The following interfaces of the **DataSource** object are supported by the current version of the Microsoft® OLE DB Provider for DB2:

- **IDBCreateSession**
- **IDBInfo**
- **IDBInitialize**
- **IDBProperties**
- **IPersist**
- **IPersistFile**
- **ISupportErrorInfo**

OLE DB Provider for DB2 ErrorObject Object

The **ErrorObject** object is created by any interface on any DB2 OLE DB object. The **ErrorObject** object is used to retrieve additional information when an error occurs.

The following interfaces of the **ErrorObject** object are supported by the current version of the Microsoft® OLE DB Provider for DB2:

- **IErrorRecords**

The IErrorRecords interface returns **ErrorRecord** objects with detailed information on the error that occurred.

OLE DB Provider for DB2 ErrorRecord Object

The **ErrorRecord** object is created by calling the IErrorRecord interface on the **ErrorObject** object. An **ErrorObject** is created on any interface on any SNA OLE DB object when an error occurs. The **ErrorRecord** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorRecord** object is supported by the current version of the Microsoft® OLE DB Provider for DB2:

- **IErrorInfo**

OLE DB interface methods return error information in two ways. The error code returned by an interface method, known as the *return code*, indicates the overall success or failure of a method. Error records provide detailed information about the error, such as a text description of the error, the GUID of the interface that defined the error, and provider-specific error information. Error objects in OLE DB are an extension of the error objects in Automation, they use many of the same mechanisms, and can be used as Automation error objects.

OLE DB error return codes are of type HRESULT. There are two general classes of return codes: success and warning codes, and error codes.

Success and warning codes begin with S_ or DB_S_ and indicate that the method successfully completed. The standard OLE DB error codes are defined in the OLEDBERR.H include file.

If the return code is other than S_OK or S_FALSE, it is likely that an error occurred from which the method was able to recover. For example, **IRowset::GetNextRows** returns DB_S_ENDOFROWSET when it is unable to return the requested number of rows due to reaching the end of the rowset. If a single warning condition occurs, the method returns the code for that condition. If multiple warning conditions occur, the method describes the hierarchy of warning return codes, indicating which warning code should be returned when given a choice between multiple warning return codes.

Error codes begin with E_ or DB_E_ and indicate that the method failed completely and was unable to do any useful work. For example, **GetNextRows** returns E_INVALIDARG when a null pointer in which the OLE DB Provider to return a pointer to an array of row handles (*prghRows*). An exception to this is that some of the methods that return DB_E_ERRORSOCCURRED allocate memory to return additional information about these errors. Consumers must free this memory. For information about which methods allocate memory in this case, see the methods that return DB_E_ERRORSOCCURRED. Although error codes can indicate run-time errors, such as running out of memory, they generally indicate programming errors. If multiple errors occur, the code that is returned is provider-specific. If both errors and warnings occur, the method fails and returns an error code.

All methods can return S_OK, E_FAIL, and E_OUTOFMEMORY. The E_OUTOFMEMORY code applies only to those methods which allocate memory that is returned to the consumer. In some cases, the E_OUTOFMEMORY code might be eliminated by calling the method requesting fewer returned values, such as fewer rows from **GetNextRows**.

OLE DB Provider for DB2 Rowset Object

Rowset objects are created by **Session** objects. The **Rowset** object exposes data in tabular format.

The following interfaces of the **Rowset** object are supported by the current version of the Microsoft® OLE DB Provider for DB2.

- **IAccessor**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetInfo**
- **IRowsetUpdate**
- ISupportErrorInfo

OLE DB Provider for DB2 Session Object

The **Session** object is created by a **DataSource** object. The **Session** object is used to create one or more **Rowset** objects.

The following interfaces of the **Session** object are supported by the current version of the Microsoft® OLE DB Provider for DB2.

- **IDBCreateCommand**
- **IDBSchemaRowset**
- **IGetDataSource**
- **IOpenRowset**
- **ISessionProperties**
- **ISupportErrorInfo**
- **ITransaction**
- **ITransactionLocal**
- **ITransactionObject**

Consumers can get information about a data store without knowing its structure by using the **IDBSchemaRowset** methods. The methods on this interface can be used to retrieve advanced schema information. The OLE DB Provider for DB2 represents each DB2 database server into a set of schemas that contain tables for each schema. These schema rowsets are identifed by GUIDs.

The following schema rowset GUIDs are supported by the OLE DB Provider for DB2:

- DBSCHEMA_COLUMNS
- DBSCHEMA_INDEXES
- DBSCHEMA_PRIMARY_KEYS
- DBSCHEMA_PROCEDURES
- DBSCHEMA_PROCEDURE_PARAMETERS
- DBSCHEMA_PROVIDER_TYPES
- DBSCHEMA_TABLES

The following table lists these GUIDs and the columns for which restrictions can be specified on the schema rowset when using the OLE DB Provider for DB2. The number of restriction columns for each schema rowset are defined as constants prefixed with CRESTRICTIONS_ in the OLEDB header files. Restriction values are treated as literals rather than as search patterns. For example, the restriction value "A_C" matches "A_C" but not "ABC".

GUID	Number of Restrictions	Restriction Columns
DBSCHEMA_COLUMNS	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME COLUMN_NAME
DBSCHEMA_INDEXES	4	TABLE_CATALOG TABLE_SCHEMA INDEX_NAME TABLE_NAME
DBSCHEMA_PRIMARY_KEYS	3	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME
DBSCHEMA_PROCEDURES	4	PROCEDURE_CATALOG PROCEDURE_SCHEMA PROCEDURE_NAME PROCEDURE_TYPE
DBSCHEMA_PROCEDURE_PARAMETERS	4	PROCEDURE_CATALOG PROCEDURE_SCHEMA PROCEDURE_NAME PARAMETER_NAME
DBSCHEMA_PROVIDER_TYPES	2	DATA_TYPE BEST_MATCH

DBSCHEMA_TABLES	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME TABLE_TYPE

Note that the TYPE restriction on the DBSCHEMA_INDEXES GUID is not supported by the OLE DB Provider for DB2.

The PROCEDURE_SCHEMA restriction on the DBSCHEMA_PROCEDURE GUID and the DBSCHEMA_PROCEDURE_PARAMETERS GUID is not supported when connecting to DB/2 on OS/390 platforms.

OLE DB Provider for DB2 Transaction Object

The **Transaction** object is created by a **Session** object. The **Transaction** object is used to manage transactions on one or more **Rowset** objects.

The following interfaces of the **Transaction** object are supported by the current version of the Microsoft® OLE DB Provider for DB2.

- **ISupportErrorInfo**
- **ITransaction**

The current implementation of the OLE DB Provider for DB2 services all OLE DB Session, Command, and Rowset objects present in a given instance of the DataSource object through a single APPC conversation or TCP/IP connection. One implication of this design is that if two Rowset objects, each created from a different OLE DB Session object, use explicit commitment control through the **ITransaction** interface, they will interfere with each other. When a Commit or Abort for one instance is invoked, all work for the DataSource object will be either committed or aborted. This may yield undesirable results. The work around to this problem is to instantiate two instances of the DataSource object.

OLE DB Property Support in the OLE DB Provider for DB2

The OLE DB Provider for DB2 included with Host Integration Server 2000 supports a different set of provider-specific properties than the earlier OLE DB Provider for DB2 supplied with SNA Server 4.0. The sections below provide information on provider-specific and standard OLE DB properties supported by the current and the earlier OLE DB provider.

This section contains:

OLE DB Provider-Specific Property Support in the OLE DB Provider for DB2

The following table summarizes the provider-specific OLE DB version 2.0 properties in the DB2OLEDB_DBPROPSET_DBINIT property set that are supported by the version of the Microsoft® OLE DB Provider for DB2 included with Host Integration Server 2000:

OLE DB Property ID	Description
DBPROP_DB2OLEDB_APPCMODE	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the APPC mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_DB2OLEDB_BINASCHAR	This property indicates whether to process binary fields (CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, don't process binary fields as character fields.
DBPROP_DB2OLEDB_CATALOGCOL	The name of the collection where the OLE DB Provider for DB2 looks for catalog information. This is the default schema, the "SCHEMA" name for the target collection of tables and views. This property is the Data Schema value when configuring data sources. The OLE DB Provider for DB2 uses this default schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the default schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the default schema is the target COLLECTION name. For DB2 Universal Database (UDB), the default schema is the SCHEMA name. If the user does not provide a VT_BSTR value for DBPROP_DB2OLEDB_CATALOGCOL, then the OLE DB Provider uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, these values for the default schema are inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DBPROP_DB2OLEDB_HOSTCCSID	The character code set identifier (CCSID) matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_DB2OLEDB_BINASCHAR property ID is set to true, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 type property defaults to 37 (U.S./Canada).
DBPROP_DB2OLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting via TCP/IP. This VT_BSTR type property defaults to SNA.

DBPROP_DB2OLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting via TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. This VT_BSTR type property defaults to 446.
DBPROP_DB2OLEDB_NETTYPE	This property which represents the dynamic link library used for transport designates whether the provider connects via SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCP/IP or SNA. If TCPIP is selected, then values for Network Address (DBPROP_DB2OLEDB_NETADDRESS) and Network Port (DBPROP_DB2OLEDB_NETPORT) are required. If SNA is selected, then values for APPC Local LU Alias (DBPROP_DB2OLEDB_LOCALLU, APPC Mode Name (DBPROP_DB2OLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_DB2OLEDB_REMOTELU) are required. This VT_BSTR type property defaults to SNA.
DBPROP_DB2OLEDB_PACKAGECOL	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be the same as the Default Schema (DBPROP_DB2OLEDB_DEFAULTSCH). The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The OLE DB Provider for DB2 will create packages dynamically in the location to which the user points using the this property ID. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the PC for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_DB2OLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, then no character code conversions will take place. This VT_I4 type property defaults to 1252 (Latin 1).
DBPROP_DB2OLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the name of the remote LU alias configured in the SNA server. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_TPNAME	This property represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, this property is set to 0X07F9F9F9. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_UNITSOFWORK	This property indicates whether two-phase commit (distributed unit of work) used for transactions is supported for this data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. The following values for this property are supported by the OLE DB Provider for DB2: RUW (remote unit of work) DUW (distributed unit of work) This VT_BSTR type property has a default value of RUW. Distributed unit of work (two-phase commit) works only with DB2 for OS/390 v5R1 or later. This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

The following table summarizes the provider-specific OLE DB version 2.0 properties in the DB2OLEDB_DBPROPSET_DBINIT property set that are supported by the version of the Microsoft® OLE DB Provider for DB2 included with SNA Server 4.0:

OLE DB Property ID	**Description**

DBPROP_DB2OLEDB_APPCMODE	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the APPC mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_DB2OLEDB_BINASCHAR	This property indicates whether to process binary fields (CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, don't process binary fields as character fields.
DBPROP_DB2OLEDB_BINDTYPE	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The NORM package binding option is designed to provide reasonable performance and maximum compatibility with different versions of DB2, DB2 for MVS, DB2 for OS/390, DB2 UDB, and DB2 for OS/400. Optionally, administrators can use the FAST method when running the Create Package utility and creating packages in many target collections. The FAST option should not be used with DB2 for MVS and DB2 UDB for NT due to known incompatibilities. This VT_BSTR property defaults to NORM. This VT_BOOL type property defaults to VARIANT_FALSE, don't process binary fields as character fields.
DBPROP_DB2OLEDB_COMMITCTRL	This property indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. This VT_BOOL type property defaults to VARIANT_TRUE (auto commit).
DBPROP_DB2OLEDB_DEFAULTSCH	The name of the Collection where the OLE DB Provider for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The OLE DB Provider uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a VT_BSTR value for Default Schema, then the OLE DB Provider uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DBPROP_DB2OLEDB_HOSTCCSID	The character code set identifier (CCSID) matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_DB2OLEDB_BINASCHAR property ID is set to true, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 type property defaults to 37 (U.S./Canada).

DBPROP_DB2OLEDB_HOSTGCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This property is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. When accessing DB2 for OS/390 or DB2 for MVS, a value must be specified for GCCSID if the "MIXED DATA" field (7) of the DB2 installation panel for Application Programming Defaults (DSNTIPF) is set to "YES". This property is currently supported only by the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2 or later and by the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 3 or later. This property only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This VT_I4 type property defaults to indicating that mixed CCSID conversions are not supported.
DBPROP_DB2OLEDB_HOSTMCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This property is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. When accessing DB2 for OS/390 or DB2 for MVS, a value must be specified for MCCSID if the "MIXED DATA" field (7) of the DB2 installation panel for Application Programming Defaults (DSNTIPF) is set to "YES". This property is currently supported only by the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2 or later and by the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 3 or later. This property only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This VT_I4 type property defaults to 0 indicating that mixed CCSID conversions are not supported.
DBPROP_DB2OLEDB_ISOLATION	This property determines the isolation level provided for this data source. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, isolation level this corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This VT_BSTR type property defaults to NC.
DBPROP_DB2OLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting via TCP/IP.
DBPROP_DB2OLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting via TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. This VT_BSTR type property defaults to 446.

DBPROP_DB2OLEDB_NETTYPE	This property which represents the dynamic link library used for transport designates whether the provider connects via SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCP/IP or SNA. If TCPIP is selected, then values for Network Address (DBPROP_DB2OLEDB_NETADDRESS) and Network Port (DBPROP_DB2OLEDB_NETPORT) are required. If SNA is selected, then values for APPC Local LU Alias (DBPROP_DB2OLEDB_LOCALLU, APPC Mode Name (DBPROP_DB2OLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_DB2OLEDB_REMOTELU) are required. This VT_BSTR type property defaults to SNA.
DBPROP_DB2OLEDB_PACKAGECOL	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be the same as the Default Schema (DBPROP_DB2OLEDB_DEFAULTSCH). The Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The OLE DB Provider for DB2 will create packages dynamically in the location to which the user points using the this property ID. This is a VT_BSTR type property.
DBPROP_DB2OLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the PC for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_DB2OLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, then no character code conversions will take place. This VT_I4 type property defaults to 1252 (Latin 1).
DBPROP_DB2OLEDB_READONLY	A property indicates whether the OLE DB Provider creates a read-only data source. When this property is true, the user has only read access to objects such as tables and cannot perform certain operations (INSERT, UPDATE, and DELETE, for example). This VT_BOOL type property defaults to VARIANT_TRUE.
DBPROP_DB2OLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the name of the remote LU alias configured in the SNA server. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_TPNAME	This property represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. This VT_BSTR type property has no default value.

OLE DB Data Source Property Support in the OLE DB Provider for DB2

The following table summarizes the standard OLE DB version 2.0 data source properties from the DBPROP_DATASOURCE property set that are supported by the version of the Microsoft® OLE DB Provider for DB2 included with Host Integration Server 2000:

OLE DB Property ID	Comments
DBPROP_CURRENTCATALOG	The name of the current catalog. This property is the derived from the Initial Catalog parameter when configuring data sources. An application can use the CATALOGS schema rowset to enumerate catalogs. This VT_BSTR type property defaults to the value configured in the data source for Initial Catalog.

ADO Object, Method, Property, and Collection Support

ActiveX® Data Objects (ADO) version 2.0 defines a number of objects, methods, properties, and collections.

The Microsoft® OLE DB Provider for AS/400 and VSAM supports the ADO objects, methods, properties, and collections that are appropriate for an OLE DB data provider accessing a non-SQL host file system. The following topics provide detailed information on ADO support:

- ADO Object Support in the OLE DB Provider for AS/400 and VSAM
- ADO Method Support in the OLE DB Provider for AS/400 and VSAM
- ADO Property Support in the OLE DB Provider for AS/400 and VSAM
- ADO Collection Support in the OLE DB Provider for AS/400 and VSAM

The Microsoft® OLE DB Provider for DB2 supports the ADO objects, methods, properties, and collections that are appropriate for an OLE DB data provider accessing an SQL database. The following topics provide detailed information on ADO support:

- ADO Object Support in the OLE DB Provider for DB2
- ADO Method Support in the OLE DB Provider for DB2
- ADO Property Support in the OLE DB Provider for DB2
- ADO Collection Support in the OLE DB Provider for DB2

The Microsoft® ODBC Driver for DB2 supports the ADO objects, methods, properties, and collections that are appropriate for an ODBC driver accessing an SQL database. The following topics provide detailed information on ADO support:

- ADO Object Support in the ODBC Driver for DB2
- ADO Method Support in the ODBC Driver for DB2
- ADO Property Support in the ODBC Driver for DB2
- ADO Collection Support in the ODBC Driver for DB2

ADO Object Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ADO version 2.0 objects that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM.

ADO object	Support
Collection	Yes, most methods
Command	Yes, some methods, some properties, and all collections
Connection	Yes, some methods, some properties, and all collections
Error	Yes, some properties
Field	Yes, all methods, properties, and collections
Parameter	No
Recordset	Yes, most methods, most properties, and all collections

The Parameter object will be supported by a later version of the OLE DB Provider for AS/400 and VSAM.

ADO Method Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ADO version 2.0 object methods that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM.

ADO object	Method	Support
Collection	**Append**	No
	Clear	Yes
	Delete	Yes
	Item	Yes
	Refresh	Yes
Command	**CreateParameter**	No
	Cancel	No
	Execute	Yes, but options must be **adCmdText**
Connection	**BeginTrans**	No
	Cancel	No
	Close	Yes
	CommitTrans	No
	Execute	Yes, but options must be **adCmdText**
	Open	Yes
	OpenSchema	Yes
	RollbackTrans	No
Field	AppendChunk	Yes
	GetChunk	Yes
	ReadFromFile	No
	WriteToFile	No
Parameter	**AppendChunk**	No
Recordset	AddNew	Yes
	Cancel	No
	CancelBatch	Yes
	CancelUpdate	Yes
	Clone	Yes
	Close	Yes
	Delete	Yes
	Find	Yes
	GetRows	Yes
	Move	Yes
	MoveFirst	Yes
	MoveLast	Yes
	MoveNext	Yes
	MovePrevious	Yes
	NextRecordset	No
	Open	Yes
	Requery	Yes
	Resync	No
	Save	Yes
	Seek	No
	Supports	Yes
	Update	Yes
	UpdateBatch	Yes

Note that the **Collection** object is a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection
- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the OLE DB provider

ADO Property Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ADO version 2.0 object properties that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM.

ADO object	Property	Support
Command	ActiveConnection	Yes
	CommandText	Yes
	CommandTimeout	No
	CommandType	Yes
	Prepared	No
	State	Yes
Connection	Attributes	Yes
	CommandTimeout	No
	ConnectionString	Yes
	ConnectionTimeout	No
	CursorLocation	Yes.
	DefaultDatabase	No
	IsolationLevel	No
	Mode	Yes
	Provider	Yes
	State	Yes
	Version	Yes
Error	Description	Yes
	HelpContext	No
	HelpFile	No
	NativeError	Yes
	Number	Yes
	Source	Yes
	SQLState	No
Field	ActualSize	Yes
	Attributes	Yes
	DataFormat	No
	DefinedSize	Yes
	Name	Yes
	NumericScale	Yes
	OriginalValue	Yes
	Precision	Yes
	Type	Yes
	UnderlyingValue	Yes
	Value	Yes
Parameter	**Attributes**	No
	Direction	No
	Name	No
	NumericScale	No
	Precision	No
	Size	No
	Type	No
	Value	No
Recordset	**AbsolutePage**	No
	AbsolutePosition	No
	ActiveCommand	Yes

	ActiveConnection	Yes
	BOF	Yes
	Bookmark	Yes
	CacheSize	Yes
	CursorLocation	Yes
	CursorType	Yes
	DataMember	No
	DataSource	No
	EditMode	Yes
	EOF	Yes
	Filter	Yes
	Index	No
	Locktype	Yes
	MarshalOptions	No
	MaxRecords	No
	PageCount	No
	PageSize	No
	RecordCount	No
	Sort	Yes
	Source	Yes
	State	Yes
	Status	Yes
	StayInSync	No

ADO Collection Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the ADO version 2.0 object collections that are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM.

ADO object	Collection	Support
Command	**Parameters**	No
	Properties	Yes
Connection	**Errors**	Yes
	Properties	Yes
Field	**Properties**	Yes
Parameter	**Properties**	No
Recordset	**Fields**	Yes
	Properties	Yes

ADO Command Object in the OLE DB Provider for AS/400 and VSAM

The ADO **Command** object is a definition of a specific command that is executed against an OLE DB data source.

Command objects are used to create a **Recordset** object and obtain records, execute a bulk operation, or manipulate the structure of a database. When using the Microsoft® OLE DB Provider for AS/400 and VSAM, some collections, methods, or properties of a **Command** object may generate an error when called.

The primary purpose of the **Command** object in the context of the OLE DB Provider for AS/400 and VSAM is to issue AS/400 Command Language (CL) commands for execution by the remote OS/400 DDM target server. For a listing of legal DDM command-line strings, see the *AS/400 DDM User's Guide* published by IBM.

The following **Command** object methods, properties, and collections are supported by the current version of the OLE DB Provider for AS/400 and VSAM:

Name	Comment
Execute method	Evaluates command text as a text string (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is not an SQL command).
ActiveConnection property	Sets or returns the information used to establish a connection to a data source (see notes following).
CommandText property	Sets or returns the command text to be executed.
CommandType property	Sets or returns the type of command in a **CommandText** property.
State property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. You can use the **Command** object to open tables or execute DDM commands on a remote DDM server. If errors occur, they can be examined with the **Errors** collection on the **Connection** object.

A **Command** object can be created independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string (see the **ConnectionString** property of the **Connection** object for the proper syntax). ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object should be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command. The syntax for the string in the **CommandText** property when used with the OLE DB Provider for AS/400 and VSAM is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution in order to optimize performance. The **CommandType** property must be set to **adCmdText** for use with OLE DB Provider for AS/400 and VSAM.

The **Command** object can also be used to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open (an **EXEC OPEN *DataSetName*** statement, for example, where *DataSetName* represents a valid data file or library member on the host). You must set the **CommandType** property to **adCmdText** for use with the OLE DB Provider for AS/400 and VSAM. If you open a host data file from a **Command** object, then the data file is opened as read-only. This results from the limitation that no

argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updateable.

ADO Connection Object in the OLE DB Provider for AS/400 and VSAM

The ADO **Connection** object represents an open connection to an OLE DB data source. The **Provider** property sets the OLE DB provider. The connection can be configured before opening the data source by setting the **ConnectionString** properties. The **Version** property determines the version of the ADO implementation in use.

The **Open** method establishes the physical connection to the data source and the **Close** method terminates the connection. If errors occur, they can be examined with the **Errors** collection.

The following methods, properties, and collections for the **Connection** object are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

Name	Comment
Close method	Closes a connection to a data source.
Execute method	Evaluates command text as a table name (only supported *Options* parameter for this method is **adCmdTable**).
Open method	Opens a connection to a data source and may optionally pass **ConnectionString** parameters with this method. (the only supported *Options* parameter for this method is **adCmdText**).
OpenSchema method	Obtains database schema information from the OLE DB provider.
Attributes property	Indicates one or more characteristics supported for a given **Connection** object.
ConnectionString property	Contains the information used to establish a connection to a data source (see note following).
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
Mode property	Indicates the available permissions for modifying data in a connection.
Provider property	Sets or returns the name of the provider for a connection.
State property	Describes the current state of an object.
Version property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

Note that the information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2. This information is either a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons.

ADO supports several standard ADO-defined arguments for the **ConnectionString** property as follows:

Argument	Description
Data Source	Name of the data source for the connection. This argument is optional when using the OLE DB Provider for AS/400 and VSAM.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed and is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	The Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password to use when opening the connection. This password is used by Host Integration Server 2000 to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	Name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB." To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB."
User ID	Valid mainframe or AS/400 user name to use when opening the connection. This user name is used by Host Integration Server 2000 to validate that the user can log on to the target host system and has appropriate access rights to the file.

The OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which will default to values in the registry. These arguments are as follows:

Argument	Description
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0; don't process binary fields as character fields). This parameter is equivalent to the DBPROP_SNAOLEDB_BINASCHAR OLE DB property ID.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37). This parameter is equivalent to the DBPROP_SNAOLEDB_HOSTCCSID OLE DB property ID.
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files. This parameter is equivalent to the DBPROP_SNAOLEDB_LIBRARY OLE DB property ID.
HCDFileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400. This parameter is equivalent to the DBPROP_SNAOLEDB_HCDPATH OLE DB property ID.
LocalLU	The name of the local LU alias configured in the SNA server. This parameter is equivalent to the DBPROP_SNAOLEDB_LOCALLU OLE DB property ID.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server 2000 configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes. This parameter is equivalent to the DBPROP_SNAOLEDB_APPCMODE OLE DB property ID.
NetAddr	When TCP/IP is selected for the Network Transport Library, this parameter indicates the IP address of the host. This parameter is equivalent to the DBPROP_SNAOLEDB_NETADDRESS OLE DB property ID.
NetPort	When TCP/IP is selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446. This parameter is equivalent to the DBPROP_SNAOLEDB_NETPORT OLE DB property ID.
NetLib	This parameter determines whether TCP/IP or SNA APPC are used for network communication. The possible values for this parameter are TCPIP or SNA; the default value is SNA. This parameter is equivalent to the DBPROP_SNAOLEDB_NETTYPE OLE DB property ID.
PCCodePage	The character code page to use on the computer. If this argument is omitted, the default value is set to Latin 1 (1252). This parameter is equivalent to the DBPROP_SNAOLEDB_PCCODEPAGE OLE DB property ID.
RDB	The Remote DataBase name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in the SNA server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry; the default is false. This parameter is equivalent to the DBPROP_SNAOLEDB_REPAIRKEY OLE DB property ID.
RemoteLU	The name of the remote LU alias configured in the Host Integration Server 2000 computer. This parameter is equivalent to the DBPROP_SNAOLEDB_REMOTELU OLE DB property ID.
StrictVal	This parameter indicates whether strict validation should be used; the default is false. This parameter is equivalent to the DBPROP_SNAOLEDB_STRICTVAL OLE DB property ID.

A sample **ConnectionString** for use with the OLE DB Provider for AS/400 and VSAM follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the Prompt connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties.

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters follows:

```
RS.Open "library/member",Conn,2,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (the **adOpenDynamic** enum is 2, for example), *LockType* (the **adLockReadOnly** enum is 1, for example), and *Options* (**adCmdText** is 1, which indicates that the Source name should be evaluated as a table name). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with OLE DB Provider for AS/400 and VSAM.

The allowable values for CCSID when using SNANLS (SNA National Language Support) for character code conversions (the default) are as follows:

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278
France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290

Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

Note that SNANLS conversion uses the locale configured for the data sources using data links. For more information on SNANLS, see the SDK documentation on SNA National Language Support.

ADO Error Object in the OLE DB Provider for AS/400 and VSAM

The ADO **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections; however, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). **Error** objects are automatically appended to the **Errors** collection by the OLE DB Provider when they occur. The following **Error** object properties are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

Property Name	Comment
Description	The text of the error alert that is returned based on the minor error code (specific to the OLE DB Provider for AS/400 and VSAM) contained in the **Error** object resulting from an error.
NativeError	A Long integer value of the error code returned by the OLE DB Provider for AS/400 and VSAM.
Number	The Long integer value of the error constant.
Source	A string that indicates the name of the object or application that originally generated an error.

ADO Field Object in the OLE DB Provider for AS/400 and VSAM

The ADO **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following **Field** object methods, properties, and collections are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

Name	Comment
AppendChunk method	Appends data to a large text or binary data **Field** object.
GetChunk method	Returns all or portions of the contents of a large text or binary data **Field** object.
ActualSize property	Actual length of a field's value.
Attributes property	One or more characteristics supported for a given **Field** object.
DefinedSize property	Defined size of a **Field** object.
Name property	Name of the **Field** object.
NumericScale property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue property	Value of a **Field** object that existed in the record before changes were made.
Precision property	Degree of precision for numeric values in a **Field** object for numeric data.
Type property	Operational type or data type for a **Field** object.
UnderlyingValue property	Current value of a **Field** object.
Value property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

ADO Recordset Object in the OLE DB Provider for AS/400 and VSAM

The ADO **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following **Recordset** object methods, properties, and collections are supported by the current version of the Microsoft® OLE DB Provider for AS/400 and VSAM:

Name	Comment
AddNew method	Creates a new record for an updateable **Recordset** object.
CancelBatch method	Cancels a pending batch update.
CancelUpdate method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close method	Closes an open object and any dependent objects.
Delete method	Deletes the current record in an open **Recordset** object or an object from a collection.
Find method	Finds the next record to match a condition (ADO 1.5 and later).
GetRows method	Retrieves multiple records of a **Recordset** into an array.
Move method	Moves the position of the current record in a **Recordset** object.
MoveFirst method	Moves to the first record in a specified **Recordset**.
MoveLast method	Moves to the last record in a specified **Recordset**.
MoveNext method	Moves to the next record in a specified **Recordset**.
MovePrevious method	Moves to the previous record in a specified **Recordset**.
Open method	Opens a cursor on a **Recordset**.
Requery method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save method	Saves a **Recordset** in a file or **Stream** object.
Seek method	
Supports method	Determines whether a specified **Recordset** object supports a particular type of function.
Update method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch method	Writes all pending batch updates to disk.
ActiveCommand property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType property	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenDynamic CursorType** is supported by the current version of the OLE DB Provider for AS/400 and VSAM.
EditMode property	Indicates the editing status of the current record type.
EOF property	Indicates whether the current record position is after the last record in a **Recordset** object.
Filter property	Indicates a filter for data in a **Recordset** (revised in ADO 1.5 and later).

LockType property	Sets or returns the types of locks placed on records during editing. All four lock types (**adLockReadOnly**, **adLockOptimistic**, **adLockPessimistic**, and **adLockBatchOptimistic**) are supported by the OLE DB Provider for AS/400 and VSAM. Note that the OLE DB provider internally maps **adLockPessimistic** to a locktype of **adLockBatchOptimistic**.
Sort property	Indicates the column names and order to sort data in a **Recordset** object (new property in ADO 1.5 and later).
Source property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State property	Describes the current state of an object.
Status property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

The syntax supported by the OLE DB Provider for AS/400 and VSAM to open a recordset (table) using the **Recordset.Open** method is:

```
EXEC OPEN TableName
```

where *TableName* represents one of the following host file naming conventions.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILE.NAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY/FILE.NAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax for command text used for the **Recordset.Open** method is:

```
RecordSet.Open "EXEC OPEN LIBRARY/FILE(""NAMES.DAT"")",...
```

The full path to the mainframe data set must be specified. In the example above, there are two path elements (LIBRARY/FILE) and one name element (NAMES.DAT).

Whenever a data set is allocated, it is given a unique name composed of one or more segments. Each segment of the data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully-qualified data set name (three path elements and one name element):

```
SAMPLES.DEMO.KSDS.TITLES
```

The high-level qualifier is SAMPLES. The low-level qualifier is TITLES. Each segment can be from 1-8 characters in length (the first character must be alphabetic, while the remainder can be alphanumeric or hyphens). The full data set name must be no more than 44 characters in length and contain no more than 22 segments.

The Recordset **Bookmark** method is supported for all AS/400 physical and logical files, as well as the following mainframe file types:

- KSDS if the file has a unique key
- RRDS if the file has a unique key

The Recordset **AddNew** method can be used on ESDS files on the AS/400 only when you are positioned at the end of the **Recordset** object (file). With Alternate Index files on the AS/400, the **AddNew** method can be used to add records when at the end of the **Recordset** object or by key. With KSDS or RRDR files on the mainframe, the **AddNew** method adds new records by key.

To use the Recordset **Find** method or the **Filter** property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If these methods or properties are used on an AS/400 nonkeyed physical file or any other mainframe file type, then the method fails.

The Recordset **Sort** property is used with an open **Recordset** object based on an AS/400 physical file. The **Sort** property enables the user to indicate which logical view to apply to an AS/400 physical file. The logical view must be a valid index specified in the description of the AS/400 physical file. The logical view is provided by the AS/400 logical file. The OLE DB Provider for AS/400 and VSAM responds to the **Sort** property request by first closing the open physical file, and then opening the logical file that points back to the data in the physical file.

The **Recordset Sort** property is only supported on AS/400 hosts. If the user opens a **Recordset** object based on an AS/400 logical file, then there is probably no need to use **Recordset**.**Sort**. For performance reasons, applications should be written to open the AS/400 logical file first, because the overhead is so much greater when opening a physical file first.

ADO Object Support in the OLE DB Provider for DB2

The following table summarizes the ADO version 2.0 objects that are supported by the current version of the Microsoft® OLE DB Provider for DB2.

ADO object	Support
Collection	Yes, most methods
Command	Yes, some methods, some properties, and all collections
Connection	Yes, some methods, some properties, and all collections
Error	Yes, some properties
Field	Yes, no methods, most properties, and all collections
Parameter	Yes, most methods, most properties, and all collections
Recordset	Yes, most methods, most properties, and all collections

The **Parameter** object will be supported by a later version of the OLE DB Provider for DB2.

ADO Method Support in the OLE DB Provider for DB2

The following table summarizes the ADO version 2.0 object methods that are supported by the current version of the Microsoft® OLE DB Provider for DB2.

ADO object	Method	Support
Collection	**Append**	No
	Clear	Yes
	Delete	Yes
	Item	Yes
	Refresh	Yes
Command	**CreateParameter**	Yes
	Cancel	No
	Execute	Yes
Connection	**BeginTrans**	Yes
	Cancel	No
	Close	Yes
	CommitTrans	Yes
	Execute	Yes
	Open	Yes
	OpenSchema	Yes
	RollbackTrans	Yes
Field	**AppendChunk**	No
	GetChunk	No
	ReadFromFile	No
	WriteToFile	No
Parameter	**AppendChunk**	No
Recordset	AddNew	Yes
	Cancel	No
	CancelBatch	Yes
	CancelUpdate	Yes
	Clone	Yes
	Close	Yes
	Delete	Yes
	Find	No
	GetRows	Yes
	Move	Yes
	MoveFirst	Yes
	MoveLast	No
	MoveNext	Yes
	MovePrevious	No
	NextRecordset	No
	Open	Yes
	Requery	Yes
	Resync	No
	Save	Yes
	Seek	No
	Supports	Yes
	Update	Yes
	UpdateBatch	Yes

Note that the **Collection** object is actually a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection

- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the OLE DB provider

ADO Property Support in the OLE DB Provider for DB2

The following table summarizes the ADO version 2.0 object properties that are supported by the current version of the Microsoft® OLE DB Provider for DB2.

ADO object	Property	Support
Command	ActiveConnection	Yes
	CommandText	Yes
	CommandTimeout	No
	CommandType	Yes
	Prepared	Yes
	State	Yes
Connection	Attributes	Yes
	CommandTimeout	No
	ConnectionString	Yes
	ConnectionTimeout	No
	CursorLocation	Yes.
	DefaultDatabase	No
	IsolationLevel	Yes. Note that versions of the OLE DB Provider for DB2 supplied with SNA Server 4.0 did not support this property. **IsolationLevel** was specified in the Default Isolation parameter in the connection string or Data Links dialog. This connection string parameter is not supported by the OLE DB provider supplied with Host Integration Server.
	Mode	Yes
	Provider	Yes
	State	Yes
	Version	Yes
Error	Description	Yes
	HelpContext	No
	HelpFile	No
	NativeError	Yes
	Number	Yes
	Source	Yes
	SQLState	Yes
Field	ActualSize	Yes
	Attributes	Yes
	DataFormat	No
	DefinedSize	Yes
	Name	Yes
	NumericScale	Yes
	OriginalValue	Yes
	Precision	Yes
	Type	Yes
	UnderlyingValue	Yes
	Value	Yes
Parameter	**Attributes**	Yes
	Direction	Yes
	Name	Yes
	NumericScale	Yes
	Precision	Yes

	Size	Yes
	Type	Yes
	Value	Yes
Recordset	**AbsolutePage**	No
	AbsolutePosition	No
	ActiveCommand	Yes
	ActiveConnection	Yes
	BOF	Yes
	Bookmark	Yes
	CacheSize	Yes
	CursorLocation	Yes
	CursorType	Yes
	DataMember	No
	DataSource	No
	EditMode	Yes
	EOF	Yes
	Filter	No
	Index	No
	Locktype	Yes
	MarshalOptions	No
	MaxRecords	Yes
	PageCount	No
	PageSize	No
	RecordCount	No
	Sort	No
	Source	Yes
	State	Yes
	Status	Yes
	StayInSync	No

ADO Collection Support in the OLE DB Provider for DB2

The following table summarizes the ADO version 2.0 object collections that are supported by the current version of the Microsoft® OLE DB Provider for DB2.

ADO object	Collection	Support
Command	**Parameters**	Yes
	Properties	Yes
Connection	**Errors**	Yes
	Properties	Yes
Field	**Properties**	Yes
Parameter	**Properties**	Yes
Recordset	**Fields**	Yes
	Properties	Yes

ADO Command Object in the OLE DB Provider for DB2

The ADO **Command** object is a definition of a specific command that is to be executed against an OLE DB data source.

Command objects can be used to create a **Recordset** object and obtain records, to execute a bulk operation, or to manipulate the structure of a database. When using the Microsoft® OLE DB Provider for DB2, some collections, methods, or properties of a **Command** object may generate an error when called.

The primary purpose of the **Command** object in the context of the OLE DB Provider for DB2 is to issue SQL commands for execution by the remote DB2 target server. Legal SQL commands are documented for the target DB2 platforms in SQL Reference Guides published by IBM.

The following **Command** object methods, properties, and collections are supported by the current version of the OLE DB Provider for DB2:

Name	Comment
Execute method	Evaluates command text (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is an SQL text command).
ActiveConnection property	Sets or returns the information used to establish a connection to a data source (see notes following).
CommandText property	Sets or returns the command text to be executed.
CommandType property	Sets or returns the type of command in a **CommandText** property.
State property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. The **Command** object can be used to open tables or execute SQL commands on a remote DB2 server. If errors occur, these can be examined with the **Errors** collection on the **Connection** object.

A **Command** object can be created independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string (see the **ConnectionString** property of the **Connection** object for the proper syntax). ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object should be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command (**SELECT ALL FROM TABLE**, for example). The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution in order to optimize performance. The **CommandType** property must be set to **adCmdText** for use with the OLE DB Provider for DB2.

ADO Connection Object in the OLE DB Provider for DB2

The ADO **Connection** object represents an open connection to an OLE DB data source. The **Provider** property sets the OLE DB provider to use. The connection can be configured before opening the data source by setting the **ConnectionString** properties. The version of the ADO implementation in use can be determined from the **Version** property.

The physical connection to the data source is established using the **Open** method and terminated with the **Close** method. If errors occur, these can be examined with the **Errors** collection.

The following **Connection** object methods, properties, and collections are supported by the current version of the Microsoft® OLE DB Provider for DB2:

Name	Comment
Close method	Closes a connection to a data source.
Execute method	Evaluates command text.
Open method	Opens a connection to a data source and may optionally pass **ConnectionString** parameters with this method.
OpenSchema method	Obtains database schema information from the OLE DB provider.
Attributes property	One or more characteristics supported for a given **Connection** object.
ConnectionString property	Contains the information used to establish a connection to a data source (see notes following).
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
IsolationLevel	Sets or returns the level of isolation for a Connection object. Note that versions of the OLE DB Provider for DB2 supplied with SNA Server 4.0 did not support this property.
Mode property	Indicates the available permissions for modifying data in a connection.
Provider property	Sets or returns the name of the provider for a connection.
State property	Describes the current state of an object.
Version property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

The information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with the OLE DB Provider for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property as follows:

Argument	Description
Data Source	Name of the data source for the connection. This argument is optional when using the OLE DB Provider for DB2.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed.
Location	The Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to main frame systems.
Password	Valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is equivalent to the DBPROP_AUTH_PASSWORD OLE DB property ID.
Provider	Name of the provider to use for the connection. To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB."
User ID	Valid mainframe or AS/400 user name to use when opening the connection. This user name validates that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is equivalent to the DBPROP_AUTH_USERID OLE DB property ID.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	Description
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDB NAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The transaction program name when used with SQL/DS.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the OLE DB Provider for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
BindType	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Commit	This parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter defaults to true (auto commit).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.

GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
IsoLvl	This parameter determines the isolation level provided for this data source. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommited Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommited. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, isolation level this corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
LocalLU	The name of the local LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.

Mode Name	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
Net Addr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
Net Port	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
Net Lib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PC Code Page	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
Pkg Col	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
Read Only	When the Read Only parameter is set to true (ReadOnly=1), the OLE DB Provider for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
Remote LU	The name of the remote LU alias configured in Host Integration.
TP Name	The transaction program name when used with SQL/DS.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the OLE DB Provider for DB2 follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PcCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the Prompt connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties.

```
Conn.ConnectionString = "Provider=DB2OLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters follows:

```
RS.Open "Accounting",Conn,0,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (the **adOpenForwardOnly** enum is 0, for example), *LockType* (the **adLockReadOnly** enum is 1, for example), and *Options* (**adCmdText** is 1, which indicates that the Source name should be evaluated as SQL text). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with OLE DB Provider for DB2.

The allowable values for CCSID when using SNANLS (SNA National Language Support) for character code conversions (the default) are as follows:

EBCDIC character set	**CCSID value**
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278
France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026

Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

Note that the SNANLS conversion uses the locale configured for the data sources using data links. For more information, see the SDK documentation on SNA National Language Support.

The allowable values for CCSID when using ANSI/OEM for character code conversions are:

ANSI/OEM character set	**CCSID value**
ANSI - Arabic	1256
ANSI - Baltic	1257
ANSI - Cyrillic	1251
ANSI - Eastern Europe	1250
ANSI - Greek	1253
ANSI - Hebrew	1255
ANSI - Latin I	1252
ANSI - Turkish	1254
ANSI/OEM - Korean (Extended Wansung)	949
ANSI/OEM - Japanese Shift-JIS	932
ANSI/OEM - Simplified Chinese GBK	936
ANSI/OEM - Traditional Chinese Big5	950
ANSI/OEM - Thai	874
ANSI/OEM - Vietnam	1258

ADO Error Object in the OLE DB Provider for DB2

The ADO **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections; however, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). **Error** objects are automatically appended to the **Errors** collection by the OLE DB Provider when they occur. The following **Error** object properties are supported by the current version of the Microsoft® OLE DB Provider for DB2:

Property Name	Comment
Description	The text of the error alert that is returned based on the minor error code (specific to the OLE DB Provider for DB2) co ntained in the **Error** object resulting from an error.
NativeError	A Long integer value of the error code returned by the OLE DB Provider for DB2.
Number	The Long integer value of the OLE DB error constant.
Source	A string that indicates the name of the object or application that originally generated an error.

ADO Field Object in the OLE DB Provider for DB2

The ADO **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following **Field** object methods, properties, and collections are supported by the current version of the Microsoft® OLE DB Provider for DB2:

Name	Comment
ActualSize property	Actual length of a field's value.
Attributes property	One or more characteristics supported for a given **Field** object.
DefinedSize property	Defined size of a **Field** object.
Name property	Name of the **Field** object.
NumericScale property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue property	Value of a **Field** object that existed in the record before changes were made.
Precision property	Degree of precision for numeric values in a **Field** object for numeric data.
Type property	Operational type or data type for a **Field** object.
UnderlyingValue property	Current value of a **Field** object.
Value property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

ADO Recordset Object in the OLE DB Provider for DB2

The ADO **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following **Recordset** object methods, properties, and collections are supported by the current version of the Microsoft® OLE DB Provider for DB2:

Name	Comment
AddNew method	Creates a new record for an updateable **Recordset** object.
CancelBatch method	Cancels a pending batch update.
CancelUpdate method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close method	Closes an open object and any dependent objects.
Delete method	Deletes the current record in an open **Recordset** object or an object from a collection.
GetRows method	Retrieves multiple records of a **Recordset** into an array.
Move method	Moves the position of the current record in a **Recordset** object.
MoveFirst method	Moves to the first record in a specified **Recordset**.
MoveNext method	Moves to the next record in a specified **Recordset**.
Open method	Opens a cursor on a **Recordset**.
Requery method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save method	Saves a **Recordset** in a file or **Stream** object.
Supports method	Determines whether a specified **Recordset** object supports a particular type of function.
Update method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch method	Writes all pending batch updates to disk.
ActiveCommand property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType property	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenForwardOnly CursorType** is supported by the current version of the OLE DB Provider for DB2.
EditMode property	Indicates the editing status of the current record type.
EOF property	Indicates whether the current record position is after the last record in a **Recordset** object.
LockType property	Sets or returns the types of locks placed on records during editing. The OLE DB Provider for DB2 supports locks of type **adLockReadOnly** and **adLockPessimistic**.
MaxRecords property	Sets or returns the maximum number of records to return to a **Recordset** from a query.
Source property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State property	Describes the current state of an object.
Status property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

ADO Object Support in the ODBC Driver for DB2

The following table summarizes the ADO version 2.0 objects that are supported by the current version of the Microsoft® ODBC Driver for DB2.

ADO object	Support
Collection	Yes, most methods
Command	Yes, some methods, some properties, and all collections
Connection	Yes, some methods, some properties, and all collections
Error	Yes, some properties
Field	Yes, no methods, most properties, and all collections
Parameter	Yes, most methods, most properties, and all collections
Recordset	Yes, most methods, most properties, and all collections

The **Parameter** object will be supported by a later version of the ODBC Driver for DB2.

ADO Method Support in the ODBC Driver for DB2

The following table summarizes the ADO version 2.0 object methods that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Method	Support
Collection	**Append**	No
	Clear	Yes
	Delete	Yes
	Item	Yes
	Refresh	Yes
Command	**CreateParameter**	Yes
	Cancel	No
	Execute	Yes
Connection	**BeginTrans**	Yes
	Cancel	No
	Close	Yes
	CommitTrans	Yes
	Execute	Yes
	Open	Yes
	OpenSchema	Yes
	RollbackTrans	Yes
Field	**AppendChunk**	No
	GetChunk	No
	ReadFromFile	No
	WriteToFile	No
Parameter	**AppendChunk**	No
Recordset	AddNew	Yes
	Cancel	No
	CancelBatch	Yes
	CancelUpdate	Yes
	Clone	Yes
	Close	Yes
	Delete	Yes
	Find	No
	GetRows	Yes
	Move	Yes
	MoveFirst	Yes
	MoveLast	Yes, when using a client-side cursor only.
	MoveNext	Yes
	MovePrevious	Yes, when using a client-side cursor only.
	NextRecordset	No
	Open	Yes
	Requery	Yes
	Resync	No
	Save	Yes
	Seek	No
	Supports	Yes
	Update	Yes
	UpdateBatch	Yes

Note that the **Collection** object is actually a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection

- **Clear** to empty all objects from a collection
- **Delete** to remove a single object from a collection
- **Item** to return a specific member object of a collection by name or ordinal number
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the ODBC Driver

ADO Property Support in the ODBC Driver for DB2

The following table summarizes the ADO version 2.0 object properties that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Property	Support
Command	ActiveConnection	Yes
	CommandText	Yes
	CommandTimeout	No
	CommandType	Yes
	Prepared	Yes
	State	Yes
Connection	Attributes	Yes
	CommandTimeout	No
	ConnectionString	Yes
	ConnectionTimeout	No
	CursorLocation	Yes.
	DefaultDatabase	No
	IsolationLevel	Yes. Note that versions of the ODBC Driver for DB2 supplied with SNA Server 4.0 did not support this property. **IsolationLevel** was specified in the DIL parameter in the connection string or Data Links dialog. This connection string parameter is not supported by the OLE DB provider supplied with Host Integration Server.
	Mode	Yes
	Provider	Yes
	State	Yes
	Version	Yes
Error	Description	Yes
	HelpContext	No
	HelpFile	No
	NativeError	Yes
	Number	Yes
	Source	Yes
	SQLState	Yes
Field	ActualSize	Yes
	Attributes	Yes
	DataFormat	No
	DefinedSize	Yes
	Name	Yes
	NumericScale	Yes
	OriginalValue	Yes
	Precision	Yes
	Type	Yes
	UnderlyingValue	Yes
	Value	Yes
Parameter	**Attributes**	Yes
	Direction	Yes
	Name	Yes
	NumericScale	Yes
	Precision	Yes

	Size	Yes
	Type	Yes
	Value	Yes
Recordset	**AbsolutePage**	No
	AbsolutePosition	No
	ActiveCommand	Yes
	ActiveConnection	Yes
	BOF	Yes
	Bookmark	Yes
	CacheSize	Yes
	CursorLocation	Yes
	CursorType	Yes
	DataMember	No
	DataSource	No
	EditMode	Yes
	EOF	Yes
	Filter	No
	Index	No
	Locktype	Yes
	MarshalOptions	No
	MaxRecords	Yes
	PageCount	No
	PageSize	No
	RecordCount	No
	Sort	No
	Source	Yes
	State	Yes
	Status	Yes
	StayInSync	No

ADO Collection Support in the ODBC Driver for DB2

The following table summarizes the ADO version 2.0 object collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Collection	Support
Command	**Parameters**	Yes
	Properties	Yes
Connection	**Errors**	Yes
	Properties	Yes
Field	**Properties**	Yes
Parameter	**Properties**	Yes
Recordset	**Fields**	Yes
	Properties	Yes

ADO Command Object in the ODBC Driver for DB2

The ADO **Command** object is a definition of a specific command that is to be executed against an ODBC Driver data source.

Command objects can be used to create a **Recordset** object and obtain records, execute a bulk operation, or manipulate the structure of a database. When using the Microsoft® ODBC Driver for DB2, some collections, methods, or properties of a **Command** object can generate an error when called.

The primary purpose of the **Command** object in the context of the ODBC Driver for DB2 is to issue SQL commands for execution by the remote DB2 target server. Legal SQL commands are documented for the target DB2 platforms in SQL Reference Guides published by IBM.

The following **Command** object methods, properties, and collections are supported by the current version of the ODBC Driver for DB2:

Name	Comment
Execute method	Evaluates command text (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is an SQL text command).
ActiveConnection property	Sets or returns the information used to establish a connection to a data source (see notes following).
CommandText property	Sets or returns the command text to be executed.
CommandType property	Sets or returns the type of command in a **CommandText** property.
State property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. The **Command** object can be used to open tables or execute SQL commands on a remote DB2 server. If errors occur, you can examine them with the **Errors** collection on the **Connection** object.

You can create a **Command** object independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string (for the proper syntax, see the **ConnectionString** property of the **Connection** object). ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object should be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command (**SELECT ALL FROM TABLE**, for example). The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with the ODBC Driver for DB2.

ADO Connection Object in the ODBC Driver for DB2

The ADO **Connection** object represents an open connection to an ODBC data source. The **Provider** property sets the ODBC Driver to use. Setting the **ConnectionString** properties configures the connection before opening the data source. The **Version** property determines the version of the ADO implementation in use.

The **Open** method establishes the physical connection to the data source and the **Close** method terminates the connection. If errors occur, these can be examined with the **Errors** collection.

The following **Connection** object methods, properties, and collections are supported by the current version of the Microsoft ODBC Driver for DB2:

Name	Comment
Close method	Closes a connection to a data source.
Execute method	Evaluates command text.
Open method	Opens a connection to a data source and can optionally pass **ConnectionString** parameters with this method.
OpenSchema method	Obtains database schema information from the ODBC Driver.
Attributes property	One or more characteristics supported for a given **Connection** object.
ConnectionString property	Contains the information used to establish a connection to a data source (see notes following).
CursorLocation property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
IsolationLevel	Sets or returns the level of isolation for a Connection object. Note that versions of the ODBC Driver for DB2 supplied with SNA Server 4.0 did not support this property.
Mode property	Indicates the available permissions for modifying data in a connection.
Provider property	Sets or returns the name of the provider for a connection.
State property	Describes the current state of an object.
Version property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

The information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with the ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property:

Argument	Description
Data Source	A required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file that is stored in the Program Files\Common Files\ODBC\Data Sources directory.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed.
Location	The Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password for use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database.
Provider	Name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
User ID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	**Description**
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.

NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, the alternative TP Name is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the ODBC Driver for DB2 supplied with SNA Server 4.0 are as follows:

Argument	Description
ACM	The Auto Commit Mode parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. The default value for this parameter is true (auto commit). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
BT	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
DIL	This Default Isolation Level parameter determines the isolation level provided for this data source in cases of simultaneous access to DB2 objects by multiple applications. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, this isolation level corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. Please note that the ALL isolation level is not allowed. Users should set the isolation level to RS since this has the equivalent meaning and is defined in DB2 (ALL is not defined in any DB2 system). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.

MCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.

RO	When the Read Only parameter is set to true (RO=1), the ODBC Driver for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the Prompt connection property. For example, the following syntax is valid with ADO 1.5 and ADO 2.0 and prompts the user for **ConnectionString** properties.

```
Conn.ConnectionString = "Provider=DB2OLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters follows:

```
RS.Open "Accounting",Conn,0,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (the **adOpenForwardOnly** enum is 0, for example), *LockType* (the **adLockReadOnly** enum is 1, for example), and *Options* (**adCmdText** is 1, which indicates that the Source name should be evaluated as SQL text). The *Options* parameter must be set to **adCmdText** (1) when used with the a data source name with ODBC Driver for DB2.

The allowable values for CCSID when using SNANLS (SNA National Language Support) for character code conversions (the default) are as follows:

EBCDIC character set	CCSID value
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (Euro)	1142
Denmark/Norway	20277
Finland/Sweden (Euro)	1143
Finland/Sweden	20278

France (Euro)	1147
France	20297
Germany (Euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (Euro)	1149
Icelandic	20871
International (Euro)	1148
International	500
Italy (Euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (Euro)	1145
Latin America/Spain	20284
Latin-1 Open System (Euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (Euro)	1140
U.S./Canada	37
United Kingdom (Euro)	1146
United Kingdom	20285

Note that the SNANLS conversions use the locale configured for the data sources using data links. For more information, see the SDK documentation on SNA National Language Support.

The allowable values for CCSID when using ANSI/OEM for character code conversions are as follows:

ANSI/OEM character set	**CCSID value**
ANSI - Arabic	1256
ANSI - Baltic	1257
ANSI - Cyrillic	1251
ANSI - Eastern Europe	1250
ANSI - Greek	1253
ANSI - Hebrew	1255
ANSI - Latin I	1252
ANSI - Turkish	1254
ANSI/OEM - Korean (Extended Wansung)	949
ANSI/OEM - Japanese Shift-JIS	932
ANSI/OEM - Simplified Chinese GBK	936
ANSI/OEM - Traditional Chinese Big5	950
ANSI/OEM - Thai	874
ANSI/OEM - Vietnam	1258

ADO Error Object in the ODBC Driver for DB2

The ADO **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections; however, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). **Error** objects are automatically appended to the **Errors** collection by the ODBC Driver when they occur. The following **Error** object properties are supported by the current version of the Microsoft® ODBC Driver for DB2:

Property Name	Comment
Description	The text of the error alert that is returned based on the minor error code (specific to the ODBC Driver for DB2) contained in the **Error** object resulting from an error.
NativeError	A Long integer value of the error code returned by the ODBC Driver for DB2.
Number	The Long integer value of the ODBC error constant.
Source	A string that indicates the name of the object or application that originally generated an error.

ADO Field Object in the ODBC Driver for DB2

The ADO **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following **Field** object methods, properties, and collections are supported by the current version of the Microsoft® ODBC Driver for DB2:

Name	Comment
ActualSize property	Actual length of a field's value.
Attributes property	One or more characteristics supported for a given **Field** object.
DefinedSize property	Defined size of a **Field** object.
Name property	Name of the **Field** object.
NumericScale property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue property	Value of a **Field** object that existed in the record before changes were made.
Precision property	Degree of precision for numeric values in a **Field** object for numeric data.
Type property	Operational type or data type for a **Field** object.
UnderlyingValue	Current value of a **Field** object.
Value property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

ADO Recordset Object in the ODBC Driver for DB2

The ADO **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following **Recordset** object methods, properties, and collections are supported by the current version of the Microsoft® ODBC Driver for DB2:

Name	Comment
AddNew method	Creates a new record for an updateable **Recordset** object.
CancelBatch method	Cancels a pending batch update.
CancelUpdate method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close method	Closes an open object and any dependent objects.
Delete method	Deletes the current record in an open **Recordset** object or an object from a collection.
GetRows method	Retrieves multiple records of a **Recordset** into an array.
Move method	Moves the position of the current record in a **Recordset** object.
MoveFirst method	Moves to the first record in a specified **Recordset**.
MoveLast method	Moves to the last record in a specified **Recordset**. This method is only supported when using a client-side cursor.
MoveNext method	Moves to the next record in a specified **Recordset**.
MovePrevious method	Moves to the previous record in a specified **Recordset**. This method is only supported when using a client-side cursor.
Open method	Opens a cursor on a **Recordset**.
Requery method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save method	Saves a **Recordset** in a file or **Stream** object.
Supports method	Determines whether a specified **Recordset** object supports a particular type of function.
Update method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch method	Writes all pending batch updates to disk.
ActiveCommand property	Returns the **Command** object that created the specified **Recordset**.
ActiveConnection property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenForwardOnly CursorType** is supported by the current version of the ODBC Driver for DB2.
EditMode property	Indicates the editing status of the current record type.
EOF property	Indicates whether the current record position is after the last record in a **Recordset** object.
LockType property	Sets or returns the types of locks placed on records during editing. The ODBC Driver for DB2 supports locks of type **adLockReadOnly** and **adLockPessimistic**.
MaxRecords	Sets or returns the maximum number of records to return to a **Recordset** from a query.
Source property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State property	Describes the current state of an object.
Status property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.

Properties collection	Collections of properties on the **Recordset**.

ADO Reference

This section provides reference information on specific ActiveX® Data Objects (ADO) methods, properties, and collections supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft® OLE DB Provider for DB2.

ActiveCommand Property

The **ActiveCommand** property on a **Recordset** object indicates which **Command** object created the associated **Recordset** object. This property returns a Variant that contains a **Command** object. The default is a **Null** object reference.

```
currentCommand = recordset.ActiveCommand
```

Remarks

The **ActiveCommand** property is property is read-only. If a **Command** object was not used to create the current **Recordset**, then a **Null** object reference is returned.

Use this property to find the associated **Command** object when you are given only the resulting **Recordset** object.

ActiveConnection Property

The **ActiveConnection** property on a Command or **Recordset** object indicates to which **Connection** object the specified **Command** or **Recordset** object currently belongs. This property sets or returns a String containing the definition for a connection or a **Connection** object. The default is a **Null** object reference.

```
command.ActiveConnection = connectionString
activeConnectionString = recordset.ActiveConnection
```

Remarks

The **ActiveConnection** property is used to determine the **Connection** object over which the specified **Command** object will execute or the specified **Recordset** will be opened.

For **Command** objects, the **ActiveConnection** property is read/write.

If you attempt to call the **Execute** method on a **Command** object before setting the **ActiveConnection** property to an open **Connection** object or valid connection string, an error occurs.

Under Microsoft® Visual Basic®, setting the **ActiveConnection** property to **Nothing** disassociates the **Command** object from the current **Connection** and causes the OLE DB Provider to release any associated resources on the data source. You can then associate the **Command** object with the same or another **Connection** object. Some providers allow you to change the **ActiveConnection** property setting from one **Connection** to another, without having to first set the property to **Nothing**.

Closing the **Connection** object with which a **Command** object is associated sets the **ActiveConnection** property to **Nothing**. Setting this property to a closed **Connection** object generates an error.

For open **Recordset** objects or for **Recordset** objects whose **Source** property is set to a valid **Command** object, the **ActiveConnection** property is read-only. Otherwise, it is read/write.

You can set the **ActiveConnection** property to a valid **Connection** object or to a valid connection string. In this case, the OLE DB Provider creates a new **Connection** object using this definition and opens the connection. Additionally, the provider may set this property to the new **Connection** object to give you a way to access the **Connection** object for extended error information or to execute other commands.

If the *ActiveConnection* parameter of the **Open** method is used to open a **Recordset** object, the **ActiveConnection** property will inherit the value of the argument.

If the **Source** property of the **Recordset** object is set to a valid **Command** object variable, the **ActiveConnection** property of the **Recordset** inherits the setting of the **Command** object's **ActiveConnection** property.

The information needed to establish a connection to a data source can be set in the **ActiveConnection** property of a **Recordset** object or passed as part of the **Open** method on a **Recordset** object in the *ActiveConnection* parameter. In either case, this information must be in a specific format for use with the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, or the Microsoft®.ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons.

ADO supports several standard ADO-defined arguments for the **ActiveConnection** property as follows:

Argument	**Description**
Data Source	Specifies the name of the data source for the connection. This argument is optional when using the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
File Name	Specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.

Location	The Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	Specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
User ID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target host system and has appropriate access rights to the file.

ActiveConnection Property Support Using the OLE DB Provider for AS/400 and VSAM

The Microsoft® OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which have default values as specified in the table below. These arguments are as follows:

Argument	Description
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0, don't process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCDFileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The Remote DataBase name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in Host Integration Server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** for use with the OLE DB Provider for AS/400 and VSAM follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the Prompt connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

ActiveConnection Property Support Using the OLE DB Provider for DB2

The Microsoft® OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDB NAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.

PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the OLE DB Provider for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
BindType	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.

CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Commit	This parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter defaults to true (auto commit).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
IsoLvl	This parameter determines the isolation level provided for this data source. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommited Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommited. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, isolation level this corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
LocalLU	The name of the local LU alias configured in Host Integration Server.

MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
ReadOnly	When the Read Only parameter is set to true (ReadOnly=1), the OLE DB Provider for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RemoteLU	The name of the remote LU alias configured in Host Integration.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the OLE DB Provider for DB2 follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PcCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

The &_ character combination is used for continuing long lines in Visual Basic.

ActiveConnection Property Support Using the ODBC Driver for DB2

The Microsoft® ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	**Description**
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.

MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.

UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 supplied with Host Integration Server 2000 is as follows:

```
Conn.Provider="MSDASQL"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

The arguments supported by the ODBC Driver for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
ACM	The Auto Commit Mode parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. The default value for this parameter is true (auto commit). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
BT	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.

CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
DIL	This Default Isolation Level parameter determines the isolation level provided for this data source in cases of simultaneous access to DB2 objects by multiple applications. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, this isolation level corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. Please note that the ALL isolation level is not allowed. Users should set the isolation level to RS since this has the equivalent meaning and is defined in DB2 (ALL is not defined in any DB2 system). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.

GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.

RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RO	When the Read Only parameter is set to true (RO=1), the ODBC Driver for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 supplied with SNA Server 4.0 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

ActualSize Property

The **ActualSize** property on a **Field** object indicates the actual length of a field's value. This property returns a returns a Long value.

```
size = field.ActualSize
```

Remarks

The **ActualSize** property is used to return the actual length of a **Field** object's value. For all fields, the **ActualSize** property is read-only. If ADO cannot determine the length of the **Field** object's value, the **ActualSize** property returns **adUnknown**.

The **ActualSize** and **DefinedSize** properties on a **Field** object can be different. For example, a **Field** object with a declared type of **adVarChar** (variable character data type) and a maximum length of 50 characters returns a **DefinedSize** property value of 50, but the **ActualSize** property value it returns is the length of the data stored in the field for the current record.

AddNew Method

The **AddNew** method on a **Recordset** object creates a new record for an updatable **Recordset** object.

```
recordset.AddNew Fields, Values
```

Parameters

Fields
This optional parameter specifies a single name or an array of names or ordinal positions of the fields in the new record.

Values
This optional parameter specifies a single value or an array of values for the fields in the new record. If *Fields* is an array, *Values* must also be an array with the same number of members; otherwise, an error occurs. The order of field names must match the order of field values in each array.

Remarks

The **AddNew** method is used to create and initialize a new record. The **Supports** method can be used with **adAddNew** to verify whether records can be added to the current **Recordset** object.

After the **AddNew** method is called, the new record becomes the current record and remains current after the **Update** method is called. If the **Recordset** object does not support bookmarks, you may not be able to access the new record after you move to another record. Depending on your cursor type, you may need to call the **Requery** method to make the new record accessible.

If **AddNew** is called while editing the current record or while adding a new record, ADO calls the **Update** method to save any changes and then creates the new record.

The behavior of the **AddNew** method depends on the updating mode of the **Recordset** object and whether or not the *Fields* and *Values* arguments are passed.

In immediate update mode, the OLE DB Provider writes changes to the underlying data source after the **Update** method is called. In immediate update mode, calling the **AddNew** method without arguments sets the **EditMode** property to **adEditAdd**. The OLE DB Provider caches any field value changes locally. Calling the **Update** method posts the new record to the database and resets the **EditMode** property to **adEditNone**. If the *Fields* and *Values* arguments are passed, ADO immediately posts the new record to the database (no **Update** call is necessary) and the **EditMode** property value does not change (**adEditNone**).

In batch update mode, the OLE DB Provider caches multiple changes and writes them to the underlying data source only when the **UpdateBatch** method is called. In batch update mode, calling the **AddNew** method without arguments sets the **EditMode** property to **adEditAdd**. The OLE DB Provider caches any field value changes locally. Calling the **Update** method adds the new record to the current **Recordset** object and resets the **EditMode** property to **adEditNone**, but the OLE DB Provider does not post the changes to the underlying database until the **UpdateBatch** method is called. If the *Fields* and *Values* arguments are passed, ADO sends the new record to the provider for storage in a cache and the **UpdateBatch** method must be called to post the new record to the underlying database.

AppendChunk Method

The **AppendChunk** method on a **Field** object appends data to a large text or binary data **Field** object.

```
field.AppendChunk Data
```

Parameters

Data
This parameter specifies a Variant containing the data to be appended to the **Field** object.

Remarks

The **AppendChunk** method is used on a **Field** object to fill it with long binary or character data. In situations where system memory is limited, the **AppendChunk** method can be used to manipulate long values in portions rather than in their entirety.

If the **adFldLong** bit in the **Attributes** property of a **Field** object is set to **True**, the **AppendChunk** method can be used for that field.

The first **AppendChunk** call on a **Field** object writes data to the field, overwriting any existing data. Subsequent **AppendChunk** calls add to existing data. If you are appending data to one field and then set or read the value of another field in the current record, ADO assumes that you are finished appending data to the first field. If the **AppendChunk** method is called on the first field again, ADO interprets the call as a new **AppendChunk** operation and overwrites the existing data. Accessing fields in other **Recordset** objects (that are not clones of the first **Recordset** object) will not disrupt **AppendChunk** operations.

If there is no current record when the **AppendChunk** method is called on a **Field** object, an error occurs.

Attributes Property

The **Attributes** property on a **Field** object or a **Property** object in a **Properties** collection indicates one or more characteristics of an object. This property returns a Long value.

```
attribute = field.Attributes
```

Remarks

The **Attributes** property is used to return characteristics of **Field** objects or **Property** objects.

For a **Field** object, the **Attributes** property is read-only and its value can be the sum of any one or more of the **FieldAttributeEnum** values. The allowable **FieldAttributeEnum** values can be one of the following constants:

Enumeration	Value	Description
adFldMayDefer	0x2	This value indicates that the field is deferred, that is, the field values are not retrieved from the data source with the whole record, but only when you explicitly access them.
adFldUpdatable	0x4	This value indicates that you can write to the field.
adFldUnknownUpdatable	0x8	This value indicates that the provider cannot determine if you can write to the field.
adFldFixed	0x10	This value indicates that the field contains fixed-length data.
adFldIsNullable	0x20	This value indicates that the field accepts Null values.
adFldMayBeNull	0x40	This value indicates that you can read Null values from the field.
adFldLong	0x80	This value indicates that the field is a long binary field. This value also indicates that the **AppendChunk** and **GetChunk** methods on the **Field** object can be used.
adFldRowID	0x100	This value indicates that the field contains some kind of record identifier (record number, unique identifier, and so on).
adFldRowVersion	0x200	This value indicates that the field contains some kind of time or date stamp (often used to track updates).
adFldCacheDeferred	0x1000	This value indicates that the provider caches field values and that subsequent reads are done from the cache.

For a **Property** object, the **Attributes** property is read-only and its value can be the sum of any one or more of the **PropertyAttributesEnum** values. The allowable **PropertyAttributesEnum** values can be one of the following constants:

Enumeration	Value	Description
adPropNotSupported	0	This value indicates that the property is not supported by the provider.
adPropRequired	0x1	This value indicates that the user must specify a value for this property before the data source is initialized.
adPropOptional	0x2	This value indicates that the user does not need to specify a value for this property before the data source is initialized.
adPropRead	0x200	This value indicates that the user can read the property.
adPropWrite	0x400	This value indicates that the user can set the property.

BOF Property

The **BOF** property on a **Recordset** object indicates that the current record position is before the first record in a **Recordset** object. This property returns a Boolean value.

```
IsBOF = recordset.BOF
```

Remarks

The **BOF** property is used to determine whether a **Recordset** object contains records or whether you have gone beyond the limits of a **Recordset** object when you move from record to record.

The **BOF** property returns **True** if the current record position is before the first record and **False** if the current record position is on or after the first record.

If the **BOF** property is **True**, there is no current record.

If a **Recordset** object is opened containing no records, both the **BOF** and **EOF** properties are set to **True**, and the **Recordset** object's **RecordCount** property setting is zero. When a **Recordset** object is opened that contains at least one record, the first record is the current record and the **BOF** and **EOF** properties are **False**.

If the last remaining record in the **Recordset** object is deleted, the **BOF** and **EOF** properties may remain **False** until you attempt to reposition the current record.

This table below indicates which **Move** methods are allowed with different combinations of the **BOF** and **EOF** properties.

	MoveFirst MoveLast	**MovePrevious Move < 0**	**Move 0**	**MoveNext Move > 0**
BOF=True EOF=False	Allowed	Error	Error	Allowed
BOF=False EOF=True	Allowed	Allowed	Error	Error
Both True	Error	Error	Error	Error
Both False	Allowed	Allowed	Allowed	Allowed

> **Note** Executing a **Move** 0 method when the **BOF** property is **True** does not currently generate an error using the OLE DB Provider for AS/400 and VSAM.

> **Note** Allowing a **Move** method does not guarantee that the method will successfully locate a record; it only means that calling the specified **Move** method will not generate an error.

The following table shows what happens to the **BOF** and **EOF** property settings when various **Move** methods are called but are unable to successfully locate a record.

	BOF property	**EOF property**
MoveFirst MoveLast	Set to **True**	Set to **True**
Move 0	No change	No change
MovePrevious Move < 0	Set to **True**	No change
MoveNext Move > 0	No change	Set to **True**

Bookmark Property

The **Bookmark** property on a **Recordset** object returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object to the record identified by a valid bookmark. This property sets or returns a Variant expression that evaluates to a valid bookmark.

```
FirstBookmark = recordset.Bookmark
recordset.Bookmark = PreviousBookmark
```

Remarks

The **Bookmark** property is used to save the position of the current record and return to that record at any time. Bookmarks are available only in **Recordset** objects (host tables) that support the bookmark feature.

When a **Recordset** object is opened, each of its records has a unique bookmark. To save the bookmark for the current record, assign the value of the **Bookmark** property to a variable. To quickly return to that record at any time after moving to a different record, set the **Recordset** object's **Bookmark** property to the value of that variable.

The user may not be able to view the value of the bookmark. Also, users should not expect bookmarks to be directly comparable —two bookmarks that refer to the same record may have different values.

If the **Clone** method is used to create a copy of a **Recordset** object, the **Bookmark** property settings for the original and the duplicate **Recordset** objects are identical and you can use them interchangeably. However, you cannot use bookmarks from different **Recordset** objects interchangeably, even if they were created from the same source or command.

Using the OLE DB Provider for AS/400 and VSAM, only some data sources can be bookmarked. Calling the **Supports** method with the **adBookmark** argument will indicate if the data source (table) can be bookmarked.

CacheSize Property

The **CacheSize** property on a **Recordset** object indicates the number of records from a **Recordset** object that are cached locally in memory. This property sets or returns a Long value that must be greater than zero. The default value for the **CacheSize** property is 1.

```
previousSize = recordset.CacheSize
recordset.CacheSize = 1
```

Remarks

The **CacheSize** property is used to control how many records the provider keeps in its buffer and how many to retrieve at one time into local memory. For example, if the **CacheSize** is 10, after first opening the **Recordset** object, the provider retrieves the first 10 records into local memory. As you move through the **Recordset** object, the provider returns the data from the local memory buffer. As soon as you move past the last record in the cache, the provider retrieves the next 10 records from the data source into the cache.

The value of the **CacheSize** property can be adjusted during the life of the **Recordset** object, but changing this value only affects the number of records in the cache after subsequent retrievals from the data source. Changing the property value alone will not change the current contents of the cache.

If there are fewer records to retrieve than the **CacheSize** property specifies, the provider returns the remaining records; no error occurs.

A **CacheSize** setting of zero is not allowed and returns an error. Non-bookmarkable files cannot have the **CacheSize** property set to greater than one, or an error will occur.

It is strongly recommended that a **CacheSize** of 1 be used with the OLE DB Provider for AS/400 and VSAM. If the **CacheSize** is set greater than 1, it is possible for the local data cached in memory to be out of date from changes made by other users on the host.

CancelBatch Method

The **CancelBatch** method on a **Recordset** object cancels a pending batch update.

```
recordset.CancelBatch AffectedRecords
```

Parameters

AffectedRecords

This optional parameter specifies an **AffectEnum** value that determines how many records the **CancelBatch** method will affect.

The **AffectEnum** value can be one of the following constants:

Enumeration	Value	Description
adAffectCurrent	1	This value cancels pending updates only for the current record.
adAffectGroup	2	This value cancels pending updates for records that satisfy the current Filter property setting. You must set the **Filter** property to one of the valid predefined constants to use this option.
adAffectAll	3	This value cancels pending updates for all the records in the **Recordset** object, including any hidden by the current **Filter** property setting. This value is the default.

Remarks

The **CancelBatch** method is used to cancel any pending updates in a **Recordset** object in batch update mode. If the **Recordset** object is in immediate update mode, calling **CancelBatch** without **adAffectCurrent** generates an error.

If you are editing the current record or are adding a new record when **CancelBatch** is called, ADO first calls the CancelUpdate method to cancel any cached changes, and then all pending changes in the recordset are canceled.

It is possible that the current record will be indeterminable after a **CancelBatch** call, especially if you were in the process of adding a new record. For this reason, it is prudent to set the current record position to a known location in the recordset after the **CancelBatch** method is called. For example, call the **MoveFirst** method.

If the attempt to cancel the pending updates fails because of a conflict with the underlying data (for example, a record has been deleted by another user), the provider returns warnings to the Errors collection but does not halt program execution. A run-time error occurs only if there are conflicts on all the requested records. The Filter property (**adFilterAffectedRecords**) and the **Status** property can be used to locate records with conflicts.

CancelUpdate Method

The **CancelUpdate** method on a **Recordset** object cancels any changes made to the current record or to a new record prior to calling the **Update** method.

```
recordset.CancelUpdate
```

Parameters

None.

Remarks

The **CancelUpdate** method is used to cancel any changes made to the current record or to discard a newly added record. You cannot undo changes to the current record or to a new record after the **Update** method is called unless the changes are part of a batch update that you can cancel with the CancelBatch method.

If you are adding a new record when the **CancelUpdate** method is called, the record that was current prior to the AddNew method call becomes the current record again.

If you have not changed the current record or added a new record, calling the **CancelUpdate** method generates an error.

Clear Method

The **Clear** method on a Collection object removes all of the objects in a collection.

```
collection.Clear
```

Parameters

None.

Remarks

The **Clear** method is used on the **Errors** collection to remove all existing **Error** objects from the collection. When an error occurs, ADO automatically clears the **Errors** collection and fills it with **Error** objects based on the new error. However, some properties and methods return warnings that appear as **Error** objects in the **Errors** collection but do not halt a program's execution. Before calling the **Resync**, **UpdateBatch**, or CancelBatch methods on a **Recordset** object or before setting the Filter property on a **Recordset** object, call the **Clear** method on the **Errors** collection. Doing so enables you to read the **Count** property of the **Errors** collection to test for returned warnings as a result of these specific calls.

Clone Method

The **Clone** method on a **Recordset** object creates a duplicate **Recordset** object from an existing **Recordset** object.

```
rstDuplicate = rstOriginal.Clone
```

Parameters

rstDuplicate
This object variable specifies the duplicate **Recordset** object to be created.
rstOriginal
This object variable specifies the **Recordset** object to be duplicated.

Remarks

The **Clone** method is used on a **Recordset** object to create multiple, duplicate **Recordset** objects, particularly if you want to be able to maintain more than one current record in a given set of records. Using the **Clone** method is more efficient than creating and opening a new **Recordset** object with the same definition as the original.

The current record of a newly created clone is set to the first record.

Changes made to one **Recordset** object are visible in all of its clones regardless of cursor type. However, after you execute **Requery** on the original **Recordset**, the clones will no longer be synchronized to the original.

Closing the original **Recordset** does not close its copies; closing a copy does not close the original or any of the other copies.

You can only clone a **Recordset** object that supports bookmarks. Bookmark values are interchangeable; that is, a bookmark reference from one **Recordset** object refers to the same record in any of its clones.

Close Method

The **Close** method on a **Connection** or **Recordset** object closes an open object and any dependent objects.

```
recordSet.Close
```

Parameters

None

Remarks

The **Close** method is used to close either a **Connection** object or a **Recordset** object to free any associated system resources. Closing an object does not remove it from memory; you may change its property settings and open it again later. To completely eliminate an object from memory, set the object variable to **Nothing**.

Using the **Close** method to close a **Connection** object also closes any active **Recordset** objects associated with the connection. A **Command** object associated with the **Connection** object you are closing will persist, but it will no longer be associated with a **Connection** object, that is, its **ActiveConnection** property will be set to **Nothing**.

You can later call the **Open** method to reestablish the connection to the same or another data source. While the **Connection** object is closed, calling any methods that require an open connection to the data source generates an error. Closing a **Connection** object while there are open **Recordset** objects on the connection rolls back any pending changes in all of the **Recordset** objects.

Using the **Close** method to close a **Recordset** object releases the associated data and any exclusive access you may have had to the data through this particular **Recordset** object. You can later call the **Open** method to reopen the recordset with the same or modified attributes. While the **Recordset** object is closed, calling any methods that require a live cursor generates an error.

If an edit is in progress while in immediate update mode, calling the **Close** method generates an error. The **Update** or CancelUpdate methods should be called first. If you close the **Recordset** object during batch updating, everything changes since the last **UpdateBatch** call is lost.

CommandText Property

The **CommandText** property on a **Command** object contains the text of a command that you want to issue against a provider. This property sets or returns a String value containing a provider command, such as an AS/400 Command Language (CL) command for execution by the remote OS/400 DDM target server or an SQL command for execution on a DB2 database server. The default value for the **CommandText** property is a zero-length string.

```
previousCommandtext = command.CommandText
command.CommandText = "EXEC COMMAND DDMCmd"
```

Remarks

The **CommandText** property is used to set or return the text of a **Command** object. When used with the OLE DB Provider for AS/400 and VSAM, the text can be an AS/400 CL command for execution by the remote OS/400 DDM target server or a request to open a table on a host (a remote DDM Server). When used with the OLE DB Provider for DB2, the text can be an SQL command for execution or a call to a stored procedure.

If the **Prepared** property of the **Command** object is set to **True** and the **Command** object is bound to an open connection when you set the **CommandText** property, ADO prepares the query when you call the **Execute** or **Open** methods.

Depending on the **CommandType** property setting, ADO may alter the **CommandText** property. The **CommandText** property can be read at any time to see the actual command text that ADO will use during execution.

The **CommandText** property defines the text version of a command. The syntax for the string in the **CommandText** property when used with the OLE DB Provider for AS/400 and VSAM is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

With the OLE DB Provider for AS/400 and VSAM, the **Command** object can also be used to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open. When used with the OLE DB Provider for AS/400 and VSAM, the syntax for the **CommandText** property string in this case is as follows:

```
EXEC OPEN DataSetName
```

where *DataSetName* represents a valid data file or library member on the host. If you open a host data file from a **Command** object, then the data file is opened as read-only. This results from the limitation that no argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updatable.

The syntax for the string in the **CommandText** property when used with the OLE DB Provider for DB2 can be one of the following:

```
EXEC SQLStatement
```

where SQLStatement represents a valid SQL statement supported by DB2.

```
CALL StoredProcedure
```

where StoredProcedure represents a valid DB2 stored procedure on the database server.

The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution in order to optimize performance. The **CommandType** property must be set to **adCmdText** for use with the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

CommandType Property

The **CommandType** property on a **Command** object Indicates the type of a **Command** object. This property sets or returns a **CommandTypeEnum** value.

```
oldType = command.CommandType
command.CommandType = newType
```

Remarks

The **CommandType** property is used to set or return the type of a **Command** object. This property specifies a **CommandTypeEnum** value that can be one of the following constants:

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandType** property has been unspecified.
adCmdText	1	This value evaluates the **CommandText** property as a textual definition of a command command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2. See remarks below regarding using stored procedures using the OLE DB Provider for DB2.
adCmdUnknown	8	This value indicates that the type of command in a **CommandText** property is not known. This is the default value.

The OLE DB Provider for AS/400 and VSAM and the OLE DB Provider for DB2 only support the **adCmdText** type for the **CommandType** property. If any other value for the **CommandType** property is set, errors will occur.

The OLE DB Provider for DB2 supports calling DB2 stored procedures. An application must use the CALL keyword before the SQL statement in order to execute a stored procedure. When using ADO, a **CommandType** property of **adCmdStoredProc** cannot be used for executing a stored procedure since ADO inserts an EXEC not CALL keyword before the command text. In order to execute a stored procedure using ADO, the **CommandType** property should be set to **adCmdText** and the CALL keyword should be used before the SQL statement containing the stored procedure to be executed.

ConnectionString Property

The **ConnectionString** property on a **Connection** object contains the information used to establish a connection to a data source. This property sets or returns a string value.

```
oldString = connection.ConnectionString
connection.ConnectionString = newString
```

Remarks

The **ConnectionString** property is used to specify a data source by passing a detailed connection string containing a series of *argument = value* statements separated by semicolons.

ADO supports several standard arguments for the **ConnectionString** property. Any other arguments are passed directly to the provider without any processing by ADO. This information must be in a specific format for use with the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, or the Microsoft® ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property as follows:

Argument	Description
DataSource	This argument specifies the name of the data source for the connection. This argument is optional when using the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
FileName	This argument specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	The Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	This argument specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	This argument specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
Remote Provider	This argument specifies the name of a provider to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
Remote Server	This argument specifies the path name of a server to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
User ID	This argument specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target host system and has appropriate access rights to the file.

Note Not all of these parameters are required. The user can also be prompted for this information.

The OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which default have default values as specified in the table below. These arguments are as follows:

Argument	Description
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0, don't process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).

Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCDFileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The Remote DataBase name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in Host Integration Server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** for use with the OLE DB Provider for AS/400 and VSAM follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the Prompt connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	Description
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the OLE DB Provider for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
BindType	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Commit	This parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter defaults to true (auto commit).

DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
IsoLvl	This parameter determines the isolation level provided for this data source. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommited Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommited. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, isolation level this corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
LocalLU	The name of the local LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.

ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
ReadOnly	When the Read Only parameter is set to true (ReadOnly=1), the OLE DB Provider for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RemoteLU	The name of the remote LU alias configured in Host Integration.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the OLE DB Provider for DB2 supplied with SNA Server 4.0 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PcCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2000 differ from the

arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	Description
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.

NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 supplied with Host Integration Server 2000 is as follows:

```
Conn.Provider="MSDASQL"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

The arguments supported by the ODBC Driver for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
ACM	The Auto Commit Mode parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. The default value for this parameter is true (auto commit). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
BT	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
DIL	This Default Isolation Level parameter determines the isolation level provided for this data source in cases of simultaneous access to DB2 objects by multiple applications. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, this isolation level corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. Please note that the ALL isolation level is not allowed. Users should set the isolation level to RS since this has the equivalent meaning and is defined in DB2 (ALL is not defined in any DB2 system). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.

MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.

RO	When the Read Only parameter is set to true (RO=1), the ODBC Driver for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.

Note Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 supplied with SNA Server 4.0 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note The &_ character combination is used for continuing long lines in Visual Basic.

After the **ConnectionString** property is set and the **Connection** object is opened, the provider may alter the contents of the property, for example, by mapping the ADO-defined argument names to their provider equivalents. Using the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2, three items are stripped from the **ConnectionString** after a **Connection** object is opened: Data Source, User ID, and Password.

The **ConnectionString** property automatically inherits the value used for the *ConnectionString* argument of the **Open** method on a **Connection** object, so you can override the current **ConnectionString** property during the **Open** method call. Therefore, the **ConnectionString** property of the **Connection** object can be set before opening the **Connection** object, or the *ConnectionString* parameter can be used to set or override the current connection parameters during the **Open** method call.

The **ConnectionString** property is read/write when the connection is closed and read-only when it is open.

If user and password information is set in both the **ConnectionString** property and in the optional *UserID* and *Password* parameters to the **Open** method, the results may be unpredictable. Such information should only be passed in either the **ConnectionString** property (or the *ConnectionString* parameter to the **Open** method call) or in the *UserID* and *Password* parameters.

There are a number of different ways to open a connection. The **Open** method can pass all of the appropriate connection information as part of the *ConnectionString* parameter or by setting the **ConnectionString** property of the **Connection** object, if this information is known in advance. The syntax in this case using the **ConnectionString** property is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.Provider="SNAOLEDB"
connection.ConnectionString = "User ID=USERNAME;Password=password;Local LU=LOCAL;Remote LU=DA
TABASE;ModeName=QPCSUPP;CCSID=37;CodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

There is a lack of spaces after the semicolons in the string. If spaces are inserted after the semicolons, an error will occur.

The simplest form of a **ConnectionString** property that contains all necessary information is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.ConnectionString = "Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME;Password=
password;ModeName=QPCSUPP"
```

Note The User ID and Password must be included. Note the lack of spaces after the semicolons in the string. If spaces are inserted after the semicolons, an error will occur.

In the case where you would like the user to input the connection information, the following syntax can be used. This syntax does not specify any connection information except the provider, which is always required unless this is set in the **ConnectionString** or **Provider** property of the **Connection** object:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.ConnectionString = "Provider=SNAOLEDB"
Conn.Properties("PROMPT")=adPromptAlways
connection.Open
```

This method of invoking the **Open** method automatically causes a dialog box to appear asking the user for the user name, password, and other necessary information.

CursorLocation Property

The **CursorLocation** property on a **Connection** object or **Recordset** object indicates the location of the cursor engine. This property sets or returns a Long value representing a **CursorLocationEnum**.

```
cursor = connection.CursorLocation
connection.CursorLocation = adUseServer
```

Remarks

The **CursorLocation** property is used to set or return the location of the cursor. This property can be set to one of the following **CursorLocationEnum** constants:

Enumeration	Value	Description
adUseNone	1	This value indicates no cursor location. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.
adUseServer	2	This value indicates that the data provider or driver-supplied cursor is used.
adUseClient	3	This value indicates that a client-side cursor supplied by a local cursor library is to be used.
adUseClientBatch	3	For backward compatibility, this value indicates that a client-side cursor supplied by a local cursor library is to be used.

This property setting only affects connections established after the property has been set. Changing the **CursorLocation** property has no effect on existing connections.

This property is read/write on a **Connection** object or a closed **Recordset**, object and read-only on an open **Recordset**.

If the **CursorLocation** property is set to **adUseClient**, the recordset will be accessible as read-only, and recordset updates to the host are not possible. When the **CursorLocation** property is set to **adUseClient** (use the client cursor engine), the **Find** method, **Filter** property, and **Sort** property will work if MDAC 2.0 or higher is installed, but will not work properly with earlier versions of ADO.

CursorType Property

The **CursorType** property on a **Recordset** object indicates the type of the cursor engine. This property sets or returns a Long value representing a **CursorTypeEnum**.

```
oldType = recordset.CursorType
recordset.CursorType = newType
```

Remarks

The **CursorType** property is used to set or return the type of the cursor that the provider should use when opening the **Recordset**. This property can be one of the following enumerated values for **CursorTypeEnum**:

Enumeration	Value	Description
adOpenUnspecified	-1	This indicates an unspecified value for the *CursorType*. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE DB Provider for DB2.
AdOpenForwardOnly	0	Specifying this value opens a forward-only-type cursor. This *CursorType* is identical to a static cursor, except that you can only scroll forward through records. This improves performance when only one pass through a **Recordset** is needed. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.
AdOpenKeyset	1	Specifying this value opens a keyset-type cursor. This *CursorType is* similar to a dynamic cursor with a few exceptions. Records that other users delete are inaccessible from your **Recordset**. Data changes to existing records by other users are still visible, but records added by other users are not visible (cannot be seen). This value is not supported by the OLE DB Provider for AS/400 and VSAM.
AdOpenDynamic	2	Specifying this value opens a dynamic-type cursor. Additions, changes, and deletions by other users are visible, and all types of movement through the recordset are allowed, except for bookmarks if the provider does not support them. A dynamic cursor is the only *CursorType* supported by the OLE DB Provider for AS/400 and VSAM.
AdOpenStatic	3	Specifying this value opens a static-type cursor. A static cursor provides a static copy of a set of records that can be used to find data or generate reports. Additions, changes, or deletions by other users are not visible with a static cursor. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

Note that the **Open** method on a **Recordset** object defaults this property to **adOpenForwardOnly**, a value that is mapped to **adOpenDynamic** by the OLE DB provider for AS/400 and VSAM.

This property setting only affects connections established after the property has been set. Changing the **CursorType** property has no effect on existing connections. The **CursorType** property is read/write when the **Recordset** is closed and read-only when it is open.

If a provider does not support the requested cursor type, the provider may return another cursor type. The **CursorType** property will change to match the actual cursor type in use when the **Recordset** object is open. To verify whether a specific returned cursor is supported, use the **Supports** method. When using the OLE DB Provider for AS/400 and VSAM, the **Supports** method returns **adMovePrevious** as true with **CursorType** set to **adOpenDynamic**. After you close the **Recordset**, the **CursorType** property reverts to its original setting.

DefinedSize Property

The **DefinedSize** property on a **Field** object indicates the defined size of a field object. This property returns a Long value that reflects the defined size of a field as a number of bytes.

```
size = field.DefinedSize
```

Remarks

The **DefinedSize** property is used to return the data capacity or length of a **Field** object. For all fields, the **DefinedSize** property is read-only. If ADO cannot determine the length of the **Field** object, the **ActualSize** property returns **adUnknown**.

The **ActualSize** and **DefinedSize** properties on a field object can be different. For example, a **Field** object with a declared type of **adVarChar** (variable character data type) and a maximum length of 50 characters returns a **DefinedSize** property value of 50, but the **ActualSize** property value it returns is the length of the data stored in the field for the current record.

Delete Method

The **Delete** method on a **Recordset** object deletes the current record or a group of records.

```
recordSet.Delete AffectedRecords
```

Parameters

AffectedRecords

This optional parameter specifies an **AffectEnum** value that determines how many records the **Delete** method will affect.

The **AffectEnum** value can be one of the following constants:

Enumeration	Value	Description
adAffectCurrent	1	This value deletes only the current record.
adAffectGroup	2	This value deletes the records that satisfy the current Filter property setting. You must set the **Filter** property to one of the valid predefined constants to use this option.

Remarks

The **Delete** method is used to mark the current record or a group of records in a **Recordset** object for deletion. If the **Recordset** object does not allow record deletion, an error occurs. If you are in immediate update mode, deletions occur in the database immediately. Otherwise, the records are marked for deletion from the cache and the actual deletion happens when the **UpdateBatch** method is called. (Use the **Filter** property to view the deleted records.)

Retrieving field values from the deleted record generates an error. After deleting the current record, the deleted record remains current until you move to a different record. After you move away from the deleted record, it is no longer accessible.

If you are in batch update mode, the CancelBatch method can be used to cancel a pending deletion or group of pending deletions.

If the attempt to delete records fails because of a conflict with the underlying data (for example, a record has already been deleted by another user), the data provider returns warnings to the **Errors** collection but does not halt program execution. A run-time error occurs only if there are conflicts on all the requested records.

Description Property

The **Description** property on a **Error** object describes the **Error** object. This property returns a String value that contains a description of the error.

```
errorString = currentError.Description
```

Remarks

The **Description** property on a **Error** object is used to obtain a short description of the error. Applications can display this property to alert the user to an error that the application does not want to handle. The string will come from either ADO or a data provider such as the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, or the Microsoft® ODBC Driver for DB2. The provider is responsible for passing specific error text to ADO.

ADO adds an **Error** object to the **Errors** collection for each provider error or warning it receives. An application can enumerate the **Errors** collection to trace the errors that the provider passes.

EditMode Property

The **EditMode** property on a **Recordset** object indicates the editing status of the current record. This property returns a Long value representing a **EditModeEnum**.

```
currentMode = recordset.EditMode
connection.CursorType = newType
```

Remarks

The **EditMode** property is used to return the editing status of the current recordset. This property can be one of the following enumerated values for **EditModeEnum**:

Enumeration	Value	Description
adEditNone	0	This value indicates that no editing operation is in progress.
adEditInProgress	1	This value indicates that data in the current record has been modified but not saved.
adEditAdd	2	This value indicates that the **AddNew** method has been called, and the current record in the copy buffer is a new record that has not been saved in the database.
adEditDelete	4	This value indicates that the current record has been deleted.

ADO maintains an editing buffer associated with the current record. The **EditMode** property indicates whether changes have been made to this buffer, or whether a new record has been created. Use the **EditMode** property to determine the editing status of the current record. You can test for pending changes if an editing process has been interrupted and determine whether you need to use the Update or CancelUpdate method.

See the AddNew method for a more detailed description of the **EditMode** property under different editing conditions.

EOF Property

The **EOF** property on a **Recordset** object indicates that the current record position is after the last record in a **Recordset** object. This property returns a Boolean value.

```
IsEOF = recordset.EOF
```

Remarks

The **EOF** property is used to determine whether a **Recordset** object contains records or whether you have gone beyond the limits of a **Recordset** object when you move from record to record.

The **EOF** property returns **True** if the current record position is after the last record and **False** if the current record position is on or before the last record.

If the **EOF** property is **True**, there is no current record.

If a **Recordset** object is opened containing no records, both the **BOF** and **EOF** properties are set to **True**, and the **Recordset** object's **RecordCount** property setting is zero. When a **Recordset** object is opened that contains at least one record, the first record is the current record and the **BOF** and **EOF** properties are **False**.

If the last remaining record in the **Recordset** object is deleted, the **BOF** and **EOF** properties may remain **False** until you attempt to reposition the current record.

This table below indicates which **Move** methods are allowed with different combinations of the **BOF** and **EOF** properties.

	MoveFirst MoveLast	**MovePrevious Move < 0**	**Move 0**	**MoveNext Move > 0**
BOF=True EOF=False	Allowed	Error	Error	Allowed
BOF=False EOF=True	Allowed	Allowed	Error	Error
Both True	Error	Error	Error	Error
Both False	Allowed	Allowed	Allowed	Allowed

Allowing a **Move** method does not guarantee that the method will successfully locate a record; it only means that calling the specified **Move** method will not generate an error.

The following table shows what happens to the **BOF** and **EOF** property settings when various **Move** methods are called, but are unable to successfully locate a record:

	BOF Property	**EOF Property**
MoveFirst MoveLast	Set to **True**	Set to **True**
Move 0	No change	No change
MovePrevious Move < 0	Set to **True**	No change
MoveNext Move > 0	No change	Set to **True**

Execute Method on Command Object

The **Execute** method on a **Command** object executes the statement specified in the **CommandText** property.

```
command.Execute( RecordsAffected, Parameters, Options )
set recordSet = command.Execute( RecordsAffected, Parameters,
Options )
```

Parameters

RecordsAffected
This optional parameter specifies a Long variable to which the provider returns the number of records that the operation affected.

Parameters
This optional parameter specifies a Variant array of parameter values passed with an SQL statement and is not used by the OLE DB Provider for AS/400 and VSAM.

Options
This optional parameter specifies a Long value representing a **CommandTypeEnum** value that indicates how the provider should evaluate the **CommandText** property of the **Command** object.

The **CommandTypeEnum** value can be one of the constants listed in the table following the Parameters section.

Constants used for CommandTypeEnum

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandText** property is unspecified. This value is not supported by the Microsoft ® OLE DB Provider for AS/400 and VSAM.
adCmdText	1	This value evaluates the **CommandText** property as a as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE DB Provider for DB2.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adCmdUnknown	8	This value indicates that the type of command in **CommandText** is not known. This value is the default. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

The default for *Option* is a**dCmdText** under the OLE DB Provider for AS/400 and VSAM and the OLE DB Provider for DB2.

Remarks

When used with the OLE DB Provider for AS/400 and VSAM, the **Execute** method on a **Command** object can be used to open tables or execute DDM commands on a remote DDM server. The *Options* parameter must be set to **adCmdText** for use with the OLE DB Provider for AS/400 and VSAM.

The primary purpose of the **Command** object in the context of the OLE DB Provider for AS/400 and VSAM is to issue AS/400 Command Language (CL) commands for execution by the remote OS/400 DDM target server. To invoke DDM commands on a remote DDM server, the **CommandText** property defines the text version of a command which must have been set to:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

Note that this method does not return the results or output of a remote DDM CL command. If the results or output of a remote command are to be captured, the ***DDMCmd*** statement to be executed must include syntax to redirect the command output to a file on the AS/400 host and then explicitly open this output file after the command has completed.

The **Execute** method on a **Command** object can also be used to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open and must be set to:

```
EXEC OPEN DataSetName
```

where *DataSetName* represents a valid data file or library member on the host. When used in this way, the **Execute** method returns a **Recordset** object. If you open a host data file from a **Command** object, then the data file is opened as read-only. This results from the limitation that no argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updatable.

When used with the OLE DB Provider for DB2, the **Execute** method on a **Command** object can be used to execute SQL statements or call a stored procedure. The **CommandText** property defines the SQL statements to execute and must be set to one of the following:

```
EXEC SQLStatement
```

where SQLStatement represents a valid SQL statement supported by DB2.

```
CALL StoredProcedure
```

where StoredProcedure represents a valid DB2 stored procedure on the database server.

If errors occur, these can be examined with the **Errors** collection on the **Command** object.

Execute Method on Connection Object

The **Execute** method on a **Connection** object executes the statement specified in the **CommandText** property.

```
connection.Execute CommandText, RecordsAffected, Options
set recordset = connection.Execute( CommandText, RecordsAffected,
Options )
```

Parameters

RecordsAffected
This optional parameter specifies a Long variable to which the provider returns the number of records that the operation affected.

Options
This optional parameter specifies a Long value representing a **CommandTypeEnum** value that indicates how the provider should evaluate the **CommandText** property of the Command object.

The CommandTypeEnum value can be one of the following constants:

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandText** property is unspecified. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE DB Provider for DB2.
adCmdText	1	This value evaluates the **CommandText** property as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure name. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdUnknown	8	This value indicates that the type of command in **CommandText** is not known. This value is the default. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

Remarks

The **Execute** method on a **Connection** object can be used to open tables or execute DDM commands on a remote DDM server. The *Options* parameter must be set to **adCmdText** for use with the OLE DB Provider for AS/400 and VSAM.

The **Execute** method on a **Connection** object is primarily used to open a data file after a **Connection** object has been created. The **CommandText** property defines the data file to open and must be set to:

```
EXEC OPEN DataSetName
```

where *DataSetName* represents a valid data file or library member on the host. When used in this way, the **Execute** method returns a **Recordset** object. If you open a host data file from a **Connection** object, then the data file is opened as read-only. This results from the limitation that no argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updatable. If a **Recordset** object is desired that is not read-only, then first create a **Recordset** object with the desired property settings, and use the **Recordset** object's **Open** method to return the open **Recordset**.

The **Execute** method on a **Connection** object can also be used to issue AS/400 Command Language (CL) commands for execution by the remote OS/400 DDM target server. To invoke DDM commands on a remote DDM server, the **CommandText** property defines the text version of a command which must have been set to:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

Note that this method does not return the results or output of a remote DDM CL command. If the results or output of a remote command are to be captured, the ***DDMCmd*** statement to be executed must include syntax to redirect the command output to a file on the AS/400 host and then explicitly open this output file after the command has completed.

If errors occur, these can be examined with the **Errors** collection on the **Connection** object.

Filter Property

The **Filter** property on a **Recordset** object indicates a filter for data in a **Recordset**. This property sets or returns a Variant value.

```
recordset.Filter = Criteria
```

Parameters

Criteria

This parameter specifies a Variant.

It can be either a criteria (a where clause) or one of the following enumerated values for **FilterGroupEnum**:

Enumeration	Value	Description
adFilterNone	0	No filter. This value removes the current filter and restores all records to view.
AdFilterPendingRecords	1	Use the pending records. This value allows viewing only those records that have changed but have not yet been sent to the server. This value is only applicable for batch update mode.
AdFilterAffectedRecords	2	Use only records affected by the last **Delete**, **Resync**, **UpdateBatch**, or **CancelBatch** call.
AdFilterFetchedRecords	3	Use the last fetched records. This value allows viewing the records in the current cache returned as a result of the last call to retrieve records (implying a resynchronization).
AdFilterConflictingRecords	5	Use the conflicting records. This value allows viewing only those records that failed the last batch update.

Remarks

The **Filter** property is not supported by the Microsoft® OLE DB Provider for DB2 or the Microsoft® ODBC Driver for DB2.

The **Filter** property is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM on certain files. In order to use the Recordset **Filter** property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this property is used on an AS/400 nonkeyed physical file or any other mainframe file type, then the method fails.

When the **Filter** property is used with a criteria, the where clause is a combination of triplets. Each triplet consists of a column name, an operator, and a literal value. These where clause triplets can be combined with **AND**s and **OR**s for more complex logical filters.

If *Criteria* is a single-condition where clause, then any operator can be used. The construction of a single-condition where clause consists of a column name (the database field), an operator (greater than or equal, for example), and a literal value.

Examples of a single-condition where clause is as follows:

- recordset.Filter = "LastName = 'Jones' "
- recordset.Filter ="Salary > 30000.0"

The *Criteria* argument can be a two-condition with the following restrictions:

- If the column name (the database field) is the same in both clauses, then the separate where clauses must define a contiguous range.
- If the column names are different, then the operators must be the same. If the operators are "LIKE", then the filtered region may be unexpected.

Examples of acceptable two-condition where clauses are as follows:

- recordset.Filter = "LastName = 'Jones' **AND** FirstName = 'Tom' "
- recordset.Filter = "Cost = 5000.00 **OR** Cost > 5000.00 "

The *Criteria* argument can be three or more conditions with the following restrictions:

- The operators must be the same for all conditions. If the operators are "LIKE", then the filtered region may be unexpected.

In all cases, if the "=" operator is used, then the column names specified in the where clause must be keyed columns in the file.

One restriction on these combinations is that **OR** clauses can only be used at the highest (major) level of the logical operation.

Examples of acceptable *Criteria* meeting these conditions are:

- recordset.Filter = "(Title='Manager' **AND** Salary>30000) **OR** (Title='Administrator' **AND** Salary>50000)"
- recordset.Filter ="Salary > 30000.0"

An example of illegal *Criteria* is:

- recordset.Filter = "(Title='Associate' **OR** Salary >30000) **AND** (Title='Administrator')"

The operator can also use wildcards (* or %) in character expressions as follows:

- recordset.Filter = "Lastname LIKE '*SMITH*'"

To determine if any records were found meeting the *Criteria*, the application should check the **Recordset EOF** property. If **EOF** is true, then no records were found meeting the where clause specified in the *Criteria* parameter.

If the CursorLocation property is set to **adUseClient** (use the client cursor engine), the **Filter** property will work if MDAC 2.0 or later is installed but will not work properly with earlier versions of ADO.

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

Find Method

The **Find** method on a **Recordset** object locates or seeks to the next record in a **Recordset** object that meets a particular condition and makes this the current record. This method can be used to seek to a specific record in a **Recordset** object based on a where clause (similar to an SQL where clause) defined by the user.

```
recordset.Find Criteria, SkipRecords, SearchDirection, Start
```

Parameters

ADO supports four arguments for the **Find** method, but the last three arguments are optional and have default values as noted below:

Criteria
This BSTR parameter specifies the criteria used for locating or seeking to a record in a **Recordset** object.

SkipRecords
This optional parameter specifies a Long expression that indicates the number of records to skip (whether to skip the current record) when locating a record in a **Recordset** object. The default value for this argument is 0 (don't skip the current record). The first time a **Find** method is used, this argument is usually set to 0 (the default). On subsequent calls to this method to seek other records that meet the specified condition, this argument would normally be set to 1, to skip one record forward before finding the next record that matches the search *Criteria*. A negative value for this parameter is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.

SearchDirection
This optional parameter is an enumeration that specifies the direction for the search.

It can be one of the following enumerated values for **SearchDirectionEnum**:

Enumeration	Value	Description
adSearchForward	0	Search forward from the current record.
AdSearchBackward	1	Search backward from the current record. This option is not supported by the OLE DB Provider for AS/400 and VSAM.

This optional argument defaults to **adSearchForward**.

Start
This optional parameter specifies the starting location for a search, which can be a bookmark or an enumeration indicating the current, first, or last record in a **Recordset** object. This argument is a Variant.

It can be either a bookmark or one of the following enumerated values for **BookmarkEnum**:

Enumeration	Value	Description
adBookmarkCurrent	0	The current record.
AdBookmarkFirst	1	The first record.
AdBookmarkLast	2	The last record.

This optional argument defaults to **adBookmarkCurrent**.

Remarks

The **Find** method is not supported by the Microsoft® OLE DB Provider for DB2 or the Microsoft® ODBC Driver for DB2.

The **Find** method is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM on certain files. In order to use the Recordset **Find** method, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this method is used on an AS/400 nonkeyed physical file or any other mainframe file type, then the method fails.

The first parameter is the only required argument for the **Find** method. All of the other arguments are optional and have default values. This first argument is a single-condition where clause. The construction of a single-condition where clause consists of a column name (the database field), an operator (greater than or equal, for example), and a literal value.

Examples of acceptable single-condition where clauses are as follows:

- recordset.Find, "Cost > 10000.00"

- recordset.Find, "Cost < 100.00"
- recordset.Find, "Cost = 5000.00"
- recordset.Find, "LastName = 'Jones' "

Note that variables cannot be used as substitutes for literal values. If the file has multiple keys in the index, using the "=" operator will always fail since the values of all keys cannot be specified.

If the CursorLocation property is set to **adUseClient** (use the client cursor engine), the **Filter** method will work if MDAC 2.0 or later is installed, but will not work properly with earlier versions of ADO.

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

GetChunk Method

The **GetChunk** method on a **Field** object returns all or a portion of the contents of a large text or binary data **Field** object.

```
variable = field.GetChunk( Size )
```

Parameters

Size
This parameter specifies a Long expression equal to the number of bytes or characters to be retrieved.

Return Values

A Variant.

Remarks

The **GetChunk** method on a **Field** object is used to retrieve part or all of its long binary or character data. In situations where system memory is limited, the **GetChunk** method can be used to manipulate long values in portions rather than in their entirety.

The data that a **GetChunk** method returns is assigned to a variable. If the *Size* parameter is greater than the remaining data, the **GetChunk** method returns only the remaining data without padding the variable with empty spaces. If the **Field** object is empty, the **GetChunk** method returns Null.

Each subsequent **GetChunk** method call retrieves data starting from where the previous **GetChunk** call left off. However, if you are retrieving data from one field and then set or read the value of another field in the current record, ADO assumes you are finished retrieving data from the first field. If the **GetChunk** method is called on the first field again, ADO interprets the call as a new **GetChunk** operation and starts reading from the beginning of the data. Accessing **Field** objects in other **Recordset** objects (that are not clones of the first **Recordset** object) will not disrupt **GetChunk** operations.

If the **adFldLong** bit in the **Attributes** property of a **Field** object is set to **True**, the **GetChunk** method can be used for that **Field** object.

If there is no current record when the **GetChunk** method is invoked on a **Field** object, error 3021 (no current record) occurs.

GetRows Method

The **GetRows** method on a **Recordset** object retrieves multiple records of a recordset into an array.

```
array = recordset.GetRows( Rows, Start, Fields )
```

Parameters

Rows

This optional parameter specifies a Long expression indicating the number of records to retrieve. The default value if this parameter is not specified is an **GetRowSetEnum** which is **adGetRowsRest** (value = -1).

Start

This optional parameter specifies the starting location for the record from which the **GetRows** operation should begin, which can be a bookmark or an enumeration indicating the current, first, or last record in a **Recordset** object. This argument is a Variant.

It can be either a bookmark or one of the following enumerated values for **BookmarkEnum**:

Enumeration	Value	Description
adBookmarkCurrent	0	The current record
adBookmarkFirst	1	The first record
adBookmarkLast	2	The last record

This optional argument defaults to **adBookmarkCurrent**.

Fields

This optional parameter is a Variant and specifies a single field name or ordinal position or an array of field names or ordinal position numbers. ADO returns only the data in these fields.

Return Values

A two-dimensional array.

Remarks

The **GetRows** method is used to copy records from a recordset into a two-dimensional array. The first subscript of the array identifies the field and the second array subscript identifies the record number. The array variable is automatically dimensioned to the correct size when the **GetRows** method returns the data.

If a value is not specified for the *Rows* parameter, the **GetRows** method automatically retrieves all the records in the **Recordset** object. If more records are requested than are available, **GetRows** returns only the number of available records.

If the **Recordset** object supports bookmarks, you can specify at which record the **GetRows** method should begin retrieving data by passing the value of that record's **Bookmark** property.

To restrict the fields that the **GetRows** method returns, you can pass either a single field name/number or an array of field names/numbers in the *Fields* argument.

After the **GetRows** method is called, the next unread record becomes the current record, or the **EOF** property is set to **True** if there are no more records.

IsolationLevel Property

The **IsolationLevel** property on a **Connection** object indicates the level of isolation for a Connection object. This property sets or returns a Long value representing an **IsolationLevelEnum**. The default value for this property is **adXactChaos.**

```
currentIsoLevel = connection.IsolationLevel
connection.IsolationLevel = newIsoLevel
```

Remarks

The **IsolationLevel** property is used to set the type of isolation level placed on a connection that the provider should use when opening the **Conection** object. This property can also be used to return the type of isolation level in use on an open **Connection** object.

This property can be one of the following enumerated values for **IsolationLevelEnum**:

Enumeration	Value	Description
adXactUnspecified	-1	This value indicates that the provider is using a different isolation level than specified, but that the level cannot be determined.
adXactChaos	16	This value indicates that pending changes from more highly isolated transactions cannot be overwritten.
adXactBrowse	256	This value indicates that from one transaction you can view uncommitted changes in other transactions.
adXactReadUncommitted	256	Same as **adXactBrowse**.
adXactCursorStability	4096	This value indicates that from one transaction you can view changes in other transactions only after they have been committed.
adXactReadCommitted	4096	Same as **adXactCursorStability**.
adXactRepeatableRead	65536	This value indicates that from one transaction you cannot see changes made in other transactions, but that requerying can retrieve new **Recordset** objects.
adXactIsolated	1048576	This value indicates that transactions are conducted in isolation of other transactions.
adXactSerializable	1048576	Same as **adXactIsolated**.

This property is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.

When setting the **IsolationLevel** property, this change does not take effect until the next time that the **BeginTrans** method is called.

If the level of isolation you request is unavailable, the provider may return the next greater level of isolation.

When used with the Microsoft® OLE DB Provider for DB2 or the Microsoft® OLE DB Driver for DB2, the ADO IsolationLevel property corresponds with the isolation level defined by the ANSI SQL standard and with IBM's DB2 implementation of isolation level. The table below indicates how the ADO IsolationLevel Property corresponds with the terms used by ANSI SQL for isolation level and with IBM documentation for isolation level in DB2.

ADO IsolationLevel Property	ANSI SQL Isolation Level	IBM Documentation
	AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 auto-commit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.
adXactReadUncommitted	READ UNCOMMITTED	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.

adXactReadCommitted or **adXactCursorStability**	READ COMMITTED	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
adXactRepeatableRead	REPEATABLE READ	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.
adXactSerializable or **adXactIsolated**	SERIALIZABLE	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

When used with the Remote Data Service on a client-side **Connection** object, the **IsolationLevel** property can be set only to **adXactUnspecified**. Because users are working with disconnected **Recordset** objects on a client-side cache, there may be multiuser issues. For instance, when two different users try to update the same record, Remote Data Service simply allows the user who updates the record first to "win." The second user's update request will fail with an error.

Item Method

The **Item** method on a **Collection** object returns a specific member object of a collection by name or ordinal number. This method is supported for the **Errors**, **Field**s, and **Properties** collections using the OLE DB Provider for AS/400 and VSAM.

```
set Object = collection.Item ( Index )
```

Parameters

Index
This parameter specifies a Variant that evaluates either to the name or to the ordinal number of an object in a collection.

Return Values

An object reference from the collection.

Remarks

The **Item** method is used to return a specific object in a collection. If the method cannot find an object in the collection corresponding to the *Index* parameter, an error occurs. Also, some collections do not support named objects; for these collections, you must use ordinal number references.

The **Item** method is the default method for all collections; therefore, the following syntax forms are interchangeable:

collection.Item (*Index*)

collection (*Index*)

This method is only supported on the **Errors**, **Field**s, and **Properties** collections under the OLE DB Provider for AS/400 and VSAM.

LockType Property

The **LockType** property on a **Recordset** object indicates the type of locks placed on records during editing. This property sets or returns a Long value representing a **LockTypeEnum**. The default value for this property is **adLockReadOnly**.

```
currentLock = recordset.LockType
recordset.LockType = newtype
```

Remarks

The **LockType** property is used to set the type of locks placed on records that the provider should use when opening the **Recordset**. This property can also be used to return the type of locking in use on an open **Recordset** object. This property can be one of the following enumerated values for **LockTypeEnum**:

Enumeration	Value	Description
adLockUnspecified	-1	This value does not specify a type of lock. For a recordset created with the **Clone** method, the clone is created with the same lock type as the original.
adLockReadOnly	1	This value indicates read-only records where the data cannot be altered.
adLockPessimistic	2	This value indicates pessimistic locking, record by record. The provider does what is necessary to ensure successful editing of the records, usually by locking records at the data source immediately after editing. This lock type is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft® OLE DB Provider for DB2. However, the OLE DB Provider for AS/400 and VSAM internally maps this lock type to **adLockBatchOptimistic**.
adLockOptimistic	3	This value indicates optimistic locking, record by record. The provider uses optimistic locking, locking records only when the **Update** method is called. This lock type is not supported by the OLE DB Provider for DB2.
adLockBatchOptimistic	4	This value indicates optimistic batch updates and is required for batch update mode. This option is not supported by the OLE DB Provider for DB2.

If a provider cannot support the requested **LockType** setting, it will substitute another type of locking. To determine the actual locking options available on a **Recordset** object, use the **Supports** method with **adUpdate** and **adUpdateBatch**.

The **adLockPessimistic** setting is not supported if the **CursorLocation** property is set to **adUseClient**. If an unsupported value is set, then no error will result; the closest supported **LockType** will be used instead.

The **LockType** property is read/write when the **Recordset** is closed and read-only when it is open.

MaxRecords Property

The **MaxRecords** property on a **Recordset** indicates the maximum number of records to return to a **Recordset** from a query. This property sets or returns a Long value that indicates the maximum number of records to return. The default value for this property is zero (no limit).

```
cntRecords = recordset.MaxRecords
recordset.MaxRecords = count
```

Remarks

The **MaxRecords** property is used to limit the number of records returned from a data source. The default setting of this property is zero, which means that all requested records are returned.

The **MaxRecords** property is read/write when the **Recordset** is closed and read-only when it is open.

Mode Property

The **Mode** property on a **Connection** object sets or returns the available permissions for modifying data on a **Connection**.

```
currentMode = connection.Mode
connection.Mode = newMode
```

Remarks

The **Mode** property is used to set or return the access permissions in use by the provider on the current connection. The Mode property can only be set when the **Connection** object is closed.

Several of the ADO enumerated values for the mode settings imply that the using certain mode settings will prevent other applications from opening a connection to the file or table. Under the Microsoft® OLE DB provider for AS/400 and VSAM, these mode settings result in a file lock, but don't prevent other applications from opening a connection.

The value for the **Mode** can be one of the following enumerated values for **ConnectModeEnum**:

Enumeration	Value	Description
adModeUnknown	0	This value indicates that the permissions have not yet been set or cannot be determined.
adModeRead	1	This value indicates read-only permissions.
adModeWrite	2	This value indicates write-only permissions. This value is not supported by the OLE DB provider for AS/400 and VSAM.
adModeReadWrite	3	This value indicates read/write permissions.
adModeShareDenyRead	4	This value prevents others from opening a connection with read permissions.
adModeShareDenyWrite	8	This value prevents others from opening a connection with write permissions. Under the OLE DB provider for AS/400 and VSAM, this mode setting is implemented as a file lock and doesn't result in excluding other applications from opening a connection. Other applications opening a connection will not receive an error, but the table or file will be locked preventing any changes from other applications.
adModeShareExclusive	0xc	This value prevents others from opening a connection. Under the OLE DB provider for AS/400 and VSAM, this mode setting is implemented as a file lock and doesn't result in excluding other applications from opening a connection. Other applications opening a connection will not receive an error, but the table or file will be locked preventing any changes from other applications.
adModeShareDenyNone	0x10	This value prevents others from opening a connection with any permissions. Under the OLE DB provider for AS/400 and VSAM this mode setting is implemented as a file lock and doesn't result in excluding other applications from opening a connection. Other applications opening a connection will not receive an error, but the table or file will be locked preventing any changes from other applications.

The **Mode** property defaults to **adModeUnknown**.

Move Method

The **Move** method on a **Recordset** object moves the position of the current record in a **Recordset** object.

```
recordset.Move NumRecords, Start
```

Parameters

NumRecords
This parameter specifies a signed Long expression specifying the number of records the current record position moves.

Start
This optional parameter specifies the starting location for the record from which the **Move** operation should begin, which can be a bookmark or an enumeration indicating the current, first, or last record in a **Recordset** object. This argument is a Variant.

It can be either a bookmark or one of the following enumerated values for **BookmarkEnum**:

Enumeration	Value	Description
adBookmarkCurrent	0	The current record
adBookmarkFirst	1	The first record
adBookmarkLast	2	The last record

This optional argument defaults to **adBookmarkCurrent**.

Return Values

None.

Remarks

The **Move** method is supported on all **Recordset** objects.

If the *NumRecords* parameter is greater than zero, the current record position moves forward (toward the end of the recordset). If *NumRecords* is less than zero, the current record position moves backward (toward the beginning of the recordset).

If the **Move** method would move the current record position to a point before the first record, ADO sets the current record to the position before the first record in the recordset (the **BOF** property is set to **True**). An attempt to move backward when the **BOF** property is already **True** generates an error.

If the **Move** call would move the current record position to a point after the last record, ADO sets the current record to the position after the last record in the recordset (the **EOF** property is set to **True**). An attempt to move forward when the **EOF** property is already **True** generates an error.

Invoking the **Move** method from an empty **Recordset** object generates an error.

If the *Start* parameter is specified, the move is relative to the record with this bookmark assuming the **Recordset** object supports bookmarks. If not specified, the move is relative to the current record.

If the **CacheSize** property is set to greater than 1 to locally cache records from the provider, passing a *NumRecords* value that moves the current record position outside of the current group of cached records forces ADO to retrieve a new group of records starting from the destination record. The **CacheSize** property determines the size of the newly retrieved group, and the destination record is the first record retrieved.

If the **Recordset** object is forward-only, a user can still pass a *NumRecords* value less than zero as long as the destination is within the current set of cached records. If the **Move** method call would move the current record position to a record before the first cached record, an error occurs. Thus, you can use a record cache that supports full scrolling over a provider that only supports forward scrolling. Because cached records are loaded into memory, you should avoid caching more records than necessary. Even if a forward-only **Recordset** object supports backward moves in this way, calling the **MovePrevious** method on any forward-only **Recordset** object still generates an error.

MoveFirst Method

The **MoveFirst** method on a **Recordset** object moves to the first record in a specified **Recordset** object and makes that record current.

```
recordset.MoveFirst
```

Parameters

None.

Remarks

The **MoveFirst** method is used to move the current record position to the first record in the recordset. The **MoveFirst** method can be invoked on a forward-only **Recordset** object; but doing so may cause the provider to re-execute the command that generated the **Recordset** object.

MoveLast Method

The **MoveLast** method on a **Recordset** object moves to the last record in a specified **Recordset** object and makes that record current.

```
recordset.MoveLast
```

Parameters

None.

Remarks

The **MoveLast** method is used to move the current record position to the last record in the recordset.

When using a server-side cursor, the **Recordset** object must support bookmarks or backward cursor movement; otherwise, the **MoveLast** method call generates an error.

MoveNext Method

The **MoveNext** method on a **Recordset** object moves to the next record in a specified **Recordset** object and makes that record current.

```
recordset.MoveLast
```

Parameters

None.

Remarks

The **MoveNext** method is used to to move the current record position one record forward (toward the bottom of the recordset). If the last record is the current record and the **MoveNext** method is invoked, ADO sets the current record to the position after the last record in the recordset (the **EOF** property is set to **True**). An attempt to move forward when the **EOF** property is already **True** generates an error.

MovePrevious Method

The **MovePrevious** method on a **Recordset** object moves to the previous record in a specified **Recordset** object and makes that record current.

```
recordset.MovePrevious
```

Parameters

None.

Remarks

The **MovePrevious** method is used to move the current record position one record backward (toward the top of the recordset).

When using a server-side cursor, if the **Recordset** object does not support either bookmarks or backward cursor movement, the **MovePrevious** method generates an error.

If the first record is the current record and the **MovePrevious** method is invoked, ADO sets the current record to the position before the first record in the recordset (the **BOF** property is set to **True**). An attempt to move backward when the **BOF** property is already **True** generates an error.

Note that if a **MovePrevious** method is invoked after **Delete** method is invoked, this moves the current record back two records instead of one.

Name Property

The **Name** property on a **Command** object sets or returns a string value indicating the name of the object. The **Name** property on a **Field** or **Property** returns a string value indicating the name of the object.

```
currentName = command.Name
command.Name = newName
```

Remarks

The **Name** property is used to assign a name to or retrieve the name of a **Command**, **Field**, or **Property** object. This value is read/write on a **Command** object and read-only on a **Property** or **Field** object. Note that the **Name** property on a **Command** object cannot be assigned (set) using the OLE DB Provider for AS/400 and VSAM.

The **Name** property of an object can be retrieved by an ordinal reference, after which you can refer to the object directly by name. For example, if recordset.Properties(20).Name yields Updatability, you can subsequently refer to this property as recordset.Properties("Updatability").

NativeError Property

The **NativeError** property on a **Error** object indicates the provider-specific error code for a given **Error** object. This property returns a a Long value that indicates the error code.

```
errorCode = currentError.NativeError
```

Remarks

The **NativeError** property on a **Error** object is used to retrieve the database-specific error information for a particular **Error** object. For example, when using the Microsoft OLE DB Provider for DB2, native error codes that originate from the OLE DB Provider for DB2 pass through ADO to the ADO **NativeError** property.

Number Property

The **Number** property on a **Error** object indicates the number that uniquely identifies an **Error** object. This property returns a a Long value that may correspond to one of the **ErrorValueEnum** constants.

```
errorNumber = currentError.Number
```

Remarks

The **Number** property on a **Error** object is used to determine which error occurred. The value of the property is a unique number that corresponds to the error condition.

The **Errors** collection returns an HRESULT. These HRESULTs can be raised by underlying components, such as OLE DB or even OLE itself.

The value for the **Number** property on the **Error** object representing an ADO error (not an OLE DB error) can be one of the following enumerated values for **ErrorValueEnum** listed in the table below. Note that three forms of the error number value are listed in the table:

- Positive decimal—The lower two bytes of the full number in decimal format. This number is displayed in the default Visual Basic error message dialog box. For example, **Run-time error '3707'**.
- Negative decimal—The decimal translation of the full error number.
- Hexadecimal—The hexadecimal representation of the full error number. The Windows facility code is the lowest hexadecimal fourth digit in the upper two bytes of the number. The facility code for ADO error numbers is *A*. For example: 0x800**A**0E7B.

Note that OLE DB errors may be passed to an ADO application. Typically, these OLE DB errors can be identified by a Windows facility code of *4*. For example, 0x800**4**xxxx. For more information about the possible error numbers returned by OLE DB, see Chapter 16 of the *OLE DB Programmer's Reference*.

Enumeration	Value	Description
adErrBoundToCommand	3707 -2146824581 0x800A0E7B	The application cannot change the **ActiveConnection** property of a **Recordset** object that has a **Command** object as its source.
adErrCannotComplete	3732 -2146824556 0x800A0E94	The server cannot complete the operation.
adErrCantChangeConnection	3748 -2146824540 0x800A0EA4	The connection was denied. The new connection requested has different characteristics than the one already in use.
adErrCantChangeProvider	3220 -2146825068 0X800A0C94	The supplied provider is different from the one already in use.
adErrCantConvertvalue	3724 -2146824564 0x800A0E8C	The data value cannot be converted for reasons other than sign mismatch or data overflow. For example, conversion would have truncated data.
adErrCantCreate	3725 -2146824563 0x800A0E8D	The data value cannot be set or retrieved because the field data type was unknown, or the provider had insufficient resources to perform the operation.

adErrCatalogNotSet	3747 -214682 4541 0x800A 0EA3	The operation requires a valid **ParentCatalog**.
adErrColumnNotOnThisRow	3726 -214682 4562 0x800A 0E8E	The record does not contain this field.
adErrDataConversion	3421 -214682 4867 0x800A 0D5D	The application uses a value of the wrong type for the current operation.
adErrDataOverflow	3721 -214682 4567 0x800A 0E89	The data value is too large to be represented by the field data type.
adErrDelResOutOfScope	3738 -214682 4550 0x800A 0E9A	The URL of the object to be deleted is outside the scope of the current record.
adErrDenyNotSupported	3750 -214682 4538 0x800A 0EA6	The provider does not support sharing restrictions.
adErrDenyTypeNotSupported	3751 -214682 4537 0x800A 0EA7	The provider does not support the requested kind of sharing restriction.
adErrFeatureNotAvailable	3251 -214682 5037 0x800A 0CB3	The object or provider is not capable of performing requested operation.
adErrFieldsUpdateFailed	3749 -214682 4539 0x800A 0EA5	The **Fields** update failed. For further information, examine the **Status** property of individual field objects.
adErrIllegalOperation	3219 -214682 5069 0x800A 0C93	The operation is not allowed in this context.
adErrIntegrityViolation	3719 -214682 4569 0x800A 0E87	The data value conflicts with the integrity constraints of the field.
adErrInTransaction	3246 -214682 5042 0x800A 0CAE	The **Connection** object cannot be explicitly closed while in a transaction.

adErrInvalidArgument	3001 -2146825287 0x800A0BB9	The arguments are of the wrong type, are out of acceptable range, or are in conflict with one another.
adErrInvalidConnection	3709 -2146824579 0x800A0E7D	The operation is not allowed on an object referencing a closed or invalid connection.
adErrInvalidParamInfo	3708 -2146824580 0x800A0E7C	The **Parameter** object is improperly defined. Inconsistent or incomplete information was provided.
adErrInvalidTransaction	3714 -2146824574 0x800A0E82	The coordinating transaction is invalid or has not started.
adErrInvalidURL	3729 -2146824559 0x800A0E91	The URL contains invalid characters. Make sure the URL is typed correctly.
adErrItemNotFound	3265 -2146825023 0x800A0CC1	The item cannot be found in the collection corresponding to the requested name or ordinal.
adErrNoCurrentRecord	3021 -2146825267 0x800A0BCD	Either the **BOF** or **EOF** property is True, or the current record has been deleted. The requested operation requires a current record.
adErrNotExecuting	3715 -2146824573 0x800A0E83	The operation cannot be performed while not executing.
adErrNotReentrant	3710 -2146824578 0x800A0E7E	The operation cannot be performed while processing event.
adErrObjectClosed	3704 -2146824584 0x800A0E78	The operation is not allowed when the object is closed.
adErrObjectInCollection	3367 -2146824921 0x800A0D27	The object is already in collection. Cannot append.
adErrObjectNotSet	3420 -2146824868 0x800A0D5C	The object is no longer valid.

adErrObjectOpen	3705 -2146824583 0x800A0E79	The operation is not allowed when the object is open.
adErrOpeningFile	3002 -2146825286 0x800A0BBA	The file could not be opened.
adErrOperationCancelled	3712 -2146824576 0x800A0E80	The operation has been cancelled by the user.
adErrOutOfSpace	3734 -2146824554 0x800A0E96	The operation cannot be performed. Provider cannot obtain enough storage space.
adErrPermissionDenied	3720 -2146824568 0x800A0E88	Insufficent permission prevents writing to the field.
adErrPropConflicting	3742 -2146824546 0x800A0E9E	Property value conflicts with a related property.
adErrPropInvalidColumn	3739 -2146824549 0x800A0E9B	Property cannot apply to the specified field.
adErrPropInvalidOption	3740 -2146824548 0x800A0E9C	Property attribute is invalid.
adErrPropInvalidValue	3741 -2146824547 0x800A0E9D	Property value is invalid. Make sure the value is typed correctly.
adErrPropNotAllSettable	3743 -2146824545 0x800A0E9F	Property is read-only or cannot be set.
adErrPropNotSet	3744 -2146824544 0x800A0EA0	Optional property value was not set.
adErrPropNotSettable	3745 -2146824543 0x800A0EA1	Read-only property value was not set.

adErrPropNotSupported	3746 -2146824542 0x800A0EA2	Provider does not support the property.
adErrProviderFailed	3000 -2146825288 0x800A0BB8	Provider failed to perform the requested operation.
adErrProviderNotFound	3706 -2146824582 0x800A0E7A	Provider cannot be found. It may not be properly installed.
adErrReadFile	3003 -2146825285 0x800A0BBB	File could not be read.
adErrResourceExists	3731 -2146824557 0x800A0E93	Copy operation cannot be performed. Object named by destination URL already exists. Specify **adCopyOverwrite** to replace the object.
adErrResourceLocked	3730 -2146824558 0x800A0E92	Object represented by the specified URL is locked by one or more other processes. Wait until the process has finished and attempt the operation again.
adErrResourceOutOfScope	3735 -2146824553 0x800A0E97	Source or destination URL is outside the scope of the current record.
adErrSchemaViolation	3722 -2146824566 0x800A0E8A	Data value conflicts with the data type or constraints of the field.
adErrSignMismatch	3723 -2146824565 0x800A0E8B	Conversion failed because the data value was signed and the field data type used by the provider was unsigned.
adErrStillConnecting	3713 -2146824575 0x800A0E81	Operation cannot be performed while connecting asynchronously.
adErrStillExecuting	3711 -2146824577 0x800A0E7F	Operation cannot be performed while executing asynchronously.
adErrTreePermissionDenied	3728 -2146824560 0x800A0E90	Permissions are insufficient to access tree or subtree.

adErrUnavailable	3736 -214682 4552 0x800A 0E98	Operation failed to complete and the status is unavailable. The field may be unavailable or the op eration was not attempted.
adErrUnsafeOperatio n	3716 -214682 4572 0x800A 0E84	Safety settings on this computer prohibit accessing a data source on another domain.
adErrURLDoesNotExis t	3727 -214682 4561 0x800A 0E8F	Either the source URL or the parent of the destination URL does not exist.
adErrURLNamedRow DoesNotExist	3737 -214682 4551 0x800A 0E99	Record named by this URL does not exist.
adErrVolumeNotFoun d	3733 -214682 4555 0x800A 0E95	Provider cannot locate the storage device indicated by the URL. Make sure the URL is typed corre ctly.
adErrWriteFile	3004 -214682 5284 0x800A 0BBC	Write to file failed.

NumericScale Property

The **NumericScale** property on a **Field** object indicates the scale of Numeric values in a **Field** object. This property returns a byte value indicating the number of decimal places to which numeric values will be resolved.

```
scale = currentfield.NumericScale
```

Remarks

The **NumericScale** property is used to determine how many digits to the right of the decimal point will be used to represent values for a numeric **Field** object.

The byte value that the **NumericScale** property will return is dependent on the data type of the **Field** object. The value for the ADO data type of the **Field** object can be one of the following enumerated values for **DataTypeEnum**:

Enumeration	Value	Description
adEmpty	0	This data type indicates that no value was specified (DBTYPE_EMPTY).
adSmallInt	2	This data type indicates a two-byte (16-bit) signed integer (DBTYPE_I2).
adInteger	3	This data type indicates a four-byte (32-bit) signed integer (DBTYPE_I4).
adSingle	4	This data type indicates a four-byte (32-bit) single precision IEEE floating point number (DBTYPE_R4).
adDouble	5	This data type indicates an eight-byte (64-bit) double precision IEEE floating point number (DBTYPE_R8).
adCurrency	6	A data type indicates a currency value (DBTYPE_CY). Currency is a fixed-point number with 4 digits to the right of the decimal point. It is stored in an eight-byte signed integer scaled by 10,000. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDate	7	This data type indicates a date value stored as a Double, the whole part of which is the number of days since December 30, 1899, and the fractional part of which is the fraction of a day. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBSTR	8	This data type indicates a null-terminated Unicode character string (DBTYPE_BSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIDispatch	9	This data type indicates a pointer to an IDispatch interface on an OLE object (DBTYPE_IDISPATCH). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adError	10	This data type indicates a 32-bit error code (DBTYPE_ERROR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBoolean	11	This data type indicates a Boolean value (DBTYPE_BOOL). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVariant	12	This data type indicates an automation variant (DBTYPE_VARIANT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIUnknown	13	This data type indicates a pointer to an IUnknown interface on an OLE object (DBTYPE_IUNKNOWN). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDecimal	14	This data type indicates numeric data with a fixed precision and scale (DBTYPE_DECIMAL).
adTinyInt	16	This data type indicates a single -byte (8-bit) signed integer (DBTYPE_I1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedTinyInt	17	This data type indicates a single-byte (8-bit) unsigned integer (DBTYPE_UI1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedSmallInt	18	This data type indicates a two-byte (16-bit) unsigned integer (DBTYPE_UI2). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adUnsignedInt	19	This data type indicates a four-byte (32-bit) unsigned integer (DBTYPE_UI4). This data type is not supported by the OLE DB Provider or the OLE DB Provider for DB2.
adBigInt	20	This data type indicates an eight-byte (64-bit) signed integer (DBTYPE_I8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adUnsignedBigInt	21	This data type indicates an eight-byte (64-bit) unsigned integer (DBTYPE_UI8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adGUID	72	This data type indicates a globally unique identifier or GUID (DBTYPE_GUID). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBinary	128	This data type indicates fixed-length binary data (DBTYPE_BYTES).
adChar	129	This data type indicates a character string value (DBTYPE_STR).
adWChar	130	This data type indicates a null-terminated Unicode character string (DBTYPE_WSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adNumeric	131	This data type indicates numeric data where the precision and scale are exactly as specified (DBTYPE_NUMERIC).
adUserDefined	132	This data type indicates user-defined data (DBTYPE_UDT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDBDate	133	This data type indicates a OLE DB date structure (DBTYPE_DATE).
adDBTime	134	This data type indicates a OLE DB time structure (DBTYPE_TIME).
adDBTimeStamp	135	This data type indicates a OLE DB timestamp structure (DBTYPE_TIMESTAMP).
adVarChar	200	This data type indicates variable-length character data (DBTYPE_STR).
adLongVarChar	201	This data type indicates a long string value.
adVarWChar	202	This data type indicates a Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adLongVarWChar	203	This data type indicates a long Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVarBinary	204	This data type indicates variable-length binary data (DBTYPE_BYTES).
adLongVarBinary	205	This data type indicates a long binary value.

Open Method on Connection Object

The **Open** method on a **Connection** object opens a connection to a data source.

```
connection.Open ConnectionString, UserID, Password
```

Parameters

ConnectionString
This optional parameter specifies a String containing connection information. See the **ConnectionString** property on a **Connection** object for details on valid settings. Possible values are listed in the table following the Parameters list.

Note Not all of these parameters are required. The user can also be prompted for this information.

UserID
This optional parameter specifies a String containing a user name to use when establishing the connection.
Password
This optional parameter specifies a String containing a password to use when establishing the connection.

Values for the ConnectionString parameter

The information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method in the *ConnectionString* parameter. In either case, this information must be in a specific format for use with the Microsoft® OLE DB Provider for AS/400 and VSAM. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property as follows:

Argument	Description
Data Source	This argument specifies the name of the data source for the connection. This argument is the Data Source name stored in the registry under the OLE DB Provider for AS/400 and VSAM.
File Name	This argument specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	This argument specifies the Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	This argument specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	This argument specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the Microsoft® OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the Microsoft® ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
Remote Provider	This argument specifies the name of a provider to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
Remote Server	This argument specifies the path name of a server to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
User ID	This argument specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target host system and has appropriate access rights to the file.

The OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which have default values as specified in the table below. These arguments are as follows:

Argument	Description
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0, don't process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCDFileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The Remote DataBase name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in Host Integration Server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote LU alias configured in the Host Integration server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	Description
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.

CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDB NAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 syste m. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is ref erred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATC HSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this par ameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will c reate packages dynamically in the location to which the user points using the Package Collection parameter.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA applicati on server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, T PName is set to 0X07F9F9F9.

UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the OLE DB Provider for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
BindType	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Commit	This parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter defaults to true (auto commit).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.

GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
IsoLvl	This parameter determines the isolation level provided for this data source. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommited Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommited. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, isolation level this corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
LocalLU	The name of the local LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.

NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
ReadOnly	When the Read Only parameter is set to true (ReadOnly=1), the OLE DB Provider for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RemoteLU	The name of the remote LU alias configured in Host Integration.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.

Not all of these parameters are required. The user can also be prompted for this information.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	**Description**
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.

CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.

PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the ODBC Driver for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**

ACM	The Auto Commit Mode parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. The default value for this parameter is true (auto commit). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
BT	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.

DIL	This Default Isolation Level parameter determines the isolation level provided for this data source in cases of simultaneous access to DB2 objects by multiple applications. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, this isolation level corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. Please note that the ALL isolation level is not allowed. Users should set the isolation level to RS since this has the equivalent meaning and is defined in DB2 (ALL is not defined in any DB2 system). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.

NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RO	When the Read Only parameter is set to true (RO=1), the ODBC Driver for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.

Remarks

The **Open** method on a **Connection** object is used to open tables on a remote DDM server. Using the **Open** method on a **Connection** object establishes the physical connection to a data source. After this method successfully completes, the connection is live and other methods can be invoked on the **Connection** object to process results.

The optional *ConnectionString* parameter is used to specify a connection string containing a series of *argument=value* statements separated by semicolons. The **ConnectionString** property on a **Connection** object automatically inherits the value used for the *ConnectionString* parameter. Therefore, the **ConnectionString** property of the **Connection** object can be set before opening the **Connection** object, or the *ConnectionString* parameter can be used to set or override the current connection parameters during the **Open** method call.

If user and password information is set in both the *ConnectionString* parameter and in the optional *UserID* and *Password* parameters, the results may be unpredictable. Such information should only be passed in either the *ConnectionString* parameter

or the *UserID* and *Password* parameters.

There are a number of different ways to open a connection. The **Open** method can pass all of the appropriate connection information as part of the *ConnectionString* parameter or by setting the **ConnectionString** property of the **Connection** object, if this information is known in advance. The syntax in this case using the *ConnectionString* parameter for use with the OLE DB Provider for AS/400 and VSAM is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.Open "Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME;Password=password;Local
LU=LOCAL;Remote LU=DATABASE;ModeName=QPCSUPP;CCSID=37;CodePage=437"
```

Note that not all of these parameters are required. The registry settings for the Data Source usually have default values set for remote LU, local LU, APPC mode, CCSID, and CodePage. If a data source is specified, this other information is not usually needed. These registry settings are configured by using the Microsoft Management Console snap-in for the OLE DB Provider for AS/400 and VSAM.

The simplest form of an **Open** command that contains all necessary information is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.Open "Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME;Password=password"
```

The Data Source, User ID and Password must be included.

In the case where you would like the user to input the connection information, the following syntax can be used. This syntax does not specify any connection information except the provider, which is always required unless this is set in the **ConnectionString** or **Provider** property of the **Connection** object:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.ConnectionString = "Provider=SNAOLEDB"
connection.Open
```

This method of invoking the **Open** method automatically causes a dialog box to appear asking the user for the data source, user name, and password.

When operations have been concluded over an open **Connection** object, the **Close** method should be invoked on the **Connection** object to free any associated system resources. Closing a **Connection** object does not remove it from memory; you may change its property settings and use the **Open** method to open it again later. To completely eliminate an object from memory, set the **Connection** object variable to **Nothing**.

If errors occur, these can be examined with the **Errors** collection on the **Connection** object.

Open Method on Recordset Object

The **Open** method on a **Recordset** object opens a cursor that represents records from a base table or the results of a query.

```
recordset.Open Source, ActiveConnection, CursorType, LockType,
Options
```

Parameters

Source
This optional parameter specifies a Variant that evaluates to a valid **Command** object variable name or a valid string specifying the command text specific to the Microsoft® OLE DB Provider for AS/400 and VSAM to open a data file on the host.

ActiveConnection
This optional parameter specifies either a Variant that evaluates to a valid **Connection** object variable name or a String containing connection information equivalent to the **ConnectionString** property of a **Connection** object. Possible values are listed in the table following the **Parameters** section.

CursorType
This optional parameter specifies a **CursorTypeEnum** value that determines the type of cursor that the provider should use when opening the **Recordset**. See the CursorType property of a **Recordset** object for more information. Possible values are listed in the table following the **Parameters** section.

LockType
This optional parameter specifies a **LockTypeEnum** value that determines what type of locking (concurrency) the provider should use when opening the recordset. See the LockType property of a **Recordset** object for more information. Possible values are listed in the table following the **Parameters** section.

Options
This optional parameter specifies a Long value representing a **CommandTypeEnum** value that indicates how the provider should evaluate the *Source* parameter. Possible values are listed in the table following the **Parameters** section.

Possible values for the *ActiveConnection* parameter

The information needed to establish a connection to a data source can be set in the **ActiveConnection** property of a **Recordset** object or passed as part of the **Open** method on a **Recordset** object in the *ActiveConnection* parameter. In either case, this information must be in a specific format for use with the OLE DB Provider for AS/400 and VSAM. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ActiveConnection** property as follows:

Argument	Description
Data Source	This argument specifies the name of the data source for the connection. This argument is the optional when used with OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE Provider for DB2.
File Name	This argument specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	This argument specifies the Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	This argument specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used by Microsoft® SNA Server to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	This argument specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
Remote Provider	This argument specifies the name of a provider to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

Remote Server	This argument specifies the path name of a server to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
User ID	This argument specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used by SNA Server to validate that the user can log on to the target host system and has appropriate access rights to the file.

The OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which have default values as specified in the table below. These arguments are as follows:

Argument	**Description**
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0, don't process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCD FileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
Local LU	The name of the local LU alias configured in the SNA server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and SNA Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The Remote DataBase name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in the SNA server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote LU alias configured in the SNA server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

Note Not all of these parameters are required. The user can also be prompted for this information.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	Description
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the OLE DB Provider for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
BindType	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Commit	This parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter defaults to true (auto commit).

DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM; SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
IsoLvl	This parameter determines the isolation level provided for this data source. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommited Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommited. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, isolation level this corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
LocalLU	The name of the local LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the OLE DB Provider for DB2 supplied with the Japanese version of the OLE DB Provider for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the OLE DB Provider for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.

ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
ReadOnly	When the Read Only parameter is set to true (ReadOnly=1), the OLE DB Provider for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RemoteLU	The name of the remote LU alias configured in Host Integration.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.

Note Not all of these parameters are required. The user can also be prompted for this information.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2000 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000 are as follows:

Argument	**Description**

BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.

PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2000 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note Not all of these parameters are required. The user can also be prompted for this information.

The arguments supported by the ODBC Driver for DB2 supplied with SNA Server 4.0 are as follows:

Argument	**Description**

ACM	The Auto Commit Mode parameter indicates whether changes to data will be automatically committed or require a separate manual commit request. This parameter allows for implicit COMMIT on all SQL statements. In auto-commit mode, every database operation is a transaction that is committed when performed. This mode is suitable for common transactions that consist of a single SQL statement. It is unnecessary to delimit or specify completion of these transactions. No ROLLBACK is allowed when using Auto Commit mode. The default value for this parameter is true (auto commit). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
BAC	When the BinAsChar parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
BT	This parameter indicates the bind type to be used when creating packages. Legal values for the package binding type are as follows. NORM—normal binding. FAST—create all 64 package sections optimally in a single network flow. NOSP—reserved for future use and currently not supported. The default value for this parameter is NORM. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.

DIL	This Default Isolation Level parameter determines the isolation level provided for this data source in cases of simultaneous access to DB2 objects by multiple applications. Legal values for the default isolation level are the following: CS—Cursor Stability. In DB2/400, this isolation level corresponds to COMMIT(*CS). In ANSI, this isolation level corresponds to Read Committed (RC). NC—No Commit. In DB2/400, this isolation level corresponds to COMMIT(*NONE). In ANSI, this isolation level corresponds to No Commit (NC). UR—Uncommitted Read. In DB2/400, this isolation level corresponds to COMMIT(*CHG). In ANSI, this isolation level corresponds to Read Uncommitted. RS—Read Stability. In DB2/400, this isolation level corresponds to COMMIT(*ALL). In ANSI, this isolation level corresponds to Repeatable Read. RR—Repeatable Read. In DB2/400, this isolation level corresponds to COMMIT(*RR). In ANSI, this isolation level corresponds to Serializable (Isolated). This parameter defaults to NC. Please note that the ALL isolation level is not allowed. Users should set the isolation level to RS since this has the equivalent meaning and is defined in DB2 (ALL is not defined in any DB2 system). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
GCCSID	The graphics character code set identifier (GCCSID) matching the DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for GCCSID are supported by the OLE DB Provider for DB2: 300, 834, 835, 837, or 4396. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MCCSID	The mixed character code set identifier (MCCSID) matching DB2 character data as represented on the remote host computer. This parameter is required when accessing DB2 databases configured to support mixed single-byte (SBCS) and double-byte (DBCS) data. This parameter only applies when accessing DB2 for OS/390 or DB2 for MVS. The following values for MCCSID are supported by the OLE DB Provider for DB2: 930, 931, 933, 935, 937, 939, 5026, or 5035. This parameter defaults to 0 indicating that mixed CCSID conversions are not supported. This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000. This parameter is supported by the Japanese version of the ODBC Driver for DB2 client included with SNA Server 4.0 with Service Pack 2, and by the ODBC Driver for DB2 client included with all versions of SNA Server 4.0 with Service Pack 3 or later.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.

NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RO	When the Read Only parameter is set to true (RO=1), the ODBC Driver for DB2 creates a read-only data source. A user has read access to objects such as tables, and cannot do update operations (INSERT, UPDATE, or DELETE, for example). This parameter is not supported by the ODBC Driver for DB2 supplied with Host Integration Server 2000.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured inHost Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.

Note Not all of these parameters are required. The user can also be prompted for this information.

Possible values for the *LockType* parameter

This parameter can be one of the following enumerated values for **LockTypeEnum**:

Enumeration	Value	Description
adLockUnspecified	-1	Indicates an unspecified value for the *LockType*. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

adLockReadOnly	1	Specifying this value opens a **Recordset** object read-only and data cannot be altered.
adLockPessimistic	2	Specifying this value opens a recordset with pessimistic locking. Record-by-record, the OLE DB Provider does whatever is necessary to ensure successful editing of the records, usually by locking records at the data source immediately upon editing. This lock type is supported by the OLE DB Provider for AS/400 and VSAM and the OLE DB Provider. However, the OLE DB Provider for AS/400 and VSAM internally maps this lock type to **adLockBatchOptimistic**.
adLockOptimistic	3	Specifying this value opens a recordset with optimistic locking. Record-by-record, the OLE DB Provider locks records only when the **Update** method is invoked on a **Recordset** object. This lock type is not supported by the OLE DB Provider for DB2.
adLockBatchOptimistic	4	Specifying this value opens a **Recordset** with batch optimistic locking. This value is required for batch update mode as opposed to immediate update. This lock type is not supported by the OLE DB Provider for DB2.

This optional argument defaults to **adLockReadOnly**.

Possible values for the *CursorType* parameter

This parameter can be one of the following enumerated values for **CursorTypeEnum**:

Enumeration	Value	Description
adOpenUnspecified	-1	This indicates an unspecified value for the *CursorType*. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE DB Provider for DB2.
adOpenForwardOnly	0	Specifying this value opens a forward-only-type cursor. This *CursorType* is identical to a static cursor, except that you can only scroll forward through records. This improves performance when only one pass through a **Recordset** is needed. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.
adOpenKeyset	1	Specifying this value opens a keyset-type cursor. This *CursorType is* similar to a dynamic cursor with a few exceptions. Records that other users delete are inaccessible from your **Recordset**. Data changes to existing records by other users are still visible, but records added by other users are not visible (cannot be seen). This value is not supported by the OLE DB Provider for AS/400 and VSAM..
adOpenDynamic	2	Specifying this value opens a dynamic-type cursor. Additions, changes, and deletions by other users are visible, and all types of movement through the recordset are allowed, except for bookmarks if the provider does not support them. A dynamic cursor is the only *CursorType* supported by the OLE DB Provider for AS/400 and VSAM.
adOpenStatic	3	Specifying this value opens a static-type cursor. A static cursor provides a static copy of a set of records that can be used to find data or generate reports. Additions, changes, or deletions by other users are not visible with a static cursor. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

This optional argument defaults to **adOpenForwardOnly**, a value that is mapped to **adOpenDynamic** by the OLE DB provider for AS/400 and VSAM.

Possible values for the *Options* parameter

The **CommandTypeEnum** value can be one of the following constants:

Enumeration	Value	Description

adCmdUnspecified	-1	This value indicates that the **CommandText** property is unspecified. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdText	1	This value evaluates the **CommandText** property as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure name. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdUnknown	8	This value indicates that the type of command in **CommandText** property is not known. This is the default value. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

Remarks

The **Open** method on a **Recordset** object is used to open tables on a remote DDM server. Using the **Open** method on a **Recordset** object establishes the physical connection to a data source and opens a cursor that represents records from a base table or the results of a query. After this method successfully completes, the **Recordset** object is live and other methods can be invoked on the **Recordset** object to process results.

The optional *Source* parameter is used to specify the command text required to open a data file on the host using the OLE DB Provider for AS/400 and VSAM. The syntax in this case is as follows:

```
recordset = CreateObject("ADODB.Recordset.2.0")
recordset.Open "EXEC OPEN LIBRARY/FILE", connection, adOpenDynamic, adLockOptimistic, adCmdTe
xt
```

Using the OLE DB Provider for AS/400 and VSAM, the *Source* parameter represents a table name and uses one of the following host file naming conventions.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILE.NAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY/FILE.NAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax for command text used for the **Recordset.Open** method is:

```
recordset = CreateObject("ADODB.Recordset.2.0")
recordset.Open "EXEC OPEN LIBRARY/FILE(""NAMES.DAT"")", connection, adOpenDynamic, adLockOpti
mistic, adCmdText
```

Note the doubled quotes are required surrounding the member name in this example since the member name contains a period. The full path to the mainframe data set must be specified when using the OLE DB Provider for AS/400 and VSAM. In the example above, there are two path elements (LIBRARY/FILE) and one name element (NAMES.DAT).

Whenever a VSAM data set is allocated, it is given a unique name composed of one or more segments. Each segment of the data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully-qualified data set name (three path elements and one name element):

```
SAMPLES.DEMO.KSDS.TITLES
```

The high-level qualifier is SAMPLES. The low-level qualifier is TITLES. Each segment can be from 1-8 characters in length (the first character must be alphabetic, while the remainder can be alphanumeric or hyphens). The full data set name must be no more than 44 characters in length and contain no more than 22 segments.

The optional *ActiveConnection* parameter corresponds to the **ActiveConnection** property on a **Recordset** object and specifies on which connection to open the **Recordset** object. If a connection string definition is passed for this argument, ADO opens a new connection using the specified parameters. The value of this **ActiveConnection** property can be changed after opening the **Recordset** to send updates to another provider. The **ActiveConnection** property is set to **Nothing** (in Microsoft® Visual Basic®) to disconnect the recordset from the OLE DB Provider. If the optional *ActiveConnection* parameter is used to specify a connection string, this string must contain a series of *argument=value* statements separated by semicolons.

The **ActiveConnection** property on a **Recordset** object automatically inherits the value used for the *ActiveConnection* parameter. Therefore, the **ActiveConnection** property of the **Recordset** object can be set before opening the **Recordset** object, or the *ActiveConnection* parameter can be used to set or override the current connection parameters during the **Open** method call.

The *CursorType* parameter cannot be omitted using the OLE DB Provider for AS/400 and VSAM since this parameter defaults to **adOpenForwardOnly**, a *CursorType* that is not supported on the OLE DB Provider. The *CursorType* parameter must be set to **adOpenDynamic**, otherwise an error will occur and results will be unpredictable.

There are a number of different ways to open a recordset and connect to a data source. The **Open** method of the **Recordset** object can pass all of the appropriate connection information as part of the *ActiveConnection* parameter or by setting the **ActiveConnection** property of the **Recordset** object, if this information is known in advance. The syntax, in this case using the *ActiveConnection* parameter and the OLE DB Provider for AS/400 and VSAM, is as follows:

```
recordset = CreateObject("ADODB.Recordset.2.0")
recordset.Open "EXEC OPEN LIBRARY/FILE","Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME
;Password=password;Local LU=LOCAL;Remote LU=DATABASE;ModeName=QPCSUPP;CCSID=37;CodePage=437",
adOpenDynamic, adLockOptimistic, adCmdText
```

> **Note** Not all of these parameters are required. The registry settings for the Data Source usually have default values set for remote LU, local LU, APPC mode, CCSID, and CodePage. If a data source is specified, this other information is not usually needed. These registry settings are configured by using the Microsoft Management Console snap-in for the OLE DB Provider for AS/400 and VSAM.

For the other parameters that correspond directly to the properties of a **Recordset** object (*Source*, *CursorType*, and *LockType*), the relationship of the parameters to the properties is as follows:

- The property is read/write before the **Recordset** object is opened.
- The property settings are used unless the corresponding parameters are passed when executing the **Open** method. If a parameter is passed, it overrides the corresponding property setting, and the property setting is updated with the parameter value.
- After the **Recordset** object is opened, these properties become read-only.

> **Note** For **Recordset** objects whose **Source** property is set to a valid **Command** object, the **ActiveConnection** property is read-only, even if the **Recordset** object is not open.

If a **Command** object is passed in the *Source* parameter and an *ActiveConnection* parameter is also passed, an error occurs. The **ActiveConnection** property of the **Command** object must already be set to a valid **Connection** object or connection string.

If a **Command** object is not passed in the *Source* argument, the *Options* argument must be set to **adCmdText**. If the *Options* argument is not defined, you may experience diminished performance because ADO must make calls to the OLE DB Provider to determine if the argument is a command statement. If you know what *Source* type you are using, setting the *Options* argument instructs ADO to jump directly to the relevant code.

If the data source returns no records, the provider sets both the **BOF** and **EOF** properties on the **Recordset** object to **True**, and the current record position is undefined. You can still add new data to this empty **Recordset** object if the cursor type allows it.

When operations have been concluded over an open **Recordset** object, the **Close** method should be invoked on the **Recordset** object to free any associated system resources. Closing a **Recordset** object does not remove it from memory; you may change its property settings and use the **Open** method to open it again later. To completely eliminate an object from memory, set the **Recordset** object variable to **Nothing**.

If errors occur, these can be examined with the **Errors** collection on the **Recordset** object.

OpenSchema Method

The **OpenSchema** method on a **Connection** object obtains database schema information from the provider.

```
recordset = connection.OpenSchema ( QueryType, Criteria, SchemaID )
```

Parameters

QueryType

This parameter specifies a **SchemaEnum** value that indicates the type of schema query to run.

The **SchemaEnum** values supported by the Microsoft® OLE DB Provider for AS/400 and VSAM are listed in a table following the Parameters section

Criteria

This optional parameter specifies an array of query constraints for each *QueryType* option, as listed below.

The values supported by the OLE DB Provider for AS/400 and VSAM can be one of the following constants depending on the *QueryType*:

> **Note** The **adSchemaindexes** TYPE restriction is not supported by the OLE DB Provider for DB2.
>
> The **adSchemaProcedures** PROCEDURE_SCHEMA, and **adSchemaProcedureParameters** PROCEDURE_SCHEMA restrictions are not supported when connecting to DB/2 on OS/390 platforms.

Values used for the Criteria parameter are listed in the table following the Parameters section.

SchemaID

This optional parameter specifies the GUID for a provider-schema schema query not defined by the OLE DB specification. This parameter is required if the *QueryType* parameter is set to **adSchemaProviderSpecific**; otherwise, it is not used. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM.

Possible values used by *QueryType*

Enumeration	Value	Description
adSchemaColumns	4	This value indicates that the *QueryType* is requesting column information for tables on the server (not supported when connecting to mainframes).
adSchemaIndexes	12	This value indicates that the *QueryType* is requesting index information about the tables on the server (not supported when connecting to mainframes).
adSchemaTables	20	This value indicates that the *QueryType* is requesting information about the tables on the server.
adSchemaProviderTypes	22	This value indicates that the *QueryType* is requesting provider-type information.

The **SchemaEnum** values supported by the Microsoft® OLE DB Provider for DB2 and the Microsoft® ODBC Driver for DB2 can be one of the following constants:

Enumeration	Value	Description
adSchemaColumns	4	This value indicates that the *QueryType* is requesting column information for tables on the server (not supported when connecting to mainframes).
adSchemaIndexes	12	This value indicates that the *QueryType* is requesting index information about the tables on the server (not supported when connecting to mainframes).
adSchemaProcedures	16	This value indicates that the *QueryType* is requesting information about stored procedures on the server.
adSchemaTables	20	This value indicates that the *QueryType* is requesting information about the tables on the server.
adSchemaProviderTypes	22	This value indicates that the *QueryType* is requesting provider-type information.
adSchemaProcedureParameters	26	This value indicates that the *QueryType* is requesting information about parameters used by stored procedures on the server.
adSchemaPrimaryKeys	28	This value indicates that the *QueryType* is requesting information about the primary keys for tables on the server.

Return Values

Returns a **Recordset** object that contains schema information requested.

Remarks

The **OpenSchema** method on a **Connection** object is used to return information about the data source, such as information about the tables on the server and the columns in the tables.

The *Criteria* argument is an array of values that can be used to limit the results of a schema query. Each schema query supports a different set of parameters. The actual schemas are defined by the OLE DB specification under the **IDBSchemaRowset** interface. The schema queries supported in ADO 1.5 and later by the OLE DB Provider for AS/400 and VSAM are listed above.

The **OpenSchema** method allows an application to pass at run time the target library of a Partioned Data Set (PDS/PDSE), a dataset, or a member name as one of the *Criteria* array arguments to retrieve the schema.

Providers are not required to support all of the OLE DB standard schema *QueryType* values. Specifically, only **adSchemaTables**, **adSchemaColumns**, and **adSchemaProviderTypes** are required by the OLE DB specification. However, the provider is not required to support the *Criteria* constraints listed above for those schema queries. Support for other schema *QueryType* values is optional.

The schema information specified in OLE DB is based on the assumption that providers support the concepts of a catalog and a schema. The ANSI SQL 92 specification defines them as follows:

- A catalog contains one or more schemas, but always contains a schema named INFORMATION_SCHEMA which contains the views and domains of the information schema. In Microsoft® SQL Server and Microsoft® Access terms, a catalog is a database; in ODBC 2.*x* terms, a catalog is a qualifier.
- A schema is a collection of database objects that are owned or have been created by a particular user. In Microsoft SQL Server and ODBC 2.*x* terms, a schema is an owner; there is no equivalent to a schema in a Microsoft Access database.

Schema information in ADO and OLE DB is retrieved using predefined schema rowsets. The following section lists the contents of each schema rowset supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adSchemaColumns

The **adSchemaColumns** *QueryType* identifies the columns of tables defined in the catalog that are accessible to a given user. This *QueryType* is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaColumns** *QueryType* contains the following columns:

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
COLUMN_NAME	DBTYPE_WSTR	The name of the column; this might not be unique. If this cannot be determined, a NULL is returned. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses. If possible, the resulting column ID should be persistent. However, some providers do not support persistent identifiers for columns. The column ID of a base table should be invariant under views.
COLUMN_GUID	DBTYPE_GUID	Column GUID.
COLUMN_PROPID	DBTYPE_UI4	Column property ID.
ORDINAL_POSITION	DBTYPE_UI4	The ordinal of the column. Columns are numbered starting from one. NULL if there is no stable ordinal value for the column.
COLUMN_HASDEFAULT	DBTYPE_BOOL	VARIANT_TRUE: The column has a default value. VARIANT_FALSE: The column does not have a default value or it is unknown whether the column has a default value.

COLUMN_DEFAULT	DBTYPE_WSTR	Default value of the column. A provider may expose DBCOLUMN_DEFAULTVALUE but not DBCOLUMN_HASDEFAULT (for SQL 92 tables) in the rowset returned by **IColumnsRowset::GetColumnsRowset**. If the default value is the NULL value, COLUMN_HASDEFAULT is VARIANT_TRUE, and the COLUMN_DEFAULT column is a NULL value.
COLUMN_FLAGS	DBTYPE_UI4	A bitmask that describes column characteristics. The DBCOLUMNFLAGS enumerated type specifies the bits in the bit mask. For information about DBCOLUMNFLAGS, see **IColumnsInfo::GetColumnInfo**. This column cannot contain a NULL value.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The column might be nullable. VARIANT_FALSE: The column is known not to be nullable.
DATA_TYPE	DBTYPE_UI2	The indicator of the column's data type. If the data type of the column varies from row to row, this must be DBTYPE_VARIANT.
TYPE_GUID	DBTYPE_GUID	The GUID of the column's data type.
CHARACTER_MAXIMUM_LENGTH	DBTYPE_UI4	The maximum possible length of a value in the column. For character, binary, or bit columns, this is one of the following: The maximum length of the column in characters, bytes, or bits, respectively, if one is defined. For example, a CHAR(5) column in an SQL table has a maximum length of five (5). The maximum length of the data type in characters, bytes, or bits, respectively, if the column does not have a defined length. Zero (0) if neither the column nor the data type has a defined maximum length. NULL for all other types of columns.
CHARACTER_OCTET_LENGTH	DBTYPE_UI4	Maximum length in octets (bytes) of the column, if the type of the column is character or binary. A value of zero means the column has no maximum length. NULL for all other types of columns.
NUMERIC_PRECISION	DBTYPE_UI2	If the column's data type is numeric, this is the maximum precision of the column. The precision of columns with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the column. If the column's data type is not numeric, this is NULL.
NUMERIC_SCALE	DBTYPE_I2	If column's type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is NULL.
DATETIME_PRECISION	DBTYPE_UI4	Datetime precision (number of digits in the fractional seconds portion) of the column if the column is a datetime or interval type.

CHARACTER_SET_CATALOG	DBTYPE_WSTR	Catalog name in which the character set is defined. NULL if the provider does not support catalogs or different character sets.
CHARACTER_SET_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the character set is defined. NULL if the provider does not support schemas or different character sets.
CHARACTER_SET_NAME	DBTYPE_WSTR	Character set name. NULL if the provider does not support different character sets.
COLLATION_CATALOG	DBTYPE_WSTR	Catalog name in which the collation is defined. NULL if the provider does not support catalogs or different collations.
COLLATION_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the collation is defined. NULL if the provider does not support schemas or different collations.
COLLATION_NAME	DBTYPE_WSTR	Collation name. NULL if the provider does not support different collations.
DOMAIN_CATALOG	DBTYPE_WSTR	Catalog name in which the domain is defined. NULL if the provider does not support catalogs or domains.
DOMAIN_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the domain is defined. NULL if the provider does not support schemas or domains.
DOMAIN_NAME	DBTYPE_WSTR	Domain name. NULL if the provider does not support domains.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the column. For example, the description for a column named Name in the Employee table might be "Employee name."

The default sort order for the **adSchemaColumns** rowset is TABLE_CATALOG, TABLE_SCHEMA, and TABLE_NAME.

adSchemaIndexes

The **adSchemaIndexes** *QueryType* identifies the indexes defined in the catalog that are owned by a given user. This *QueryType* is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaIndexes** *QueryType* contains the following columns:

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
INDEX_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
INDEX_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
INDEX_NAME	DBTYPE_WSTR	Index name.
PRIMARY_KEY	DBTYPE_BOOL	Whether the index represents the primary key on the table. NULL if this is not known.
UNIQUE	DBTYPE_BOOL	Whether index keys must be unique. One of the following: VARIANT_TRUE: The index keys must be unique. VARIANT_FALSE: Duplicate keys are allowed.
CLUSTERED	DBTYPE_BOOL	Whether an index is clustered. One of the following: VARIANT_TRUE: The leaf nodes of the index contain full rows, not bookmarks. This is a way to represent a table clustered by key value. VARIANT_FALSE: The leaf nodes of the index contain bookmarks of the base table rows whose key value matches the key value of the index entry.
TYPE	DBTYPE_UI2	The type of the index. One of the following: DBPROPVAL_IT_BTREE: The index is a B+-tree. DBPROPVAL_IT_HASH: The index is a hash file using, for example, linear or extensible hashing. DBPROPVAL_IT_CONTENT: The index is a content index. DBPROPVAL_IT_OTHER: The index is some other type of index.
FILL_FACTOR	DBTYPE_I4	For a B+-tree index, this property represents the storage utilization factor of page nodes during the creation of the index. The value is an integer from 1 to 100 representing the percentage of use of an index node. For a linear hash index, this property represents the storage utilization of the entire hash structure (the ratio of used area to total allocated area) before a file structure expansion occurs.

INITIAL_SIZE	DBTYPE_I4	The total amount of bytes allocated to this structure at creation time.
NULLS	DBTYPE_I4	Whether null keys are allowed. One of the following: DBPROPVAL_IN_DISALLOWNULL: The index does not allow entries where the key columns are NULL. If the consumer attempts to insert an index entry with a NULL key, then the provider returns an error. DBPROPVAL_IN_IGNORENULL: The index does not insert entries containing NULL keys. If the consumer attempts to insert an index entry with a NULL key, then the provider ignores that entry and no error code is returned. DBPROPVAL_IN_IGNOREANYNULL: The index does not insert entries where some column key has a NULL value. For an index having a multicolumn search key, if the consumer inserts an index entry with NULL value in some column of the search key, then the provider ignores that entry and no error code is returned.
SORT_BOOKMARKS	DBTYPE_BOOL	How the index treats repeated keys. One of the following: VARIANT_TRUE: The index sorts repeated keys by bookmark. VARIANT_FALSE: The index does not sort repeated keys by bookmark.
AUTO_UPDATE	DBTYPE_BOOL	Whether the index is maintained automatically when changes are made to the corresponding base table. One of the following: VARIANT_TRUE: The index is automatically maintained. VARIANT_FALSE: The index must be maintained by the consumer through explicit calls to **IRowsetChange**. Ensuring consistency of the index as a result of updates to the associated base table is the responsibility of the consumer.
NULL_COLLATION	DBTYPE_I4	How NULLs are collated in the index. One of the following: DBPROPVAL_NC_END: NULLs are collated at the end of the list, regardless of the collation order. DBPROPVAL_NC_START: NULLs are collated at the start of the list, regardless of the collation order. DBPROPVAL_NC_HIGH: NULLs are collated at the high end of the list. DBPROPVAL_NC_LOW: NULLs are collated at the low end of the list.
ORDINAL_POSITION	DBTYPE_UI4	Ordinal position of the column in the index, starting with one.
COLUMN_NAME	DBTYPE_WSTR	Column name. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses.
COLUMN_GUID	DBTYPE_GUID	Column GUID.
COLUMN_PROPID	DBTYPE_UI4	Column property ID.
COLLATION	DBTYPE_I2	One of the following: DB_COLLATION_ASC: The sort sequence for the column is ascending. DB_COLLATION_DESC: The sort sequence for the column is descending. NULL: A column sort sequence is not supported.
CARDINALITY	DBTYPE_I4	Number of unique values in the index.
PAGES	DBTYPE_I4	Number of pages used to store the index.
FILTER_CONDITION	DBTYPE_WSTR	The WHERE clause identifying the filtering restriction.

The default sort order for the **adSchemaIndexes** rowset is UNIQUE, TYPE, INDEX_CATALOG, INDEX_SCHEMA, INDEX_NAME, and ORDINAL_POSITION.

adSchemaPrimaryKeys

The **adSchemaPrimaryKeys** *QueryType* identifies the primary key columns defined in the catalog by a given user. This *QueryType* is supported by the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaPrimaryKeys** *QueryType* contains the following columns:

TABLE_CATALOG	DBTYPE_WSTR	Catalog name in which the table is defined. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the table is defined. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
COLUMN_NAME	DBTYPE_WSTR	Primary key column name. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses.
COLUMN_GUID	DBTYPE_GUID	Primary key column GUID.
COLUMN_PROPID	DBTYPE_UI4	Primary key column property ID.
ORDINAL	DBTYPE_UI4	The order of the column names (and GUIDs and property IDs) in the key.
PK_NAME	DBTYPE_WSTR	Primary key name. NULL if the provider does not support primary key constraints.

The default sort order for the **adSchemaPrimaryKeys** rowset is UNIQUE, TABLE_CATALOG, TABLE_SCHEMA, and TABLE_NAME.

adSchemaProcedures

The **adSchemaProcedures** *QueryType* identifies information about the columns of rowsets returned by procedures. This *QueryType* is supported by the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaProcedures** *QueryType* contains the following columns:

Column name	Type indicator	Description
PROCEDURE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
PROCEDURE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
PROCEDURE_NAME	DBTYPE_WSTR	Table name.
COLUMN_NAME	DBTYPE_WSTR	The name of the column; this might not be unique. If this cannot be determined, a NULL is returned. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses. If possible, the resulting column ID should be persistent. However, some providers do not support persistent identifiers for columns. The column ID of a base table should be invariant under views.
COLUMN_GUID	DBTYPE_GUID	Column GUID.
COLUMN_PROPID	DBTYPE_UI4	Column property ID.
ROWSET_NUMBER	DBTYPE_UI4	Number of the rowset containing the column. This is greater than one only if the procedure returns multiple rowsets.
ORDINAL_POSITION	DBTYPE_UI4	The ordinal of the column. Columns are numbered starting from one. NULL if there is no stable ordinal value for the column.

IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The column might be nullable. VARIANT_FALSE: The column is known not to be nullable.
DATA_TYPE	DBTYPE_UI2	The indicator of the column's data type. If the data type of the column varies from row to row, this must be DBTYPE_VARIANT.
TYPE_GUID	DBTYPE_GUID	The GUID of the column's data type.
CHARACTER_MAXIMUM_LENGTH	DBTYPE_UI4	The maximum possible length of a value in the column. For character, binary, or bit columns, this is one of the following: The maximum length of the column in characters, bytes, or bits, respectively, if one is defined. For example, a CHAR(5) column in an SQL table has a maximum length of five (5). The maximum length of the data type in characters, bytes, or bits, respectively, if the column does not have a defined length. Zero (0) if neither the column nor the data type has a defined maximum length. NULL for all other types of columns.
CHARACTER_OCTET_LENGTH	DBTYPE_UI4	Maximum length in octets (bytes) of the column, if the type of the column is character or binary. A value of zero means the column has no maximum length. NULL for all other types of columns.
NUMERIC_PRECISION	DBTYPE_UI2	If the column's data type is numeric, this is the maximum precision of the column. The precision of columns with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the column. If the column's data type is not numeric, this is NULL.
NUMERIC_SCALE	DBTYPE_I2	If column's type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is NULL.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the column. For example, the description for a column named Name in the Employee table might be "Employee name."

The default sort order for the **adSchemaProcedures** rowset is PROCEDURE_CATALOG, PROCEDURE_SCHEMA, and PROCEDURE_NAME.

adSchemaProcedureParameters

The **adSchemaProcedureParameters** *QueryType* identifies information about the parameters and return codes of procedures. This *QueryType* is supported by the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaProcedureParameters** *QueryType* contains the following columns:

Column name	Type indicator	Description
PROCEDURE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
PROCEDURE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
PROCEDURE_NAME	DBTYPE_WSTR	Table name.
PARAMETER_NAME	DBTYPE_WSTR	Parameter name. NULL if the parameter is not named.
ORDINAL_POSITION	DBTYPE_UI2	If the parameter is an input, input/output, or output parameter, this is the one-based ordinal position of the parameter in the procedure call. If the parameter is the return value, this is zero.
PARAMETER_TYPE	DBTYPE_UI2	One of the following: DBPARAMTYPE_INPUT—The parameter is an input parameter. DBPARAMTYPE_INPUTOUTPUT—The parameter is an input/output parameter. DBPARAMTYPE_OUTPUT—The parameter is an output parameter. DBPARAMTYPE_RETURNVALUE—The parameter is a procedure return value. If the provider cannot determine the parameter type, this is NULL.
PARAMETER_HASDEFAULT	DBTYPE_BOOL	VARIANT_TRUE: The parameter has a default value. VARIANT_FALSE: The parameter does not have a default value or it is unknown whether the parameter has a default value.
PARAMETER_DEFAULT	DBTYPE_WSTR	Default value of the parameter. If the default value is the NULL value, PARAMETER_HASDEFAULT is VARIANT_TRUE, and the PARAMETER_DEFAULT value is a NULL value.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The parameter might be nullable. VARIANT_FALSE: The parameter is not nullable.
DATA_TYPE	DBTYPE_UI2	The indicator of the parameter's data type.

CHARACTER_MAXIMUM_LENGTH	DBTYPE_UI4	The maximum possible length of a value in the parameter. For character, binary, or bit columns, this is one of the following: The maximum length of the parameter in characters, bytes, or bits, respectively, if one is defined. For example, a CHAR(5) column in an SQL table has a maximum length of five (5). The maximum length of the data type in characters, bytes, or bits, respectively, if the parameter does not have a defined length. Zero (0) if neither the parameter nor the data type has a defined maximum length. NULL for all other types of parameters.
CHARACTER_OCTET_LENGTH	DBTYPE_UI4	Maximum length in octets (bytes) of the parameter, if the type of the parameter is character or binary. A value of zero means the parameter has no maximum length. NULL for all other types of parameter.
NUMERIC_PRECISION	DBTYPE_UI2	If the parameter's data type is numeric, this is the maximum precision of the parameter. The precision of parameters with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the parameters. If the parameter's data type is not numeric, this is NULL.
NUMERIC_SCALE	DBTYPE_I2	If parameter's type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is NULL.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the parameter. For example, the description for a parameter named Name in a procedure that adds a new employee might be "Employee name."
TYPE_NAME	DBTYPE_WSTR	Provider-specific data type name.
LOCAL_TYPE_NAME	DBTYPE_WSTR	Localized version of TYPE_NAME. NULL is returned if a localized name is not supported by the data provider.

The default sort order for the **adSchemaProcedureParameters** rowset is PROCEDURE_CATALOG, PROCEDURE_SCHEMA, and PROCEDURE_NAME.

adSchemaProviderTypes

The **adSchemaProviderTypes** *QueryType* identifies the data types supported by the data provider. This *QueryType* is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaProviderType** *QueryType* contains the following columns:

Column name	Type indicator	Description
TYPE_NAME	DBTYPE_WSTR	Provider-specific data type name.
DATA_TYPE	DBTYPE_UI2	The indicator of the data type.
COLUMN_SIZE	DBTYPE_UI4	The length of a non-numeric column or parameter refers to either the maximum or the defined length for this type by the provider. For character data, this is the maximum or defined length in characters. If the data type is numeric, this is the upper bound on the maximum precision of the data type.
LITERAL_PREFIX	DBTYPE_WSTR	Character or characters used to prefix a literal of this type in a text command.

LITERAL_SUFFIX	DBTYPE_WSTR	Character or characters used to suffix a literal of this type in a text command.
CREATE_PARAMS	DBTYPE_WSTR	The creation parameters are specified by the consumer when creating a column of this data type. For example, the SQL data type DECIMAL needs a precision and a scale. In this case, the creation parameters might be the string "precision,scale". In a text command, to create a DECIMAL column with a precision of 10 and a scale of 2, the value of the TYPE_NAME column might be DECIMAL() and the complete type specification would be DECIMAL(10,2). The creation parameters appear as a comma-separated list of values, in the order they are to be supplied, with no surrounding parentheses. If a creation parameter is length, maximum length, precision, or scale, "length", "max length", "precision", and "scale" should be used, respectively. If the creation parameters are some other value, it is provider-specific what text is used to describe the creation parameter. If the data type requires creation parameters, "()" generally appears in the type name. This indicates the position at which to insert the creation parameters. If the type name does not include "()", the creation parameters are enclosed in parentheses and appended to the end of the data type name.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The data type is nullable. VARIANT_FALSE: The data type is not nullable. NULL: It is not known whether the data type is nullable.
CASE_SENSITIVE	DBTYPE_BOOL	VARIANT_TRUE: The data type is a character type and is case-sensitive. VARIANT_FALSE: The data type is not a character type or is not case-sensitive.
SEARCHABLE	DBTYPE_UI4	If the provider supports **ICommandText**, then this column is an integer indicating the searchability of a data type, otherwise this column is NULL. One of the following: DB_UNSEARCHABLE: The data type cannot be used in a WHERE clause. DB_LIKE_ONLY: The data type can be used in a WHERE clause only with the LIKE predicate. DB_ALL_EXCEPT_LIKE: The data type can be used in a WHERE clause with all comparison operators except LIKE. DB_SEARCHABLE: The data type can be used in a WHERE clause with any comparison operator.

UNSIGNED_ATTRIBUTE	DBTYPE_BOOL	VARIANT_TRUE: The data type is unsigned. VARIANT_FALSE: The data type is signed. NULL: Not applicable to data type.
FIXED_PREC_SCALE	DBTYPE_BOOL	VARIANT_TRUE: The data type has a fixed precision and scale. VARIANT_FALSE: The data type does not have a fixed precision and scale.
AUTO_UNIQUE_VALUE	DBTYPE_BOOL	VARIANT_TRUE: Values of this type can be auto-incrementing. VARIANT_FALSE: Values of this type cannot be auto-incrementing.
LOCAL_TYPE_NAME	DBTYPE_WSTR	Localized version of TYPE_NAME. NULL is returned if a localized name is not supported by the data provider.

MINIMUM_SCALE	DBTYPE_I2	If the type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the minimum number of digits allowed to the right of the decimal point. Otherwise, this is NULL.
MAXIMUM_SCALE	DBTYPE_I2	If the type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the maximum number of digits allowed to the right of the decimal point. Otherwise, this is NULL.
GUID	DBTYPE_GUID	The GUID of the type. All types supported by a provider are described in a type library, so each type has a corresponding GUID.
TYPELIB	DBTYPE_WSTR	The type library containing the description of this type. All types supported by a provider are described in one or more type libraries.
VERSION	DBTYPE_WSTR	The version of the type definition. Providers may wish to version type definitions. Different providers may use different version schemes, such as a timestamp or number (integer or float). NULL if not supported.

IS_LONG	DBTYPE_BOOL	VARIANT_TRUE: The data type is a BLOB that contains very long data; the definition of very long data is provider-specific. VARIANT_FALSE: The data type is a BLOB that does not contain very long data or is not a BLOB. This value determines the setting of the DBCOLUMNFLAGS_ISLONG flag returned by **GetColumnInfo** in **IColumnsInfo** and **GetParameterInfo** in **ICommandWithParameters**. For more information, see **GetColumnInfo** and **GetParameterInfo**.
BEST_MATCH	DBTYPE_BOOL	VARIANT_TRUE: The data type is the best match between all data types in the data source and the OLE DB data type indicated by the value in the DATA_TYPE column. VARIANT_FALSE: The data type is not the best match. For each set of rows in which the value of the DATA_TYPE column is the same, the BEST_MATCH column is set to VARIANT_TRUE in only one row.

The default sort order for the **adSchemaProviderTypes** rowset is DATA_TYPE.

adSchemaTables

The **adSchemaTables** *QueryType* identifies the tables defined in the catalog that are accessible to a given user. This *QueryType* is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft® OLE DB Provider for DB2.

The rowset returned by an **adSchemaTables** *QueryType* contains the following columns:

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified Schema Name. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
TABLE_TYPE	DBTYPE_WSTR	Table type. One of the following or a provider-specific value. "ALIAS" "TABLE" "SYNONYM" "SYSTEM TABLE" "VIEW" "GLOBAL TEMPORARY" "LOCAL TEMPORARY"
TABLE_GUID	DBTYPE_GUID	GUID that uniquely identifies the table. Providers that do not use GUIDs to identify tables should return NULL in this column.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the table.

The default sort order for the **adSchemaTables** rowset is TABLE_TYPE, TABLE_CATALOG, TABLE_SCHEMA, and TABLE_NAME.

Precision Property

The **Precision** property on a **Field** object indicates the degree of precision for Numeric values for numeric **Field** objects. This property returns a byte value indicating the maximum number of digits used to represent numeric values in a **Field** object.

```
numericPrecision = currentfield.Precision
```

Remarks

The **Precision** property is used to return the precision of a numeric field object.

The byte value that the **Precision** property will return is dependent on the data type of the **Field** object. The value for the ADO data type of the **Field** object can be one of the following enumerated values for **DataTypeEnum**:

Enumeration	Value	Description
adEmpty	0	This data type indicates that no value was specified (DBTYPE_EMPTY).
adSmallInt	2	This data type indicates a two-byte (16-bit) signed integer (DBTYPE_I2).
adInteger	3	This data type indicates a four-byte (32-bit) signed integer (DBTYPE_I4).
adSingle	4	This data type indicates a four-byte (32-bit) single precision IEEE floating point number (DBTYPE_R4).
adDouble	5	This data type indicates an eight-byte (64-bit) double precision IEEE floating point number (DBTYPE_R8).
adCurrency	6	A data type indicates a currency value (DBTYPE_CY). Currency is a fixed-point number with 4 digits to the right of the decimal point. It is stored in an eight-byte signed integer scaled by 10,000. This data type is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE DB Provider for DB2.
adDate	7	This data type indicates a date value stored as a Double, the whole part of which is the number of days since December 30, 1899, and the fractional part of which is the fraction of a day. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBSTR	8	This data type indicate a null-terminated Unicode character string (DBTYPE_BSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIDispatch	9	This data type indicates a pointer to an IDispatch interface on an OLE object (DBTYPE_IDISPATCH). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adError	10	This data type indicates a 32-bit error code (DBTYPE_ERROR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBoolean	11	This data type indicates a Boolean value (DBTYPE_BOOL). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adVariant	12	This data type indicates an automation variant (DBTYPE_VARIANT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIUnknown	13	This data type indicates a pointer to an IUnknown interface on an OLE object (DBTYPE_IUNKNOWN). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDecimal	14	This data type indicates numeric data with a fixed precision and scale (DBTYPE_DECIMAL).
adTinyInt	16	This data type indicates a single -byte (8-bit) signed integer (DBTYPE_I1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedTinyInt	17	This data type indicates a single-byte (8-bit) unsigned integer (DBTYPE_UI1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedSmallInt	18	This data type indicates a two-byte (16-bit) unsigned integer (DBTYPE_UI2). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adUnsignedInt	19	This data type indicates a four-byte (32-bit) unsigned integer (DBTYPE_UI4). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBigInt	20	This data type indicates an eight-byte (64-bit) signed integer (DBTYPE_I8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adUnsignedBigInt	21	This data type indicates an eight-byte (64-bit) unsigned integer (DBTYPE_UI8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adGUID	72	This data type indicates a globally unique identifier or GUID (DBTYPE_GUID). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBinary	128	This data type indicates fixed-length binary data (DBTYPE_BYTES).
adChar	129	This data type indicates a character string value (DBTYPE_STR).
adWChar	130	This data type indicates a null-terminated Unicode character string (DBTYPE_WSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adNumeric	131	This data type indicates numeric data where the precision and scale are exactly as specified (DBTYPE_NUMERIC).
adUserDefined	132	This data type indicates user-defined data (DBTYPE_UDT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDBDate	133	This data type indicates a OLE DB date structure (DBTYPE_DATE).
adDBTime	134	This data type indicates a OLE DB time structure (DBTYPE_TIME).
adDBTimeStamp	135	This data type indicates a OLE DB timestamp structure (DBTYPE_TIMESTAMP).
adVarChar	200	This data type indicates variable-length character data (DBTYPE_STR).
adLongVarChar	201	This data type indicates a long string value.
adVarWChar	202	This data type indicates a Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adLongVarWChar	203	This data type indicates a long Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVarBinary	204	This data type indicates variable-length binary data (DBTYPE_BYTES).
adLongVarBinary	205	This data type indicates a long binary value.

Note that the **Precision** property returns values that differ from the precision of the host data type for the following ADO data types:

ADO Data Type	Comments
adSmallInt	The precision on the host is 4, but the OLE DB Provider returns a precision of 5.
adInteger	The precision on the host is 8, but the OLE DB Provider returns a precision of 10.

adSingle	The precision on the host is 9, but the OLE DB Provider returns a precision of 7.
adDouble	The precision on the host is 17, but the OLE DB Provider returns a precision of 15.

OriginalValue Property

The **OriginalValue** property on a **Field** object indicates the value of a **Field** that existed in the record before any changes were made. This property returns a Variant.

```
oldValue = currentfield.OriginalValue
```

Remarks

The **OriginalValue** property is used to return the original field value for a field from the current record.

In immediate update mode (the provider writes changes to the underlying data source once the **Update** method is called), the **OriginalValue** property returns the field value that existed prior to any changes (that is, since the last **Update** method call). This is the same value that the **CancelUpdate** method uses to replace the **Value** property.

In batch update mode (the provider caches multiple changes and writes them to the underlying data source only when the **UpdateBatch** method is called), the **OriginalValue** property returns the field value that existed prior to any changes (that is, since the last **UpdateBatch** method call). This is the same value that the **CancelBatch** method uses to replace the **Value** property. When this property is used with the **UnderlyingValue** property, you can resolve conflicts that arise from batch updates.

Provider Property

The **Provider** property on a **Connection** object indicates the name of the provider. This property sets or returns a String value.

```
oldProvider = currentConnection.Provider
currentConnection.Provider = "SNAOLEDB"
```

Remarks

The **Provider** property is used to set or return the name of the provider for the connection. This property can also be set by the contents of **ConnectionString** property or the **ConnectionString** argument of the **Open** method. However, specifying a provider in more than one place while calling the **Open** method can have unpredictable results. If no provider is specified, the property will default to MSDASQL (Microsoft® OLE DB Provider for ODBC).

The Microsoft® OLE DB Provider for AS/400 and VSAM requires "SNAOLEDB" as the **Provider** property string.

The Microsoft® OLE DB Provider for DB2 requires "DB2OLEDB" as the **Provider** property string.

The **Provider** property is read/write when the connection is closed and read-only when it is open. The setting does not take effect until either the **Connection** object is opened or the **Properties** collection of the **Connection** object is accessed. If the setting is invalid, an error occurs.

Refresh Method

The **Refresh** method on a **Collection** object updates the objects in a collection to reflect objects available from and specific to the OLE DB provider.

```
collection.Refresh
```

Parameters

None.

Remarks

This method is only supported on the **Field**s and **Properties** collections under the Microsoft® OLE DB Provider for AS/400 and VSAM.

The **Refresh** method accomplishes different tasks depending on the collection object on which it is called.

Using the **Refresh** method on the **Field**s collection has no visible effect. To retrieve changes from the underlying database structure, either the **Requery** method must be used or, if the **Recordset** object does not support bookmarks, the **MoveFirst** method must be used.

Using the **Refresh** method on a **Properties** collection of some objects populates the collection with the dynamic properties the provider exposes. These properties provide information about features specific to the provider beyond the built-in properties ADO supports. The OLE DB Data Provider for AS/400 and VSAM does not support any provider-specific properties.

Requery Method

The **Requery** method on a **Recordset** object updates the data in a **Recordset** object by re-executing the query on which the object is based.

```
recordset.Requery
```

Parameters

None.

Remarks

The **Requery** method is used to refresh the entire contents of a **Recordset** object from the data source by reissuing the original command and retrieving the data a second time. Calling this method is equivalent to calling the **Close** and **Open** methods in succession. If you are editing the current record or adding a new record, an error occurs.

While the **Recordset** object is open, the properties that define the nature of the cursor (**CursorType**, **LockType**, **MaxRecords**, and other properties) are read-only. Thus, the **Requery** method can only refresh the current cursor. To change any of the cursor properties and view the results, the **Close** method must be used so that the properties become read/write again. You can then change the property settings and call the **Open** method to reopen the cursor.

Save Method

The **Save** method on a **Recordset** object saves the Recordset in a file or Stream object.

```
recordset.Save Destination, Persistent Format
```

Parameters

Destination
This optional parameter specifies a Variant representing the complete path name of the file where the **Recordset** is to be saved, or a reference to a **Stream** object.

Persistent Format
This optional parameter specifies a Long integer value representing a **PersistFormatEnum** value that specifies the format in which the **Recordset** is to be saved (XML or ADTG). The default value is **adPersistADTG**.

The **PersistFormatEnum** value can be one of the following constants:

Enumeration	Value	Description
adPersistADTG	0	This value indicates Microsoft Advanced Data TableGram (ADTG) format.
adPersistXML	1	This value indicates Extensible Markup Language (XML) format.

Remarks

The **Save** method can only be invoked on an open **Recordset**. Use the **Open** method to later restore the **Recordset** from *Destination*.

When using the Microsoft® OLE DB Provider for AS/400 and VSAM and the Filter property is in effect for the **Recordset**, then only the rows accessible under the filter are saved.

The first time you save the **Recordset**, it is optional to specify *Destination*. If the *Destination* parameter is omitted, a new file will be created with a name set to the value of the Source property of the **Recordset**.

The *Destination* parameter should be omitted when you subsequently call **Save** after the first save, or a run-time error will occur. If you subsequently call **Save** with a new *Destination*, the **Recordset** is saved to the new destination. However, the new destination and the original destination will both be open.

Save does not close the **Recordset** or *Destination*, so you can continue to work with the **Recordset** and save your most recent changes. *Destination* remains open until the **Recordset** is closed, during which time other applications can read but not write to *Destination*.

For reasons of security, the **Save** method permits only the use of low and custom security settings from a script executed by Microsoft® Internet Explorer. For a more detailed explanation of security issues, see "ADO and RDS Security Issues in Microsoft Internet Explorer" found in the ActiveX® Data Objects (ADO) Technical Articles of the Microsoft Data Access Technical Articles.

If the **Save** method is called while an asynchronous **Recordset** fetch, execute, or update operation is in progress, then **Save** waits until the asynchronous operation is complete.

Records are saved beginning with the first row of the **Recordset**. When the **Save** method is finished, the current row position is moved to the first row of the **Recordset**.

For best results, set the CursorLocation property to **adUseClient** with **Save**. If your provider does not support all of the features necessary to save **Recordset** objects, the Cursor Service will provide these features.

When a **Recordset** is persisted with the **CursorLocation** property set to **adUseServer**, the update capability for the **Recordset** is limited. Typically, only single-table updates, insertions, and deletions are allowed (dependent on features supported by the provider). The **Resync** method is also unavailable in this configuration.

Note that saving a **Recordset** with **Fields** of type **adVariant**, **adIDispatch**, or **adIUnknown** is not supported by ADO and can cause unpredictable results.

Because the *Destination* parameter can accept any object that supports the OLE DB IStream interface, a **Recordset** can be saved directly to the ASP Response object. For more information, see the XML Recordset Persistence Scenario in the *ADO Programmer's Reference*.

Sort Property

The **Sort** property on a **Recordset** object indicates that a recordset should be sorted.

```
Recordset.Sort BSTR Criteria
```

Parameters

Criteria

This parameter specifies the criteria used for sorting the **Recordset** object. This **Sort** property contains a comma-delimited list of column names and a direction specifier (ascending or descending) to be used for sorting records in a **Recordset** object. The direction specifier is a string (ASC or DESC). When a direction is not specified, the direction defaults to ascending.

An example of a **Sort** property criteria is as follows:

"LastName ASC, FirstName DESC, Initial"

Remarks

The **Sort** property is not supported by the OLE DB Provider for DB2 or the ODBC Driver for DB2.

The **Sort** property is used with an open **Recordset** object based on an AS/400 physical file. The **Sort** property allows the user to indicate which logical view to apply to an AS/400 physical file. The logical view must be a valid index specified in the description of the AS/400 physical file. The logical view is provided by the AS/400 logical file. The Microsoft® OLE DB Provider for AS/400 and VSAM responds to a **Sort** request by first closing the open physical file, and then opening the logical file that points back to the data in the physical file.

The **Recordset Sort** property is only supported on AS/400 hosts. If the user opens a **Recordset** object based on an AS/400 logical file, then there is likely no need to use **Recordset**.**Sort**. For performance reasons, applications should be written to open the AS/400 logical file first, because the overhead is so much greater when opening a physical file first.

If the CursorLocation property is set to **adUseClient** (use the client cursor engine), the **Sort** property will work if MDAC 2.0 or later is installed but will not work properly with earlier versions of ADO.

Source Property on Error Object

The **Source** property on a **Error** object indicates the name of the object or application that originally generated an error. This property returns a String value that indicates the name of an object or application.

```
errorSource = currentError.Source
```

Remarks

The **Source** property on a **Error** object is used to determine the name of the object or application that originally generated an error. This could be the object's class name or programmatic ID.

For errors in ADO, the property value will be **ADODB.***ObjectName*, where *ObjectName* is the name of the object that triggered the error. For ADOX and ADO MD, the value will be **ADOX.***ObjectName* and **ADOMD.***ObjectName,* respectively.

Based on the error documentation from the **Source**, Number, and Description properties of **Error** objects, you can write code that will handle the error appropriately.

The **Source** property is read-only for **Error** objects.

Source Property on Recordset Object

The **Source** property on a **Recordset** object indicates the data source for the Recordset object. This property sets a String value or **Command** object reference or returns only a String value that indicates the source of the **Recordset**.

```
currentSource = currentRecordset.Source
recordset.Source = newSource
```

Remarks

The **Source** property on a Recordset is used to specify a data source for a **Recordset** object.

Using the Microsoft® OLE DB Provider for AS/400 and VSAM, the **Source** property can be either a **Command** object variable or a table name.

Using the Microsoft® OLE DB Provider for DB2, the Source property can be one of the following: a **Command** object variable, an SQL statement, or a stored procedure. If the **Source** property is an SQL statement or a stored procedure, you can optimize performance by passing the appropriate *Options* argument with the **Open** method call.

If you set the **Source** property to a **Command** object, the **ActiveConnection** property of the **Recordset** object will inherit the value of the **ActiveConnection** property for the specified **Command** object. However, reading the **Source** property does not return a **Command** object; instead, it returns the **CommandText** property of the **Command** object to which you set the **Source** property.

The **Source** property is read/write for closed **Recordset** objects and read-only for open **Recordset** objects.

State Property

The **State** property on a **Connection**, **Command**, or **Recordset** object describes the current state of an object. This property sets or returns a Long value.

```
oldState = currentConnection.State
currentConnection.State = adStateClosed
```

Remarks

The **State** property is used to set or return the current state of an object. The value of the **State** property can be one of the following enumerated values:

Enumeration	Value	Description
adStateClosed	0	This value indicates that the object is closed. This is the default value.
AdStateOpen	1	This value indicates that the object is open.

The **State** property can be used to determine the current state of a given object at any time.

Status Property

The **Status** property on a **Recordset** object indicates the status of the current record with respect to batch updates or other bulk operations. This property returns a Long value.

```
oldStatus = currentRecordset.Status
```

Remarks

The **Status** property is used to return the current status of a recordset object at any time. The value of the **Status** property returns a sum of the following RecordStatusEnum enumerated values:

Enumeration	Value	Description
adRecOK	0	This value indicates that the recordset object was successfully updated.
AdRecNew	0x1	This value indicates that the recordset object is new.
AdRecModified	0x2	This value indicates that the recordset object was modified.
AdRecDeleted	0x4	This value indicates that the recordset object was deleted.
AdRecUnmodified	0x8	This value indicates that the recordset object was not modified.
adRecInvalid	0x10	This value indicates that the recordset object was not saved because its bookmark is invalid.
adRecMultipleChanges	0x40	This value indicates that the recordset object was not saved because it would have affected multiple records.
adRecPendingChanges	0x80	This value indicates that the recordset object was not saved because it refers to a pending insert.
adRecCanceled	0x100	This value indicates that the recordset object was not saved because the operation was canceled.
adRecCantRelease	0x400	This value indicates that the new recordset object was not saved because of existing record locks.
adRecConcurencyViolation	0x800	This value indicates that the recordset object was not saved because optimistic concurrency was in use.
adRecIntegrityViolation	0x1000	This value indicates that the recordset object was not saved because the user violated integrity constraints.
adRecMaxChangesExceeded	0x2000	This value indicates that the recordset object was not saved because there were too many pending changes.
adRecObjectOpen	0x4000	This value indicates that the recordset object was not saved because of a conflict with an open storage object.
adRecOutOfMemory	0x8000	This value indicates that the recordset object was not saved because the computer has run out of memory.
adRecPermissionDenied	0x10000	This value indicates that the recordset object was not saved because the user has insufficient permissions.
adRecSchemaViolation	0x20000	This value indicates that the recordset object was not saved because it violates the structure of the underlying database.
adRecDBDeleted	0x40000	This value indicates that the recordset object has already been deleted from the data source.

Use the **Status** property to see what changes are pending for records modified during batch updating. You can also use the **Status** property to view the status of records that fail during bulk operations such as when you call the **Resync**, **UpdateBatch**, or **CancelBatch** methods on a recordset object, or set the **Filter** property on a recordset object to an array of bookmarks. With this property, you can determine how a given record failed and resolve it accordingly.

Supports Method

The **Supports** method on a **Recordset** object determines whether a specified **Recordset** object supports a particular type of feature.

```
boolean = recordset.Supports ( CursorOptions )
```

Parameters

CursorOptions
This parameter specifies a Long expression that consists of one or more of the **CursorOptionEnum** values indicating which feature is being queried. The **CursorOptionEnum** value can be one of the constants shown in the table following the Parameters section.

Values for the CursorOptions parameter

Enumeration	Value	Description
adAddNew	0x1000400	This value indicates whether the **AddNew** method can be used to add new records.
adApproxPosition	0x4000	This value indicates whether the **AbsolutePosition** and **AbsolutePage** properties can read and set.
adBookMark	0x2000	This value indicates whether the **Bookmark** property can be used to access specific records.
adDelete	0x1000800	This value indicates whether the **Delete** method can be used to delete records.
adFind	0x80000	This value indicates whether the **Find** method can be used to locate a row in a **Recordset**.
adHoldRecords	0x100	This value indicates whether you can retrieve more records or change the next retrieve position without committing all pending changes.
adIndex	0x100000	This value indicates whether the **Index** property can be name an index.
adMovePrevious	0x200	This value indicates whether the **MoveFirst** and **MovePrevious** methods, and **Move** or **GetRows** methods can be used to move the current record position backward without requiring bookmarks.
adNotify	0x40000	This value indicates that the underlying data provider supports notifications (which determines whether **Recordset** events are supported).
adResync	0x20000	This value indicates whether the recordset cursor can be updated with the data visible in the underlying database using the **Resync** method.
adSeek	0x200000	This value indicates whether the **Seek** method can be used to locate a row in a **Recordset**.
adUpdate	0x18000	This value indicates whether the **Update** method can be used to modify existing data.
adUpdateBatch	0x10000	This value indicates whether batch updating can be used on the recordset (the **UpdateBatch** and **CancelBatch** methods) to transmit changes to the provider in groups.

Return Values

Returns a Boolean value that indicates whether all of the features identified by the *CursorOptions* argument are supported by the provider.

Remarks

The **Supports** method is used to determine what types of features (methods and properties) a **Recordset** object supports. If the **Recordset** object supports the features whose corresponding constants are in *CursorOptions*, the **Supports** method returns **True**. Otherwise, it returns **False**.

Although the **Supports** method may return **True** for a given feature, it does not guarantee that the OLE DB Provider can make the feature available under all circumstances. The **Supports** method simply returns whether the provider can support the specified function assuming certain conditions are met. For example, the **Supports** method may indicate that a **Recordset** object supports updates even though the cursor is based on a multitable join, some columns of which are not updatable.

Type Property

The **Type** property on a **Field** object indicates the operational type or data type for **Field** or **Property** objects. This property sets or returns a **DataTypeEnum** value.

```
datatype = currentfield.Type
```

Remarks

The **Type** property is used to return the data type of a numeric field object.

The value returned by the **Type** property on a **Field** object can be one of the following enumerated values for **DataTypeEnum**:

Enumeration	Value	Description
adEmpty	0	This data type indicates that no value was specified (DBTYPE_EMPTY).
AdSmallInt	2	This data type indicates a two-byte (16-bit) signed integer (DBTYPE_I2).
AdInteger	3	This data type indicates a four-byte (32bit) signed integer (DBTYPE_I4).
AdSingle	4	This data type indicates a four-byte (32-bit) single-precision IEEE floating-point number (DBTYPE_R4).
AdDouble	5	This data type indicates an eight-byte (64-bit) double-precision IEEE floating-point number (DBTYPE_R8).
adCurrency	6	A data type indicates a currency value (DBTYPE_CY). Currency is a fixed-point number with four digits to the right of the decimal point. It is stored in an eight-byte signed integer scaled by 10,000. This data type is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft® OLE DB Provider for DB2.
adDate	7	This data type indicates a date value stored as a Double, the whole part of which is the number of days since December 30, 1899, and the fractional part of which is the fraction of a day. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBSTR	8	This data type indicates a null-terminated Unicode character string (DBTYPE_BSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIDispatch	9	This data type indicates a pointer to an **IDispatch** interface on an OLE object (DBTYPE_IDISPATCH). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adError	10	This data type indicates a 32-bit error code (DBTYPE_ERROR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBoolean	11	This data type indicates a Boolean value (DBTYPE_BOOL). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adVariant	12	This data type indicates an Automation variant (DBTYPE_VARIANT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIUnknown	13	This data type indicates a pointer to an **IUnknown** interface on an OLE object (DBTYPE_IUNKNOWN). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDecimal	14	This data type indicates numeric data with a fixed precision and scale (DBTYPE_DECIMAL).
adTinyInt	16	This data type indicates a single-byte (8-bit) signed integer (DBTYPE_I1). This data type is not supported by the OLE DB Provider.
adUnsignedTinyInt	17	This data type indicates a singlebyte (8-bit) unsigned integer (DBTYPE_UI1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedSmallInt	18	This data type indicates a two-byte (16-bit) unsigned integer (DBTYPE_UI2). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adUnsignedInt	19	This data type indicates a four-byte (32-bit) unsigned integer (DBTYPE_UI4). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBigInt	20	This data type indicates an eight-byte (64-bit) signed integer (DBTYPE_I8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adUnsignedBigInt	21	This data type indicates an eight-byte (64-bit) unsigned integer (DBTYPE_UI8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adGUID	72	This data type indicates a globally unique identifier or GUID (DBTYPE_GUID). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBinary	128	This data type indicates fixed-length binary data (DBTYPE_BYTES).
adChar	129	This data type indicates a character string value (DBTYPE_STR).
adWChar	130	This data type indicates a null-terminated Unicode character string (DBTYPE_WSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adNumeric	131	This data type indicates numeric data where the precision and scale are exactly as specified (DBTYPE_NUMERIC).
adUserDefined	132	This data type indicates user-defined data (DBTYPE_UDT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDBDate	133	This data type indicates a OLE DB date structure (DBTYPE_DATE).
adDBTime	134	This data type indicates a OLE DB time structure (DBTYPE_TIME).
adDBTimeStamp	135	This data type indicates a OLE DB timestamp structure (DBTYPE_TIMESTAMP).
adVarChar	200	This data type indicates variable-length character data (DBTYPE_STR).
adLongVarChar	201	This data type indicates a long string value.
adVarWChar	202	This data type indicates a Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adLongVarWChar	203	This data type indicates a long Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVarBinary	204	This data type indicates variable-length binary data (DBTYPE_BYTES).
adLongVarBinary	205	This data type indicates a long binary value.

The corresponding OLE DB type indicator is shown in parentheses in the description column of the above table. For more information on OLE DB data types, see the *OLE DB 2.0 Programmer's Reference*.

UnderlyingValue Property

The **UnderlyingValue** property on a **Field** object indicates the **Field** object's current value in the database. This property returns a Variant.

```
actualValue = currentfield.UnderlyingValue
```

Remarks

The **UnderlyingValue** property is used to return the current field value from the database. The field value in the **UnderlyingValue** property is the value that is visible to your transaction and may be the result of a recent update by another transaction. This may differ from the **OriginalValue** property, which reflects the value that was originally returned to the **Recordset**.

This is similar to the affect of calling the **Resync** method, however the **UnderlyingValue** property returns only the value for a specific field from the current record. This is the same value that the **Resync** method uses to replace the **Value** property.

When this property is used with the **OriginalValue** property, you can resolve conflicts that arise from batch updates.

Update Method

The **Update** method on a **Recordset** object saves any changes you make to the current record of a **Recordset** object.

```
recordset.Update Fields, Values
```

Parameters

Fields
This optional parameter specifies a Variant representing a single name or a Variant array representing names or ordinal positions of the field or fields you wish to modify.

Values
This optional parameter specifies a Variant representing a single value or a Variant array representing values for the field or fields in the new record.

Remarks

The **Update** method is used to save any changes you make to the current record of a **Recordset** object since calling the **AddNew** method or since changing any field values in an existing record. The **Recordset** object must support updates for the **Update** method to be used successfully.

To set field values, do one of the following:

- Assign values to a **Field** object's **Value** property and call the **Update** method.
- Pass a field name and a value as arguments with the **Update** call.
- Pass an array of field names and an array of values with the **Update** call.

When arrays of fields and values are used, there must be an equal number of elements in both arrays. Also, the order of field names must match the order of field values. If the number and order of fields and values do not match, an error occurs.

If the **Recordset** object supports batch updating, then multiple changes to one or more records can be cached locally when the **UpdateBatch** method is called. If you are editing the current record or adding a new record when the **UpdateBatch** method is called, ADO will automatically call the **Update** method to save any pending changes to the current record before transmitting the batched changes to the OLE DB Provider.

If you move from the record you are adding or editing before calling the **Update** method, ADO will automatically call **Update** to save the changes. The **CancelUpdate** method must be called if you want to cancel any changes made to the current record or to discard a newly added record.

The current record remains current after the **Update** method is called.

UpdateBatch Method

The **UpdateBatch** method on a **Recordset** object writes all pending batch updates to the host.

```
recordset.UpdateBatch AffectedRecords
```

Parameters

AffectedRecords

This optional parameter specifies an **AffectEnum** value that determines how many records the **UpdateBatch** method will affect.

The **AffectEnum** value can be one of the following constants:

Enumeration	Value	Description
adAffectCurrent	1	This value writes pending changes only for the current record.
adAffectGroup	2	This value writes pending changes for the records that satisfy the current Filter property setting. You must set the **Filter** property to one of the valid predefined constants to use this option.
adAffectAll	3	This value writes pending changes for all the records in the **Recordset** object, including any hidden by the current **Filter** property setting. This value is the default.

Remarks

The **UpdateBatch** method is used when modifying a **Recordset** object in batch update mode to transmit all changes made in a **Recordset** object to the underlying database.

If the **Recordset** object supports batch updating, then multiple changes to one or more records can be cached locally until the **UpdateBatch** method is called. If you are editing the current record or adding a new record when the **UpdateBatch** method is called, ADO will automatically call the **Update** method to save any pending changes to the current record before transmitting the batched changes to the provider.

If the attempt to transmit changes fails because of a conflict with the underlying data (for example, a record has already been deleted by another user), the provider returns warnings to the **Errors** collection but does not halt program execution. A run-time error occurs only if there are conflicts on all the requested records. Use the **Filter** property (**adFilterAffectedRecords**) and the **Status** property to locate records with conflicts.

To cancel all pending batch updates, use the **CancelBatch** method.

Value Property

The **Value** property on a **Field** object indicates the value assigned to a **Field** or **Property** object. This property sets or returns a Variant value. The default value depends on the **Type** property of the **Field** object.

```
oldValue = currentfield.Value
currentField.Value = newValue
```

Remarks

The **Value** property is used to set or return data from **Field** objects or to set or return property settings with **Property** objects. Whether the **Value** property is read/write or read-only depends upon numerous factors. For a **Field** object, this includes whether the **Recordset** was opened as read-only or read/write.

ADO allows setting and returning long binary data with the **Value** property.from the database.

Version Property

The **Version** property on a **Connection** object indicates the ADO version number. This property returns a String value.

```
versionADO = currentConnection.Version
```

Remarks

The **Version** property is used to return the version number of the ADO implementation. The version of the provider will be available as a dynamic property in the **Properties** collection.

Data Queue ActiveX Control Reference

This section provides reference information on specific ActiveX® methods, properties, and event notifications supported by the Microsoft® Data Queue ActiveX Control. The function syntax and code examples are based on Microsoft Visual Basic.

AddQueueItem Method

The **AddQueueItem** method on an **IEGDataQueue** object adds a record to a specified data queue using the Data Queue ActiveX Control.

```
object.AddQueueItem QueueItem, fBlock
```

Parameters

QueueItem
This required parameter representing an **IEIGDataQueueItem** object instance specifying the queue item to add to the queue.
fBlock
This optional parameter specifies whether the operation should block until the completion status is known. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the fBlock Values table which follows the Parameters section.

***fBlock* Values**

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should block until the completion status is known.
eigAnswerNo	1	This value indicates that the operation should not block. This is the default value for this parameter if it is omitted from the method call.

Remarks

The queue the item is sent to is represented by **QItemType** property on the **IEIGDataQueueItem**. The *QueueItem* is an object of type IEIGDataQueueItem that may have been initialized by the user or returned by a call to **GetQueueItem**.

Cancel Method

The **Cancel** method on an **IEGDataQueue** object terminates a transfer operation that is already in progress. This method cancels an item transfer using the Data Queue ActiveX Control.

```
object.Cancel
```

Parameters

None.

Remarks

The **Cancel** method is used to cancel a transfer operation that is already in progress.

CancelQueue Method

The **CancelQueue** method on an **IEGDataQueue** object indicates that an application using the Data Queue ActiveX Control no longer wants to be notified of an incoming queue data item. This can be used to stop pending notifications that were queued as a result of calling **GetQueueItem**.

```
object.CancelQueue CancelReqCount, CancelReqType, KeyValue
```

Parameters

CancelReqCount
This optional parameter is a count (a short value) of the number of outstanding queue receive requests to cancel. This parameter defaults to a value of 1.

CancelReqType
This optional parameter specifies the type of queue request to cancel. This parameter can be set to one of the **eigQItemTypeEnum** constants shown in the CancelReqType Values table which follows the Parameters section.

KeyValue
This optional parameter is a VARIANT representing the key value and has no default value. If the *CancelReqType* is eigKQItem, then this value specifies the key value to stop waiting on.

***CancelReqType* Values**

Enumeration	Value	Description
eigKQItem	0	A keyed item.
eigQItem	1	A non-keyed item. This is the default value for this parameter if it is not specified.

Remarks

An application can call the **CancelQueue** method passing a *CancelReqCount* value of 0, in order to retrieve the number of queued receive requests.

It is possible that a notification event is in process during this method call. If this occurs, the application may receive a notification following the successful completion of this function. Entering a *CancelReqCount* value that is larger than the queued requests will result in all requests being cancelled. No error will be returned under this condition. Calling this method while no queued requests are outstanding will result in a non-critical error return code indicating this condition.

CCSID Property

The **CCSID** property on an **IEGDataQueueCtrl** object indicates the character code set identifier (CCSID) that must match the data in the queue as represented on the remote host computer. This property affects how data conversion is handled using the Data Queue ActiveX Control. This property sets or returns a short value representing a host CCSID for the data file. The default value for this property is 37 representing a CCSID for U.S./Canada.

```
current CCSID = object.CCSID
object.CCSID = 37
```

Remarks

The **CCSID** property is used to set or return the character code set identifier (CCSID) matching the data in the data queue as represented on the remote host computer. This value is used for data conversion of any character data in the host data queue to the **PCCodePage** property specified representing ANSI or Unicode character data on the Windows machine.

ClearAll Method

The **ClearAll** method on the EIGDataQueue object removes all items from the queue.

```
object.ClearAll OverWrite
```

Parameters

OverWrite
This optional parameter specifies whether to overwrite data in the queue. This parameter can be set to one of the **eigAnswerYesNoEnum** constants shown in the table following the Parameters list.

Possible values for *OverWrite*

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should overwrite data in the queue. This is the default value for this parameter if it is omitted from the method call.
eigAnswerNo	1	This value indicates that the operation should not overwrite data in the queue.

Connect Method

The **Connect** method on an **IEGDataQueueCtrl** object establishes a connection to the configured host using the Data Queue ActiveX Control and reports to the user an indication of the success or failure of the action.

```
object.Connect
```

Parameters

None.

Remarks

The **Connect** method is used to establish a connection to the host.

If the Data Queue ActiveX Control support DLL cannot be loaded, the Win32 **SetErrorMode** function is called with an error value of SEM_NOOPENFILEERRORBOX | SEM_FAILCRITICALERRORS. Other types of errors are returned using the **ISupportErrorInfo** object.

ConnectionState Property

The **ConnectionState** property on an **IEGDataQueueCtrl** object indicates the current state of the connection to the host using the Data Queue ActiveX Control. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting. This property returns a Long value representing a **eigConnectionStateEnum**. The default value for this property is **eigConnStateIdle**.

```
currentConnectionState = object.ConnectionState
```

Remarks

The **ConnectionState** property is used to return the current state of the connection to the host. This property is read only and can be one of the following **eigConnectionStateEnum** constants:

Enumeration	Value	Description
eigConnStateUnspecified	-1	This value indicates that the connection state is unspecified.
eigConnStateIdle	0	This value indicates that the connection state is idle and no connection to the host exists.
eigConnStateConnecting	1	This value indicates that the connection state is in the process of connecting to the host.
eigConnStateConnected	2	This value indicates that the connection state is connected indicating a connection to the host.
eigConnStateDisconnecting	3	This value indicates that the connection state is in the process of disconnecting from the host.

ConnectionType Property

The **ConnectionType** property on an **IEGDataQueueCtrl** object indicates the network transport used for this connection. This property sets or returns a Long value representing a **eigConnectionTypeEnum**. The default value for this property is **eigConnTypeAPPC** indicating an APPC connection using SNA.

```
currentConnectionType = object.ConnectionType
```

Remarks

The **ConnectionType** property is used to set or return the connection type used to connect to the host. This property can be one of the following **eigConnectionTypeEnum** constants:

Enumeration	Value	Description
eigConnTypeUnspecified	-1	This value indicates that the connection type is unspecified.
eigConnTypeAPPC	0	This value indicates an APPC connection to the host using SNA LU 6.2.

If APPC (SNA LU 6.2) is selected for **ConnectionType**, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required.

CreateQueue Method

The **CreateQueue** method on an **IEGDataQueue** object creates a data queue using the Data Queue ActiveX Control. Following the successful creation of the queue, the object has a virtual connection to the data queue, such that a single instance of this object represents a single queue connection. In order to break this connection, the application can modify the **QueueName** property thus altering the queue association to a new value.

```
object.CreateQueue MaxMsgLength, QAuthority, QueueClass,
    AddSenderInfo, HostCCSID, InitialSize, queueLoc, recordLenCls,
    Title, AllowDupKeys, MakeKeyLen
```

Parameters

MaxMsgLength
This required parameter indicates the maximum length of a record in the queue represented as a short integer with possible values ranging from 1 to 31,744. This parameter defaults to a value of 256.

QAuthority
This required parameter specifies the authority to grant users of this queue. This parameter can be set to one of the **eigQAuthorityEnum** constants listed in the QAuthority Values table which follows the Parameters section.

QueueClass
This required parameter indicates how the data will be received from the data queue. This parameter can be set to one of the **eigQClassEnum** constants listed in the QueueClass Values table which follows the parameter section.

AddSenderInfo
This required parameter indicates whether the queue sender's ID should be kept. This parameter can be set to one of the **eigAnswerYesNoEnum** constants shown in the AddSenderInfo Values table which follows the Parameters section.

HostCCSID
This optional parameter indicates the character code set identifier (CCSID) represented as a short to be used on the host and affects how data conversion is handled. This value must match the data in the queue as represented on the remote host computer. This parameter has no default value, but if this parameter is not specified the *HostCCSID* defaults to the value of the **CCSID** property set on the **IEGDataQueueCtl** object.

InitialSize
This optional parameter indicates the initial data queue size represented as a short integer.

queueLoc
This optional parameter indicates the queue location represented as VARIANT_BOOL.

recordLenCls
This optional parameter indicates the record length class. This parameter can be set to one of the **eigRecordLenClsEnum** constants listed in the recordLenCls Values table which follows the Parameters section.

Title
This optional parameter indicates a text description of the queue represented as a BSTR with a maximum length of 50 characters. The default value for this parameter is an empty string.

AllowDupKeys
This optional parameter indicates whether duplicate keys are allowed. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the AllowDupKeys Values table which follows the Parameters section. Note that this parameter is only valid if the *QueueClass* is specified as **eigQClassKeyed**.

MakeKeyLen
This optional parameter indicates the maximum length of a key for this data queue represented as a short integer ranging from 1 to 256. Note that this parameter is only valid if the *QueueClass* is specified as **eigQClassKeyed**. This parameter has no default value.

***QAuthority* Values**

Enumeration	Value	Description
eigQAuthUnspecified	-1	This value indicates that the authority is unspecified.
eigQAuthDefault	0	This value indicates directory default authorization. This is the default value for this parameter if it is not specified.
eigQAuthAll	1	This value indicates all authorization.
eigQAuthExclude	2	This value indicates exclude authorization.
eigQAuthChange	3	This value indicates change authorization.

eigQAuthUse	4	This value indicates use authorization.
eigQAuthLibCreate	5	This value indicates library create authorization.

***AddSenderInfo* Values**

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the sender ID should be kept.
eigAnswerNo	1	This value indicates that the sender ID should not be kept. This is the default value for this parameter if it is not specified in the method call.

***QueueClass* Values**

Enumeration	Value	Description
eigQClassUnspecified	-1	
eigQClassFIFO	0	A first in, first out queue. This is the default value for this parameter if it is not specified.
eigQClassLIFO	1	A last in, first out queue.
eigQClassKeyed	2	A keyed ordered queue.

***recordLenCls* Values**

Enumeration	Value	Description
eigRecordLenUnspecified	-1	This value indicates that the record length class is unspecified.
eigRecordLenFixed	0	This value indicates fixed length records. This is the default value for this parameter if it is not specified.
eigRecordLenInitVarLen	1	This value indicates initial variable record length.
eigRecordLenVarLen	2	This value indicates variable record length.

***AllowDupKeys* Values**

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that duplicate key capability is supported.
eigAnswerNo	1	This value indicates that duplicate key capability is not supported. This is the default value for this parameter if it is not specified in the method call.

Remarks

The type of data queue created is dependent on the value of the *QueueClass* parameter. If a *QueueClass* of **eigQClassKeyed** is specified, then a keyed data queue is created. A *QueueClass* of **eigQClassFIFO** and **eigQClassLIFO** will result in a non-keyed data queue being created.

CreateQueueContainer Method

The **CreateQueue** method on an **IEGDataQueueCtl** object creates an instance of a **IEIGDataQueue** container object using the Data Queue ActiveX Control and optionally initializes the **QueueName** property. The default value for this property is VT_EMPTY.

```
object.CreateQueueContainer QueueName
```

Parameters

QueueName
This optional parameter is a BSTR string representing the name of the data queue that this object instance is connected to. This parameter corresponds with the value for the QueueName property.

Remarks

The created queue object is assumed to be associated with the connection object that created it for the life of the connection or the life of the queue object.

DeleteQueue Method

The **DeleteQueue** method on an **IEGDataQueue** object clears all messages from the queue and then deletes the queue using the Data Queue ActiveX Control.

```
object.DeleteQueue OverWriteData
```

Parameters

OverWriteData

This required parameter indicates whether data should be overwritten in the data queue. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the OverWriteData Values table which follows the Parameters section.

This parameter had a default value of **eigAnswerYes.**

***OverWriteData* Values**

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should overwrite data in the queue. This is the default value for this parameter if it is omitted from the method call.
eigAnswerNo	1	This value indicates that the operation should not overwrite data in the queue.

Disconnect Method

The **Disconnect** method on an **IEGDataQueueCtrl** object terminates an existing connection to a host machine using the Data Queue ActiveX Control.

```
object.Disconnect
```

Parameters

None.

Remarks

The **Disconnect** method is used to terminate a connection to the host. Errors are returned using the **ISupportErrorInfo** object.

GetQueueItem Method

The **GetQueueItem** method on an **IEGDataQueue** object receives an item from a keyed queue.using the Data Queue ActiveX Control.

```
object.GetQueueItem QueueType, BlockComplete, PeekQItem,
    ProvideExtInfo, TimeOut, UserProfile, SenderInfo, SearchKey,
    SearchOrder, QueueItem
```

Parameters

QueueType
This required parameter specifies the type of the queue request. This parameter can be set to one of the **eigQItemTypeEnum** constants listed in the QueueType Values table which follows the Parameters section.

BlockComplete
This required parameter specifies whether the operation should block until the completion status is known. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the BlockComplete Values table which follows the parameters section.

PeekQItem
This required parameter indicates whether to keep the record in the data queue. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the PeekQItem Values table which follows the Parameters section.

ProvideExtInfo
This required parameter indicates whether to provide information in the External Job, name, and user properties. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the ProvideExtInfo Values table which follows the Parameters section.

TimeOut
This required parameter indicates the amount of time in seconds represented as a short value to block before indicating a failure. This parameter has a default value of 0.

UserProfile
This required parameter indicates whether to provide user profile feedback. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the UserProfile Values table which follows the Parameters section.

SenderInfo
This required parameter indicates whether the sender's ID should be returned. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the SenderInfo Values table which follows the Parameters section.

SearchKey
This optional parameter indicates the key used in conjunction with the *SearchOrder* parameter used to identify the queue data item being requested. This must be the same length as specified in the **CreateDataQueue** method call. This parameter is represented as a VARIANT and has no default value.

Note that this parameter is only valid when the *QueueClass* for the data queue is **eigQClassKeyed**.

SearchOrder
This optional parameter indicates the relational order used in receiving keyed data queue items. This parameter can be set to one of the **eigSearchKeyEnum** constants listed in the SearchOrder Values table which follows the Parameters section.

Note that this parameter is only valid when the *QueueClass* for the data queue is **eigQClassKeyed**.

QueueItem
This returned parameter is the requested **IEGDataQueueItem**.

***QueueType* Values**

Enumeration	Value	Description
eigKQItem	0	A keyed item.
eigQItem	1	A non-keyed item. This is the default value for this parameter if it is not specified.

***BlockComplete* Values**

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should block until the completion status is known.

eigAnswerNo	1	This value indicates that the operation should not block. Although this is the default value for this parameter if it is omitted from the method call, this value is not supported by the Data Queue ActiveX Control. Asynchronous read operations are not supported.

PeekQItem Values

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the record should be kept in the data queue.
eigAnswerNo	1	This value indicates that the record should not be kept in the data queue. This is the default value for this parameter if it is omitted from the method call.

UserProfile Values

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that user profile feedback should be provided in the queue item.
eigAnswerNo	1	This value indicates that user profile feedback should not be provided in the queue item. This is the default value for this parameter if it is omitted from the method call.

***ProvideExtInfo* Values**

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that information should be provided in the External Job, name, and user properties on the **IEGDataQueueItem** to be returned.
eigAnswerNo	1	This value indicates that information should not be provided in the External Job, name, and user properties on the **IEGDataQueueItem** to be returned. This is the default value for this parameter if it is not specified in the method call.

SenderInfo Values

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the sender ID should be returned.
eigAnswerNo	1	This value indicates that the sender ID should not be returned. This is the default value for this parameter if it is not specified in the method call.

SearchOrder Values

Enumeration	Value	Description
eigSearchKeyUnspecified	-1	This value indicates that the *SearchOrder* parameter is unspecified.
eigSearchKeyEqual	0	This value indicates a search for items equal to the specified *SearchKey* parameter.
eigSearchKeyGreaterThan	1	This value indicates a search for items greater than the specified *SearchKey* parameter.
eigSearchKeyLessThan	2	This value indicates a search for items less than the specified *SearchKey* parameter.
eigSearchKeyGreaterEqual	3	This value indicates a search for items greater than or equal to the specified *SearchKey* parameter.
eigSearchKeyLessEqual	4	This value indicates a search for items less than or equal to the specified *SearchKey* parameter.

Remarks

If the *BlockComplete* parameter is **eigAnswerNo** and no queue item is available, the request will be queued. Following the receipt of a queue data item, an event will be fired to the client indicating the availability of data. The client application will be

required to call this function again in order to receive the queue data.

If the *BlockComplete* parameter is **eigAnswerYes** and no data arrives on the queue within the specified amount of time, the operation is cancelled and no data is returned. An error indication is returned to the client indicating that a timeout has occurred.

Each call to this method may result in a queued process. Multiple calls may result in multiple notifications.

If the *SenderInfo* item is empty, then the information will not be returned. The client must allocate the storage as an indication that it wishes to receive this information. The type of data queue is dependent on the value of the *QueueClass* parameter when the data queue is created. For a *QueueClass* of **eigQClassKeyed**, a keyed data queue is created. A *QueueClass* of **eigQClassFIFO** or **eigQClassLIFO** will result in a non-keyed data queue being created.

LocalLU Property

The **LocalLU** property on an **IEGDataQueueCtrl** object indicates the local LU alias for an APPC (SNA LU 6.2) connection type to the remote host computer using the Data Queue ActiveX Control. This property sets or returns a BSTR string value representing the local LU name. The default value for this property is the "LOCAL" string.

```
currentLocalLu = object.LocalLU
object.LocalLu = "Local2"
```

Remarks

The **LocalLU** property is used to set or return the local LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager.

ModeName Property

The **ModeName** property on an **IEGDataQueueCtrl** object indicates the APPC mode used for an APPC (SNA LU 6.2) connection type to the remote host computer using the Data Queue ActiveX Control. This property sets or returns a BSTR string value representing the APPC mode. The default value for this property is the "QPCSUPP" string.

```
currentAppcMode = object.ModeName
object.ModeName = "QPCSUPP"
```

Remarks

The **ModeName** property is used to set or return the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Host Integration Server configuration. This property is ignored when TCP/IP is selected for the **ConnectionType** property.

Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security).

Password Property

The **Password** property on an **IEGDataQueueCtrl** object indicates the password used for authentication. This property affects connection and authentication to a host computer using the Data Queue ActiveX Control. This property sets or returns a BSTR and has no default value.

```
currentUserPassword = object.Password
object.Password = Dialog.UserPassword
```

Remarks

The **Password** property is used to set or return the password used for authenticating the user on a host computer. A valid user name and password are normally required to access data on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes.

PCCodePage Property

The **PCCodePage** property on an **IEGDataQueueCtrl** object indicates the code page to be used on the PC. This property affects how data conversion is handled using the Data Queue ActiveX Control. This property sets or returns a short value representing the PC code page for the data file. The default value for this property is 1252 representing a PC code page of Latin 1.

```
currentPCCodePage = object.PCCodePage
object.PCCodePage = 1252
```

Remarks

The **PCCodePage** property is used to set or return the code page to be used on the PC. This value is used for data conversion of any character data in the host file to ANSI or Unicode character data in the local file on the Windows machine.

QueryAttribute Method

The **QueryAttribute** method on the EIGDataQueue object returns the value of an attribute associated with a data queue.

```
object.QueryAttribute Attribute, Value
```

Parameters

Attribute
This required parameter indicates the attribute value to be retrieved. This parameter can be set to one of the **eigAttributeEnum** constants listed in the Attribute Values table which follows the Parameters section.

Value
This required parameter points to a variant that will receive the value for this attribute.

Attribute Values

Enumeration	Value	Description
eigAttributeUnspecified	-1	
eigAttributeCCSID	0	The code character set identifier used on the host.
eigAttributeDirName	1	Directory name
eigAttributeDataClass	2	Data class name
eigAttributeKeyDef	3	Key definition
eigAttributeDupKeys	4	Indicates whether the duplicate keys capability is enabled for this data queue.
eigAttributeMgmCls	5	Management class name
eigAttributeQueCls	6	The queue class corresponding with the *QueueClass* parameter on the **CreateQueue** method.
eigAttributeSize	7	The queue initial size
eigAttributeQLoc	8	Queue location
eigAttributeSenderInfo	9	Queue senders ID kept
eigAttributeMaxMsgLen	10	The maximum record length for a message.
eigAttributeRecLenClass	11	Record length class
eigAttributeStgClass	12	Storage class name
eigAttributeTitle	13	Description text

Remarks

Most of these attributes correspond with the parameters specified to the CreateQueue method when the data queue is created.

QueueName Property

The **QueueName** property on an **IEGDataQueue** object indicates the name of the data queue this object is associated with.

```
currentQueueName = object.QueueName
object.QueueName = "OrderEntry"
```

Remarks

The value of the **QueueName** property is the name of the queue represented as a BSTR string.

Following the successful creation of a queue using the CreateQueue method, the object has a virtual connection to the data queue, such that a single instance of this object represents a single queue connection. In order to break this connection, a client application can modify the **QueueName** property thus altering the queue association to a new value.

RemoteLU Property

The **RemoteLU** property on an **IEGDataQueueCtrl** object indicates the remote LU alias for an APPC (SNA) connection type to the remote host computer using the Data Queue ActiveX Control. This property sets or returns a BSTR string value representing the remote LU name. This property has no default value.

```
currentRemoteLu = object.RemoteLU
object.RemoteLu = "Remote10"
```

Remarks

The **RemoteLU** property is used to set or return the remote LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the remote LU alias configured using SNA Manager.

SetAttribute Method

The **SetAttribute** method on the EIGDataQueue object changes an attribute associated with a data queue.

```
object.SetAttribute Attribute, Value
```

Parameters

Attribute
This required parameter indicates the attribute to be set. This parameter can be set to one of the **eigAttributeEnum** constants listed in the Attribute Values table which follows the Parameters section.

Value
This required parameter specifies a variant representing the value to set for this attribute.

Attribute Values

Enumeration	Value	Description
eigAttributeUnspecified	-1	
eigAttributeCCSID	0	Coded character set identifier
eigAttributeDirName	1	Directory name
eigAttributeDataClass	2	Data class name
eigAttributeKeyDef	3	Key definition
eigAttributeDupKeys	4	Duplicate keys capability
eigAttributeMgmCls	5	Management class name
eigAttributeQueCls	6	The queue class corresponding with the *QueueClass* parameter on the **CreateQueue** method.
eigAttributeSize	7	Queue initial size
eigAttributeQLoc	8	Queue location
eigAttributeSenderInfo	9	Queue senders ID kept
eigAttributeMaxMsgLen	10	Record length
eigAttributeRecLenClass	11	Record length class
eigAttributeStgClass	12	Storage class name
eigAttributeTitle	13	Description text

Remarks

Most of these attributes correspond with the parameters specified to the CreateQueue method when the data queue is created.

StopQueue Method

The **StopQueue** method on an **IEGDataQueue** object suspend send and receive operations for a queue using the Data Queue ActiveX Control.

```
object.StopQueue
```

Parameters

None.

UserID Property

The **UserID** property on an **IEGDataQueueCtrl** object indicates the username used for authentication. This property affects connection and authentication to a host computer using the Data Queue ActiveX Control. This property sets or returns a BSTR and has no default value.

```
currentUserName = object.UserID
object.UserID = Dialog.UserName
```

Remarks

The **UserID** property is used to set or return the username used for authenticating the user on a host computer. A valid user name and password are normally required to access data on a host computer. The username is case sensitive.

Host File Transfer ActiveX Control Reference

This section provides reference information on specific ActiveX® methods, properties, and event notifications supported by the Microsoft® Host File Transfer ActiveX Control. The function syntax and code examples are based on Microsoft Visual Basic.

AppendToEnd Property

The **AppendToEnd** property on an **IEIGFileTransferCtl** object indicates whether a file transfer operation should append to the end of a file if the file exists, or whether a file transfer operation should overwrite the existing contents replacing the data with the new information. This property affects file transfer operations using the Host File Transfer ActiveX Control.This property sets or returns a Long value representing a **eigAnswerYesNoEnum**. The default value for this property is **eigAnswerYes**.

```
currentAppendFlag = object.AppendToEnd
object.AppendToEnd = eigAnswerYes
```

Remarks

The **AppendToEnd** property is used to set or return a flag that indicates whether a file transfer operation will append to the end of a file or overwrite the file. This property can be set to one of the following **eigAnswerYesNoEnum** constants:

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the file transfer operation will append to the end of a file if it exists.
eigAnswerNo	1	This value indicates that the file transfer operation will overwrite the existing contents of a file if it exists.

The **AppendToEnd** property and the **OverwriteHostFile** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd** defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order that these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until **AppendToEnd** property is set to no (disabled).

Cancel Method

The **Cancel** method on an **IEIGFileTransferCtl** object terminates a file transfer operation that is already in progress. This method cancels a file transfer using the Host File Transfer ActiveX Control.

```
object.Cancel
```

Parameters

None.

Remarks

The **Cancel** method is used to cancel a file transfer operation that is already in progress. If the **Cancel** method is executed while uploading a file with the **AppendToEnd** property set to yes, this will result in no change to the host file. However, if the **Cancel** method is executed while uploading a file with the **OverwriteHostFile** property set to yes, this will result in an empty host file. The **Cancel** method implies the transfer has been stopped and all the files are at their original values but this is not really the case when the **OverwriteHostFile** property is set to yes.

CCSID Property

The **CCSID** property on an **IEIGFileTransferCtl** object indicates the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer. This property affects how data conversion is handled using the Host File Transfer ActiveX Control. This property sets or returns a short value representing a host CCSID for the data file. The default value for this property is 37 representing a CCSID for U.S./Canada.

```
current CCSID = object.CCSID
object.CCSID = 37
```

Remarks

The **CCSID** property is used to set or return the character code set identifier (CCSID) matching the data in the file as represented on the remote host computer. This value is used for data conversion of any character data in the host file to the **PCCodePage** property specified representing ANSI or Unicode character data on the Windows computer.

Connect Method

The **Connect** method on an **IEIGFileTransferCtl** object establishes a connection to the configured host using the Host File Transfer ActiveX Control and reports to the user an indication of the success or failure of the action.

```
object.Connect
```

Parameters

None.

Remarks

The **Connect** method is used to establish a connection to the host.

If the Host File Transfer Control support DLL cannot be loaded, the Win32 **SetErrorMode** function is called with an error value of SEM_NOOPENFILEERRORBOX | SEM_FAILCRITICALERRORS. Other types of errors are returned using the **ISupportErrorInfo** object.

ConnectionState Property

The **ConnectionState** property on an **IEIGFileTransferCtl** object indicates the current state of the connection to the host using the Host File Transfer ActiveX Control. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting. This property returns a Long value representing a **eigConnectionStateEnum**. The default value for this property is **eigConnStateIdle**.

```
currentConnectionState = object.ConnectionState
```

Remarks

The **ConnectionState** property is used to return the current state of the connection to the host. This property is read only and can be one of the following **eigConnectionStateEnum** constants:

Enumeration	Value	Description
eigConnStateUnspecified	-1	This value indicates that the connection state is unspecified.
eigConnStateIdle	0	This value indicates that the connection state is idle and no connection to the host exists.
eigConnStateConnecting	1	This value indicates that the connection state is in the process of connecting to the host.
eigConnStateConnected	2	This value indicates that the connection state is connected indicating a connection to the host.
eigConnStateDisconnecting	3	This value indicates that the connection state is in the process of disconnecting from the host.

ConnectionType Property

The **ConnectionType** property on an **IEIGFileTransferCtl** object indicates the network transport used for this connection. The **ConnectioneType** property designates whether the Host File Transfer ActiveX Control connects via APPC (SNA LU6.2) or TCP/IP. This property sets or returns a Long value representing a **eigConnectionTypeEnum**. The default value for this property is **eigConnTypeAPPC** indicating an APPC connection using SNA.

```
currentConnectionType = object.ConnectionType
object.ConnectionType = eigConnTypeTCPIP
```

Remarks

The **ConnectionType** property is used to set or return the connection type used to connect to the host. This property can be one of the following **eigConnectionTypeEnum** constants:

Enumeration	Value	Description
eigConnTypeUnspecified	-1	This value indicates that the connection type is unspecified.
eigConnTypeAPPC	0	This value indicates an APPC connection to the host using SNA LU 6.2.
eigConnTypeTCPIP	1	This value indicates a TCP/IP connection to the host.

If APPC (SNA) is selected for **ConnectionType**, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required.

If TCP/IP is selected for **ConnectionType**, then values for the **NetAddr** and **NetPort** properties are required.

CreateIfNonExisting Property

The **CreateIfNonExisting** property on a **IEIGFileTransferCtl** object indicates whether a file transfer operation should create a new destination file if one does not already exist. This property affects file transfer operations using the Host File Transfer ActiveX Control. This property sets or returns a Long value representing a **eigAnswerYesNoEnum**. The default value for this property is **eigAnswerNo**.

```
currentCreateFlag = object.CreateIfNonExisting
object.CreateIfNonExisting = eigAnswerYes
```

Remarks

The **CreateIfNonExisting** property is used to set or return a flag that indicates whether a file transfer operation should create a new destination file if one does not already exist. This property can be set to one of the following **eigAnswerYesNoEnum** constants:

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the file transfer operation will create a new destination file if the file does not already exist.
eigAnswerNo	1	This value indicates that the file transfer operation will not create a new destination file if the file does not already exi st. If the destination file does not already exist, then the file copy operation will not take place.

Disconnect Method

The **Disconnect** method on an **IEIGFileTransferCtl** object terminates an existing connection to a host machine using the Host File Transfer ActiveX Control.

```
object.Disconnect
```

Parameters

None.

Remarks

The **Disconnect** method is used to terminate a connection to the host. Errors are returned using the **ISupportErrorInfo** object.

GetFile Method

The **GetFile** method on an **IEIGFileTransferCtl** object copies a file from host storage to local storage using the Host File Transfer ActiveX Control.

```
object.GetFile LocalFile, HostFile
```

Parameters

LocalFile
This required parameter specifies the path of a local file that will be written to as a result of this operation.
HostFile
This required parameter specifies the name of the host file that will be copied to the local file.

Remarks

The **GetFile** method can only be called after a connection has been established to the host (when the ConnectionState property is connected). The behavior of the **GetFile** method is affected by the values of the AppendToEnd, CreateIfNonExisting, and OverwriteHostFile properties.

Errors are returned for this method using the **ISupportErrorInfo** object.

LocalLU Property

The **LocalLU** property on an **IEIGFileTransferCtl** object indicates the local LU alias for an APPC (SNA) connection type to the remote host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR string value representing the local LU name. The default value for this property is the "LOCAL" string.

```
currentLocalLu = object.LocalLU
object.LocalLu = "Local2"
```

Remarks

The **LocalLU** property is used to set or return the local LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager.

This property is ignored when TCP/IP is selected for the **ConnectionType** property.

ModeName Property

The **ModeName** property on an **IEIGFileTransferCtl** object indicates the APPC mode used for an APPC (SNA) connection type to the remote host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR string value representing the APPC mode. The default value for this property is the "QPCSUPP" string.

```
currentAppcMode = object.ModeName
object.ModeName = "QPCSUPP"
```

Remarks

The **ModeName** property is used to set or return the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Host Integration Server configuration. This property is ignored when TCP/IP is selected for the **ConnectionType** property.

Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security).

NetAddr Property

The **NetAddr** property on an **IEIGFileTransferCtl** object indicates the IP address of the host computer for a TCP/IP connection type to the remote host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR string value representing the IP address of the host computer. This property has no default value.

```
currentHostIP = object.NetAddr
object.NetAddr = "207.136.131.30"
```

Remarks

The **NetAddr** property is used to set or return the IP address of the host computer. When TCP/IP is selected for the ConnectionType property, this property must match the IP address of the host computer used where files will be transferred. This property can be an IP address or the name representing the host IP address using the Domain Name System (sna.microsoft.com, for example). This property is ignored when SNA is selected for the **ConnectionType** property.

NetPort Property

The **NetPort** property on an **IEIGFileTransferCtl** object indicates the TCP/IP port used for communication with the host for a TCP/IP connection type to the remote host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR string value representing the TCP/IP port used for communication with the host. The default value for this property is the string "446" representing TCP/IP port 446.

```
currentIPPort = object.NetPort
object.NetPort = "446"
```

Remarks

The **NetPort** property is used to set or return the TCP/IP port used for communication with the host. When TCP/IP has been selected for the ConnectionType property, this parameter is the TCP/IP port used for communication with the host. This property is ignored when SNA is selected for the **ConnectionType** property.

OverwriteHostFile Property

The **OverwriteHostFile** property on a **IEIGFileTransferCtl** object indicates whether a file transfer operation request to copy a file that will write over an existing file will be executed. This property affects file transfer operations using the Host File Transfer ActiveX Control.This property sets or returns a Long value representing a **eigAnswerYesNoEnum**. The default value for this property is **eigAnswerNo**.

```
currentOverwriteFlag = object.OverwriteHostFile
object.OverwriteHostFile = eigAnswerYes
```

Remarks

The **OverwriteHostFile** property is used to set or return a flag that indicates whether a file transfer operation will over an existing file. This property can be set to one of the following **eigAnswerYesNoEnum** constants:

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the file transfer operation will overwrite an existing host file if it exists.
eigAnswerNo	1	This value indicates that the file transfer operation will not overwrite and existing host file file if it exists.

The **OverwriteHostFile** property and the **AppendToEnd** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd**defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order that these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until **AppendToEnd** property is set to no (disabled).

Password Property

The **Password** property on an **IEIGFileTransferCtl** object indicates the password used for authentication. This property affects connection and authentication to a host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR and has no default value.

```
currentUserPassword = object.Password
object.Password = Dialog.UserPassword
```

Remarks

The **Password** property is used to set or return the password used for authenticating the user on a host computer. A valid user name and password are normally required to access files on a host computer. The password is case sensitive and is normally displayed as asterisks in a dialog box for security purposes.

PCCodePage Property

The **PCCodePage** property on an **IEIGFileTransferCtl** object indicates the code page to be used on the PC. This property affects how data conversion is handled using the Host File Transfer ActiveX Control. This property sets or returns a short value representing the PC code page for the data file. The default value for this property is 1252 representing a PC code page of Latin 1.

```
currentPCCodePage = object.PCCodePage
object.PCCodePage = 1252
```

Remarks

The **PCCodePage** property is used to set or return the code page to be used on the PC. This value is used for data conversion of any character data in the host file to ANSI or Unicode character data in the local file on the Windows machine.

PutFile Method

The **PutFile** method on an **IEIGFileTransferCtl** object copies a file from host storage to local storage using the Host File Transfer ActiveX Control.

```
object.PutFile HostFile, LocalFile
```

Parameters

HostFile
This required parameter specifies the name of the host file that will be written to as a result of this operation. This parameter is a BSTR.

LocalFile
This required parameter specifies the path to a local file that will be copied to the host file. This parameter is a BSTR.

Remarks

The **PutFile** method can only be called after a connection has been established to the host (when the ConnectionState property is connected). The behavior of the **PutFile** method is affected by the values of the AppendToEnd, CreateIfNonExisting, and OverwriteHostFile properties.

Errors are returned for this method using the **ISupportErrorInfo** object.

RDBName Property

The **RDBName** property on an **IEIGFileTransferCtl** object indicates the remote database name and the Host Column Description (HCD) file that describes the data types and data conversions used to transfer this file using the Host File Transfer ActiveX Control. This property sets or returns a BSTR string value and has no default value.

```
currentRDbName = object.RDBName
object.RDBName = "Inventory"
```

Remarks

The **RDBName** property is used to set or return the name of the remote database name and the Host Column Description (HCD) file that describes the data types and data conversions used to transfer this file. The HCD file describing the data should be located in the system subdirectory below the root directory where Host Integration Server was installed. Setup defaults to the following location: C:\Program Files\Host Integration Server

When TCP/IP is selected for the **ConnectionType** property, the **RDBName** must also match the name of the remote database system.

RemoteLU Property

The **RemoteLU** property on an **IEIGFileTransferCtl** object indicates the remote LU alias for an APPC (SNA) connection type to the remote host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR string value representing the remote LU name. This property has no default value.

```
currentRemoteLu = object.RemoteLU
object.RemoteLu = "Remote10"
```

Remarks

The **RemoteLU** property is used to set or return the remote LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the remote LU alias configured using SNA Manager.

This property is ignored when TCP/IP is selected for the **ConnectionType** property.

UserID Property

The **UserID** property on an **IEIGFileTransferCtl** object indicates the username used for authentication. This property affects connection and authentication to a host computer using the Host File Transfer ActiveX Control. This property sets or returns a BSTR and has no default value.

```
currentUserName = object.UserID
object.UserID = Dialog.UserName
```

Remarks

The **UserID** property is used to set or return the username used for authenticating the user on a host computer. A valid user name and password are normally required to access files on a host computer. The username is case sensitive.

Host Column Description

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a host column description (HCD) file to specify how data on the host is converted by the OLE DB provider. These HCD files are not necessary when used with AS/400 machines since the host data format is automatically determined by the OLE DB Provider. When used with AS/400 machines, the OLE DB Provider uses default conversions from host data type to OLE DB data types. However, HCD files can be used with AS/400 machines to override the host data format and specify a particular local OLE DB data type that the data is to be converted to.

The following topics describe the host column description file format in detail and provide an example of an HCD file for illustration.

Host Column Description File Format

The Microsoft® OLE DB Provider for AS/400 and VSAM uses a host column description (HCD) file to describe the format of data files on IBM mainframes and dictate how the data in columns or fields in these files is to be converted by the OLE DB provider. Host column description files can also be used for data on AS/400 machines to override the data format description maintained by the AS/400 host.

The default naming convention for the HCD file is <*data source*>.hcd, where <*data source*> is the remote LU alias, and hcd is the file extension of the record description file. For example, if the remote LU alias configured on Host Integration Server is named ABC01234, the host column description file would be named ABC01234.hcd as the default. Any name may be used for an HCD file as long as the file extension is ".hcd."

All the VSAM files that have local record descriptions are listed in the [Files] section of the record description file. Each file that is listed in the [Files] section has a record description section, and that section name is the same as the file name. For example, a VSAM file named PUBS/AUTHORS has its record description saved in the [PUBS/AUTHORS] section.

The first key of a record description section is the number of the columns for the file. The syntax is as follows:

```
numcol=<number of columns>
```

where <*number of columns*> is the actual number of columns described in the section. Each column of a file is described by one key. The naming convention for the key name is as follows:

```
col<column number>
```

For example the ninth column's key is **col9**. Each key has an attribute list that contains eleven concatenated attributes that describe the column. Attributes are separated by semicolons.

Host Column Description Attributes

Attributes are shown in the following table:

Attribute	Field number	Description
Reserved	1	Always zero
Column Name	2	Character string
Alias	3	Character string
Precision	4	Numeric value
Scale	5	Numeric value
Length	6	Numeric value
Host Type	7	Keyword representing the host data type
OLE DB Type	8	Keyword representing the local OLE DB data type
Nullable	9	Y or N
CCSID	10	Numeric value
Title	11	Character string

Column Name

The column name attribute is the character string that represents the name of the column. This attribute may be null.

Alias

The alias attribute is an optional character string that represents an alias label for the column string name. This attribute may be null.

Precision

The precision is the total number of decimal digits in the column containing numeric data on the host. The only two fixed-point numeric data types that require this information are the NUMERIC and DECIMAL keyword data types, and for these types this field cannot be null and must contain a valid numeric value.

The precision must be set the same as the length attribute for CHAR and BINARY keyword data types, and set to zero for the other types. (Note that under ODBC, the precision was also used to indicate the length of nonnumeric data types including character, date, time, and binary data types.) Precision has no default value and must not be left null.

Scale

The scale is the number of decimal digits to the right of any decimal point for numeric data on the host. The only two numeric data types that require this information are the NUMERIC and DECIMAL keyword data types, and for these types this field cannot be null and must contain a valid numeric value. For other numeric (the SINGLE and DOUBLE keywords, for example) and nonnumeric data types (binary, character, date, time, and timestamp), the scale should be set to zero. This field must not be left null and must contain a numeric value.

Length

The length attribute is the total length of the data on the host. This field must not be left empty and must contain a numeric value.

Host Type

The Host Type attribute is a keyword value that represents the data type of the host data. This keyword value is based on standard data types used on AS/400 and VSAM files. If no keyword is entered, this attribute defaults to the BINARY keyword. The allowable types are as follows:

Host type name	Keyword	Comment
Binary	BINARY	Fixed-length binary data (no character code conversions). The length must be specified.
Character	CHAR	Fixed-length character data. The length must be specified.
Date	DATE	The date represented as character data in the format yyyy-mm-dd that fits in 10 bytes
DBCS	DBCS	Fixed-length character data that can contain only DBCS data.
DCBS – Mixed Either	MIXED_EITHER	Fixed-length character data that can contain either DBCS or alphanumeric data.
DCBS – Mixed Open	MIXED_OPEN	Fixed-length character data that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with shift-control characters.
DBCS – Variable	VARDBCS	Variable-length character data with a prefix of 2 bytes for length that contains only DBCS data. The maximum possible length for the column containing this data type must be specified.

DCBS – Variable Mixed Either	VARMIXED_EITHER	Variable-length character data with a prefix of 2 bytes for length that can contain either DBCS or alphanumeric data. The maximum possible length for the column containing this data type must be specified.
DCBS – Variable Mixed Open	VARMIXED_OPEN	Variable-length character data with a prefix of 2 bytes for length that can contain both DBCS and alphanumeric data. DBCS data is distinguished from alphanumeric data with shift-control characters. The maximum possible length for the column containing this data type must be specified.
Double	DOUBLE	Floating-point data that fits in 8 bytes (64 bits).
Long	LONG	Integer data that fits in 4 bytes (32 bits).
Long Variable Binary	LONGVARBINARY	Variable-length binary data represented as an unsigned character array with prefix 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Long Variable Character	LONGVARCHAR	Variable-length character data with a prefix of 2 bytes for the length. The maximum possible length for the column containing this data type must be specified.
Packed	PACKED	Packed decimal numeric data where the precision, and scale are exactly as specified.
Short	SHORT	Integer data that fits in 2 bytes (16 bits).
Single	SINGLE	Floating-point data that fits in 4 bytes (32 bits).
Time	TIME	The time represented as character data in the format hh:mm:ss that fits in 8 bytes.
Time Stamp	TIMESTAMP	Timestamp represented as characters in the format yyyy-mm-dd hh:mm:ss.ffffff that fits in 19 bytes.
Variable Binary	VARBINARY	Variable-length binary data represented as an unsigned character array with prefix 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Variable Character	VARCHAR	Variable-length character data with a prefix of 2 bytes for length. The maximum possible length for the column containing this data type must be specified.
Zoned	ZONED	Zoned decimal numeric data where the precision and scale are exactly as specified.

Note that the OLE DB provider limits the maximum length character field that can be accessed on an AS/400 machine to 32,745. Attempting to access a character field greater than this length on an AS/400 machine can have unpredictable results and can cause the OLE DB Provider to hang.

Note that the floating-point data format assumed by the OLE DB Provider for AS/400 and VSAM depends on the host. For AS/400, the host floating-point data format is assumed to be IEEE. On mainframe hosts, floating-point data types are assumed to be in IBM floating-point formats. Since OLE DB supports the IEEE floating-point format, data conversion errors can occur when converting the extreme values of VSAM floating-point data in IBM format to IEEE floating-point data by the OLE DB provider.

Note that the DECIMAL, FLOAT, INTEGER, NUMERIC, REAL, and SMALLINT keywords should not be used in HCD files and should be replaced with the newer keywords as follows:

The DOUBLE keyword replaces the FLOAT keyword.

The LONG keyword replaces the INTEGER keyword.

The PACKED keyword replaces the NUMERIC keyword.

The SHORT keyword replaces the SMALLINT keyword.

The SINGLE replaces the REAL keyword.

The ZONED keyword replaces the DECIMAL keyword.

The Data Descriptions management console snap-in provided with Host Integration Server will not work properly with HCD files containing these older keywords and will give unpredictable results.

OLE DB Type

The OLE DB Type attribute is a keyword that represents the data type of the local PC data. This keyword value is based on the standard OLE DB data types as defined in the OLEDB.H header file included with the OLE DB SDK version 1.5 and later The data structures for the date, time, and timestamp C data types are defined as typedefs in the OLEDB.H header file included with the OLE DB SDK. Similar data types are also used by ODBC. If no keyword is entered, this attribute defaults to the BINARY keyword.

For the decimal and numeric host data types, the OLE DB Type attribute must be set to DBTYPE_STR. These two fixed-point numeric types are currently converted to character data strings by the DDM layer of the Microsoft OLE DB Provider for AS/400 and VSAM. If these host types are converted to any of the defined OLE DB numeric C types, then numeric accuracy can be lost.

The allowable types are as follows:

OLE DB type name	Keyword	Comment
DBTYPE_BYTES	BINARY	Fixed-length binary data represented as an unsigned char array.
DBTYPE_DBDATE	DATE	The OLE DB DBDATE typedef struct as defined in the OLEDB.H header file.
DBTYPE_DBTIME	TIME	The OLE DB DBTIME typedef as defined in the OLEDB.H header file.
DBTYPE_DBTIMESTAMP	TIMESTAMP	The OLE DB DBTIMESTAMP typedef struct as defined in the OLEDB.H header file.
DBTYPE_DECIMAL	DECIMAL	The OLE DB DECIMAL typedef struct as defined in the OLEDB.H header file.
DBTYPE_I2	SHORT	Integer data stored in 2 bytes (16 bits).
DBTYPE_I4	LONG	Integer data stored in 4 bytes (32 bits).
DBTYPE_NUMERIC	NUMERIC	The OLE DB NUMERIC typedef struct as defined in the OLEDB.H header file.
DBTYPE_R4	FLOAT	Floating-point data stored in 4 bytes (32 bits).
DBTYPE_R8	DOUBLE	Floating-point data stored in 8 bytes (64 bits).
DBTYPE_STR	CHAR	Character data.
DBTYPE_I1		Not supported (signed tiny integer stored in one byte, 8 bits).
DBTYPE_I8		Not supported (signed long long integer stored in eight bytes, 64 bits).
DBTYPE_UI1		Not supported (unsigned tiny integer stored in one byte, 8 bits).
DBTYPE_UI2		Not supported (unsigned short integer stored in two bytes, 16 bits).
DBTYPE_UI4		Not supported (unsigned long integer stored in four bytes, 32 bits).
DBTYPE_UI8		Not supported (unsigned long long integer stored in eight bytes, 64 bits).

Nullable

The Nullable attribute indicates whether this field can be a null value. Legal values for this field are Y or N. If this field is empty, the default value for nullable is N. The current version of the OLE DB Provider for AS/400 and VSAM does support nullable fields, so this value must be set to N.

CCSID

The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this field is empty, the default value for CCSID is set to EBCDIC US English (37). The CCSID setting used by the OLE DB Provider must be set to match the CCSID actually used on the host, otherwise data loss will occur. Note that some AS/400 systems default to a CCSID of 937, rather than 37, for enabling double-byte character sets (DBCS).

If the CCSID is set to 0 or 65535, then no character translation will take place when converting character data from the host to the PC by the OLE DB Provider. The allowable values for CCSID when used with OLE DB Provider for AS/400 and VSAM are as follows:

EBCDIC character set	CCSID value
U.S./Canada	37
Germany	273
Denmark/Norway	277
Finland/Sweden	278
Italy	280
Latin America/Spain	284
United Kingdom	285
France	297
International	500

Note that this value needs to correspond to the CCSID used on the host.

Title

The Title attribute is an optional character string that represents a comment describing the column. This attribute may be null.

Host Column Description Example File

The following is an example for an HCD file containing two sample database file descriptions — SAMPLE/ACCOUNTS and PUBS/AUTHORS. The first sample file (SAMPLE/ACCOUNTS) has four columns of data while the second example (PUBS/AUTHORS) has nine columns that must be described.

```
[files]
SAMPLE/ACCOUNTS=1
PUBS/AUTHORS=1

[SAMPLE/ACCOUNTS]
numcol=4
col1=0;CUST_NO;CUST_NO;8;0;0;ZONED;LONG;N;37;;
col2=0;CUST_NAME;CUST_NAME;0;0;40;CHAR;CHAR;N;37;;
col3=0;BALANCE;BALANCE;10;2;0;ZONED;FLOAT;N;37;;
col4=0;LAST_ACC;LAST_ACC;0;0;26;TIMESTAMP;TIMESTAMP;N;37;;

[PUBS/AUTHORS]
NumCol=9
Col1=0;AU_ID;AU_ID;11;0;11;CHAR;CHAR;N;37;;
Col2=0;AU_LNAME;AU_LNAME;0;0;40;VARCHAR;CHAR;N;37;;
Col3=0;AU_FNAME;AU_FNAME;0;0;20;VARCHAR;CHAR;N;37;;
Col4=0;PHONE;PHONE;0;0;12;CHAR;CHAR;N;37;;
Col5=0;ADDRESS;ADDRESS;0;0;40;VARCHAR;CHAR;N;37;;
Col6=0;CITY;CITY;0;0;20;VARCHAR;CHAR;N;37;;
Col7=0;STATE;STATE;2;0;2;CHAR;CHAR;N;37;;
Col8=0;ZIP;ZIP;0;0;5;CHAR;SHORT;N;37;;
Col9=0;CONTRACT;CONTRACT;0;0;9;BINARY;BINARY;N;37;;
```

Conversion from Host to OLE DB Data Types

The external record description for data files residing on mainframes is configured in a host column description (HCD) file using the SNA OLE DB Management snap-in. This HCD file is used to convert from host EBCDIC data types to ASCII C data types for the PC in the Distributed Data Management (DDM) DLL. These C data types are then mapped to OLE DB data types by the SNAOLEDB DLL.

Default OLE DB Data Types

The following table indicates the default OLE DB data types that result from the mapping of the host data types by the Microsoft OLE DB Provider for AS/400 and VSAM.

Host data type	OLE DB data type	Comments
Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char)
Character	DBTYPE_STR	Null-terminated ASCII character string
Date	DBTYPE_DBDATE	The DBDATE typedef struct defined in OLEDB.H header file.
DBCS	DBTYPE_STR	Null-terminated ASCII character string
DCBS – Mixed Either	DBTYPE_STR	Null-terminated ASCII character string
DCBS – Mixed Open	DBTYPE_STR	Null-terminated ASCII character string
DBCS – Variable	DBTYPE_STR	Null-terminated ASCII character string
DCBS – Variable Mixed Either	DBTYPE_STR	Null-terminated ASCII character string
DCBS – Variable Mixed Open	DBTYPE_STR	Null-terminated ASCII character string
Double	DBTYPE_R8	8-byte floating-point data
Float	DBTYPE_R8	8-byte floating-point data
Long Integer	DBTYPE_I4	4-byte signed integer
Long Variable Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char)
Long Variable Character	DBTYPE_STR	Null-terminated ASCII character string
Packed	DBTYPE_DECIMAL	The DECIMAL structure typedef defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.
Real	DBTYPE_R4	4-byte floating-point data
Short	DBTYPE_I2	2-byte signed integer
Single	DBTYPE_R4	4-byte floating-point data
Time	DBTYPE_DBTIME	The DBTIME typedef defined in OLEDB.H header file.
Time Stamp	DBTYPE_DBTIMESTAMP	The DBTIMESTAMP typedef defined in OLEDB.H header file.
Variable Binary	DBTYPE_BYTES	A fixed-length array of bytes (unsigned char)
Variable Character	DBTYPE_STR	Null-terminated ASCII character string
Zoned	DBTYPE_NUMERIC	The NUMERIC typedef structure defined in OLEDB.H. This is an exact numeric value with a fixed precision and fixed scale.

The host Binary, VarBinary, and Long VarBinary data types are converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_BYTES data type by the SNAOLEDB DLL. The host Zoned data type is converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_NUMERIC data type by the SNAOLEDB DLL. The host Packed data type is converted to SQL_C_CHAR type by the DDM DLL and mapped to the DBTYPE_DECIMAL data type by the SNAOLEDB DLL.

DBDATE

The **DBDATE** structure typedef is defined as follows:

```
typedef struct tagDBDATE {
    SHORT  year;
    USHORT month;
    USHORT day
} DBDATE;
```

Members

year
The year (0 to 9999) is measured from 0 A.D.

month
The month ranges from 1 to 12 representing January through December.

day
The day ranges from 1 to a maximum of 31, depending on the number of days in the month.

DBTIME

The **DBTIME** structure typedef is defined as follows:

```
typedef struct tagDBTIME {
    USHORT hour;
    USHORT minute;
    USHORT second
} DBTIME;
```

Members

hour
The hour ranges from 0 to 23.

minute
The minute ranges from 0 to 59.

second
The second ranges from 0 to 59.

DBTIMESTAMP

The **DBTIMESTAMP** structure typedef is defined as follows:

```
typedef struct tagDBTIMESTAMP {
    SHORT  year;
    USHORT month;
    USHORT day;
    USHORT hour;
    USHORT minute;
    USHORT second;
    ULONG  fraction
} DBTIMESTAMP;
```

Members

year
The year (0 to 9999) is measured from 0 A.D.

month
The month ranges from 1 to 12 representing January through December.

day
The day ranges from 1 to a maximum of 31, depending on the number of days in the month.

hour
The hour ranges from 0 to 23.

minute
The minute ranges from 0 to 59.

second
The second ranges from 0 to 59.

fraction
The fraction represents billionths of a second ranging from 0 to 999,999,999.

DECIMAL

The **DECIMAL** typedef structure is an exact numeric value with a fixed precision and fixed scale, stored in the same way as in OLE Automation. The **DECIMAL** typedef structure is defined as follows:

```
typedef struct tagDECIMAL {
    USHORT wReserved;
    union {
        struct {
            BYTE scale;
            BYTE sign;
         };
        USHORT signscale;
    };
    ULONG Hi32;
    union {
        struct {
             ULONG Lo32;
             ULONG Mid32;
          };
         ULONGLONG Lo64;
    };
} DECIMAL;
```

Members

wReserved
This member is reserved and should be 0.

scale
Specifies the number of digits to the right of the decimal point and ranges from 0 to 28.

sign
The sign is 0 if positive, 0x80 if negative.

Hi32
The high part of the integer (32-bit aligned).

Mid32
The middle part of the integer (32-bit aligned).

Lo32
The low part of the integer (32-bit aligned).

For example, to specify the number 12.345, the scale is 3, the sign is 0, and the number stored in the 12-byte integer is 12345.

NUMERIC

The **NUMERIC** typedef structure is an exact numeric value with a fixed precision and fixed scale. The **NUMERIC** typedef structure is defined as follows:

```
typedef struct tagNUMERIC {
    BYTE precision;
    BYTE scale;
    BYTE sign;
    BYTE val[16];
} DB_NUMERIC;
```

Members

precision
The maximum number of digits in base 10.

scale
The number of digits to the right of the decimal point.

sign
The sign is 1 for positive numbers, and 0 for negative numbers.

val
A number stored as a 16-byte scaled integer, with the least-significant byte on the left.

For example, to specify the base 10 number 20.003 with a scale of 4, the number is scaled to an integer of 200030 (20.003 shifted by four tens digits), which is 186AA in hexadecimal. The value stored in the 16-byte integer is 5E 0D 03 00 00 00 00 00 00 00 00 00 00 00 00 00, the precision is the maximum precision, the scale is 4, and the sign is 1.

Character Code Conversions

Character code conversions under the OLE DB Provider for AS/400 and VSAM are controlled by a hierarchy of parameters. When connecting to mainframes all of these parameters are controlled on the PC. However, when connecting to data sources on the AS/400, parameter settings on the AS/400 as well as parameter settings on the PC can be involved.

The Character Code Set Identifier (CCSID) used by the host for a data source can be specified in several locations. The Host CCSID setting used by the OLE DB Provider must bet set to match the CCSID actually used on the host otherwise data loss will occur. Note that some AS/400 systems default to a CCSID of 937 rather than 37 for enabling double-byte character sets (DBCS).

The following table illustrates the separate hierarchy controlling the Host CCSID parameter on the SNA client, AS/400 host, and mainframe host:

SNA client	**AS/400 host**	**Mainframe host**
SNA OLE DB Provider (defaults to U.S./Canada 37)	System (DSPSYSVAL, QCCSID)	None. Determined by the Data Description (HCD file) on the SNA Client.
Data Source (the Host CCSID parameter in the Data Links file describing the Data Source)	User identifier (wrk usrprf)	
Data Description (HCD file)	Job (dspjob, crtjobd)	
	File (dspfd, crtpf)	
	Column (dspffd)	

Only those fields in a Data Source that contain character data will be affected by the Host CCSID parameters and character conversions.

Host CCSID and SNA OLE DB Provider

The Host CCSID setting at the OLE DB provider level defaults to U.S./Canada (37).

Host CCSID and Data Source

The Host CCSID setting at the Data Source level is configured using Data Links for each Data Source. The **Host CCSID** parameter is configured under the **All** tab of the **Data Links** dialog box.

Valid values for the Host CCSID registry setting are any CCSID, including 65535. If the Host CCSID attribute is set to 65535, then no character conversion will occur (the data will be treated as binary). If the Host CCSID setting at the Data Source level does not exist, then the value for Host CCSID defaults to the value at the SNA OLE DB Provider level.

Host CCSID and Data Description

A Host CCSID attribute can be applied at the Data Description level. Each column in a Host Column Description (HCD) file can have a Host CCSID attribute that determines how the character data in the column is to be converted. These attributes in the HCD file at the Data Description level should be configured using the SNA OLE DB Management Console snap-in (see Configuring Data Descriptions). Valid values are any CCSID including 65535.

The Host CCSID attribute at the column Data Description level can be any value and may be empty. A Host CCSID value at the Data Description level overrides the value specified at the Data Source and OLE DB Provider levels. If the Host CCSID is blank, then the value for Host CCSID defaults to the value at the Data Source level. If the Host CCSID attribute is set to 65535, then no character conversion will occur (the data will be treated as binary).

Host CCSID and the Process Binary As Character Parameter

There is a Data Source parameter configurable using Data Links that affects whether binary data is considered as character data and is converted based on the Host CCSID setting. This **Process Binary As Character** parameter defaults to false. If this parameter is false, binary data is not treated as character (binary data is not affected by the Host CCSID setting). If this parameter is set to true, then binary data will be converted based on the Host CCSID setting.

This parameter is configured for each Data Source using Data Links under the **All** tab of the **Data Links** dialog box.

Architecture

The table below lists the architectural components used to support the Microsoft OLE DB Provider for AS/400 and VSAM.

Module	Description
DDMSERV.EXE	The DDM Server implements a source-only DDM Application Requester that communicates with the target DDM Servers running on MVS, OS/390, or OS/400. The DDM Server handles connection management, memory management, file management, and error handling. On Microsoft® Windows 2000 and Windows NT®, DDMSERV runs by default as an auto-started Windows NT service, although this behavior can be changed.
MMCRLIO.DLL	The Data Descriptions Management Console snap-in provided with Host Integration Server and Host Integration Client. This component manages data descriptions and host column description files under the Microsoft® Windows 2000, Windows NT, Windows® 98, and Windows® 95 operating systems.
SNAOLEDB.DLL	The OLE DB provider for AS/400 and VSAM. Server-based and client-based OLE DB and ADO programs call this provider to gain record-level access to host files.

The following additional components must be installed in the system subdirectory below the root directory where Host Integration Server 2000 is installed (setup defaults to C:\Program Files\Host Integration Server) to support the OLE DB Provider for AS/400 and VSAM:

CONV.DLL

DCONV2.DLL

DDM.DLL

DDMAPI.DLL

DDMRLIO.DLL

DDMRC.DLL

DDMSTR.DLL

DDMTCP2.DLL

DDMWAPPC.DLL

SNADDMEL.DLL

SNAOLEDB.MSC

WAPPC32.DLL

WINAPPC.DLL

The following additional components must be installed in the WINDOWS SYSTEM subdirectory (typically WINNT\System32 on Windows 2000 and Windows NT and Windows\System on Windows 98 and Windows 95) to support the OLE DB Provider for AS/400 and VSAM:

MSVBVM50.DLL

MSVBVM60.DLL

The following utilities are also supplied to support the OLE DB Provider for AS/400 and VSAM:

CrtPkg.exe

NewSnaDS.exe

reg2udl.exe

The table below lists the architectural components used to support the Microsoft OLE DB Provider for DB2.

Module	Description

DRDA_VB.EXE	The DRDA Application Requester implemented as a service that communicates with the target DD2 Servers running on MVS, OS/390, or OS/400. The DRDA requester handles connection management, memory management, data access, and error handling. On Microsoft® Windows 2000 and Windows NT®, DRDA_VB runs by default as an auto-started Windows NT service, although this behavior can be changed.
DB2OLEDB.DLL	The OLE DB provider for DB2. Server-based and client-based OLE DB and ADO programs call this provider to gain access to DB2.

The following additional components must be installed in the system subdirectory below the root directory where Host Integration Server 2000 is installed (setup defaults to C:\Program Files\Host Integration Server) to support the OLE DB Provider for DB2:

CONV.DLL

DB2WAPPPC.DLL

DCONV2.DLL

DDMRC.DLL

DDMSTR.DLL

DDMTCP2.DLL

MSEIDRDA.DLL

MSEIDPM.DLL

MSEIDT.DLL

DRDAPERF.DEF

DRDAPERF.INI

SNADDMEL.DLL

WAPPC32.DLL

WINAPPC.DLL

The following additional components must be installed in the WINDOWS SYSTEM subdirectory (typically WINNT\System32 on Windows 2000 and Windows NT and Windows\System on Windows 98 and Windows 95) to support the OLE DB Provider for DB2:

MSVBVM50.DLL

MSVBVM60.DLL

The following utilities are also supplied to support the OLE DB Provider for DB2:

CrtPkg.exe

CrtPkg.dll

NewSnaDS.exe

The table below lists the architectural components used to support the Microsoft ODBC Driver for DB2.

Module	**Description**
DRDA_VB.EXE	The DRDA Application Requester implemented as a service that communicates with the target DD2 Servers running on MVS, OS/390, or OS/400. The DRDA requester handles connection management, memory management, data access, and error handling. On Microsoft® Windows 2000 and Windows NT®, DRDA_VB runs by default as an auto-started Windows NT service, although this behavior can be changed.
MSEIDBC.DLL	The ODBC Driver for DB2 configuration DLL.

MSEIDBD.DLL	The ODBC Driver for DB2.

The following additional components must be installed in the system subdirectory below the root directory where Host Integration Server 2000 is installed (setup defaults to C:\Program Files\Host Integration Server) to support the ODBC Driver for DB2:

CONV.DLL

DB2WAPPPC.DLL

DCONV2.DLL

DDMRC.DLL

DDMSTR.DLL

DDMTCP2.DLL

MSEIDRDA.DLL

MSEIDPM.DLL

MSEIDT.DLL

DRDAPERF.DEF

DRDAPERF.INI

SNADDMEL.DLL

WAPPC32.DLL

WINAPPC.DLL

The following additional components must be installed in the WINDOWS SYSTEM subdirectory (typically WINNT\System32 on Windows 2000 and Windows NT and Windows\System on Windows 98 and Windows 95) to support the ODBC Driver for DB2:

MSVBVM50.DLL

MSVBVM60.DLL

The following utilities are also supplied to support the ODBC Driver for DB2:

CrtPkg.exe

CrtPkg.dll

NewSnaDS.exe

The table below lists the architectural components used to support the Microsoft Host File Transfer ActiveX Control.

Module	**Description**
DDMSERV.EXE	The DDM Server implements a source-only DDM Application Requester that communicates with the target DDM Servers running on MVS, OS/390, or OS/400. The DDM Server handles connection management, memory management, file management, and error handling. On Microsoft® Windows 2000 and Windows NT®, DDMSERV runs by default as an auto-started Windows NT service, although this behavior can be changed.
MMCRLIO.DLL	The Data Descriptions Management Console snap-in provided with Host Integration Server and Host Integration Client. This component manages data descriptions and host column description files under the Microsoft® Windows 2000, Windows NT, Windows® 98, and Windows® 95 operating systems.
MSEIGFT.DLL	The Host File Transfer ActiveX Control library.

The following additional components must be installed in the system subdirectory below the root directory where Host Integration Server 2000 is installed (setup defaults to C:\Program Files\Host Integration Server) to support the Host File Transfer ActiveX Control:

CONV.DLL

DCONV2.DLL

DDM.DLL

DDMAPI.DLL

DDMRLIO.DLL

DDMRC.DLL

DDMSTR.DLL

DDMTCP2.DLL

DDMWAPPC.DLL

WAPPC32.DLL

WINAPPC.DLL

WINCSV.DLL

WINCSV32.DLL

The following additional components must be installed in the WINDOWS SYSTEM subdirectory (typically WINNT\System32 on Windows 2000 and Windows NT and Windows\System on Windows 98 and Windows 95) to support the Host File Transfer ActiveX Control:

MSVBVM50.DLL

MSVBVM60.DLL

SDK Components for Data Integration

The Microsoft® Host Integration Server 2000 SDK contains software components used for data integration applications and data access. The components used for data access are described in the following topics.

Program and DLL Files for Data Integration

The following executable system file and DLL library files are included with the Host Integration Server 2000 SDK for use with the OLE DB Provider for AS/400 and VSAM, the OLE DB Provider for DB2, the ODBC Driver for DB2, the AS/400 Data Queue ActiveX Control, and the Host File Transfer ActiveX Control:

File name	Description
conv.dll	DDM support library used for ASCII-to-EBCDIC conversion during host logon.
CrtPkg.dll	Support library for DB2 create package utility.
CrtPkg.exe	Create package utility for use with the OLE DB Provider for DB2 and the ODBC Driver for DB2.
db2oledb.dll	The OLE DB provider for DB2.
dconv2.dll	DDM support library used for data conversion.
ddm.dll	DDM Record Level I/O Requester library that communicates with the DDM Server.
ddmapi.dll	DDM Record Access Library.
DDMRC.dll	DDM support library containing resource strings used by error-handling routines.
ddmrlio.dll	DDM support library used by snaoledb.dll.
ddmserv.exe	The DDM Server handles connection management, memory management, file management, and error handling.
DDMStr.dll	DDM support library containing the OLE DB provider error string resources.
ddmtcp2.dll	DDM support library used by TCP/IP by the OLE DB Provider for DB2 and the ODBC Driver for DB2.
ddmwappc.dll	DDM support library used for OLE DB Data configuration and communication with the WINAPPC.DLL.
drda_vb.exe	The DRDA Server handles connection management, memory management, file management, and error handling.
mmcrlio.dll	The Data Descriptions Management Console snap-in support library used to create or modify data descriptions for use with the OLE DB Provider for AS/400 and VSAM or with the Host File Transfer ActiveX Control.
mmcrlio.chm	Help file for the MMC snap-in for the OLE DB Provider for AS/400 and VSAM.
mmcRLIO.msc	The Data Descriptions Management Console snap-in utility used to configure or modify data description files for use with the OLE DB Provider for AS/400 and VSAM or with the Host File Transfer ActiveX Control.

msei db2c .dll	The ODBC Driver for DB2 configuration DLL (installed in the Windows 2000 or Windows NT System 32 directory).
msei db2d .dll	The ODBC Driver for DB2 (installed in the Windows 2000 or Windows NT System 32 directory).
msei drda. dll	Support library for use by the OLE DB Provider for DB2 and the ODBC Driver for DB2 used to provide the DRDA agent for t he DB2 provider.
MSEI DPM .dll	Support library for use by the OLE DB Provider for DB2 and the ODBC Driver for DB2 used for DB2 performance monitorin g.
MSEI DT.dl l	Support library for use by the OLE DB Provider for DB2 and the ODBC Driver for DB2 used for DB2 data transformation.
MSEI GFT. dll	The Host File Transfer ActiveX Control library.
MSEI GDQ .dll	The AS/400 Data Queues ActiveX Control library.
MSV BVM 50.D LL	Visual Basic 5.0 runtime dynamic link library.
Msv bvm 60.dl l	Visual Basic 6.0 runtime dynamic link library.
New Sna DS.e xe	A utility program to create new Data Links UDL files used with Host Integration Server 2000.
reg2 udl.e xe	A utility program to convert Win32 registry-based data sources used with previous versions of the OLE DB Provider for AS/ 400 and VSAM supplied with SNA Server 4.0 to Data Links UDL files used with Host Integration Server 2000. This file is loca ted in the Options\Maintenance folder on the Host Integration Server CD-ROM and is not installed as part of the product.
snad dmel .dll	Event log resource file.
snao ledb. dll	The OLE DB provider for AS/400 and VSAM.

The following executable system file and DLL library files were included with SNA Server 4.0 Service Pack 3 and Service Pack 4 for use with the OLE DB Provider for AS/400 and VSAM, the OLE DB Provider for DB2, and the ODBC Driver for DB2:

File na me	**Description**
CONV.D LL	DDM support library used for ASCII-to-EBCDIC conversion during host logon.
DB2OLE DB.DLL	The OLE DB provider for DB2.
DB2SER V.EXE	The DB2 Server handles connection management, memory management, file management, and error handling.
DB2WA PPC.DLL	Support library used for OLE DB Data configuration and communication with the WINAPPC.DLL.
DCONV. DLL	DDM support library used for data conversion.
DDM.DL L	DDM Record Level I/O Requester library that communicates with the DDM Server.

DDMAPI.DLL	DDM Record Access Library.
DDMRLIO.DLL	DDM support library used by SNAOLEDB.DLL.
DDMSERV.EXE	The DDM Server handles connection management, memory management, file management, and error handling.
DDMSQL.DLL	DDM support library used by DB2OLEDB.DLL.
DDMSTR.DLL	DDM support library containing the OLE DB provider error string resources.
DDMTCP2.DLL	DDM support library used by TCP/IP by the OLE DB Provider for DB2 and the ODBC Driver for DB2. (DDMTCP.DLL was supplied with the earlier SNA Server 4.0.)
DDMTCP.DLL	DDM support library used by TCP/IP by the OLE DB Provider for AS/400 and VSAM.
DDMWAPPC.DLL	DDM support library used for OLE DB Data configuration and communication with the WINAPPC.DLL.
DRDA.DLL	DRDA support library.
DRDAAPI.DLL	DRDA support library.
DRDAPERF.DEF	Performance Monitor support file.
DRDAPERF.INI	Performance Monitor support file.
MMCRLIO.DLL	The Data Descriptions OLE DB Management Console snap-in used to create or modify data descriptions for use with the OLE DB Provider for AS/400 and VSAM.
MMCRLIO.HLP	Help file for the MMC snap-in for the OLE DB Provider for AS/400 and VSAM.
MSDB2BAS.DLL	Support library for ODBC Driver for DB2.
MSDB2OLE.DLL	Support library for ODBC Driver for DB2.
MSDB2OLE.HLP	Help file for the ODBC Driver for DB2.
MSDB2UTL.DLL	Utility support library for ODBC Driver for DB2.
MSVBVM50.DLL	Visual Basic 5.0 runtime dynamic link library.
PMHLPRDR.DLL	Performance Monitor support file.
PMPRXYDR.DLL	Performance Monitor support file.
REG2UDL.EXE	A utility program to convert Win32 registry-based data sources used with previous versions of the OLE DB Provider for AS/400 and VSAM supplied with SNA Server 4.0 to Data Links UDL files used with Host Integration Server 2000.
SNADDMEL.DLL	Event log resource file.
SNAOLEDB.DLL	The OLE DB provider for AS/400 and VSAM.
SNAOLEDB.MSC	SNA OLE DB Management Console snap-in utility used to configure data sources in the registry and host column description files.

Symbol Files for Data Integration

The following symbol files for use when debugging are included with Host Integration Server 2000 for use with the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, the Microsoft® ODBC Driver for DB2, the Microsoft Host File Transfer ActiveX Control, and the Microsoft Data Queues ActiveX Control. These files are installed as part of the Host Integration Server package and a copy of these files are also located on the Host Integration Server CD-ROM under the Support\Symbols folder:

File name	Description
DLL\conv.dbg	Symbols from Conv.dll
DLL\CrtPkg.dbg	Symbols from CrtPkg.dll
EXE\CrtPkg.dbg	Symbols from CrtPkg.exe
DLL\db2oledb.dbg	Symbols from db2oledb.dll
DLL\dconv2.dbg	Symbols from dconv2.dll
DLL\ddm.dbg	Symbols from ddm.dll
DLL\ddmapi.dbg	Symbols from ddmapi.dll
DLL\ddmrlio.dbg	Symbols from ddmrlio.dll
DLL\ddmserv.dbg	Symbols from ddmserv.exe
DLL\DDMStr.dbg	Symbols from DDMStr.dll
DLL\ddmtcp2.dbg	Symbols from ddmtcp2.dll
DLL\ddmwappc.dbg	Symbols from ddmwappc.dll
EXE\DRDA_VB.dbg	Symbols from drdda_vb.exe
DLL\mmcrlio.dbg	Symbols from mmcrlio.dll
DLL\mdeidb2c.dbg	Symbols from MSEIDB2C.DLL
DLL\mseidb2d.dbg	Symbols from MSEIDB2D.DLL
DLL\mseidrda.dbg	Symbols from mseidrda.dll
DLL\MSEIDPM.dbg	Symbols from MSEIDPM.dll
DLL\MSEIDSBD.dbg	Symbols from MSEIDSBD.DLL
DLL\MSEIDSBN.dbg	Symbols from MSEIDSBN.DLL
DLL\MSEIDSBP.dbg	Symbols from MSEIDSBP.DLL
DLL\MSEIDT.dbg	Symbols from MSEIDT.dll
DLL\MSEIGFT.dbg	Symbols from MSEIGFT.dll
DLL\MSEIGDQ.dbg	Symbols from MSEIGDQ.dll
EXE\NewSnaDS.dbg	Symbols from NewSnaDS.exe
DLL\reg2udl.dbg	Symbols from REG2UDL.EXE
DLL\snaddmel.dbg	Symbols from snaddmel.dll
DLL\snaoledb.dbg	Symbols from snaoledb.dll

The following symbol files for use when debugging were included with SNA Server 4.0 Service Pack 3 and Service Pack 4 for use with the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, and the Microsoft® ODBC Driver for DB2:

File name	Description
CONV.DBG	Symbols from CONV.DLL
CRTPKG.DBG	Symbols from CRTPKG.EXE
CRTPKGW.DBG	Symbols from CRTPKGW.EXE
DB2OLEDB.DBG	Symbols from DB2OLEDB.DLL
DB2SERV.DBG	Symbols from DB2SERV.EXE
DB2WAPPC.DBG	Symbols from DBWAPPC.DLL
DCONV.DBG	Symbols from DCONV.DLL
DDM.DBG	Symbols from DDM.DLL
DDMAPI.DBG	Symbols from DDMAPI.DLL
DDMRLIO.DBG	Symbols from DDMRLIO.DLL
DDMSERV.DBG	Symbols from DDMSERV.EXE
DDMSQL.DBG	Symbols from DDMSQL.DLL
DDMSTR.DBG	Symbols from DDMSTR.DLL

DDMTCP.DBG	Symbols from DDMTCP.DLL
DDMTCP2.DBG	Symbols from DDMTCP2.DLL
DDMWAPPC.DBG	Symbols from DDMAPPC.DLL
DRDA.DBG	Symbols from DRDA.DLL
DRDAAPI.DBG	Symbols from DRDAAPI.DLL
MMCRLIO.DBG	Symbols from MMCRLIO.DLL
MSDB2BAS.DBG	Symbols from MSDB2BAS.DLL
MSDB2OLE.DBG	Symbols from MSDB2OLE.DLL
MSDB2UTL.DBG	Symbols from MSDB2UTL.DLL
PMHLPRDR.DBG	Symbols from PMHLPRDR.DLL
PMPRXYDR.DBG	Symbols from PMPRXYDR.DLL
REG2UDL.DBG	Symbols from REG2UDL.EXE
SNADDMEL.DBG	Symbols from SNADDMEL.DLL
SNAOLEDB.DBG	Symbols from SNAOLED.DLL

Header Files for Data Integration

Provider-specific header files needed to build the ADO, OLE DB, and ODBC sample applications are included with the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, and the Microsoft® ODBC Driver for DB2. These header files are located in the SDK\Include subdirectory on the Host Integration Server 2000 CD-ROM.

The following provider-specific files are provided for developing applications using ADO, OLE DB, and ODBC using the OLE DB Provider for AS/400 and VSAM, the OLE DB Provider for DB2, and the ODBC Driver for DB2:

File name	Description
db2oledb.h	GUID definitions, enumeration constants, and error codes for use with the OLE DB Provider for DB2.
snaoledb.h	GUID definitions, enumeration constants, and error codes for use with the OLE DB Provider for AS/400 and VSAM.

The following header files are provided as part of the OLE DB version 2.1 and ADO version 2.1 SDK. These OLE DB and ADO header files are generally required to build applications in C or C++ using the Host Integration Server SDK and may be downloaded from the Microsoft Universal Data Access Free Downloads page. http://go.microsoft.com/fwlink/?LinkId=12754 as part of the Microsoft Data Access SDK 2.1.

File name	Description
ADOID.H	ADO GUID definitions.
ADOINT.H	ADO Interface header for calling from C++.
ADOJAVAS.INC	ADO constants include file for JavaScript.
ADOVBS.INC	ADO constants include file for VBScript.
MSDADC.H	OLE DB Data Conversion include file.
MSDAGUID.H	Microsoft Data Access GUID definitions.
MSDASC.H	Microsoft Data Access Datalinks interfaces.
MSDASQL.H	OLE DB Provider for ODBC data.
ODBCINST.H	ODBC install include file.
OLEDB.H	Primary OLE DB include file.
OLEDBERR.H	OLE DB error include file.
OLEDBJVS.INC	OLE DB error constant include file for JavaScript.
OLEDBVBS.INC	OLE DB error constant include file for VBScript.
SQL.H	Main include file for ODBC core functions.
SQLEXT.H	Include file for applications using Microsoft SQL extensions.
SQLTYPES.H	Defines types used in ODBC.
SQLUCODE.H	Unicode include file for ODBC core functions.
TRANSACT.H	Transactions header file.

These include files are also included in the SDK\INC subdirectory on the SNA Server 4.0 Service Pack 3 and Service Pack 4 CD-ROM for Win32 platforms on I386 and Alpha.

Import Library Files for OLE DB Data Integration

The following import library files are on Microsoft Developer Network CD-ROMs and as a downloadable Software Development Kit from the the Microsoft Universal Data Access Free Downloads Web site at http://go.microsoft.com/fwlink/?LinkId=12754 provided as part of the Microsoft Data Access SDK 2.0 and the Microsoft Data Access SDK 2.1 update:

File name	Description
ADOID.LIB	GUID library for client C++ classes
MSDASC.LIB	Data Links library
OLEDB.LIB	The OLE DB library
OLEDBD.LIB	The OLE DB debug library

The MSDASC.LIB, OLEDB.LIB, and OLEDBD.LIB library files are also included in the SDK\LIB\WINNT subdirectory on the SNA Server 4.0 Service Pack 3 and Service Pack 4 CD-ROM for Win32 platforms on I386 and Alpha.

Import Library Files for ODBC Data Integration

The following import library files are on Microsoft Developer Network CD-ROMs and as a downloadable Software Development Kit from the the Microsoft Universal Data Access Free Downloads Web site at http://go.microsoft.com/fwlink/?LinkId=12754 provided as part of the Microsoft Data Access SDK 2.1 update:

File name	Description
GTRTST32.LIB	An ODBC support library
ODBC32.LIB	The main ODBC library
ODBCCP32.LIB	An ODBC support library

These files are also included with the Microsoft® ODBC Driver for DB2 in the SDK\LIB\WINNT subdirectory on SNA Server 4.0 Service Pack 3 and Service Pack 4 CD-ROM for Win32 platforms on I386 and Alpha.

OLE DB and ADO Import Library Files

The following import library files are on Microsoft Developer Network CD-ROMs and as a downloadable Software Development Kit from the Microsoft Universal Data Access Free Downloads Web site at http://go.microsoft.com/fwlink/?LinkId=12754 provided as part of the Microsoft Data Access SDK 2.0 and the Microsoft Data Access SDK 2.1 update:

File name	Description
ADOID.LIB	GUID library for client C++ classes
MSDASC.LIB	Data Links library
OLEDB.LIB	The OLE DB library
OLEDBD.LIB	The OLE DB debug library

The MSDASC.LIB, OLEDB.LIB, and OLEDBD.LIB library files are also included in the SDK\LIB\WINNT subdirectory on the SNA Server 4.0 Service Pack 3 and Service Pack 4 CD-ROM for Win32 platforms on I386 and Alpha.

Data Integration Samples

This section of the Microsoft® Host Integration Server 2000 Developer's Guide describes the sample applications that implement data integration using DB providers, drivers, and ActiveX® controls.

This section contains:

Sample Programs for Data Access

The source code and executable files for several sample programs that illustrate using the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft® OLE DB Provider for DB2, and the Microsoft® ODBC Driver for DB2 are included on the Microsoft® Host Integration Server 2000 CD-ROM and as part of the Microsoft Developer Network (MSDN) Platform SDK. These sample programs are located in the \SDK\Samples\DataAccess subdirectory on the Host Integration Server 2000 CD-ROM. These files are also copied to your hard drive during Host Integration Server and Host Integration Client installation when the SDK option is selected.

When installed as part of the MSDN Platform SDK, these samples are located under the Samples\NetDS\HIS\DataAccess subdirectory below where the MSDN Platform SDK has been installed.

These sample programs include the files in the following subdirectories:

Subdirectory	Description
DRDA_ASP	ADO sample script written in Microsoft® Active Server Pages (ASP) using the OLE DB Provider for DB2
DRDA_VB	ADO sample program written in Microsoft® Visual Basic® using the OLE DB Provider for DB2
DRDA_VBS	ADO sample script written in Microsoft® VBScript using the OLE DB Provider for DB2
RLIO_ASP	ADO sample script written in Microsoft® Active Server Pages (ASP) using the OLE DB Provider for AS/400 and VSAM
RLIO_VB	ADO sample program written in Microsoft® Visual Basic® using the OLE DB Provider for AS/400 and VSAM
RLIO_VBS	ADO sample script written in Microsoft® VBScript using the OLE DB Provider for AS/400 and VSAM

The file named SAMPLE.HCD located in the DataAccess subdirectory contains two examples of a Host Column Description (HCD) file required to access host VSAM files using the OLE DB Provider for AS/400 and VSAM. Please see documentation on the Host Column Description in the Data Access Reference section for more information. The SAMPLE.HCD file is described in this same reference section as well.

Several sample programs with source code are provided with Host Integration Server 2000 that illustrate data access. These sample programs include the following:

- Visual Basic ADO sample program This application allows you to open a connection through the OLE DB Provider, open a recordset, and browse the records of a host file. Two versions of this sample application are provided. The sample in the DRDA_VB folder is for use with the OLE DB Provider for DB2. The sample in the RLIO_VB folder is for use with the OLE DB Provider for AS/400 and VSAM. Seeking on a key value in a host indexed file is also possible with this sample when the version of this sample is used with the OLE DB Provider for AS/400 and VSAM.
- Visual Basic Script ADO sample program This VBScript application allows you to open a connection through the OLE DB Provider, open a recordset, and browse the records of a host file. Two versions of this sample application are provided. The sample in the DRDA_VBS folder is for use with the OLE DB Provider for DB2. The sample in the RLIO_VBS folder is for use with the OLE DB Provider for AS/400 and VSAM.
- Active Server Pages (ASP) sample programs Two ASP sample programs are included. One is a report application that allows you to return and display the first ten records in a host file to a client browser in a table view. The second sample allows you to display columns of a host file in a form view. Two versions of these sample applications are provided. The samples in the DRDA_ASP folder are for use with the OLE DB Provider for DB2. The samples in the RLIO_ASP folder are for use with the OLE DB Provider for AS/400 and VSAM.

Several additional SDK sample files for data access are included with Microsoft Data Access Components (MDAC) SDK and are available as part of the Microsoft MSDN Platform SDK. These data access sample programs include the following files:

Sample Program	Description
ODBCQuery	The ODBC Query demo application written in C. This sample can be used with the ODBC Driver for DB2.
RowsetViewer	The OLE DB RowsetViewer sample application written in C++. This sample can be with either the OLE DB Provider for DB2 or the OLE DB Provider for AS/400 and VSAM.

These sample programs with source code are provided as part of the MDAC SDK and the MSDN Platform SDK can be used with the data access features of Host Integration Server 2000:

- OLE DB RowsetViewer sample program This application written on C++ allows you to connect to the OLE DB Provider, open a table window, type the host file name or database, return a rowset, and browse the contents. You can navigate the table,

using seek and set range on indexed files when the version of this sample is used with the OLE DB Provider for AS/400 and VSAM.

Before running any of these examples with the OLE DB Provider for AS/400 and VSAM, it is necessary to create a data file on the SNA host that will be used for demonstration purposes. After a suitable file is created on the host, it is necessary to run the Data Descriptions management console snap-in application in order to configure the appropriate default settings for the OLE DB Provider for AS/400 and VSAM, such as APPC mode, the character code set Identifier (CCSID) to be used when converting host data, and the Code Page to be used on the local PC.

If the data is on a mainframe host, it is also necessary to configure a data description (create a host column description file) using the Data Descriptions management console snap-in. The host column description specifies the column description of the data file on the host and how the OLE DB Provider for AS/400 and VSAM should convert data from the host to the PC. Although an HCD file is unnecessary to access data files on the AS/400, a host column description can be specified that will override the default conversions.

The following sections discuss setting up and using each sample application in more detail.

Visual Basic ADO Sample

The SDK\Samples\DataAccess folder contains an ADO sample application written in Visual Basic version 6.0 that accesses data provided by an OLE DB Provider. Two versions of this sample are supplied. One sample is for use with the Microsoft OLE DB Provider for AS/400 and VSAM (source files located in the RLIO_VB subdirectory). One sample is for use with the Microsoft OLE DB Provider for DB2(source files located in the DRDA_VB subdirectory).

This sample illustrates using ADO to access data on a host.

In order to use this sample, the ConnectionString property will need to be changed to point to a host you can access and a data file or DB2 database to browse on the host.

This application allows you to open a connection through the OLE DB Provider, open a recordset, and browse the records on a host file. This sample is built with ActiveX® Data Objects version 2.0. Before building this Visual Basic sample, be sure to include the Microsoft ActiveX Data Objects 2.0 Library in your project. You can do this from inside the Visual Basic Integrated Development Environment by selecting **References** on the **Project** menu.

The sample application can be built with Microsoft Visual Basic version 5.0 or later.

Visual Basic Script ADO Sample

The SDK\Samples\DataAccess folder contains a sample web client application written in VBScript using ADO designed to access data provided by an OLE DB provider. Two versions of this sample are supplied. One sample is for use with the Microsoft® OLE DB Provider for AS/400 and VSAM (source files located in the RLIO_VBS subdirectory). One sample is for use with the Microsoft® OLE DB Provider for DB2 (source files located in the DRDA_VBS subdirectory).

This web client application allows you to open a connection through the OLE DB Provider, open a recordset, and browse the records of a host file.

In order to use this sample, the ConnectionString property will need to be changed to point to a host you can access and a data file or DB2 database to browse on the host.

Active Server Pages Samples

The SDK\Samples\DataAccess folder contains an Active Server Pages sample web server application designed to access data provided by an OLE DB provider. Two versions of this sample application are supplied. One sample is for use with the Microsoft® OLE DB Provider for AS/400 and VSAM (source files located in the RLIO_ASP subdirectory). One sample is for use with the Microsoft® OLE DB Provider for DB2 (source files located in the DRDA_ASP subdirectory).

These sample applications require Microsoft Internet Information Server version 3.0 or higher with Active Server Pages installed.

REPORT.ASP will return and display the first ten (10) records in a host file to a client browser in a table view.

OLEDBDDM.ASP and GLOBAL.ASA combine to display columns of a host file in a form view.

You will need to edit the host table names or DB2 database names in order to use these samples in your environment.

OLE DB RowsetViewer Sample

The Microsoft® Data Access SDK and the Microsoft Developer Network (MSDN) Platform SDK contain an OLE DB RowsetViewer sample application written in C++. This application allows you to connect to either the Microsoft OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2, open a table window, type the host file name or DB2 database, return a rowset, and browse the contents. You can navigate the table, using seek and set range on indexed files when this sample is used with the OLE DB Provider for AS/400 and VSAM.

To open a rowset using the OLE DB Provider for AS/400 and VSAM, type the following command in the command window:

```
exec open library/filename
```

You can use "/" or "." depending on whether you are accessing a host mainframe or an AS/400 file. Note that if a "." appears in the host filename, then the filename must be enclosed in double quotes.

This sample is written to access bookmarkable AS/400 and VSAM file types only. You will not be able to access mainframe SAM, ESDS, PDS/PDSE because these data set types do not support bookmarks.

You may not be able to build this sample application, if certain OLE DB header and library files are not installed. The Microsoft® Host Integration Server 2000 CD-ROM does not include a copy of the Microsoft Data Access SDK (DASDK) or the earlier OLE DB SDK. If you do not have the Data Access SDK or the OLE DB SDK installed, then you need to copy the following header files from the Microsoft Platform SDK into your project.

```
adoid.h
adoint.h
db2oledb.h
msdadc.h
msdaguid.h
msdasql.h
oledb.h
oledberr.h
snaoledb.h
transact.h
```

If you do not have the Data Access SDK or the Platform SDK installed, then you will need to build your application using one of the following library files copied from the Microsoft Platform SDK.

```
OLEDB.LIB
OLEDBD.LIB (debug version of OLEDB library)
```

Note that only i386 LIB files are supported using Host Integration Server 2000. On the Microsoft® SNA Server 4.0 CD-ROM, different OLE DB LIB files are supplied for i386 and Alpha processors.

Sample Programs for Data Queues

The source code for several sample programs that illustrate using the Microsoft® Data Queue ActiveX Control are included on the Microsoft® Host Integration Server 2000 CD-ROM and as part of the Microsoft Developer Network (MSDN) Platform SDK. These sample programs are located in the \SDK\Samples\DataQueues subdirectory on the Host Integration Server 2000 CD-ROM. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\DataQueues subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Host Integration Server SDK, by default).

When installed as part of the MSDN Platform SDK, these samples are located under the Samples\NetDS\HIS\DataQueues subdirectory below where the MSDN Platform SDK has been installed (C:\Program Files\Microsoft SDK, by default).

These sample programs include the files in the following subdirectories:

Subdirectory	**Description**
DQChatC	A chat program written in Microsoft® Visual C++ that illustrates using the Data Queue ActiveX Control and AS/400 data queues.
DQChatB	A chat program written in Microsoft Visual Basic that illustrates using the Data Queue ActiveX Control and AS/400 data queues.

The DQChatC sample is designed to be built using Microsoft® Visual C/C++ 6.0 or later using the command-line compiler or using the Microsoft® Visual Studio 6.0 or Microsoft® Visual Studio .NET interactive development environment (IDE). To build the DQChatC sample using the command-line compiler, set up your build environment as follows:

- Run VCVARS32.bat (for VS6) or VSVARS32.bat (for VS.NET) from the Visual Studio bin directory(by default, C:\Program Files\Microsoft Visual Studio\VC98\Bin for VS6 or C:\Program Files\Microsoft Visual Studio .NET\Common7\Tools for VS.NET))

To build the DQChatC sample, open an MS-DOS Command Prompt window, navigate to DataQueues\DQChatC subdirectory, and invoke NMAKE.

To build the DQChatC using the Visual Studio .NET IDE, start Microsoft Visual Studio .NET 7.0 and open the appropriate Visual C++ 7.0 project file (DataQueues\DQChatC\dqchatc.vcproj) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each VC7 project file has two configurations, one for a DEBUG build and one for a RETAIL build.

DQChatC Sample

The sample program DQChatC is a Microsoft Visual C++ program that demonstrates the use of Data Queues in the form of an Internet "chat room". Data, in the form of messages or "chat" strings, is transferred back and forth through a data queue. The DQChatC program was created using the Visual C++ AppWizard.

The files initially created by AppWizard included for this sample program are:

- DQChatC.dsp

  The Visual C++ project file used to build this sample. Other users can share the project (.dsp) file, but they should export any makefiles locally.

- DQChatC.h

  This is the main header file for the application. It includes other project specific headers (including Resource.h) and declares the CDQChatCApp application class.

- DQChatC.cpp

  This is the main application source file that contains the application class CDQChatCApp.

- DQChatC.rc

  This is a listing of all of the Microsoft Windows resources that the program uses. It includes the icons, bitmaps, and cursors that are stored in the RES subdirectory. This file can be directly edited in Microsoft Visual C++.

- DQChatC.clw

  This file contains information used by the Visual C++ ClassWizard to edit existing classes or add new classes. ClassWizard also uses this file to store information needed to create and edit message maps and dialog data maps and to create prototype member functions.

- DQChatCDlg.h, DQChatCDlg.cpp - the dialog

  These files contain your CDQChatCDlg class. This class defines the behavior of your application's main dialog. The dialog's template is in DQChatC.rc, which can be edited in Microsoft Visual C++.

- eigdataqueue.cpp

  This source file contains machine generated IDispatch wrapper classes created by Microsoft Visual C++.

- eigdataqueue.h

  This header file contains machine generated IDispatch wrapper classes created by Microsoft Visual C++.

- StdAfx.h, StdAfx.cpp

  These files are used to build a precompiled header (PCH) file named DQChatC.pch and a precompiled types file named StdAfx.obj used by Visual C++.

- Resource.h

  This is the standard header file, which defines new resource IDs. Microsoft Visual C++ reads and updates this file.

The following files are located in the DataQueues\DQChatC\res subdirectory:

- DQChatC.ico

  This is an icon file, which is used as the application's icon. This icon is included by the main resource file DQChatC.rc.

- res\DQChatC.rc2

  This file contains resources that are not edited by Microsoft Visual C++. All resources that are not able to be edited should be placed in this file.

Sample Programs for Host File Transfer

The source code for several sample programs that illustrate using the Microsoft® Host File Transfer ActiveX Control are included on the Microsoft® Host Integration Server 2000 CD-ROM and as part of the Microsoft Developer Network (MSDN) Platform SDK. These sample programs are located in the \SDK\Samples\FileTransfer subdirectory on the Host Integration Server 2000 CD-ROM. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\FileTransfer subdirectory below where the Host Integration Server software is installed (C:\Program Files\Host Integration Server SDK, by default).

When installed as part of the MSDN Platform SDK, these samples are located under the Samples\NetDS\HIS\FileTransfer subdirectory below where the MSDN Platform SDK has been installed (C:\Program Files\Microsoft SDK, by default).

These sample programs include the files in the following subdirectories:

Subdirectory	Description
TestConnectC	A sample script written in Microsoft® Visual C++ using the Host File Transfer ActiveX Control.
TestConnectVB	A sample program written in Microsoft® Visual Basic® using the Host File Transfer ActiveX Control.

The TestConnectC sample is designed to be built using Microsoft® Visual C/C++ 6.0 or later using the command-line compiler or using the Microsoft® Visual Studio 6.0 or Microsoft® Visual Studio .NET interactive development environment (IDE). To build the TestConnectC sample using the command-line compiler, set up your build environment as follows:

- Run VCVARS32.bat (for VS6) or VSVARS32.bat (for VS.NET) from the Visual Studio bin directory(by default, C:\Program Files\Microsoft Visual Studio\VC98\Bin for VS6 or C:\Program Files\Microsoft Visual Studio .NET\Common7\Tools for VS.NET))

To build the TestConnectC sample, open an MS-DOS Command Prompt window, navigate to FileTransfer\TestConnectC subdirectory, and invoke NMAKE.

To build the TestConnectC using the Visual Studio .NET IDE, start Microsoft Visual Studio .NET 7.0 and open the appropriate Visual C++ 7.0 project file (FileTransfer\TestConnectC\testconnectc.vcproj) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each VC7 project file has two configurations, one for a DEBUG build and one for a RETAIL build.

SNA Application Programming

This section describes how to create applications in a Systems Network Architecture (SNA) environment.

This section contains:

- APPC Applications
- CPI-C Applications
- LUA Applications
- 3270 Emulator Interface Specifications
- AFTP File Transfer Protocol

APPC Applications

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information required to develop C-language applications that use Advanced Program-to-Program Communications (APPC) to exchange data in a Systems Network Architecture (SNA) environment.

This section contains:

About the APPC Guide

This section of the *Microsoft Host Integration Server 2000 Developer's Guide* provides information required to develop C-language applications that use Advanced Program-to-Program Communications (APPC) to exchange data in a Systems Network Architecture (SNA) environment.

This guide is intended for the programmer writing applications that use CPI-C to exchange data. It provides conceptual information and detailed reference information.

To use this guide effectively, you should be familiar with:

- Microsoft® Host Integration Server 2000
- One of the following operating environments:
    - Microsoft Windows® 2000
    - Microsoft Windows NT®
    - Microsoft Windows 98
    - Microsoft Windows 95
- SNA concepts

Operating Systems Support for APPC Development

This section of the guide contains information relating to following operating systems:

- Microsoft® Windows® 2000
- Microsoft Windows NT®
- Microsoft Windows 98
- Microsoft Windows 95
- Microsoft Windows version 3.*x*
- Microsoft MS-DOS®
- OS/2

Microsoft Host Integration Server 2000 supports the development of APPC applications for Windows 2000, Windows NT, Windows 98, and Windows 95. Under these operating systems, support for APPC applications is provided only for the Win32® subsystem.

The previous Microsoft SNA Server product also supported the development of APPC applications for Windows 3.*x*, MS-DOS, and OS/2. Most APPC applications developed for Windows 3.x, MS-DOS, and OS/2 with SNA Server can be used with Host Integration Server 2000. The Windows 3.x, MS-DOS, and OS/2 interface is described here for completeness, but Windows 3.x, MS-DOS, or OS/2 APPC application development is not supported using Host Integration Server.

Finding Further Information

This guide does not describe the products, architectures, or standards developed by other companies or organizations. For information about the Microsoft® Windows® graphical environment, Windows NT®, Windows 95, Windows 98, and the MS-DOS® and IBM OS/2 operating systems, consult your product documentation.

The following documents provide additional information about SNA Server APIs:

- *Microsoft Host Integration Server CPI-C Programmer's Guide*
- *Microsoft Host Integration LUA Programmer's Guide*

For more information about SNA and about 3270 information display systems, see the following manuals:

- *IBM 3270 Information Display System: 3274 Control Unit Description and Programmer's Guide*
- *IBM 3270 Information Display System: Color and Programmed Symbols*
- *IBM 3270 Information Display System: 3274 Control Unit Display Station: Operator's Guide*

APPC Programmer's Guide

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information about programming the Advanced Program-to-Program Communications (APPC) in a distributed processing environment.

This section contains:

Introduction to APPC

This section introduces the fundamental concepts of Advanced Program-to-Program Communications (APPC) in a distributed processing environment. These concepts include:

- APPC verbs
- Microsoft® Windows® APPC extensions
- Using APPC verbs in C programs
- Operating system considerations

Detailed descriptions of APPC verbs are provided in APPC Management Verbs, APPC TP Verbs, and APPC Conversation Verbs.

APPC is an application programming interface (API) that allows peer-to-peer communications in a Systems Network Architecture (SNA) environment. Through APPC, programs distributed across a network can work together, communicating with each other and exchanging data, to accomplish a single processing task such as querying a remote database, copying a remote file, or sending and receiving electronic mail.

APPC Verb Overview

APPC verbs fall into three categories: management, transaction program (TP), and conversation.

Management Verbs

Management verbs provide management functions. They are:

ACTIVATE_SESSION

CNOS

DEACTIVATE_SESSION

DISPLAY

TP Verbs

TP verbs start and end TPs, and get and set TP properties. They are:

GET_TP_PROPERTIES

SET_TP_PROPERTIES

TP_ENDED

TP_STARTED

Conversation Verbs

Conversation verbs enable TPs to allocate and deallocate conversations, send and receive data, and change conversation states. The conversation verbs are listed in the following table.

Conversation verbs fall into two groups: mapped conversation verbs and basic conversation verbs. The mapped conversation is intended for programs that use the conversation directly. The basic conversation is intended for more complex programs that provide services to other users. In typical situations, end-user TPs use mapped conversations and service TPs use basic conversations.

Mapped conversation verbs can only be issued by a TP in mapped conversations, while basic conversation verbs are reserved for basic conversations. There is one exception to this rule: **ALLOCATE** can be used to start either a basic or a mapped conversation.

Mapped conversation verbs	Basic conversation verbs
MC_ALLOCATE	**ALLOCATE**
MC_CONFIRM	**CONFIRM**

MC_CONFIRMED	**CONFIRMED**
MC_DEALLOCATE	**DEALLOCATE**
MC_FLUSH	**FLUSH**
MC_GET_ATTRIBUTES	**GET_ATTRIBUTES**
GET_LU_STATUS	**GET_LU_STATUS**
GET_STATE	**GET_STATE**
GET_TYPE	**GET_TYPE**
MC_POST_ON_RECEIPT	**POST_ON_RECEIPT**
MC_PREPARE_TO_RECEIVE	**PREPARE_TO_RECEIVE**
RECEIVE_ALLOCATE	**RECEIVE_ALLOCATE**
MC_RECEIVE_AND_POST	**RECEIVE_AND_POST**
MC_RECEIVE_AND_WAIT	**RECEIVE_AND_WAIT**
MC_RECEIVE_IMMEDIATE	**RECEIVE_IMMEDIATE**
MC_RECEIVE_LOG_DATA	**RECEIVE_LOG_DATA**
MC_REQUEST_TO_SEND	**REQUEST_TO_SEND**
MC_SEND_CONVERSATION	**SEND_CONVERSATION**
MC_SEND_DATA	**SEND_DATA**
MC_SEND_ERROR	**SEND_ERROR**
MC_TEST_RTS	**TEST_RTS**

Mapped and basic verbs have the same functions in their respective types of conversation. For example, **MC_CONFIRM** performs the same function in a mapped conversation that **CONFIRM** performs in a basic conversation.

APPC Verb Summary

This section briefly describes each APPC verb, grouped by function.

Verbs for Starting Conversations

ALLOCATE or MC_ALLOCATE
: Issued by the local TP. This verb allocates a session between the local logical unit (LU) and a partner LU, and establishes a conversation between the local TP and the partner TP.

  ALLOCATE can establish either a basic or a mapped conversation. **MC_ALLOCATE** can start only a mapped conversation. After the conversation is allocated, APPC uses this verb to return a conversation identifier (**conv_id**).

RECEIVE_ALLOCATE
: Issued by the partner TP. This verb confirms that the partner TP is ready to begin a conversation with the local TP that issued **ALLOCATE** or **MC_ALLOCATE**. Upon successful execution, this verb returns a TP identifier (**tp_id**) for the partner TP and the **conv_id**.

TP_STARTED
: Issued by the local TP. This verb notifies APPC that the local TP is starting. Upon successful execution, this verb returns a **tp_id** for the local TP.

Verbs for Sending Data

CONFIRM or MC_CONFIRM
: Sends the contents of the local LU's send buffer and a confirmation request to the partner TP.

FLUSH or MC_FLUSH
: Flushes the local LU's send buffer, sending the contents of the buffer to the partner LU and TP. If the send buffer is empty, no action takes place.

PREPARE_TO_RECEIVE or MC_PREPARE_TO_RECEIVE
: Changes the state of the conversation from SEND to RECEIVE. Before changing the conversation state, this verb performs the equivalent of **FLUSH**, **MC_FLUSH**, **CONFIRM**, or **MC_CONFIRM**. After this verb has successfully executed, the local TP can receive data.

REQUEST_TO_SEND or MC_REQUEST_TO_SEND
: Informs the partner TP that the local TP wants to send data. The local TP must wait until the partner TP issues

PREPARE_TO_RECEIVE, **MC_PREPARE_TO_RECEIVE**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT**, and the conversation state changes to RECEIVE for the partner TP, before the local TP begins sending data.

SEND_DATA or MC_SEND_DATA

Puts data in the local LU's send buffer for transmission to the partner TP.

The data collected in the local LU's send buffer is transmitted to the partner LU and partner TP when one of the following occurs:

- The send buffer fills up.
- The local TP issues FLUSH, MC_FLUSH, CONFIRM, MC_CONFIRM, DEALLOCATE, MC_DEALLOCATE, or another verb that flushes the local LU's send buffer.

Verbs for Receiving Data

POST_ON_RECEIPT or MC_POST_ON_RECEIPT (Microsoft® Windows 2000, Microsoft Windows NT®, Microsoft Windows® 98, and Microsoft Windows® 95 operating systems only)

Issuing this verb allows the application to register to receive a notification when data or status arrives at the local LU without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state.

When the TP issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied, the Win32® event specified as a parameter is signalled and the verb completes. Then the TP looks at the return code in the verb control block to determine whether or not any data or status notification has arrived at the local LU and issues a **RECEIVE_IMMEDIATE** or **RECEIVE_AND_WAIT** verb to actually receive the data or status notification.

This verb is only supported by Host Integration Server 2000 or by SNA Server 3.0 with Service Pack 1 or later when the APPC applications are running on Windows 2000, Windows NT 4.0, Windows 98, or Windows 95.

RECEIVE_AND_POST or MC_RECEIVE_AND_POST (Windows 2000, Windows NT, Windows 98, Windows 95, and OS/2 operating systems only)

Issuing this verb while the conversation is in RECEIVE state changes the conversation state to PENDING_POST and causes the local TP to receive data asynchronously. This allows the local TP to proceed with processing while data is still arriving at the local LU.

Issuing this verb while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to PENDING_POST. The local TP then begins to receive data asynchronously.

RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT

Issuing this verb while the conversation is in RECEIVE state causes the local TP to receive any data that is currently available from the partner TP. If no data is available, the local TP waits for data to arrive.

Issuing this verb while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to RECEIVE. The local TP then begins to receive data.

RECEIVE_IMMEDIATE or MC_RECEIVE_IMMEDIATE

Receives any data that is currently available from the partner TP. If no data is available, the local TP does not wait.

TEST_RTS or MC_TEST_RTS

Determines whether a **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND** or notification has been received.

Verbs for Confirming Data or Reporting Errors

CONFIRMED or MC_CONFIRMED

Replies to a confirmation request from the partner TP. It informs the partner TP that the local TP has received and processed the data without error.

RECEIVE_LOG_DATA or MC_RECEIVE_LOG_DATA

Issuing this verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another buffer (that is, until the TP issues another **RECEIVE_LOG_DATA** or **MC_RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all).

This verb is only supported by Host Integration Server 2000 or by SNA Server 3.0 with Service pack 1 or later when the APPC applications are running on Windows 2000, Windows NT 4.0, Windows 98, and Windows 95.

SEND_CONVERSATION or MC_SEND_CONVERSATION

Issued by the invoking TP, this verb allocates a session between the local LU and partner LU, sends data on the session, and then deallocates the session.

SEND_ERROR or MC_SEND_ERROR
Notifies the partner TP that the local TP has encountered an application-level error.

Verbs for Getting and Setting Information

GET_ATTRIBUTES or MC_GET_ATTRIBUTES
Used by a TP to get the attributes of the conversation.

GET_LU_STATUS
Used to report the status of a particular remote LU.

GET_STATE
Used by a TP to interrogate the state of a particular conversation.

GET_TP_PROPERTIES
Returns attributes of the TP and the current transaction.

GET_TYPE
Used by a TP to determine the conversation type (basic or mapped) of a particular conversation. With this information, the TP can decide whether to issue basic or mapped conversation verbs.

SET_TP_PROPERTIES
Used to set the attributes of the TP and the current transaction.

Verbs that Provide Management Functions

ACTIVATE_SESSION
Activates a session between the local LU and a specified partner LU, using a specified mode.

This APPC verb is only supported by applications running on Windows 2000, Windows NT, Windows 98, and Windows 95.

CNOS (Change Number of Sessions)
Establishes APPC LU 6.2 session limits.

DEACTIVATE_SESSION
Deactivates a particular session, or all sessions on a particular mode.

This APPC verb is only supported by APPC applications running on Windows 2000, Windows NT, Windows 98, and Windows 95.

DISPLAY
Returns configuration information and current operating values for the SNA node.

Verbs for Ending Conversations

DEALLOCATE or MC_DEALLOCATE
Deallocates a conversation between two TPs. Before deallocating the conversation, this verb performs the equivalent of **FLUSH**, **MC_FLUSH**, **CONFIRM**, or **MC_CONFIRM**.

TP_ENDED
Issued by both the local and partner TPs. It notifies APPC that the TP is ending. Issuing this verb also terminates any active conversations.

Windows APPC Overview

A Windows SNA standard was created to provide one common API to port applications from various operating environments to Microsoft® Windows NT®, Windows® 95, and Windows version 3.*x*. As a direct result of this work, Windows APPC was developed.

The information provided in this guide is source code and executable code compatible with the following implementations of APPC:

- APPC applications based on Host Integration Server 2000 or SNA Server residing on the server or on a client. These applications can be running on Windows 2000, Windows NT, Windows 98, Windows 95, Windows 3.x, MS-DOS®, or OS/2.

- IBM APPC Extended Services for OS/2 version 1.0.

Programs written to use this implementation of APPC can exchange data with programs written to use other implementations of APPC that adhere to the SNA LU 6.2 architecture.

The use of the Windows APPC interface on Windows 2000, Windows NT, Windows 98, Windows 95, and OS/2 will cause additional threads to be created within the calling process. These other threads perform interprocess communication with the Host Integration Server 2000 or SNA Server service over the LAN interface that the client is configured to use (TCP/IP, IPX/SPX, or named pipes, for example).

If an application using Windows APPC is running on Windows 2000 or Windows NT, stopping the SNABASE service will cause the application to be unloaded from memory.

Windows APPC Asynchronous Support

A program that issues a call and does not regain control until the call completes cannot perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients. Asynchronous call completion returns the initial call immediately so the application can continue with other processes.

Microsoft® Host Integration Server 2000 or SNA Server uses the **RegisterWindowsMessage** function for asynchronous support for APPC applications. With "WinAsyncAPPC" as the input string, an application passes a window handle by which it can be notified of verb completion. The application then issues the verb. When the verb completes, a message is posted to the window handle that was passed, notifying the application that the verb is complete.

With the exception of asynchronous RECEIVE_AND_WAIT, MC_RECEIVE_AND_WAIT, RECEIVE_AND_POST, and MC_RECEIVE_AND_POST, which can issue certain other verbs while pending, a conversation can have only one incomplete operation at any time.

APPC Verbs and Windows Extensions

This topic describes the APPC verbs and Windows extensions that are supported by Host Integration Server 2000 and SNA Server:

APPC Verbs

The following APPC verb descriptions contain important features and should be read before using this version of Windows APPC.

ALLOCATE or MC_ALLOCATE

Issued by the invoking TP, this verb allocates a session between the local LU and partner LU and (in conjunction with RECEIVE_ALLOCATE) establishes a conversation between the invoking TP and the invokable TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

For a user or group using TPs, 5250 emulators, or APPC applications, you can assign default local and remote LUs. In this case, the field for LU alias is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information on using default LUs, see the *Network Integration Services* section of the Microsoft Host Integration Server 2000 online guide.

For Windows version 3.*x* systems, it is recommended that you use WinAsyncAPPC rather than the blocking version of these calls.

RECEIVE_ALLOCATE

Issued by the invokable TP to confirm that it is ready to begin a conversation with the invoking TP that issued ALLOCATE or MC_ALLOCATE. This must be the first APPC verb issued by the invokable TP. The initial state is RESET. If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RECEIVE.

RECEIVE_AND_POST or MC_RECEIVE_AND_POST

Receives application data and status information asynchronously. This allows the local TP to proceed with processing while data is still arriving at the local LU. **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** are only supported by the Windows NT, Windows 95, and OS/2 operating systems. For similar functionality under the Windows version 3.*x* system, use **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** in conjunction with WinAsyncAPPC.

While an asynchronous **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** is outstanding, the following verbs can be issued:

REQUEST_TO_SEND or **MC_REQUEST_TO_SEND**

GET_TYPE

GET_ATTRIBUTES or **MC_GET_ATTRIBUTES**

TEST_RTS or **MC_TEST_RTS**

DEALLOCATE

SEND_ERROR or **MC_SEND_ERROR**

TP_ENDED

RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT

Receives any data that is currently available from the partner TP. If no data is currently available, the local TP waits for data to arrive. For Windows version 3.*x* systems, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

RECEIVE_AND_WAIT and **MC_RECEIVE_AND_WAIT** have been altered to act like **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST**. While an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** is outstanding, the following verbs can be issued:

REQUEST_TO_SEND or **MC_REQUEST_TO_SEND**

GET_TYPE

GET_ATTRIBUTES or **MC_GET_ATTRIBUTES**

TEST_RTS or **MC_TEST_RTS**

DEALLOCATE

SEND_ERROR or **MC_SEND_ERROR**

TP_ENDED

TP_STARTED

Issued by the invoking TP, this verb notifies APPC that the TP is starting. For a user or group using TPs, 5250 emulators, or APPC applications, you can assign default local and remote APPC LUs. These default LUs are accessed when the user or group member starts an APPC program (a TP, 5250 emulator, or APPC application) and the program does not specify LU aliases. For more information on using default LUs, see the *Network Integration Services* section of the Microsoft Host Integration Server 2000 online guide.

Windows Extensions

Windows APPC provides a complete set of Windows extensions that allow asynchronous communication using Windows version 3.*x*. These extensions provide maximum programming compatibility between Windows 2000, Windows NT, Windows 98, Windows 95, and Windows version 3.*x*. They include the following:

WinAPPCCancelAsyncRequest

Cancels an outstanding **WinAsyncAPPC**-based request.

WinAPPCCancelBlockingCall

Cancels any outstanding blocking operation for its thread.

WinAPPCCleanup

Terminates and deregisters an application from a Windows APPC implementation. When an application is finished, it must call this function to deregister itself from a Windows APPC implementation.

WinAPPCIsBlocking

Determines if a thread is executing while waiting for a previous blocking call to finish.

WinAPPCSetBlockingHook

Allows a Windows APPC implementation to block APPC function calls by means of a new function. This call is used by Windows version 3.*x* applications to make blocking calls without blocking the rest of the system. Blocking procedures apply only if you do not use asynchronous calls. If a function needs to block, the blocking procedure is called repeatedly until the original request completes. This allows Windows to continue to run while the original application waits for the call to return. Note that while inside the blocking procedure, the application can be re-entered.

WinAPPCSetBlockingHook is used by Windows version 3.*x* applications that go into a **PeekMessageLoop** to make blocking calls without blocking the rest of the system.

By default, Windows NT, Windows 95, and Windows 98 do not go into a **PeekMessageLoop**; they actually block on an event waiting for the call to complete. The only time you need to use **WinAPPCSetBlockingHook** on Windows 2000, Windows NT, Windows 98, or Windows 95 is when a single-threaded application for these systems and Windows version 3.*x* share common source code. In this case, you must explicitly make this call. This is in contrast with the **WinAPPCIsBlocking** and **WinAPPCUnhookBlockingHook** functions.

WinAPPCStartup

Registers an application and specifies the version of Windows APPC required. An application must call this extension to register itself with a Windows APPC implementation before issuing any further Windows APPC calls.

WinAPPCUnhookBlockingHook

Removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism.

WinAsyncAPPC

Provides an asynchronous version for all of the APPC verbs. It is recommended that you use this extension instead of the blocking versions of the verbs if you run your application under Windows version 3.*x*. APPC verbs that can block are:

ALLOCATE or **MC_ALLOCATE**

CONFIRM or **MC_CONFIRM**

CONFIRMED or **MC_CONFIRMED**

DEALLOCATE or **MC_DEALLOCATE**

FLUSH or **MC_FLUSH**

PREPARE_TO_RECEIVE or **MC_PREPARE_TO_RECEIVE**

RECEIVE_ALLOCATE

RECEIVE_AND_WAIT or **MC_RECEIVE_AND_WAIT**

REQUEST_TO_SEND or **MC_REQUEST_TO_SEND**

SEND_CONVERSATION or **MC_SEND_CONVERSATION**

SEND_DATA or **MC_SEND_DATA**

SEND_ERROR or **MC_SEND_ERROR**

TP_ENDED

TP_STARTED

Limits

Host Integration Server 2000 and SNA Server permit one outstanding Windows APPC asynchronous call per connection and one blocking verb per thread. For example:

```
void ProcessVerbCompletion (WPARAM wParam, LPARAM lParam)
{
    int i;

    for (i = 0; i < nPendingVerbs; i++)
        if (pPendingVerbs[i].hAsync == wParam)
            ProcessVCB( (LPVCB) lParam);
}    . . .

LRESULT CALLBACK SampleWndProc ( ... )
{
    if (msg == uAsyncAPPC) {
        ProcessVerbCompletion(wParam; lParam);
    }
        else switch (msg) {
        case WM_USER:
            if (hAsync = WinAsyncAPPC(hwnd, &vcb))
               pPendingVerbs [nPendingVerbs++].hAsync = hAsync;

            break;
    }
```

```
}

WinMain ( ... )
{
    if ( ( WinAPPCStartup ( ...) = = FALSE ) {
    return FALSE ;

    }

    uAsyncAPPC = RegisterWindowsMessage ("WinAsyncAPPC") ;
    while (GetMessage ( ...)  )  {

    ...
    WinAPPCCleanup ( ... )

}
```

> **Note** The exceptions to the rule of one outstanding asynchronous call are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT. While these verbs are outstanding, certain other verbs can also be called.

Using APPC Verbs in C Programs

This implementation of APPC is available for programs written in Microsoft® C version 5.1 or later. A C program calls APPC through the external function **APPC**. For compatibility with previous versions of Microsoft C, the external function **APPC_C** is also supported.

> **Note** Compilers other than the Microsoft C compiler can also be used to build applications using this implementation of APPC.

Verb Control Block

The only parameter passed to the **APPC** function is the address of a verb control block (VCB). The VCB is a structure made up of variables that:

- Identify the APPC verb to be executed.
- Supply information to be used by the verb.
- Contain information returned by the verb when execution is complete.

Each APPC verb has its own VCB structure, which is declared in the WINAPPC.H header file. For compatibility with earlier versions, the APPC_C.H header file is also supported.

The WINAPPC.H file is supplied as part of the Host Integration Server 2000 or SNA Server Software Development Kit.

APPC Definition

The prototype definitions of the **APPC** function are as follows:

```
void WINAPI APPC(long);
HANDLE WINAPI WinAsyncAPPC (hWnd, LPAPPC);
```

The VCB address parameter, a 32-bit pointer, is declared as a long integer and thus requires casting from a pointer to a long integer.

Issuing an APPC Verb

The following procedure is required to issue a blocking APPC verb. In the sample code, the verb issued is **MC_SEND_DATA**.

To issue a blocking APPC verb

1. Create a structure variable from the VCB structure that applies to the APPC verb to be issued.

```
#include <winappc.h>
    .
    .
struct mc_send_data  mcsend;

The VCB structures are declared in WINAPPC.H; one of these structures is:
mc_send_data
```

2. Clear (set to zero) the variables within the VCB structure.

```
memset( mcsend, '\0', sizeof( mcsend ) );
```

3. Assign values to the VCB variables that supply information to APPC.

```
mcsend.opcode = AP_M_SEND_DATA;
mcsend.opext = AP_MAPPED_CONVERSATION;
memcpy( mcsend.tp_id, tp_id, sizeof( tp_id ) );
mcsend.conv_id = conv_id;
mcsend.dlen = datalen;
mcsend.dptr = sharebufptr;
```

4. The values AP_MAPPED_CONVERSATION and AP_M_SEND_DATA are symbolic constants representing integers. These constants are defined in WINAPPC.H.

5. Invoke the **APPC** function. The only parameter is a pointer to the address of the structure containing the VCB for the desired verb.

```
APPC ( ( long ) (void FAR * ) &mcsend );
```

6. Use WinAsyncAPPC if you are running the application under Windows version 3.*x*.

7. To call **WinAsyncAPPC**:

8.
```
HANDLE WINAPI WinAsyncAPPC (hWnd, lpVCB)
```

9. When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncAPPC" as the input string.
10. Use the variables that were returned by APPC.

```
if( mcsend.primary_rc != AP_OK )
/* Do error routine */
    .
    .
    .
```

Windows 2000, Windows NT, Windows 98, and Windows 95 Considerations

This topic summarizes information about developing transaction programs (TPs) using APPC for the Microsoft® Windows® 2000, Windows NT®, Windows 98, and Windows 95 operating systems.

Host Integration Server 2000 with Service Pack 1 runs on the following additional operating systems:

- Microsoft Windows XP Professional

- Microsoft Windows XP Home Edition
- Microsoft Windows Millennium Edition

Byte ordering

The values of constants defined in WINAPPC.H and WINCSV.H are dependent on the byte ordering of the hardware used. Macros are used to set the constants to the correct value.

By default, Intel little-endian byte ordering is used, with the low byte of a 16-bit value followed by the high byte. However, when defining inline macros, the NON_INTEL_BYTE_ORDER macro used in WINAPPC.H and WINCSV.H will not reverse (flip) the byte order for constants. Non-constant input parameters in VCBs (such as lengths, pointers, and so on) are always in the native format.

For example, the primary return code of AP_PARAMETER_CHECK is defined to have a value of 0x0001. Depending on the environment (byte ordering), the constant AP_PARAMETER_CHECK may or may not be 0x0001. Some formats define the value as it appears in memory; others define it as a 2-byte variable. Because you cannot assume that the application will always use provided constants rather than hardwired values, you can define a macro to swap the bytes. The following is an example of using the macro:

```
/* when NON_INTEL_BYTE_ORDER is specified, the APPC_FLIPI macro defined in WINAPPC.H macro b
ecomes */
#define APPC_FLIPI(x)    (x)

/* otherwise this macro flips bytes by defining */
#define APPC_FLIPI(X) APPC_MAKUS(APPC_HI_UC(X),APPC_LO_UC(X))

/* the AP_PARAMETER_CHECK macro is now defined using the APPC_FLIPI macro */
#define AP_PARAMETER_CHECK APPC_FLIPI (0X0001)      /* X '0001' */
```

Events

To receive data asynchronously, an event handle is passed in the semaphore field of the VCB. This event must be in the non-signaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

Library names

In order to support the coexistence of Win16 and Win32® API libraries on the same computer, the Win32 DLL names have been changed.

Old DLL names	New DLL names
WINAPPC.DLL	WAPPC32.DLL
WINCSV.DLL	WINCSV32.DLL

The old DLL names should be used for Win32-based applications that are required to run on SNA Server version 2.0. The new DLL names should be used for Win32-based applications that are intended to run only on SNA Server version 2.1 or later and Host Integration Server 2000.

If you intend your Win32-based application to be used with SNA Server version 2.0, you should link with the libraries included with SNA Server version 2.0. Otherwise, use the new libraries provided with SNA Server versions 2.1, 3.0, and 4.0 and provided with Host Integration Server 2000.

Limits

For Windows 2000, Windows NT, Windows 98, and Windows 95, the number of simultaneous CSVs allowed per process is 64. Only one of these verbs per thread can be synchronous (blocking).

Using APPC, the maximum number of simultaneous conversations per process is 15,000. Each process supports up to 15,000 simultaneous TPs.

Multiple threads

A TP can have multiple threads that issue verbs. Windows APPC makes provisions for multithreaded Windows-based processes. A process contains one or more threads of execution. All references to threads refer to actual threads in the multithreaded Windows 2000, Windows NT, Windows 98, and Windows 95 environments.

With the exception of RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT, only one conversation verb can be outstanding at a time on any conversation; however, other verbs can be issued for other conversations. This guideline also applies to TP verbs and TPs. Although multiple TP verbs can be issued, only one TP verb can be outstanding at a time on a TP. This applies to both multithreaded applications and single-threaded applications that use asynchronous calls.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or DWORD (4-byte) boundaries, whichever is smaller. As a result, DWORDs are aligned on DWORD boundaries, WORDs are aligned on WORD boundaries, and BYTEs are aligned on BYTE boundaries. This means, for example, that there is a 2-byte gap between the primary and secondary return codes. Therefore, the elements in a VCB should only be accessed using the structures provided.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers. For compatibility with the supplied LUA libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Registering and deregistering applications

All Windows APPC applications must call WinAPPCStartup at the beginning of the session to register the application and WinAPPCCleanup at the end of the session to deregister the application.

All Windows CSV applications must call the Windows SNA extension WinCSVStartup at the beginning of the session to register the application and WinCSVCleanup to deregister the application when the session is finished.

Run-time linking

For a TP to be dynamically linked to APPC at run time, the TP must issue the following calls:

- LoadLibrary to load the dynamic-link libraries WINAPPC.DLL or WAPPC32.DLL.
- GetProcAddress to specify APPC on all the desired entry points to the DLL such as APPC, WinAsyncAPPC, WinAPPCStartup, and WinAPPCCleanup.

For a TP to be dynamically linked to CSV at run time, the TP must issue the following calls:

- LoadLibrary to load WINCSV.DLL or WINCSV32.DLL, the dynamic-link libraries for Windows CSV.
- GetProcAddress to specify CSV on all the desired entry points to the DLL such as ACSSVC, WinAsyncCSV, WinCSVStartup, and WinCSVCleanup.

The TP must issue the **FreeLibrary** call when the APPC or CSV library is no longer required.

Yielding to other components

Because the Windows 2000, Windows NT, Windows 98, and Windows 95 environments are multithreaded, there is no need to yield to other components. However, if an application is single-threaded and is intended for both Windows version 3.*x* and these other operating systems, use the Windows extensions WinAPPCSetBlockingHook and WinAPPCUnhookBlockingHook. These extensions must be explicitly called to accomplish the yield procedure.

Windows 3.x Considerations

This topic summarizes information about developing TPs for the Microsoft® Windows® version 3.*x* system.

Blocking routines

Do not use blocking functions if your application runs in Windows version 3.*x*. Instead, use WinAsyncAPPC in conjunction with a **WinAsyncAPPC** Windows message.

Limits

For the Windows version 3.x system, the number of simultaneous CSVs allowed per process is 64. Only one of these verbs per process can be synchronous.

Using APPC, the maximum number of simultaneous conversations per process is 64. Each process supports up to 16 simultaneous TPs.

Load-time linking

For a TP to be dynamically linked to APPC at load time, you must do one of the following at link time:

- Insert the following IMPORTS statements in the definition (.DEF) file used to link the TP:

```
IMPORTS WINAPPC.APPC
IMPORTS WINAPPC WinAsyncAPPC.APPC
```

- Link the TP to WINAPPC.LIB, which contains the entry point linkage information for APPC. If you intend to use CSVs, you must also link to WINCSV.LIB, which contains the entry point information for CSVs.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or WORD (2-byte) boundaries, whichever is smaller. As a result, DWORDs and WORDs are aligned on WORD boundaries and BYTEs are aligned on BYTE boundaries. For portability to Win32, VCBs should be accessed using the structures provided since the alignment of structure members differs.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers producing 16-bit code. For compatibility with the supplied LUA libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

RECEIVE_AND_POST and MC_RECEIVE_AND_POST

These verbs have been replaced for Windows version 3.*x* by calling RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT using WinAsyncAPPC.

Registering and deregistering applications

All Windows APPC applications must call WinAPPCStartup at the beginning of the session to register the application and WinAPPCCleanup at the end of the session to deregister the application.

All Windows CSV applications must call the Windows SNA extension WinCSVStartup at the beginning of the session to register the application and WinCSVCleanup to deregister the application when the session is finished.

Run-time linking

For a TP to be dynamically linked to APPC at run time, the TP must issue the following calls:

- **LoadLibrary** to load WINAPPC.DLL, the dynamic-link library for APPC.
- **GetProcAddress** to specify APPC on all the desired entry points to the DLL such as APPC, WinAsyncAPPC, WinAPPCStartup, and WinAPPCCleanup.

The TP must issue the **FreeLibrary** call when the APPC library is no longer required.

Simultaneous conversations

A TP can participate in as many as 64 conversations simultaneously within the Windows 3.x environment. However, if more than one TP is active at once, the total number of conversations cannot exceed 64.

Translating service TP names to ASCII for WIN.INI

For service TPs on Host Integration Server 2000 or SNA Server clients running Windows version 3.*x*, a line must be added to the WIN.INI file, specifying the TP name in ASCII. For more information, see Translating SNA Service TP Names to ASCII for WIN.INI.

Yielding to other components

Because Windows version 3.*x* is single-threaded, there is only one thread of execution. In the case where a function must wait before completing a task, the only thread of execution could block to allow other tasks to proceed.

This means that while in a blocking call, the calling application's Window procedure can be called. To test if this is the case, the extension WinAPPCIsBlocking is provided. Any attempt to make a second blocking call with one already outstanding will cause the call to fail with the return code AP_THREAD_BLOCKING.

Windows APPC and CSV contain a default yield procedure for Windows version 3.*x* that can yield to other functions while waiting for the first function to complete. The default is:

```
BOOL DefaultBlockingHook (void)  {
    MSG msg:
    /* get the next message if any */
    if ( PeekMessage (&msg,0,0,PM_NOREMOVE)  )   {
if  ( msg.message = = WM_QUIT  )
    return FALSE;   / /  let app process WM_QUIT
PeekMessage  ( &msg,0,0,PM_REMOVE)  ;
TranslateMessage  (&msg)  ;
DispatchMessage  (&msg)  ;
    }
    /*TRUE if no WM_QUIT received */
    return TRUE;
}
```

Besides the default yield procedure, Windows APPC provides WinAPPCSetBlockingHook to support applications that require more complex message processing. This call allows a Windows APPC implementation to block APPC function calls by means of a new function. It is used by Windows version 3.*x* applications to make blocking calls without blocking the rest of the system. To call **WinAPPCSetBlockingHook:**

```
FARPROC WINAPI WinAPPCSetBlockingHook (FARPROC lpBlockFunc)
```

WinAPPCUnhookBlockingHook removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism. To call **WinAPPCUnhookBlockingHook**:

```
BOOL WINAPI WinAPPCUnhookBlockingHook (void)
```

MS-DOS Considerations

This topic summarizes information about developing TPs for the Microsoft® MS-DOS® system.

AS/400 PC Support Router API

MS-DOS support for Windows APPC is handled in one of two ways:

- The call-level interface through the DOSACS.LIB library provided with the Host Integration Server 2000 or SNA Server Software Development Kit
- The software interrupt PC Support Router API

For additional information on the PC Support Router API, see the *IBM PC Support/400 Application Program Interface Reference*, part number SC41-8254.

CSV restrictions when SnaBase is not loaded

If your application uses the Windows-based client or an MS-DOS-based client supplied with Host Integration Server 2000 or SNA Server, and SnaBase has not been loaded, only the following verbs are available:

GET_CP_CONVERT_TABLE

CONVERT

Under these circumstances, **CONVERT** cannot use a type G conversion table. Attempting to use a type G conversion table causes the system to return the SV_TABLE_ERROR primary return code.

Attempting to issue COPY_TRACE_TO_FILE, DEFINE_TRACE, LOG_MESSAGE, or TRANSFER_MS_DATA causes the system to return the SV_COMM_SUBSYSTEM_NOT_LOADED primary return code.

Limits

For the MS-DOS system, only one outstanding CSV verb is allowed per process. Only one outstanding verb per process can be synchronous.

Using APPC, the maximum number of simultaneous conversations per process is 16. Each process supports up to four simultaneous TPs.

Link library

The link library for APPC is DOSACS.LIB.

Packing

For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned on either the size of the member type or WORD (2-byte) boundaries, whichever is smaller. As a result, DWORDs and WORDs are aligned on WORD boundaries and BYTEs are aligned on BYTE boundaries. For portability to Win32, VCBs should be accessed using the structures provided since the alignment of structure members differs.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers producing 16-bit code. For compatibility with the supplied LUA libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Partner TPs

Host Integration Server 2000 or SNA Server invokable TPs cannot be run on MS-DOS-based clients. No support is provided for autostarting MS-DOS partner TPs. The call-level interface contains the same syntax as that of OS/2.

RECEIVE_AND_POST and MC_RECEIVE_AND_POST

These verbs are not available with MS-DOS.

Simultaneous conversation
In an MS-DOS environment, a TP can participate in as many as 16 conversations simultaneously.

SnaBase
When running a TP on a Host Integration Server 2000 or SNA Server MS-DOS-based client, you must use SnaBase, which supports APPC. If you attempt to use something other than SnaBase, your TP will not run.

OS/2 Considerations

This topic summarizes information about developing TPs for the OS/2 system.

Critical sections
Exercise great caution when using critical sections, which are the parts of a program that must run without interruption. A TP must not issue an APPC verb within a critical section.

Data segments
Data is sent from and received in data buffers established by the TP. A data buffer must reside on an unnamed shared data segment and it must fit entirely within the data segment. Many data buffers can reside on the same data segment.

To allocate a data segment, use the **DosAllocSeg** function with *Flags* equal to 1.

To improve efficiency, a TP can reuse the same data segment each time it issues a verb requiring a data buffer. If necessary, the program can allocate a segment of up to 64K and then partition the segment into data buffers.

Limits
For the OS/2 system, only one outstanding CSV verb is allowed per process. Only one outstanding verb per process can be synchronous.

Using APPC, the maximum number of simultaneous conversations per process is 64. Each process supports up to 64 simultaneous TPs.

Load-time linking
For a TP to be dynamically linked to APPC at load time, you must do one of the following at link time:

- Insert the following IMPORTS statement in the definition (.DEF) file used to link the TP:

```
IMPORTS APPC.APPC
```

- Link the TP to APPC.LIB, which contains the entry point linkage information for various APIs, including APPC.

Multiple processes
Multiple processes cannot have the same TP identifier (**tp_id**). Only the process that issues TP_STARTED or RECEIVE_ALLOCATE can use the **tp_id** returned by the verb. Another process that needs to use APPC must issue **TP_STARTED** or **RECEIVE_ALLOCATE** to obtain its own **tp_id**.

Two or more instances of the same TP can be run as different processes, but each will be assigned a different **tp_id**.

One process can contain many TPs, each with its own **tp_id**. In this case, you may want to create a separate thread for each TP to avoid the possibility of a deadlock. (A deadlock occurs when an APPC verb that is hung blocks the execution of verbs in other conversations and TPs.)

A process containing many TPs can issue two or more verbs simultaneously, provided that each verb is for a different TP (specifies a different **tp_id**).

Multiple threads
A TP can have multiple threads that issue verbs. Windows APPC makes provisions for multithreaded processes. A process contains one or more threads of execution. All references to threads refer to actual threads in the multithreaded OS/2 environment.

With the exception of RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT, only one conversation verb can be outstanding at a time on any conversation; however, other verbs can be issued for other conversations. This guideline also applies to TP verbs and TPs. Although multiple TP verbs can be issued, only one TP verb can be outstanding at a time on a TP. This applies to both multithreaded applications and single-threaded applications that use asynchronous calls.

Packing
For performance considerations, the VCBs are not packed. VCB structure member elements after the first element are aligned

on either the size of the member type or WORD (2-byte) boundaries, whichever is smaller. As a result, DWORDs and WORDs are aligned on WORD boundaries and BYTEs are aligned on BYTE boundaries. For portability to Win32, VCBs should be accessed using the structures provided since the alignment of structure members differs.

This option for structure and union member alignment is the default behavior for Microsoft C/C++ compilers producing 16-bit code. For compatibility with the supplied LUA libraries, make sure to use an equivalent structure and union member packing option when using other C/C++ compilers or when explicitly specifying a structure alignment option when using Microsoft compilers.

Run-time linking

For a TP to be dynamically linked to APPC at run time, the TP must issue the following calls:

- DosLoadModule to load APPC.DLL, the DLL for APPC.
- DosGetProcAddr to specify APPC as the desired entry point to the DLL.

Unlinking (the **DosFreeModule** call) is not supported.

Simultaneous conversations

A TP can simultaneously participate in as many as 64 conversations for each OS/2 process.

SNA Server or Host Integration Server CSVs

Applications running on Host Integration Server 2000 or SNA Server using common service verbs (CSVs) are compatible with the common services programming interface provided by IBM ES for OS/2 version 1.0, with the following exceptions:

- VCBs are not packed. As a result, DWORDs and WORDs are on WORD boundaries, and BYTEs are on BYTE boundaries. This means, for example, that there is not a 2-byte gap between the primary and secondary return codes. VCBs should be accessed using the structures provided, and compiler options that change this packing method should be avoided.
- Trace information for products is stored in trace files, not in a storage buffer. With the Host Integration Server 2000 or SNA Server implementation of COPY_TRACE_TO_FILE_sna_COPY_TRACE_TO_FILE_appc, the trace information in these files is copied to a single trace file.
- The additional tracing features of DEFINE_TRACE_sna_DEFINE_TRACE_appc are not applicable because of differences between the architecture of the Host Integration Server 2000 and SNA Server products and the architecture of IBM Communications Manager. The tracing features provided in IBM OS/2 ES version 1.0 include event tracing, automatic tracing, and tracing support for the following:

X.25 API verbs, frame data, and data link control (DLC) data
Twinaxial data

- With the Host Integration Server 2000 or SNA Server implementation of GET_CP_CONVERT_TABLE, user-defined code pages are applicable only in an OS/2 environment. These code pages are supported for only the Windows NT, Windows 95, and OS/2 systems because of the additional memory occupancy in the MS-DOS and Windows environments. The new user-defined code pages are explained in the description of the verb.
- With the Host Integration Server 2000 and SNA Server implementation of TRANSFER_MS_DATA, support for the PD_STATS subvector type is retained.
- **DEFINE_DUMP** and **SET_USER_LOG_QUEUE**, provided in IBM OS/2 ES version 1.0, are not applicable because of differences between the architecture of Host Integration Server 2000 and SNA Server and the architecture of IBM Communications Manager. If either verb is called, INVALID_VERB is returned.

Stack size

The recommended stack size for a TP is at least 3000 bytes.

When executing a verb, APPC uses the calling TP's stack. The combination of OS/2 and APPC requires 2560 bytes of stack space, and the TP requires additional stack space for its variables.

Translating service TP names to ASCII for SNA.INI

For service TPs on Host Integration Server 2000 or SNA Server clients running OS/2, a line must be added to the SNA.INI file, specifying the TP name in ASCII. For more information, see Translating SNA Service TP Names to ASCII for SNA.INI.

VCB segment

The segment containing the VCB must be a writable segment.

About Transaction Programs

A processing task accomplished by programs using APPC is called a transaction. Consequently, programs that use APPC are called transaction programs, or TPs. These programs communicate as peers, on an equal (rather than hierarchical) basis. The TPs use APPC verbs to exchange status information and application data. Each TP uses APPC verbs to supply parameters to APPC, which performs the desired function and returns parameters to the TP.

TPs distributed across a local or wide area network perform distributed transaction processing.

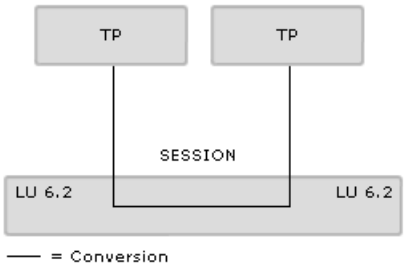
This section describes how to write TPs and how to configure the systems on which TPs run. The topics in this section cover the following general areas:

- Understanding fundamental concepts related to TPs
- Designing and coding TPs
- Configuring registry and environment variables for invokable TPs
- Configuring Microsoft® Host Integration Server 2000 or Microsoft SNA Server 4.0 to work with your TPs
- Sync Point Level 2 support

This section contains:

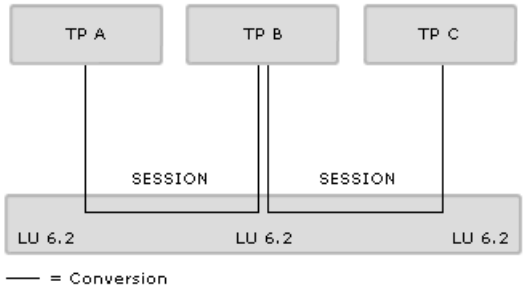
Communication Between TPs

Various hardware and software elements in the SNA environment are required for two TPs to communicate with each other. The following figure shows several fundamental elements.



Each TP is associated with a logical unit (LU) of type 6.2. The LU allows the TP to access the network. Several TPs can be associated with the same LU.

A partner TP can invoke another TP which, in turn, invokes another TP, and so on. In the following figure, TP A invokes TP B and TP B invokes TP C.



This section contains:

- Fundamental Terms for TPs and LUs
- Sample TPs Illustrating Fundamental Concepts
- Configuring and Controlling TPs
- Creating TPs and Their Supporting Configuration

Fundamental Terms for TPs and LUs

The following terms describe some fundamental characteristics of TPs communicating through LUs:

asynchronous verb
An APPC verb for which the initial function call returns immediately, so that the normal operation of the program is not blocked while processing of the verb completes. For more information, see Receiving Data Asynchronously.

basic conversation
A type of conversation more complex than a mapped conversation and generally used by service TPs (SNA-based programs that provide services to other programs). For more information, see Basic and Mapped Conversations Compared.

conversation
The interaction between TPs carrying out a specific task. Each conversation requires an LU-LU session. A TP can be involved in several conversations simultaneously, as shown with TP B in Communication Between TPs.

invokable TP
A TP that can be invoked by another TP. Invokable TPs are usually server-type applications; that is, they work in the same general way that an application such as CICS works. Parameters for an invokable TP are configured through registry or environment variables.

There are several types of invokable TPs:

operator-started invokable TP

A TP that is started manually in preparation for being invoked.

autostarted invokable TP

A TP that is automatically started by APPC when invoked.

queued TP

A TP that, when invoked multiple times, loads once and then queues up subsequent requests to be dealt with one at a time. All operator-started TPs and some autostarted TPs are queued.

nonqueued TP

A TP loaded multiple times, once for every time it is invoked. Some autostarted TPs are nonqueued but no operator-started TPs are nonqueued.

For more information, see Invokable TPs.

invoking TP
A TP that can invoke (that is, initiate a conversation with) other TPs. Invoking TPs are usually client-type applications; that is, they work in the same general way that an emulator works. For more information, see Invoking TPs.

local LU and **local TP**
An LU and TP working together, when viewed as the "home base" for a particular conversation. From this viewpoint, some other LU and TP are seen as the "partner" or "remote" LU and TP.

LU alias
The string that identifies an LU to a TP. The alias can be up to eight characters long.

LU-LU session
The communication between two LUs over a specific connection for a specific amount of time. An LU-LU session is needed for two TPs to interact. One session can be used serially by many pairs of TPs.

An LU 6.2 can have multiple sessions (two or more concurrent sessions with different partner LUs) and parallel sessions (two or more concurrent sessions with the same partner LU).

LUs as well as LU-LU pairs and modes are configured using the SNA Manager on Host Integration Server 2000 and configured using SNA Explorer on SNA Server 4.0.

mapped conversation
A type of conversation simpler than a basic conversation and generally used by application TPs (programs that accomplish tasks for end users). The characters **MC_** at the beginning of a verb stand for mapped conversation. For more information, see Basic and Mapped Conversations Compared.

partner LU and **partner TP**, or **remote LU** and **remote TP**
An LU and TP working together, when viewed as being at the far end of a particular conversation.

synchronous verb
An APPC verb that blocks further program operations until the processing of the verb is complete.

Sample TPs Illustrating Fundamental Concepts

A set of sample TPs is provided on the Host Integration Server and on the SNA Server CD-ROM in the \SDK\SAMPLES directory. Included with the sample code in the \SDK\SAMPLES\SNA\TPSETUP directory on the Host Integration Server CD-ROM is TPSETUP, a program that simplifies the setting of registry or environment variables needed by autostarted invokable TPs. Without an interface like that provided by TPSETUP, configuring such variables can be complicated and error-prone. Therefore, it is recommended that you use code like TPSETUP in installation programs for autostarted invokable TPs.

The source code for TPSETUP (INSTALL.C) can be compiled to work in the Microsoft Windows® 2000, Windows NT®, Windows 98, Windows 95, or Windows version 3.*x* environment.

For information about TPSETUP and about the sample TPs, see Sample APPC TPs in the SDK.

Configuring and Controlling TPs

The following table shows how the characteristics of the TPs and selection of the LUs for a conversation are controlled.

Characteristic	How controlled
Type of verb: synchronous or asynchronous	Written into the code. Synchronous verbs use blocking calls; asynchronous verbs avoid blocking calls. See Receiving Data Asynchronously and WinAsyncAPPC.
Type of conversation: basic or mapped	Written into the code. The **MC_** prefix is used on verbs in mapped conversations and omitted on verbs in basic conversations. For two TPs to communicate successfully, both must use the same type of conversation, basic or mapped. See Basic and Mapped Conversations Compared.
Type of TP: invoking or invokable	Written into the code. Invoking TPs start with TP_STARTED, which identifies the invoking TP, and ALLOCATE or MC_ALLOCATE, which identifies the requested invokable TP. Invokable TPs start with RECEIVE_ALLOCATE, which identifies the invokable TP. See Invoking TPs and Invokable TPs.
The local LU alias to be used by an invoking TP	Three options: • Written into the code in TP_STARTED. • Configured (in Host Integration Server Manager or SNA Explorer) as the default local APPC LU for the user who starts the invoking TP. • Configured as a member of the default outgoing local APPC LU pool using the SNA Manager on Host Integration Server 2000 and using SNA Explorer on SNA Server 4.0 See Configuring Invoking TPs on Host Integration Server and SNA Server.
The invokable TP requested by an invoking TP	Written into the ALLOCATE or MC_ALLOCATE request in the invoking TP.
The LU alias to be used by an invokable TP	Two options: • Written into the invoking TP (not the invokable TP), in ALLOCATE or MC_ALLOCATE. • Configured as the default remote APPC LU for the user who starts the invoking TP. See Configuring Invoking TPs on Host Integration Server and SNA Server and Matching Invoking and Invokable TPs.
Type of autostarted invokable TP: queued or nonqueued	Configured with registry or environment variables. See Configuring Invokable TPs.
Local LU and remote LU aliases	Configured using SNA Manager on Host Integration Server 2000 and configured using SNA Explorer on SNA Server 4.0. For information, see the *Microsoft Host Integration Server 2000 online books*.
The pairing of local and remote LUs, and the mode used for each LU-LU pair	Configured using SNA Manager on Host Integration Server 2000 and configured using SNA Explorer on SNA Server 4.0. For information, see the *Microsoft Host Integration Server 2000 online books*.

Creating TPs and Their Supporting Configuration

The following procedure describes how to create TPs and set up a supporting configuration.

To create TPs and set up a supporting configuration

1. Write, compile, and link each TP.
2. Place each TP on an appropriate computer.

   For TPs that you will start many times or that will be started by a user, arrange for the TP to be started easily. That is, for graphical interfaces, create a program icon for starting the TP; for non-graphical interfaces, make sure the TP is in the path.

3. On one or more servers running Host Integration Server or SNA Server, configure LUs, modes, and LU-LU pairs for use by the TPs.

   For information about how to set up LU-LU pairs to support TPs, see Using Invoking and Invokable TPs and the *Microsoft Host Integration Server 2000 online books*.

4. Set any registry or environment variables needed for the invokable TP.

   For autostarted invokable TPs, it is recommended that you use the sample TP configuration program, TPSETUP, for this step. When you write an installation program for autostarted invokable TPs, it is recommended that you include code similar to TPSETUP.

   For information about registry or environment variables, see Configuring Invokable TPs. For information about TPSETUP, see Sample APPC TPs in the SDK.

5. If the invokable TP is operator-started, start it, or arrange for it to be started when the computer is restarted and then restart the computer.

   If the invokable TP is autostarted, Host Integration Server 2000 will start it when needed.

6. Start the invoking TP.

Designing and Coding TPs

The following topics provide background information about designing and coding TPs.

This section contains:

Conversation States

The state of the conversation (as viewed by a particular TP) governs which APPC verbs can be issued by the TP at a particular time. For example, a TP cannot issue MC_SEND_DATA if the conversation is not in SEND state for that TP.

The state of a conversation depends on the TP from which it is viewed. A local TP can view a conversation as being in SEND state while the partner TP views the conversation as being in RECEIVE state. A particular TP can be in several conversations, each of which is in a different state.

The possible conversation states are summarized here.

CONFIRM
The TP has received a request for confirmation of receipt of data; it must respond positively or send error information to the partner TP.

CONFIRM_DEALLOCATE
The TP has received a request for confirmation; it must respond positively or send error information. If the TP responds positively, the conversation is automatically deallocated.

CONFIRM_SEND
The TP has received a request for confirmation; it must respond positively or send error information. After responding, the TP can begin to send data.

PENDING_POST
The TP is receiving data asynchronously. The TP can perform other processing not related to this conversation.

RECEIVE
The TP can receive application data and status information from the partner TP. When the conversation is in RECEIVE state, the TP can also send error information and request permission to send data.

RESET
The conversation has not started or has been terminated.

SEND
The TP can send data to the partner TP and request confirmation. When the conversation is in SEND state, the TP can also begin to receive data, which changes the state to RECEIVE.

SEND_PENDING
The TP issued a receive verb and the **what_rcvd** parameter returned by that verb indicated both data received and a status indication of SEND. This only affects the use of the **err_dir** parameter for SEND_ERROR and MC_SEND_ERROR_sna_MC_SEND_ERROR_appc. Otherwise, the state is the same as the SEND state.

This section contains:

- State Checks
- Changing Conversation States

State Checks

A state check occurs when a TP issues an APPC verb and the conversation is not in the appropriate state. For example, a state check occurs if a TP issues MC_SEND_DATA_sna_MC_SEND_DATA_appc while the conversation is in RECEIVE state. When a state check occurs, APPC does not execute the verb; it returns state check information through primary and secondary return codes.

Changing Conversation States

A change in the conversation state can result from:

- A verb issued by the local TP.
- A verb issued by the partner TP.
- An error condition.

The following example shows how APPC verbs can change the state of the conversation from SEND to RECEIVE and from RECEIVE to SEND.

> Any TP can send or receive data, regardless of whether it is the invoking TP (the TP that started the conversation) or the invokable TP (the TP that responded to a request to start a conversation).

This example shows how APPC verbs can change the conversation state. In this table, each conversation state appears in bold and precedes the APPC verbs that are used while in that state.

Issued by the invoking TP	**Issued by the invokable TP**
TP_STARTED	
Conversation state: RESET	
MC_ALLOCATE	
(synclevel=AP_CONFIRM_SYNC_LEVL)	
Conversation state: SEND	
MC_SEND_DATA

	(primary_rc=AP_OK)
	(what_rcvd=AP_CONFIRM_DEALLOCATE)
	Conversation state: CONFIRM_DEALLOCATE
	MC_CONFIRMED
Conversation state: RESET	**Conversation state: RESET**
TP_ENDED	TP_ENDED

Initial States

Before the conversation is allocated, the state is RESET for both TPs.

In the example, after the conversation is allocated, the initial state is SEND for the invoking TP and RECEIVE for the invokable TP.

Changing to RECEIVE State

MC_PREPARE_TO_RECEIVE allows a TP to change the conversation from SEND to RECEIVE state. This verb:

- Flushes the local LU's send buffer.
- Sends the AP_CONFIRM_SEND indicator to the partner TP through the what_rcvd parameter of a receive verb. This indicator tells the partner TP that an MC_CONFIRMED response is expected before the partner TP can begin to send data.

Confirmation processing is performed when the following conditions are true:

- The **ptr_type** parameter is set to AP_SYNC_LEVEL.
- The synchronization level of the conversation is set to AP_CONFIRM_SYNC_LEVEL.

For more information about confirmation processing, see Confirmation Processing.

> Issuing MC_RECEIVE_AND_WAIT while the conversation is in SEND state flushes the LU's send buffer and changes the conversation state to RECEIVE. Changing the conversation state in this manner does not support confirmation processing.

Changing to SEND State

MC_REQUEST_TO_SEND informs the partner TP (for which the conversation is in SEND state) that the local TP (for which the conversation is in RECEIVE state) wants to send data. This request is communicated to the partner TP through the **rts_rcvd** parameter of MC_CONFIRM. (The **rts_rcvd** parameter is also returned to MC_SEND_DATA and other verbs.)

When the partner TP issues MC_PREPARE_TO_RECEIVE, the conversation state changes to RECEIVE for the partner TP, making it possible for the local TP to send data.

> Issuing MC_REQUEST_TO_SEND does not change the state of the conversation. Upon receiving a request to send, the partner TP is not required to change the conversation state; it can ignore the request.

Confirmation Processing

The sequence of events for confirmation processing is as follows:

1. Establish the synchronization level.
2. Send a confirmation request.
3. Receive data and confirmation request.
4. Respond to the confirmation request.
5. Deallocate the conversation.

Using confirmation processing, a TP sends a confirmation request with the data; the partner TP confirms receipt of the data or indicates that an error occurred. Each time the two TPs exchange a confirmation request and response, they are synchronized.

> Although the example in this section does not show this, any TP can send or receive data, regardless of whether the TP is the invoking TP or the invokable TP.

The following example illustrates confirmation processing.

Issued by the invoking TP	**Issued by the invokable TP**
TP_STARTED	
MC_ALLOCATE	
(synclevel=AP_CONFIRM_SYNC_LEVEL)	
MC_SEND_DATA	
(type=AP_SEND_DATA_CONFIRM)	
	RECEIVE_ALLOCATE
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_YES)
	(what_rcvd= AP_DATA_COMPLETE_CONFIRM)
	MC_CONFIRMED
MC_SEND_DATA	
(type=AP_SEND_DATA_DEALLOC_SYNC_LEVEL)	
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_YES)
	(what_rcvd= AP_DATA_COMPLETE_CONFIRM_ DEALLOCATE)
	MC_CONFIRMED
TP_ENDED	TP_ENDED

Establishing the Synchronization Level

The **synclevel** parameter of MC_ALLOCATE determines the synchronization level of the conversation. There are three possible synchronization levels:

- AP_NONE, under which confirmation processing does not occur.
- AP_CONFIRM_SYNC_LEVEL, under which the TPs can request confirmation of receipt of data and respond to requests for confirmation of data.
- AP_SYNCPT, under which the TPs operate under Sync Point Level 2 support for confirmation of receipt of data.

Sending a Confirmation Request

MC_SEND_DATA with type AP_SEND_DATA_CONFIRM has two effects:

- It flushes the local LU's send buffer and sends any data contained in the buffer to the partner TP.
- It sends a confirmation request that the partner TP receives through the what_rcvd parameter of a receive verb.

After issuing **MC_SEND_DATA**, the local TP waits for confirmation from the partner TP.

Receiving Data and Confirmation Request

The **what_rcvd** parameter of MC_RECEIVE_AND_WAIT indicates:

- Status of the data received: complete or incomplete.
- Future processing expected of the local TP.

In the example, **what_rcvd** is AP_DATA_COMPLETE_CONFIRM, indicating that the status is complete and a confirmation is requested.

Responding to a Confirmation Request

The partner TP issues MC_CONFIRMED to confirm receipt of data. This frees the local TP to resume processing.

Deallocating the Conversation

MC_SEND_DATA sends a confirmation request with the data when all of the following conditions are true:

- The conversation's synchronization level (established by the **synclevel** parameter of MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL.
- The type parameter of MC_SEND_DATA is set to AP_SEND_DATA_DEALLOC_SYNC_LEVEL.
- The what_rcvd parameter of the final MC_RECEIVE_AND_WAIT is AP_DATA_COMPLETE_CONFIRM_DEALLOCATE, indicating that a confirmation of receipt of data is required before APPC will deallocate the conversation. The local TP waits for this confirmation until the partner TP issues MC_CONFIRMED.

Receiving Data Asynchronously

When using the Windows 2000, Windows NT, Windows 98, Windows 95, Windows version 3.*x*, and OS/2 operating systems, a TP can receive data asynchronously, without regard to other events occurring within the TP. The following table shows the methods by which a TP can receive data asynchronously. The table also indicates how asynchronous methods can be applied to actions other than receiving data.

Operating system	Method
Windows 2000, Windows NT, Windows 98, Windows 95, or Windows 3.*x*	**Through a Windows message:** Issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** with **WinAsyncAPPC**; the application is notified of completion through a **PostMessage** to the defined window handle. This method is not restricted to RECEIVE_AND_WAIT and MC_RECEIVE_AND_WAIT, but can be applied to any APPC verb.
Windows 2000, Windows NT, Windows 98, or Windows 95	**Through a Win32® event:** Issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** with **WinAsyncAPPCEx**; the application is notified of completion through a Win32 event. This method is not restricted to RECEIVE_AND_WAIT and MC_RECEIVE_AND_WAIT, but can be applied to any APPC verb.
Windows 2000, Windows NT, Windows 98, Windows 95, or OS/2	With **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST:** Issue the **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** verb. With OS/2, the application is notified of completion through a semaphore. With Windows NT and Windows 95, the application is notified of completion through a Win32 event (the unsignaled event, not a semaphore, is passed in the **sema** member).

The following list gives details about these methods of receiving data asynchronously. For complete information, see the verb descriptions.

RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT with WinAsyncAPPC
: This method is defined as part of Windows SNA. It allows an application to issue a verb and be notified through a **PostMessage** when the action is complete. To retrieve the message number that will be posted to the window, call **RegisterWindowMessage** with "WinAsyncAPPC" as the input string. Then issue **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** using the **WinAsyncAPPC** entry point.

RECEIVE_AND_WAIT or **MC_RECEIVE_AND_WAIT** with WinAsyncAPPCEx
: This method allows an application to be notified through a Win32 event. This is particularly useful when writing applications that need to service multiple conversations simultaneously. The event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

RECEIVE_AND_POST or MC_RECEIVE_AND_POST
: When using **RECEIVE_AND_POST** or **MC_RECEIVE_AND_POST** with Windows 2000, Windows NT, Window 98, or Windows 95, the application is notified through a Win32 event. The event must be in the nonsignaled state when passed to APPC, and the handle must have EVENT_MODIFY_STATE access to the event.

  When using RECEIVE_AND_POST or MC_RECEIVE_AND_POST with OS/2, the application is notified through a semaphore. Use DosSemSet to set the semaphore; APPC will clear the semaphore when the TP finishes receiving data asynchronously.

While receiving data asynchronously, the TP performs tasks not related to this conversation; the TP cannot issue most APPC verbs until notification is received. For information about the verbs that can be issued, see the descriptions of WinAsyncAPPC or WinAsyncAPPCEx.

After a verb has completed asynchronously, check the primary_rc to find out whether the data was received without error.

> If the initial call to issue the verb returns successfully, the application is guaranteed to be notified (by the applicable method) when the verb completes, regardless of whether the verb is ultimately successful.

Conversation Security

You can use conversation security to require that the invoking TP provide a user identifier and password before APPC will allocate a conversation with the invokable TP. If security is activated, the invoking TP must supply a combination of the user identifier and password as parameters of ALLOCATE or MC_ALLOCATE. Conversation security is activated and configured through registry or environment variables on the computer where the invokable TP is located.

With communication involving more than two TPs, the verification of a user identifier and password can be passed from one TP to another. Suppose that TP A invokes TP B, which requires security information, and TP B in turn invokes TP C, which also requires security information. Through ALLOCATE or MC_ALLOCATE, TP B can inform TP C that conversation security has already been verified.

For information about the registry or environment variables affecting conversation security, see Configuring Invokable TPs.

Basic and Mapped Conversations Compared

The following table offers some guidelines for choosing between basic and mapped conversations for your TPs. For definitions of basic and mapped conversations, see Fundamental Terms for TPs and LUs.

Characteristic	Basic conversations	Mapped conversations
Common use	Generally used for service TPs.	Generally used for application TPs.
Partnering	Must be used to communicate with an existing TP that uses basic verbs.	Must be used to communicate with an existing TP that uses mapped verbs.
Sending and receiving method	Before a TP can begin a send operation, it must convert data records into logical records. The TP does this by adding a 2-byte prefix that indicates the length of the record. A TP can send several logical records at one time. When a partner TP receives logical records, it must reconstruct them into usable data records. For more information, see Logical Records Used in Basic Conversations.	A TP sends data one record at a time. Neither the sending TP nor the receiving TP needs to convert data records between different forms.
Abnormal termination	In the DEALLOCATE verb, a TP can indicate whether an error or ABEND (abnormal program termination) was caused by a TP or by a program using the TP.	A TP can indicate an error or ABEND, but cannot tell whether a problem was caused by a TP or by a program using a TP.
	A TP can indicate whether an ABEND was caused by a timeout or by a critical error.	A TP cannot indicate the cause of an ABEND.
Error logging	For an error or ABEND, a TP can send an error message, in the form of a general data stream (GDS) error log variable, to the local log and to the partner LU.	For an error or ABEND, a TP cannot send an error message to the local log or to the partner LU.

This section contains:

- Logical Records Used in Basic Conversations
- An Example of a Mapped Conversation

Logical Records Used in Basic Conversations

Logical records are sent and received in basic conversations only.

A TP can send or receive multiple logical records with a single SEND_DATA or receive verb. The receive verbs are RECEIVE_AND_POST (Windows 2000, Windows NT, Windows 98, Windows 95, and OS/2), RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT. A TP can also send or receive a logical record in successive portions: beginning, middle, and end.

A logical record is made up of:

- A 2-byte record-length (LL) field.
- A data field that can range in length from 0 bytes through 32765 bytes.

The LL field contains a hexadecimal value that is the length of the data field plus two bytes (for the LL field). For example, if a record contains 228 bytes of application data, the logical record length is 230. The LL field is 0x00E6, the hexadecimal equivalent of 230. If the length of the data field is 0, the value contained in the LL field is 0x0002.

Logical records are sent from or received in a data buffer established by the TP. In the data buffer, the LL field must not be in Intel byte-swapped format. For example, a length of 230 must be 0x00E6, not 0xE600.

The LL field cannot be 0x0000 or 0x0001, which allow less than the two bytes required for the LL field itself. The LL field also cannot be greater than or equal to 0x8000, which is equivalent to decimal 32768 and therefore allows for a data field greater than 32765 or an LL field greater than 2.

Setting the most significant bit of the LL field to 1 indicates that the information contained in the current logical record is continued in the next logical record.

An Example of a Mapped Conversation

For background information about mapped conversations, see Basic and Mapped Conversations Compared.

The following example of a mapped conversation shows the APPC verbs used to start a conversation, exchange data, and end the conversation. APPC verb parameters are in parentheses.

Issued by the invoking TP	Issued by the invokable TP
TP_STARTED	
MC_ALLOCATE	
MC_SEND_DATA	
MC_DEALLOCATE	
TP_ENDED	RECEIVE_ALLOCATE
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_OK)
	(rtn_status=AP_NO)
	(what_rcvd=AP_DATA_COMPLETE)
	MC_RECEIVE_AND_WAIT
	(primary_rc=AP_DEALLOC_NORM)
	TP_ENDED

The following paragraphs describe the verbs that are used in a mapped conversation.

Verbs for Starting a Mapped Conversation

To start a mapped conversation, the invoking TP issues the following verbs:

- TP_STARTED, which notifies APPC that the local TP is beginning a conversation.
- MC_ALLOCATE, which requests that APPC establish a conversation between the local TP and the partner TP.

The invokable TP issues RECEIVE_ALLOCATE, which informs APPC that it is ready to begin a conversation with the invoking TP.

Verbs for Sending Data in a Mapped Conversation

MC_SEND_DATA puts one data record (a record containing application data to be transmitted) in the send buffer of the local LU. Data transmission to the partner TP does not happen until one of the following events occurs:

- The send buffer fills up.
- The sending TP issues a verb that forces APPC to flush the buffer and send data to the partner TP.

In the preceding example, the send buffer contains both the data record and the MC_ALLOCATE request (which precedes the data record). Therefore, in the example, MC_DEALLOCATE flushes the buffer, sending the **MC_ALLOCATE** request and data record to the partner TP. Other verbs that flush the buffer are MC_CONFIRM and MC_FLUSH.

Verbs for Receiving Data in a Mapped Conversation

The MC_RECEIVE_AND_WAIT verb allows a TP to receive a data record or status information. If no data is currently available, the TP waits for data to arrive. For Windows 2000, Windows NT, Windows 98, Windows 95, and Windows 3.*x* systems, issue **MC_RECEIVE_AND_WAIT** in conjunction with WinAsyncAPPC rather than the blocking version of this call.

In the example, the receiving TP issues MC_RECEIVE_AND_WAIT twice. The first time, it issues the verb to receive data. When it finishes receiving the complete data record (what_rcvd is AP_DATA_COMPLETE), it issues MC_RECEIVE_AND_WAIT again to receive a return code. The return code AP_DEALLOC_NORMAL indicates that the conversation has been deallocated.

> MC_RECEIVE_IMMEDIATE performs the same function as **MC_RECEIVE_AND_WAIT**, except that it does not wait if data is not currently available from the partner TP. Instead, it returns a no-data-available response to the calling TP.

Verbs for Ending a Mapped Conversation

To end a mapped conversation, one of the TPs issues MC_DEALLOCATE, which causes APPC to deallocate the conversation between the two TPs.

After the conversation has been deallocated, both TPs issue TP_ENDED.

> A TP can participate in multiple conversations simultaneously. In this case, the TP issues **TP_ENDED** after all conversations have been deallocated.

Using Invoking and Invokable TPs

There are two kinds of TPs: TPs that can invoke (that is, initiate a conversation with) other TPs, and TPs that can be invoked. A TP that can invoke another TP is called an invoking TP, and a TP that can be invoked is called an invokable TP.

The following topics describe how:

- Invoking TPs request invokable TPs.
- Invokable TPs identify themselves to Host Integration Server or SNA Server in preparation for being invoked.
- An invokable TP is matched to an invoking TP's request.

For information about how to configure LUs to support TPs, see Configuring TPs on Host Integration Server and SNA Server and the *Microsoft Host Integration Server 2000 online books*.

This section contains:

Invoking TPs

An invoking TP can be located on any system on the SNA network. An invoking TP identifies itself by issuing TP_STARTED, which specifies the name of the invoking TP and can specify the LU alias that the TP uses. If the LU alias is not specified in **TP_STARTED**, Host Integration Server or SNA Server must be configured to supply it through one of two types of default local LU; otherwise, **TP_STARTED** will fail. For more information, see Configuring Invoking TPs on Host Integration Server and SNA Server.

Next, the invoking TP initiates the invoking process by issuing ALLOCATE or MC_ALLOCATE, in which it specifies the name of the invokable TP, and can also specify the partner LU alias (the LU alias to be used by the invokable TP). If the partner LU is not specified in ALLOCATE or MC_ALLOCATE, Host Integration Server 2000 must be configured to supply one through the default remote APPC LU assigned to the user who started the invoking TP; otherwise, ALLOCATE or MC_ALLOCATE will fail. For more information, see Configuring Invoking TPs on Host Integration Server and SNA Server.

After a TP successfully issues an ALLOCATE or MC_ALLOCATE verb, an allocation request flows. For more information about what happens after an invoking TP requests an invokable TP, see Matching Invoking and Invokable TPs.

Invoking TPs and Contention

The following information applies only to cases where LUs are communicating in complex ways (such as chains of LUs) over multiple sessions. In such cases, two LUs may attempt to allocate a conversation on the same session at the same time. If this happens, one LU must win (the contention winner) and one must lose (the contention loser). The contention-winner LU and the contention-loser LU are determined for each session when the session is established. During that particular session, the contention-loser LU must receive permission from the contention-winner LU before allocating a conversation. In contrast, the contention-winner LU on that session allocates a conversation as needed.

Note that when two LUs are communicating over multiple sessions, one LU can be the contention winner for some of the sessions, and the other LU the contention winner for others.

An invoking TP will operate most efficiently if the number of concurrent ALLOCATE or MC_ALLOCATE requests that the TP issues is matched by the number of sessions on which the local LU is the contention winner. The choice of contention winner is controlled through the modes configured at the two ends of the communication. The mode is configured using SNA Manager on Host Integration Server 2000 and configured using SNA Explorer on SNA Server 4.0. A mode must be configured to work with the mode on the remote system for communication to begin between two LUs. For more information about modes, see the *Microsoft Host Integration Server 2000 online books*.

Invokable TPs

An invokable TP is a TP that can be invoked by another TP. Invokable TPs are written or configured through registry or environment variables to supply their names to Host Integration Server 2000 or SNA Server as a notification that they are available for incoming requests. Invokable TPs can be run on any Host Integration Server 2000 or SNA Server client or server running Windows 2000, Windows NT, Windows 98, Windows 95, Windows 3.*x*, or OS/2.

> Invokable TPs cannot be run on Microsoft MS-DOS®-based clients.

There are two types of invokable TPs:

Operator-started invokable TPs

An operator-started invokable TP must be started by an operator before the TP can be invoked. When the operator-started invokable TP is started, it notifies Host Integration Server 2000 or SNA Server of its availability by issuing a RECEIVE_ALLOCATE verb. The **RECEIVE_ALLOCATE** causes the name of the invokable TP along with the alias of an associated LU if one has been configured through a registry or environment variable to be communicated to all the servers running Host Integration Server 2000 or SNA Server in the SNA domain.

Autostarted invokable TPs

An autostarted invokable TP can be started by Host Integration Server 2000 or SNA Server when needed. The TP must be registered through registry entries or environment variables on its local system, so that it can be identified to the SnaBase component of the Host Integration Server 2000 or SNA Server client software. The registered information defines the TP as autostarted and must specify the TP name. The registered information can also specify the local LU alias that the invokable TP will use.

The recommended method for setting registry or environment variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP, or similar code written into your own installation program. For more information about registry or environment variables for invokable TPs, see Configuring Invokable TPs. For information about TPSETUP, see Sample APPC TPs in the SDK.

If no local LU alias is registered with autostarted TPs, the resulting Host Integration Server 2000 or SNA Server configuration can be more flexible in responding to invoking requests. For more information about such flexible configurations, see TP Name Not Unique; Local LU Alias Unspecified.

After an autostarted invokable TP is started by Host Integration Server 2000, the TP issues RECEIVE_ALLOCATE just as an operator-started TP does. RECEIVE_ALLOCATE must provide the TP name that was registered for the TP.

Autostarted TPs must be configured through registry or environment variables to be either queued or nonqueued. All operator-started TPs act as queued TPs.

Queued TPs

If an autostarted TP is configured as queued, or if the TP is operator-started, incoming allocation requests are queued and then sent only when the invokable TP issues **RECEIVE_ALLOCATE**. For autostarted invokable TPs, if a copy of the TP is not yet running, one is started when an incoming allocation request specifies that TP.

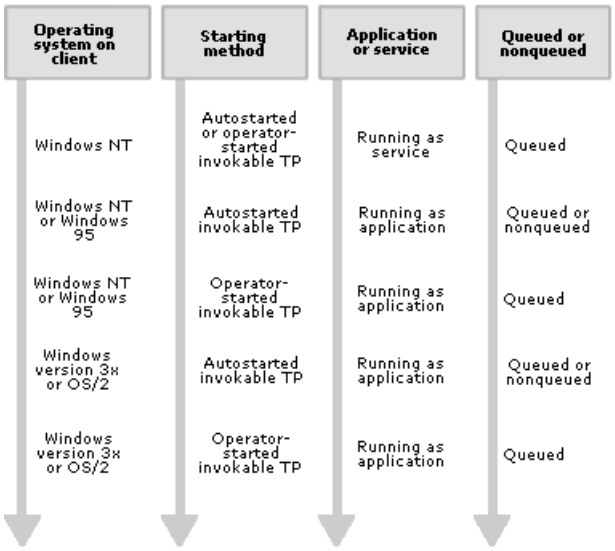
> For Windows 2000 and Windows NT, only one copy of a service can be running at any given time; this means that all autostarted TPs that run as services under Windows 2000 or Windows NT must be queued. To write an autostarted TP so it will run under Windows 2000 or Windows NT as a service and also run in a nonqueued way, write a multithreaded program with a **RECEIVE_ALLOCATE** always outstanding.

Nonqueued TPs

If an autostarted TP is configured as nonqueued, a new copy will be started every time an ALLOCATE or MC_ALLOCATE is received for the TP. Nonqueued TPs should process the conversation they have been allocated and then exit, since they will not receive any additional **ALLOCATE** or **MC_ALLOCATE** requests.

Subcategories for Invokable TPs

The following figure shows subcategories for invokable TPs.



The concept of a TP "running as a service" or "running as an application" is distinct from a service TP or an application TP. Service TP and application TP are SNA terms that describe how a TP is used: either as a supportive service program for other APPC programs, or directly by a user, as an application. For detailed information about services and applications on Windows 2000 and Windows NT, see the Microsoft Developer Network (MSDN®) Platform Software Development Kit.

To write an autostarted TP so it will run under Windows 2000 or Windows NT as a service and also run in a nonqueued way, write a multithreaded program with a RECEIVE_ALLOCATE always outstanding. See Invokable TPs.

To run an autostarted TP as an application under Windows NT, make sure the TPSTART program is always started before the TP. See Sample APPC TPs in the SDK.

Matching Invoking and Invokable TPs

Each computer running Host Integration Server 2000 or SNA Server maintains a list of available invokable TP names and any LU aliases to be associated with the TP names. This information is obtained as follows:

- For autostarted invokable TPs, registry or environment variables identify a TP name containing a maximum of eight characters, and can specify an associated LU. This information is sent from the client to the server that sponsors the client. A client learns about the domain through a sponsor connection to a server; clients must establish the sponsor connection before proceeding with any other tasks.
- For operator-started invokable TPs, a TP name (with a maximum of 64 characters) is specified with the RECEIVE_ALLOCATE verb. The TP name is truncated to eight characters and sent from the client to the server that sponsors the client, along with the alias of an associated LU if one has been configured through a registry or environment variable.

> If you want a TP name to be unique, it is recommended that you limit the name to eight characters or fewer, or make the name unique within the first eight characters. This is because the preliminary routing of allocation requests is carried out using the first eight characters. Although further matching is later carried out between the full TP names specified in ALLOCATE or MC_ALLOCATE and **RECEIVE_ALLOCATE**, it is inefficient to allow the preliminary routing to succeed when in some cases the later matching will fail.

The next step in the matching of invoking and invokable TPs is that the invoking TP issues the **ALLOCATE** or **MC_ALLOCATE** verb. After an invoking TP in an Host Integration Server or SNA Server domain successfully issues this verb, an allocation request flows to the partner LU specified in the **ALLOCATE** or **MC_ALLOCATE** verb, stating the name of the invokable TP that has been requested.

When an allocation request arrives, the SNA server compares the requested invokable TP name and LU alias to the list of available invokable TPs (which can include associated LU aliases). The comparison can be modified by registry variables, but by default is carried out as follows:

- Although the TP name requested in the **ALLOCATE** or **MC_ALLOCATE** verb can be as long as 64 characters, any name received through a registry or environment variable is limited to eight characters or less. Therefore, only the first eight characters of TP names are used in comparisons.
- The comparison is carried out first on both the TP name and the LU alias. An invokable TP for which there is a match on both TP name and LU alias will be chosen ahead of a TP for which no LU alias has been configured through a registry or environment variable. A TP for which no LU alias has been configured can be matched with any request that specifies that TP name, since there cannot be a mismatch based on LU alias.
- The comparison of requested and available TP names is carried out in a specific order:

  1. Host Integration Server or SNA Server first checks for operator-started invokable TPs on the local system (the local computer running Host Integration Server 2000 or SNA Server).
  2. If no match is found, Host Integration Server or SNA Server checks for autostarted invokable TPs on the local system (the local computer running Host Integration Server 2000 or SNA Server).
  3. If no match is found, Host Integration Server or SNA Server checks for operator-started invokable TPs on other Host Integration Server 2000 or SNA Server clients or servers.
  4. If no match is found, Host Integration Server or SNA Server checks for autostarted invokable TPs on other Host Integration Server or SNA Server clients or servers.

This comparison can be modified somewhat by registry entries for the SnaServr service. The entries are called **DloadMatchTPOnly** and **DloadMatchLocalFirst**, and are described in the *Microsoft Host Integration Server 2000 Reference online book*.

If a match is found, the Host Integration Server or SNA Server signals the system containing the requested TP to connect to that server running Host Integration Server 2000 or SNA Server. If no match is found, Host Integration Server or SNA Server rejects the incoming request.

For suggestions about specific ways to handle TP names and LU aliases, see Arranging TPs Within an SNA Network.

> Because of the way APPC works, an allocation request will not flow until local data buffers are full, or a confirm or flush verb is issued. This can mean that the allocation request does not flow until some time after the ALLOCATE or MC_ALLOCATE verb is issued. Therefore, any allocation failure caused by the rejection of the allocation request at the partner LU will be observed as the failure of a later verb with one of the allocation failure return codes.

Configuring Invokable TPs

The following topics discuss how to configure invokable TPs for the various Microsoft Host Integration Server 2000 or Microsoft SNA Server client types.

This section contains:

Clients Running Windows 2000 or Windows NT

On clients running Windows 2000 or Windows NT, invokable TPs are configured through the Windows 2000 or Windows NT registry.

> With Windows 2000 or Windows NT, the recommended method for setting registry variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile INSTALL.C, the source code for TPSETUP, for the Windows NT environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see Sample APPC TPs in the SDK.

For clients running Windows 2000 or Windows NT, it is recommended that autostarted invokable TPs be written as Windows 2000 or Windows NT services. Be sure to include code like that in TPSETUP in the program that installs your TPs. Among other things, TPSETUP shows how to use the **CreateService** function when installing a TP. For important information about how services work under Windows 2000 and Windows NT, see the Microsoft Developer Network (MSDN) Platform Software Development Kit for Windows 2000 and Windows NT.

The following table lists the registry entries used for the types of invokable TPs that can be run on Windows-2000 or Windows NT clients:

Type of TP	**Location in registry**	**Possible registry entries**
Autostarted invokable TP running as a service on a Windows 2000 or Windows NT client	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services *TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— Linkage OtherDependencies:REG_MULTI_SZ:SnaBase Parameters SNAServiceType:REG_DWORD:0x5 LocalLU:REG_SZ:*LUalias* Parameters:REG_SZ:*ParameterList* Timeout:REG_DWORD:*number* ConversationSecurity:REG_SZ:{ YES | NO } AlreadyVerified:REG_SZ:{ YES | NO }[2] *Username1*:REG_SZ:*Password1*[2] ... *UsernameX*:REG_SZ:*PasswordX*[2]
Autostarted invokable TP running as an application1 on a Windows 2000 or Windows NT client	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters TPs *TPName*** Parameters	**SNAServiceType:**REG_DWORD:{ 0x5 | 0x6 } **PathName:**REG_EXPAND_SZ:*path* **LocalLU:**REG_SZ:*LUalias* **Parameters:**REG_SZ:*ParameterList* **TimeOut:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO }2 ***Username1*:**REG_SZ:*Password1*[2] ... ***UsernameX*:**REG_SZ:*PasswordX*[2]

Operator-started invokable TP running as a service on a Windows 2000 or Windows NT client	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services *TPName*** (and subkeys)	Registry entries created by the **CreateService** call, including entries that specify the path, display name, and other characteristics of the service. —plus— Linkage OtherDependencies:REG_MULTI_SZ:SnaBase Parameters SNAServiceType:REG_DWORD:0x1A LocalLU:REG_SZ:*LUalias* Timeout:REG_DWORD:*number* ConversationSecurity:REG_SZ:{ YES | NO } AlreadyVerified:REG_SZ:{ YES | NO }[2] *Username1*:REG_SZ:*Password1*[2] ... *UsernameX*:REG_SZ:*PasswordX*[2]
Operator-started invokable TP on a Windows 2000 or Windows NT client	**HKEY_LOCAL_MACHINE SYSTEM CurrentControlSet Services SnaBase Parameters TPs *TPName*** Parameters	**SNAServiceType:**REG_DWORD:0x1A **LocalLU:**REG_SZ:*LUalias* **TimeOut:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO }2 ***Username1:***REG_SZ:*Password1*[2] ... ***UsernameX:***REG_SZ:*PasswordX*[2]

Notes

1 Before an autostarted TP can be started as an application on a Windows 2000 or Windows NT client, the TPSTART program must be started. For more information, see Sample APPC TPs in the SDK.

2 AlreadyVerified and Username/Password entries are used only if ConversationSecurity is set to YES.

This section contains:

- Registry Entries for Clients Running Windows 2000 or Windows NT
- Example of Windows 2000 or Windows NT Registry Entries for an Invokable TP

Registry Entries for Clients Running Windows 2000 or Windows NT

The following list gives details about registry entries for clients running Windows 2000 or Windows NT. For each TP type, the applicable variables and their locations are shown in Clients Running Windows 2000 or Windows NT.

Registry Entries for TPName on Clients Running Windows 2000 or Windows NT

TPName:REG_MULTI_SZ
The name of the transaction program (TP) that is executed. A TP name is up to 64 ASCII characters in length and cannot contain spaces or nulls.

SNA service TPs are a special set of TPs defined by the SNA protocols. Each service TP is a specially-defined function with a special name. An SNA service TP name is represented by up to four EBCDIC bytes; the first byte is a hexadecimal number in the range 0x00 to 0x3F, and the remaining bytes are EBCDIC characters. The first byte defines the function class of the TP. Therefore, to convert a service TP name to an ASCII TP name form, convert the first byte as shown in the following table, and convert the EBCDIC values to ASCII letter equivalents.

First byte of TP name (hexadecimal number)	ASCII character equivalent for WIN.INI
0x07	DDM
0x20	DIA
0x21	SNAD
0x24	FS
0x30	PO
All others	UN

For example, an EBCDIC service TP name of 0x21 0xD7 0xD7 is equivalent to a TP name of SNADPP (0x21 converts to SNAD and each 0xD7 converts to P).

Registry Entries for the TPName Subtree on Clients Running Windows 2000 or Windows NT

OtherDependencies:REG_MULTI_SZ:SnaBase
For a TP running as a service, ensures that the SnaBase service will be started before the TP is started. This entry belongs under the **Linkage** subkey.
SNAServiceType:REG_DWORD:{ 0x5 | 0x6 | 0x1A }
Indicates the type of TP. Use a value of 0x5 for an autostarted queued TP, 0x6 for an autostarted nonqueued TP, and 0x1A for an operator-started TP.

Note that the value for an autostarted TP running as a service must be 0x5, because these TPs are always queued, as described in Invokable TPs.

PathName:REG_SZ**:***path*
For an autostarted TP running as an application, specifies the path and file name of the TP. The data type of REG_EXPAND_SZ means that the path can contain an expandable data string; for example, %SystemRoot% represents the directory containing the Windows NT system files. Note that for a TP running as a service, an equivalent entry is inserted by the **CreateService** call; no additional path entry is needed.
LocalLU:REG_SZ:*LUalias*
Specifies the alias of the local LU to be used when this TP is started on this computer.
Parameters:REG_SZ:*ParameterList*
Lists parameters to be used by the TP. Separate parameters with spaces.
Timeout:REG_DWORD:*number*
Specifies the time, in milliseconds, that a RECEIVE_ALLOCATE will wait before timing out. Specify *number* in decimal; the registry editor converts this to hexadecimal before displaying it. The default is infinity (no limit).
ConversationSecurity:REG_SZ:{ YES | NO }

Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified:REG_SZ:{ YES | NO }

Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO. The default value is NO.

For a diagram of three TPs in a conversation, where the third TP can be invoked with a password that is already verified by the second TP, see Communication Between TPs. The following table shows the requirements for using password verification in a chain of TPs.

First TP (invoking TP)	**Second TP (invokable TP that confirms password and then invokes another TP)**	**Third and subsequent TPs (invokable TPs that invoke other TPs)**
Does not need registry or environment variables.	**ConversationSecurity** setting must be YES.	**ConversationSecurity** setting must be YES.
Does not need registry or environment variables.	**AlreadyVerified** setting can be YES or NO.	**AlreadyVerified** setting must be YES.
ALLOCATE or MC_ALLOCATE in this TP has a **security** parameter of AP_PGM; as a result, the TP passes along the **user_id** and **pwd** values supplied in **ALLOCATE** or **MC_ALLOCATE**.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, after confirming the user identifier and password, the TP passes along the user identifier and an already-verified flag.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, the TP passes along the user identifier as received, along with the already-verified flag.

If you set **AlreadyVerified** to NO, this TP cannot join in a chain of conversations where password verification is already done. The exception to this is when **ConversationSecurity** is set to NO, in which case the TP could be the final TP in such a chain, since it performs no checking.

If you are configuring a TP that sometimes needs to confirm a password and sometimes accepts an already-verified flag, set AlreadyVerified to YES and configure the *UsernameX* variable appropriately. In this case, whenever the TP is invoked without the already-verified flag set, AlreadyVerified is ignored; verification is attempted with the user identifier and password configured for the TP.

If you want to have a chain of conversations where the user identifier and password are reverified at every step, carry out the following. For all the TPs, set ConversationSecurity to YES, and in each ALLOCATE or MC_ALLOCATE issued, set the security parameter to AP_PGM and the pwd and user_id parameters to valid combinations.

If you set AlreadyVerified to YES, make sure that ConversationSecurity is also set to YES.

Username1:REG_SZ:Password1

...

UsernameX:REG_SZ:PasswordX

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can each be as many as 10 characters. Both parameters are case-sensitive.

This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the AlreadyVerified entry.

Example of Windows 2000 or Windows NT Registry Entries for an Invokable TP

For an autostarted invokable TP called **BounceTP** and running as a service, the following registry entries might be added to a Windows 2000 or Windows NT-based client. The entries would be added to **HKEY_LOCAL_MACHINE\ SYSTEM\ CurrentControlSet\ Services\ SnaBase**, under the subkeys shown in bold type.

> In the following list, the parameters listed directly under the **BounceTP** key (such as **DisplayName** and **ErrorControl**) are service parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code; they should not be set manually. For more information about TPSETUP, see Sample APPC TPs in the SDK.

BounceTP
DisplayName:REG_SZ:BounceTP
ErrorControl:REG_DWORD:0x1
ImagePath:REG_EXPAND_SZ:c:\sna\system\bouncetp.exe
ObjectName:REG_SZ:LocalSystem
Start:REG_DWORD:0x3
Type:REG_DWORD:0x10

Linkage

OtherDependencies:REG_MULTI_SZ:SnaBase

Parameters

SNAServiceType:REG_DWORD:0x5
LocalLU:REG_SZ:JohnDoe
Parameters:REG_SZ:Arg1 Arg2 Arg3
Timeout:REG_DWORD:0x100
ConversationSecurity:REG_SZ:yes
AlreadyVerified:REG_SZ:no
JohnDoe:REG_SZ:SecretPassword

Security

Security:REG_BINARY:

For an autostarted invokable TP called **BounceTP** running as an application, the following registry entries might be added to a Windows NT-based client. The entries would be added to **HKEY_LOCAL_MACHINE\SYSTEM\ CurrentControlSet\Services\SnaBase\Parameters\Tps**, under the subkeys shown in bold type.

> In the following list, the parameters listed under the **BounceTP** key (such as **PathName** and **ConversationSecurity**) are parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code; they should not be set manually. For more information about TPSETUP, see Sample APPC TPs in the SDK.

BounceTP
Parameters

SNAServiceType:REG_DWORD:0x5
PathName:REG_SZ:C:\sna\system\bouncetp.exe
LocalLU:REG_SZ:JohnDoe
Parameters:REG_SZ:Arg1 Arg2 Arg3
Timeout:REG_DWORD:0x100
ConversationSecurity:REG_SZ:yes
AlreadyVerified:REG_SZ:no
JohnDoe:REG_SZ:SecretPassword

Clients Running Windows 98 or Windows 95

On clients running Windows 98 or Windows 95, invokable TPs are configured through the Windows 98 or Windows 95 registry.

> On Windows 98 or Windows 95, the recommended method for setting registry variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile the source code for TPSETUP (INSTALL.C,), for the Windows 98 or Windows 95 environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see Sample APPC TPs in the SDK.

The following table lists the registry entries used for the types of invokable TPs that can be run on Windows 98 or Windows 95 clients:

Type of TP	**Location in registry**	**Possible registry entries**
Autostarted invokable TP running as an application on a Windows 98 or Windows 95 client	**HKEY_LOCAL_MACHINE** **SYSTEM** **SOFTWARE** **Microsoft** **SnaBase** **Parameters** **TPs** ***TPName*** Parameters	**SNAServiceType:**REG_DWORD:{ 0x5 | 0x6 } **PathName:**REG_EXPAND_SZ:*path* **LocalLU:**REG_SZ:*LUalias* **Parameters:**REG_SZ:*ParameterList* **TimeOut:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO } ***Username1*:**REG_SZ:*Password1* ... ***UsernameX*:**REG_SZ:*PasswordX*
Operator-started invokable TP on a Windows 98 or Windows 95 client	**HKEY_LOCAL_MACHINE** **SYSTEM** **SOFTWARE** **Microsoft** **SnaBase** **Parameters** **TPs** ***TPName*** Parameters	**SNAServiceType:**REG_DWORD:0x1A **LocalLU:**REG_SZ:*LUalias* **TimeOut:**REG_DWORD:*number* **ConversationSecurity:**REG_SZ:{ YES | NO } **AlreadyVerified:**REG_SZ:{ YES | NO } ***Username1*:**REG_SZ:*Password1* ... ***UsernameX*:**REG_SZ:*PasswordX*[1]

Note

1 **AlredyVerified** and Username/Password entries are used only if **ConversationSecurity** is set to YES.

This section contains:

- Registry Entries for Clients Running Windows 98 or Windows 95
- Example of Windows 98 or Windows 95 Registry Entries for an Invokable TP

Registry Entries for Clients Running Windows 98 or Windows 95

The following list gives details about registry entries for clients running Windows 98 or Windows 95. For each TP type, the applicable variables and their locations are shown in Clients Running Windows 98 or Windows 95.

Registry Entries for TPName on Clients Running Windows 98 or Windows 95

TPName:REG_MULTI_SZ
The name of the transaction program (TP) that is executed. A TP name is up to 64 ASCII characters in length and cannot contain spaces or nulls.

SNA service TPs are a special set of TPs defined by the SNA protocols. Each service TP is a specially-defined function with a special name. An SNA service TP name is represented by up to four EBCDIC bytes; the first byte is a hexadecimal number in the range 0x00 to 0x3F, and the remaining bytes are EBCDIC characters. The first byte defines the function class of the TP. Therefore, to convert a service TP name to an ASCII TP name form, convert the first byte as shown in the following table, and convert the EBCDIC values to ASCII letter equivalents.

First byte of TP name (hexadecimal number)	ASCII character equivalent for WIN.INI
0x07	DDM
0x20	DIA
0x21	SNAD
0x24	FS
0x30	PO
All others	UN

For example, an EBCDIC service TP name of 0x21 0xD7 0xD7 is equivalent to a TP name of SNADPP (0x21 converts to SNAD and each 0xD7 converts to P).

Registry Entries for the TPName Subtree on Clients Running Windows 95

SNAServiceType:REG_DWORD:{ 0x5 | 0x6 | 0x1A }
Indicates the type of TP. Use a value of 0x5 for an autostarted queued TP, 0x6 for an autostarted nonqueued TP, and 0x1A for an operator-started TP.

PathName:REG_SZ:*path*
For an autostarted TP running as an application, specifies the path and file name of the TP. The data type of REG_EXPAND_SZ means that the path can contain an expandable data string; for example, %SystemRoot% represents the directory containing the Windows 95 system files.

LocalLU:REG_SZ:*LUalias*
Specifies the alias of the local LU to be used when this TP is started on this computer.

Parameters:REG_SZ:*ParameterList*
Lists parameters to be used by the TP. Separate parameters with spaces.

Timeout:REG_DWORD:*number*
Specifies the time, in milliseconds, that a RECEIVE_ALLOCATE will wait before timing out. Specify *number* in decimal; the registry editor converts this to hexadecimal before displaying it. The default is infinity (no limit).

ConversationSecurity:REG_SZ:{ YES | NO }
Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified:REG_SZ:{ YES | NO }
Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO. The default value is NO.

For a diagram of three TPs in a conversation, where the third TP can be invoked with a password that is already verified by the second TP, see Communication Between TPs. The following table shows the requirements for using password verification in a chain of TPs.

First TP (invoking TP)	Second TP (invokable TP that confirms password and then invokes another TP)	Third and subsequent TPs (invokable TPs that invoke other TPs)
Does not need registry or environment variables.	**ConversationSecurity** setting must be YES.	**ConversationSecurity** setting must be YES.
Does not need registry or environment variables.	**AlreadyVerified** setting can be YES or NO.	**AlreadyVerified** setting must be YES.
ALLOCATE or MC_ALLOCATE in this TP has a **security** parameter of AP_PGM; as a result, the TP passes along the **user_id** and **pwd** values supplied in **ALLOCATE** or **MC_ALLOCATE**.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, after confirming the user identifier and password, the TP passes along the user identifier and an already-verified flag.	**ALLOCATE** or **MC_ALLOCATE** in this TP has a **security** parameter of AP_SAME; as a result, the TP passes along the user identifier as received, along with the already-verified flag.

If you set **AlreadyVerified** to NO, this TP cannot join in a chain of conversations where password verification is already done. The exception to this is when **ConversationSecurity** is set to NO, in which case the TP could be the final TP in such a chain, since it performs no checking.

If you are configuring a TP that sometimes needs to confirm a password and sometimes accepts an already-verified flag, set AlreadyVerified to YES and configure the *UsernameX* variable appropriately. In this case, whenever the TP is invoked without the already-verified flag set, AlreadyVerified is ignored; verification is attempted with the user identifier and password configured for the TP.

If you want to have a chain of conversations where the user identifier and password are reverified at every step, carry out the following. For all the TPs, set ConversationSecurity to YES, and in each ALLOCATE or MC_ALLOCATE issued, set the security parameter to AP_PGM and the pwd and user_id parameters to valid combinations.

If you set AlreadyVerified to YES, make sure that ConversationSecurity is also set to YES.

Username1:REG_SZ:Password1

...

UsernameX:REG_SZ:PasswordX

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can each be as many as 10 characters. Both parameters are case-sensitive.

This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the AlreadyVerified entry.

Example of Windows 98 or Windows 95 Registry Entries for an Invokable TP

For an autostarted invokable TP called **BounceTP** and running as an application, the following registry entries might be added to a Windows 98 or Windows 95 client. The entries would be added to **HKEY_LOCAL_MACHINE\ SYSTEM\ SOFTWARE\ Microsoft\ SnaBase\ Parameters\ TPs**, under the subkeys shown in bold type.

> In the following list, the parameters listed directly under the **BounceTP Parameters** key (such as **DPathName** and **AlreadyVerified**) are parameters created when TPSETUP or similar code is run to install the TP. These parameters should be created by TPSETUP or similar code; they should not be set manually. For more information about TPSETUP, see Sample APPC TPs in the SDK.

BounceTP
Parameters

SNAServiceType:REG_DWORD:0x5
PathName:REG_SZ:C:\sna\system\bouncetp.exe
LocalLU:REG_SZ:JohnDoe
Parameters:REG_SZ:Arg1 Arg2 Arg3
Timeout:REG_DWORD:0x100
ConversationSecurity:REG_SZ:yes
AlreadyVerified:REG_SZ:no
JohnDoe:REG_SZ:SecretPassword

Clients Running Windows Version 3.x

On clients running Windows version 3.*x*, invokable TPs are configured through entries in the WIN.INI file.

> With Windows version 3.*x*, the recommended method for setting environment variables for autostarted invokable TPs is to use the sample TP configuration program, TPSETUP. Compile the source code for TPSETUP (INSTALL.C) for the Windows version 3.*x* environment. When you write an installation program for autostarted invokable TPs, it is recommended that you add code similar to TPSETUP to the installation program. For information about TPSETUP, see Sample APPC TPs in the SDK.

The following table lists the section headings and environment variables used in the WIN.IN file for invokable TPs on clients running Windows version 3.*x*:

Type of TP	**Section in WIN.INI listing TP names only**	**Section and possible environment variables defining TP**
Autostarted invokable TP on a client running Windows version 3.*x*	**[SNAServerAutoTPs]** ***TPName1***=*SectionName1* ... ***TPNameX***=*SectionNameX*	**[*SectionName1*]** **PathName**=*path* **LocalLU**=*LUalias* **Parameters**=*ParameterList* **TimeOut**=*number* **Queued**={ YES | NO } **ConversationSecurity**={ YES | NO } **AlreadyVerified**={ YES | NO }1 ***Username1***=*Password1*1 ... ***UsernameX***=*PasswordX*1
Operator-started invokable TP on a client running Windows version 3.*x*	**[SNAServerAutoTPs]** ***TPNameN***=*SectionNameN* ... ***TPNameX***=*SectionNameX*	**[*SectionNameN*]** **LocalLU**=*LUalias* **TimeOut**=*number* **Queued**=OPERATOR **ConversationSecurity**={ YES | NO } **AlreadyVerified**={ YES | NO }1 ***Username1***=*Password1*1 ... ***UsernameX***=*PasswordX*1

Note

1 **AlreadyVerified** and Username/Password lines are used only if **ConversationSecurity** is set to YES.

This section contains:

- Environment Variables for Clients Running Windows Version 3.x
- Translating SNA Service TP Names to ASCII for WIN.INI
- Example of WIN.INI Lines for an Invokable TP

Environment Variables for Clients Running Windows Version 3.x

The following list shows the correct form for the sections and entries to add to the WIN.INI file for autostarted invokable TPs on a client running Windows version 3.*x*. The section headings are shown enclosed in square brackets; include the brackets when adding the section to the WIN.INI file.

For each TP type, the applicable variables and their locations are shown in Clients Running Windows Version 3.x.

[SNAServerAutoTPs]
TPNameX=*SectionNameX*
For all TPs. Associates *TPnameX* with *SectionNameX*. Additional lines can follow *TPNameX*=*SectionNameX*, each one using the same syntax to name a different TP and the section containing the information for that TP.
[*SectionName*]
Forms a section heading for entries applying to one TP. *SectionName* must match a section name listed under **[SNAServerAutoTPs]**.
PathName=*path*
Specifies the full path and file name of the executable file. The default is TPNAME.EXE.
LocalLU=*LUalias*
Specifies the alias of the local LU to be used when this TP is started on this computer.
Parameters=*ParameterList*
Lists strings to be passed as command-line parameters for the TP. Separate parameters with spaces. The default is no parameters.
Timeout=*number*
Specifies the time in milliseconds that a RECEIVE_ALLOCATE will wait before timing out. The default is infinity (no limit).
Queued={ YES | NO }
Queued=OPERATOR
Specifies the type of TP: YES for an autostarted queued TP, NO for an autostarted nonqueued TP, or OPERATOR for an operator-started TP (which must always be queued). The default is YES.
ConversationSecurity={ YES | NO }
Indicates whether this TP supports conversation security. The default is NO.
AlreadyVerified={ YES | NO }
Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO.

For detailed information about the **AlreadyVerified** variable, see its description under Registry Entries for Clients Running Windows 2000 or Windows NT.

The default is NO.

Username1=Password1
...
UsernameX=PasswordX
Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can have as many as 10 characters each. Both parameters are case-sensitive. This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the **AlreadyVerified** entry.

Translating SNA Service TP Names to ASCII for WIN.INI

For SNA service TPs on Host Integration Server 2000 or SNA Server clients running Windows version 3.*x*, the line naming the TP in the WIN.INI file must specify the TP name in ASCII. The following paragraphs tell how to convert a TP name to this form. The line should be placed in the **[SNAServerAutoTPs]** section of the file, as shown in Clients Running Windows Version 3.x.

An SNA service TP name is normally up to four bytes in length; the first byte is a hexadecimal number in the range 0x00 to 0x3F, and the remaining bytes are EBCDIC characters. The first byte defines the function class of the TP. Therefore, to convert a service TP name to an ASCII form, convert the first byte as shown in the following table, and convert the EBCDIC values to ASCII letter equivalents.

First byte of TP name (hexadecimal number)	ASCII character equivalent for WIN.INI
0x07	DDM
0x20	DIA
0x21	SNAD
0x24	FS
0x30	PO
All others	UN

For example, a service TP name of 0x21 0xD7 0xD7 is equivalent to SNADPP (0x21 converts to SNAD and each 0xD7 converts to P).

Example of WIN.INI Lines for an Invokable TP

For autostarted invokable TPs called **BounceTP** and **TestTP** on a client running Windows version 3.*x*, the following WIN.INI lines might be added:

```
[SNAServerAutoTPs]
BounceTP=bnceprms
TestTP=testprms

[bnceprms]
PathName=c:\sna\wbounce.exe
LocalLU=Eric
Parameters=/t
timeout=60000
queued=yes

[testprms]
PathName=c:\sna\testtp.exe
LocalLU=LU1
Parameters=/v
timeout=60000
queued=no
```

Clients Running OS/2

On OS/2-based clients, invokable TPs are configured through entries in the SNA.INI file. The following table lists the section headings and environment variables used:

Type of TP	Section in SNA.INI listing TP names only	Section and possible environment variables defining TP
Autostarted invokable TP on a client running OS/2	**[SNAServerAutoTPs]** ***TPName1***=*SectionName1* ... ***TPNameX***=*SectionNameX*	**[*SectionName1*]** **PathName**=*path* **LocalLU**=*LUalias* **Parameters**=*ParameterList* **TimeOut**=*number* **Queued**={ YES | NO } **ConversationSecurity**={ YES | NO } **AlreadyVerified**={ YES | NO }[1] ***Username1***=*Password1*[1] ... ***UsernameX***=*PasswordX*[1] **Environment**=*VariableList* **NewScreenGroup**={ 1 | 0 } **IconFile**=*path* **SessionType**=*number* **PgmControl**=*number* **InitXPos**=*number* **InitYPos**=*number* **InitXSize**=*number* **InitYSize**=*number*
Operator-started invokable TP on a client running OS/2	**[SNAServerAutoTPs]** ***TPNameN***=*SectionNameN* ... ***TPNameX***=*SectionNameX*	**[*SectionNameN*]** **LocalLU**=*LUalias* **TimeOut**=*number* **Queued**=OPERATOR **ConversationSecurity**={ YES | NO } **AlreadyVerified**={ YES | NO }[1] ***Username1***=*Password1*[1] ... ***UsernameX***=*PasswordX*

Note

1 **AlreadyVerified** and Username/Password lines are used only if **ConversationSecurity** is set to YES.

This section contains:

- Environment Variables for OS/2-Based Clients
- Translating SNA Service TP Names to ASCII for SNA.INI

Environment Variables for OS/2-Based Clients

The following list shows the correct form for the sections and entries to add to the SNA.INI file (located in the root Host Integration Server 2000 directory) for autostarted invokable TPs on an OS/2-based client. The section headings are shown enclosed in square brackets; include the brackets when adding the section to the SNA.INI file.

For each TP type, the applicable variables and their locations are shown in Clients Running OS/2.

[SNAServerAutoTPs]

TPNameX=*SectionNameX*

For all TPs. Associates *TPnameX* with *SectionNameX*. Additional lines can follow *TPNameX*=*SectionNameX*, each one using the same syntax to name a different TP and the section containing the information for that TP.

[*SectionName*]

Forms a section heading for entries applying to one TP; *SectionName* must match a section name listed under **[SNAServerAutoTPs]**.

PathName=*path*

Specifies the full path and file name of the executable file. The default is TPNAME.EXE.

LocalLU=*LUalias*

Specifies the alias of the local LU to be used when this TP is started on this computer.

Parameters=*ParameterList*

Lists strings to be passed as command line parameters for the TP. Separate parameters with spaces. The default is no parameters.

Timeout=*number*

Specifies the time in milliseconds that a RECEIVE_ALLOCATE will wait before timing out. The default is infinity (no limit).

Queued={ YES | NO }

Queued=OPERATOR

Specifies the type of TP: YES for an autostarted queued TP, NO for an autostarted nonqueued TP, or OPERATOR for an operator-started TP (which must always be queued). The default is YES.

ConversationSecurity={ YES | NO }

Indicates whether this TP supports conversation security. The default is NO.

AlreadyVerified={ YES | NO }

Indicates whether this TP can be invoked with a user identifier and password that have already been verified. **AlreadyVerified** is ignored if **ConversationSecurity** is set to NO.

For detailed information about the AlreadyVerified variable, see its description under Registry Entries for Clients Running Windows 2000 or Windows NT.

The default is NO.

Username1*=*Password1[1]

...

UsernameX*=*PasswordX[1]

Sets one or more user names and passwords to be compared with those sent by the invoking TP. The user name and password can have as many as 10 characters each. Both parameters are case-sensitive. This variable is ignored if conversation security is not activated or if the password has already been verified, as described for the **AlreadyVerified** entry.

Environment=*VariableList*

For an autostarted TP, lists the variables to be set in the TP's environment. Separate multiple variables with spaces.

NewScreenGroup={ 1 | 0 }

For an autostarted TP, specifies 1 to indicate that the TP runs in the foreground, or 0 to indicate that the TP runs in the background. The default is 1 (foreground).

IconFile=*path*

For an autostarted TP, specifies the full path and file name of the icon file. The default is no icon file.

SessionType=*number*

For an autostarted TP, specifies a value used by OS/2; see the note following. The default is 0.

PgmControl=*number*

For an autostarted TP, specifies a value used by OS/2; see the note following. The default is 32768.

InitXPos=*number*

For an autostarted TP, specifies a value used by OS/2; see the note following. The default is 80.

InitYPos=*number*

For an autostarted TP, specifies a value used by OS/2; see the note following. The default is 80.

InitXSize=*number*

For an autostarted TP, specifies a value used by OS/2; see the note following. The default is 470.

InitYSize=*number*

For an autostarted TP, specifies a value used by OS/2; see the note following. The default is 330.

SessionType, **PgmControl**, **InitXPos**, **InitYPos**, **InitXSize**, and **InitYSize** are filled directly into the **STARTDATA** structure passed to the OS/2 **DosStartSession** call for the new session.

Translating SNA Service TP Names to ASCII for SNA.INI

For SNA service TPs on Host Integration Server 2000 or SNA Server clients running OS/2, the line naming the TP in the SNA.INI file must specify the TP name in ASCII. The following paragraphs tell how to convert a TP name to this form. The line should be placed in the **[SNAServerAutoTPs]** section of the file, as shown in Clients Running OS/2.

An SNA service TP name is normally up to four bytes in length; the first byte is a hexadecimal number in the range 0x00 to 0x3F, and the remaining bytes are EBCDIC characters. The first byte defines the function class of the TP. Therefore, to convert a service TP name to an ASCII form, convert the first byte as shown in the following table, and convert the EBCDIC values to ASCII letter equivalents.

First byte of TP name (hexadecimal number)	ASCII character equivalent for SNA.INI
0x07	DDM
0x20	DIA
0x21	SNAD
0x24	FS
0x30	PO
All others	UN

For example, a service TP name of 0x21 0xD7 0xD7 is equivalent to SNADPP (0x21 converts to SNAD and each 0xD7 converts to P).

Clients Running MS-DOS

Host Integration Server 2000 and SNA Server do not support invokable TPs on MS-DOS–based clients.

Configuring TPs on Host Integration Server and SNA Server

The following topics describe how configuration of invoking and invokable TPs works on Microsoft Host Integration Server 2000 and Microsoft SNA Server 4.0.

This section contains:

Configuring Invoking TPs on Host Integration Server and SNA Server

For a server running Host Integration Server 2000 or SNA Server to support the beginning of the invoking process (that is, to accept the TP_STARTED and ALLOCATE or MC_ALLOCATE verbs issued by an invoking TP), the following parameters must be configured correctly:

1. If the invoking TP specifies in **TP_STARTED** the LU alias that it uses, that LU alias must match a local APPC LU alias on the supporting server running Host Integration Server or SNA Server. If the invoking TP leaves the LU alias blank in **TP_STARTED**, one of two methods for designating a default LU must be carried out on the supporting server running Host Integration Server or SNA Server:

   Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which **TP_STARTED** is issued).

   —or—

2. Designate one or more LUs as members of the default outgoing local APPC LU pool. The SNA server first attempts to determine the default local APPC LU of the user who started the TP, then attempts to assign an available LU from the default outgoing local APPC LU pool; if these attempts fail, the SNA server rejects the request.

   - In most situations, the supporting SNA server must contain an appropriate connection to another system (host or peer). Sometimes, for testing purposes, the server running Host Integration Server 2000 or SNA Server contains two local LUs paired together (for invoking and invokable TPs that are in the same domain); in this situation, a connection to a host or peer is not necessary.
   - If the invoking TP specifies in ALLOCATE or MC_ALLOCATE the partner LU alias, that LU alias must match an LU alias that is paired with the local LU alias specified in TP_STARTED. If the partner LU alias is left unspecified in ALLOCATE or MC_ALLOCATE, a default remote APPC LU must be assigned to the user who started the invoking TP. The default remote APPC LU is configuring using SNA Manager on Host Integration Server 2000 and configured using SNA Explorer on SNA Server 4.0. If the default remote APPC LU is used, it must be paired with the local LU that will be used. Otherwise, ALLOCATE or MC_ALLOCATE fails.

The preceding parameters support the beginning of the invoking process. For the invoking process to successfully complete, additional parameters must be configured as described in Configuring Invokable TPs on Host Integration Server and SNA Server.

Configuring Invokable TPs on Host Integration Server and SNA Server

For a computer running Host Integration Server 2000 or SNA Server to receive allocation requests from an invoking TP on another system and route those requests to an invokable TP, certain parameters must be configured correctly:

- The Host Integration Server or SNA Server must have a connection to the system from which the invoking TP's request is sent.
- The Host Integration Server or SNA Server must have a remote LU capable of receiving the incoming request. This remote LU can be configured either explicitly or implicitly.

  When configured explicitly, there is an explicit match between a remote LU alias on the Host Integration Server or SNA Server and the alias of the LU that conveys the invoking TP's request.

  When configured implicitly, an implicit incoming remote LU (with its implicit incoming mode) is used. This means that several items must work together. First, the LU alias specified in the incoming request (the LU alias requested for the invokable TP) must match a local LU alias on the Host Integration Server or SNA Server receiving the request. Second, the local LU on the Host Integration Server 2000 server must have an implicit incoming remote LU assigned to it. The properties of the implicit incoming remote LU will be used for that LU-LU session. For more details about how an implicit incoming remote LU works, see the *Microsoft Host Integration Server 2000 online books*.
- Appropriate local LUs must be defined in the Host Integration Server or SNA Server configuration. For descriptions of several ways to set up these local LUs, see Arranging TPs Within an SNA Network.

Arranging TPs Within an SNA Network

If your installation of Microsoft Host Integration Server or Microsoft SNA Server contains multiple systems (multiple clients and/or multiple SNA servers), you can place a given invokable TP on more than one system. When an invoking request is received in such an installation, there can be a choice of systems on which to run the invokable TP. You can maintain specific control over this choice; alternatively, by following the instructions in TP Name Not Unique; Local LU Alias Unspecified, you can allow Host Integration Server or SNA Server to make the choice randomly to distribute the load.

You can maintain specific control over the choice of system by setting up invokable TPs with unique names, or by setting up each invokable TP to run only with a specific, unique LU alias. With this arrangement, the information provided by the invoking TP (in the ALLOCATE or MC_ALLOCATE verb) specifies the system on which the invokable TP should run.

You can allow Host Integration Server or SNA Server to make the system choice randomly by setting the DloadMatchLocalFirst registry entry to NO and using invokable TPs that leave the local LU alias unspecified. Then, when an incoming request is received, it is routed randomly, rather than preferentially to the local Host Integration Server or SNA Server; in addition, no matter what LU alias is requested for the invokable TP, there cannot be a mismatch. Host Integration Server or SNA Server starts one instance of the requested TP, choosing randomly among the available systems.

The following topics describe some of the possible arrangements that can be made for running TPs.

This section contains:

TP Name Unique for Each TP

One way to specify the intended system where the invokable TP will run is to use a unique TP name for each invokable TP. In this arrangement, the invoking TP identifies the intended invokable TP (and system) simply by naming the TP. This makes it unnecessary for an invokable TP to specify any LU alias in registry or environment variables.

TP Name Not Unique; Local LU Alias Unique

Another way to specify the intended system where the invokable TP will run is to give the same name to multiple invokable TPs, but associate each TP with a unique local LU alias. To do this, configure each invokable TP (through registry or environment variables) to use a unique local LU alias. Then set up the invoking TPs so that each one is routed not only to the correct TP name but also to the correct partner LU alias for the intended invokable TP.

TP Name Not Unique; Local LU Alias Unspecified

If it does not matter on which system an invokable TP runs, use the same name for multiple invokable TPs and do not specify an LU alias in the registry or environment variables for the TPs. In this situation, there are no associated LU aliases in the list of available invokable TP names on a SNA server. Thus, a request received from an invoking TP cannot cause a mismatch on the LU alias, and will match according to the TP name.

In this situation, if you set the DloadMatchLocalFirst registry entry to NO, Host Integration Server OR SNA Server randomly routes the request to one of the available TPs. This spreads the processing load among multiple systems and provides hot backup (the ability to take systems online and offline without disrupting service).

Troubleshooting for Invokable TPs

If there are difficulties with starting an invokable TP, there may be a mismatch between the information for the invokable TP, the invoking TP, and/or LUs in the Host Integration Server or SNA Server configuration. That is, there may be a mismatch between the parameters for RECEIVE_ALLOCATE, TP_STARTED, ALLOCATE, or MC_ALLOCATE and/or LU aliases specified in server configuration. LU aliases are configured using SNA Manager on Host Integration Server 2000 and configured using SNA Explorer on SNA Server 4.0. For details about how to specify LU aliases see the *Microsoft Host Integration Server 2000 onine books*.

Simplifying APPC Configuration

There are several features in Host Integration Server 2000 and SNA Server that can simplify configuration for APPC:

- The implicit incoming remote LU and the implicit incoming mode, which allow Host Integration Server or SNA Server to accept requests that arrive by unrecognized remote LUs and modes.
- The default local APPC LU and the default remote APPC LU, which allow LU aliases to be associated with user or group names, simplifying the routing of incoming requests and the configuration of client systems.
- The default outgoing local APPC LU pool, which allows LUs to be allocated dynamically to any invoking TP that does not specify a local LU.
- Automatic partnering, which automatically creates LU-LU pairs and assigns modes to the pairs.

For more information about these features, see the *Microsoft Host Integration Server online books*.

Sync Point Level 2 Support in Host Integration Server and SNA Server

The following topics describe additions to Microsoft Host Integration Server 2000 and Microsoft SNA Server 4.0 that enable Sync Point Level 2 support to the LU 6.2 protocol stack.

This section assumes familiarity with the existing Host Integration Server or SNA Server APPC basic and mapped conversation interfaces. It does not attempt to explain the SNA formats and protocols for implementing Sync Point protocols, which are described in *SNA LU6.2 Reference: Peer Protocols* published by IBM (Document SC31-6808-1).

This section contains:

Sync Point Functional Overview

The Sync Point support additions to Host Integration Server 2000 and SNA Server 4.0 allow vendors to provide Sync Point services over LU 6.2 conversations provided by the LU 6.2 protocol stack in Host Integration Server or SNA Server 4.0. These additions do not implement the architected Sync Point components and TPs necessary for a complete Sync Point implementation. In particular, the following Sync Point components are not implemented, and must be provided by the vendor.

- Sync Point Services (SPS)
- Conversation-Protected Resource Manager (C-PRM)
- Resynchronization TP

These vendor-supplied components and applications are expected to implement the **SYNCPT** and **BACKOUT** verbs used for Sync Point services. The **SYNCPT** verb is used to synchronize transactions. The **BACKOUT** verb is used to back out of a transaction.

SPS, C-PRM, and the Resynchronization TP are specific components of the SNA Sync Point architecture described in *SNA LU6.2 Reference: Peer Protocols* published by IBM.

Host Integration Server 2000 and SNA Server 4.0 have been modified to add the features necessary to support these components, namely:

- Additions to the existing APPC API to support implementation of Sync Point verbs.
- Accounting support for Sync Point protocols.
- Modifications to invokable TP initiation.

Changes to the APPC basic and mapped conversation APPC APIs are made so as to ensure backward compatibility with existing APPC applications that adhere strictly to the API.

> Applications must zero all reserved verb control block (VCB) members before issuing an APPC verb. If this is not done, the application may inadvertently invoke one of the new APPC features.

Sync Point Support Architecture

The Sync Point support provided by Host Integration Server 2000 and SNA Server 4.0 assumes a particular implementation architecture by the vendor, as follows:

- The vendor provides a communication interface to its own clients requiring Sync Point Services (SPS).
- The vendor API maps its communication and Sync Point requests to the Host Integration Server or SNA Server APPC API.
- The vendor provides a single Microsoft® Windows 2000 or Microsoft® Windows NT® process, the Transaction Monitor, that is responsible for:
    - Issuing all APPC verbs.
    - Implementing the architected Resynchronization TP.
    - Implementing the architected Conversation-Protected Resource Manager (C-PRM) component of the LU.
    - Implementing the architected SPS component of the LU.

  The Transaction Monitor must reside on the same computer as the Host Integration Server or SNA Server containing the LUs for which it is providing Sync Point services. Both incoming and outgoing Sync Point conversations for this Transaction Monitor will be routed through this Host Integration Server 2000 server only.

Detailed descriptions of the three architected Sync Point components can be found in *SNA LU6.2 Reference: Peer Protocols* published by IBM.

Sync Point Session Support

This section discusses support for Sync Point session activation and deactivation in Host Integration Server 2000 and SNA Server 4.0.

This section contains:

Sync Point Session Activation

If Host Integration Server 2000 or SNA Server 4.0 are to support Sync Point conversations, this must be specified at session activation time. The configuration of Host Integration Server 2000 and SNA Server 4.0 is modified to allow the system administrator to specify which (if any) local LUs will be used for Sync Point conversations.

The Local LU Configuration property page on Host Integration Server or SNA Server contains a new check box. When checked, it indicates that the local LU can participate in Sync Point sessions. Host Integration Server or SNA Server uses this option to determine the parameters it sends on BIND requests and responses.

When Host Integration Server or SNA Server initiates an LU 6.2 session on an LU designated as supporting Sync Point, it sets the synchronization level on BIND requests to indicate that the session can support Sync Point and Backout. If the partner LU also supports Sync Point and Backout, the session is available for conversations requiring Sync Point support. If the partner LU does not support Sync Point, the session will not be used for Sync Point conversations.

Similarly, if the local LU is configured for Sync Point and the partner LU's BIND request indicates that it supports Sync Point, Host Integration Server or SNA Server sends BIND responses specifying that Sync Point is supported. In this case, the session can be used for Sync Point conversations.

Sync Point Session Deactivation

A Sync Point implementation needs to determine whether it has lost connectivity to a partner when establishing Sync Point conversations so that it can know whether or not to resynchronize. To obtain this information, Host Integration Server and SNA Server provide a new APPC verb, GET_LU_STATUS that reports the status of a particular remote LU. The information returned by this verb is as follows:

- Current number of active LU 6.2 sessions between the remote LU and the TP's local LU.
- Whether or not the number of active sessions dropped to zero at any time since this verb was last issued for the remote LU.

Note that the zero sessions indicator is reset to AP_NO each time the verb is issued by any process. It is therefore imperative that only one process issues this verb; otherwise information may be lost.

Starting Local Sync Point TPs

Local TPs are created by issuing the TP_STARTED verb to Host Integration Server or SNA Server. The **TP_STARTED** verb has been modified by adding the new VCB member **syncpoint_rqd** to allow a TP to specify that it requires Sync Point services.

By setting syncpoint_rqd to AP_YES, a TP indicates that it requires Sync Point services from Host Integration Server or SNA Server 4.0. A value of AP_NO (the default) indicates that Sync Point services are not required.

Since this member cannot be incorporated within the existing TP_STARTED VCB, the TP must use a larger VCB structure. To indicate that the VCB is longer than usual, the opext member of the VCB must be combined using OR with the value AP_EXTD_VCB before calling APPC.

If the TP is started on a server running SNA Server earlier than version 3.0 with the opext member of the VCB set for Sync Point support, the TP_STARTED verb will fail with a primary return code of AP_INVALID_OPCODE.

Conversations started by TPs requiring Sync Point support will be routed only by the Host Integration Server or SNA Server software running on the same computer. They will not be routed to other LAN-attached servers.

Sync Point Conversation Activation

This section discusses support for Sync Point conversation activation in Host Integration Server and SNA Server 4.0.

This section contains:

Locally Initiated Conversations

Conversations are initiated locally by issuing an ALLOCATE or MC_ALLOCATE verb. The **ALLOCATE** and **MC_ALLOCATE** verbs are modified to support additional parameters required by Sync Point support. The supplied **synclevel** parameter of the **ALLOCATE** and **MC_ALLOCATE** verbs can take on a value of AP_SYNCPT, which specifies that the conversation requested is a Sync Point conversation.

Remotely Initiated Conversations

Applications wishing to receive remotely initiated conversations (incoming Attaches) issue a RECEIVE_ALLOCATE verb. To accommodate Sync Point support, the **RECEIVE_ALLOCATE** verb is modified in a number of ways as follows:

- The returned **sync_level** parameter of the **RECEIVE_ALLOCATE** verb can take on a value of AP_SYNCPT, specifying that the conversation is a Sync Point conversation. The value of the **sync_level** parameter can also be determined by issuing a GET_ATTRIBUTES verb on the new conversation.
- Support is added for the receipt of program initiation parameters (PIP) data by a new parameter to the RECEIVE_ALLOCATE verb:

  The **pip_incoming** parameter is set by the application to indicate whether it is willing to accept incoming PIP data, and is returned by Host Integration Server or SNA Server to indicate whether PIP data is available to be received. If the application does not wish to receive PIP data, this member should be set to AP_NO, the default, before issuing the **RECEIVE_ALLOCATE** verb. If it is willing to accept PIP data, this member should be set to AP_YES. On completion of the **RECEIVE_ALLOCATE** verb, this member will be set to AP_YES if PIP data is available to be received by the application and to AP_NO otherwise.

- If PIP data is available, the application can receive it by issuing one of the verbs for receiving data on completion of the RECEIVE_ALLOCATE verb. For basic conversations, these receive verbs include RECEIVE_AND_POST, RECEIVE_AND_WAIT, and RECEIVE_IMMEDIATE. On basic conversations the PIP data will be returned inclusive of the general data stream (GDS) header for PIP data (GDS identifier 0x12F5). For mapped conversations, these receive verbs include MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE. On mapped conversations, Host Integration Server 2000 removes the 4-byte GDS header, and returns the PIP data only.
- For basic conversations, if the application issues a SEND_ERROR, DEALLOCATE, or TP_ENDED verb before the PIP data is received, the PIP data will be discarded. For mapped conversations, if the application issues an MC_SEND_ERROR, MC_DEALLOCATE, or TP_ENDED verb before the PIP data is received, the PIP data will be discarded.
- If PIP data is received for a TP that cannot or does not want to receive it, the conversation is rejected with a primary return code of AP_ALLOCATION_ERROR, and a secondary return code of AP_PIP_NOT_ALLOWED.

Already Verified Support

In an implementation where a Host Integration Server or SNA Server application acts as a gateway between an SNA network and a non-SNA network, it is possible that non-Host Integration Server or SNA Server clients of the gateway may require Sync Point Level 2 conversation security. Since the originating client will have validated the relevant user identifier and password, the gateway application should specify conversation security of AP_SAME when starting a conversation on behalf of the client. In this case, however, Host Integration Server and SNA Server assume that the user identifier to be used has previously been received on an Attach targeted at the TP. In the case of a non-Host Integration Server or SNA Server client this is not the case.

To allow such a gateway to support Sync Point Level 2 conversation security, Host Integration Server and SNA Server provide a new verb, SET_TP_PROPERTIES that allows the gateway application to set the user identifier for the TP before allocating a conversation with security of AP_SAME. This verb will normally be issued once, immediately after TP_STARTED, to set the user identifier for all the TP's conversations.

Presentation Header Support in Data Transfers

For basic conversations, Sync Point commands are sent by means of presentation headers (PS) across LU 6.2 conversations using the SEND_DATA or MC_SEND_DATA verb. All presentation headers contain length fields that specify a length of 1, which is usually illegal. To support Sync Point conversations, the following modifications are made to the Host Integration Server or SNA Server presentation services component:

- On basic conversations with a **synclevel** of AP_SYNCPT, data transferred specifying a general data stream (GDS) variable length of 1 will not be rejected. If the **synclevel** is not AP_SYNCPT, they will be rejected as before.
- On mapped conversations, PS headers will not be wrapped as mapped conversation application data logical records (with GDS identifier 0x12FF) when they are sent, or have the GDS header stripped off when they are received.
- On mapped conversations, it is the responsibility of the application to provide the compete PS header including the length field. Similarly, the length field will be included in PS header data returned by receive verbs.

To achieve the latter the MC_SEND_DATA verb and the receive verbs (MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE) require modifications as follows:

- A new parameter, **data_type**, is added to the **MC_SEND_DATA** verb. When this is set to AP_APPLICATION (the default, 0x00), the data is sent as application data (GDS identifier 0x12FF) as usual. When it is set to AP_PS_HEADER, the data is sent as described above.
- The following two new values are added for the what_rcvd member of the receive verbs to specify that the received data is a PS header:

  AP_PS_HEADER_COMPLETE

  AP_PS_HEADER_INCOMPLETE

- If an application issues a receive verb with **rtn_status** set to AP_YES, Host Integration Server or SNA Server will return status in combination with AP_PS_HEADER_COMPLETE, with the exception of AP_DEALLOCATE_NORMAL and AP_CONFIRM_DEALLOCATE. This is to prevent the conversation being prematurely disconnected from the LU 6.2 session when a COMMIT PS header arrives with the end of conversation indication.

It is the responsibility of the vendor-supplied Sync Point support component to convert these PS headers into the appropriate Sync Point return codes (for example, TAKE_SYNCPT).

User Control Data

For mapped conversations, the MC_SEND_DATA verb and the receive verbs (MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE) are modified to allow applications to send and receive data in user control data general data stream (GDS) variables instead of the regular application data GDS variables. The **MC_SEND_DATA** verb is modified as follows:

- A new parameter, **data_type**, is added. When **data_type** is set to AP_USER_CONTROL_DATA, the data is sent as user control data (GDS identifier 0x12F2). When it is set to AP_APPLICATION (the default), the data is sent as application data (GDS identifier 0x12FF). Note that the APPC library automatically creates the GDS header on behalf of the application for both AP_APPLICATION and AP_USER_CONTROL_DATA data records.
- The mapped conversation receive verbs are modified to allow applications to receive user control data by adding two new values for the what_rcvd parameter, as follows:

  AP_USER_CONTROL_DATA_COMPLETE

  AP_USER_CONTROL_DATA_INCOMPLETE

Implied Forget

LU 6.2 Sync Point sessions can use an optimization of the architected message flows known as implied forget. When the protocol specifies that a FORGET presentation header (PS) is required, the next data flow on the session implies that a FORGET has been received, even though it has not. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However it is possible that the last message that flows is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. To provide the TP with this notification, the DEALLOCATE and MC_DEALLOCATE verbs are modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a data link control (DLC) outage.

The callback procedure can take any name because the address of the procedure is passed into the APPC DLL.

Note that the DEALLOCATE and MC_DEALLOCATE verbs will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

The DEALLOCATE and MC_DEALLOCATE verbs are modified as follows to support implied forget:

- A new member, **callback**, is added to allow the TP to specify the address of the function to call on the next data flow on the session being used by the conversation being deallocated. If this member is NULL, no notification will be provided. A vendor would normally supply this callback function.
- The DEALLOCATE and MC_DEALLOCATE verbs also contain a correlator member which is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

Host Integration Server and SNA Server allow TPs to deallocate conversations immediately after sending data by specifying the **type** member in the SEND_DATA and MC_SEND_DATA verbs as AP_SEND_DATA_DEALLOC_FLUSH, AP_SEND_DATA_DEALLOC_SYNC_LEVEL, AP_SEND_DATA_DEALLOC_ABEND, and AP_SEND_DATA_DEALLOC_CONFIRM. However, the **SEND_DATA** and **MC_SEND_DATA** verbs do not contain the implied forget callback function. TPs wishing to receive implied forget notification must issue a DEALLOCATE or MC_DEALLOCATE verb explicitly.

Sync Point Level 2 Confirm Support

The current APPC implementation in Host Integration Server and SNA Server supports conversations with **synclevel** of AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT. The DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs specify a **type** member indicating the synchronization level required. This parameter is interpreted as follows:

Allocated synclevel	Type specified	Action performed
AP_NONE	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_NONE	AP_SYNCLEVEL	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_SYNCPT	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_SYNCPT or AP_CONFIRM_SYNC_LEVEL	AP_CONFIRM_TYPE	Action of CONFIRM or MC_CONFIRM verb before deallocation or change of direction.
AP_SYNCPT	AP_SYNCLEVEL	It is assumed that a Sync Point implementation built using the APPC API in Host Integration Server or SNA Server implements the defer states appropriately. See the note below.

With an allocated **synclevel** of AP_SYNCPT and a specified **type** of AP_SYNCLEVEL, it is assumed that a vendor-supplied Sync Point component implements the defer states appropriately. A vendor-supplied Sync Point system must:

- Intercept DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs on Sync Point Level 2 conversations when type AP_SYNCLEVEL is specified for **synclevel**.
- Maintain the defer state until one of the verbs valid in that state completes.
- On completion of the verb, issue the original DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, or MC_PREPARE_TO_RECEIVE verb to Host Integration Server 2000.

Host Integration Server and SNA Server do not implement the defer states directly. In particular, when a **DEALLOCATE**, **MC_DEALLOCATE**, **PREPARE_TO_RECEIVE**, or **MC_PREPARE_TO_RECEIVE** verb is received with a **type** specified as AP_SYNCLEVEL on a Sync Point conversation, this is treats as if the conversation has a **synclevel** of AP_NONE.

So that Sync Point Level 2 conversations can use confirm type synchronization, the DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs are modified to support a type member of AP_CONFIRM_TYPE.

Versions of SNA Server prior to SNA Server 3.0 support conversations with synclevel of AP_NONE or AP_CONFIRM_SYNC_LEVEL. The DEALLOCATE, MC_DEALLOCATE, PREPARE_TO_RECEIVE, and MC_PREPARE_TO_RECEIVE verbs specify a type member indicating the synchronization level required. This parameter is interpreted as follows:

Allocated synclevel	Type specified	Action performed
AP_NONE	AP_FLUSH	Action of FLUSH or MC_FLUSH verb before deallocation or change of direction.
AP_NONE	AP_SYNCLEVEL	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_CONFIRM_SYNC_LEVEL	AP_FLUSH	Action of **FLUSH** or **MC_FLUSH** verb before deallocation or change of direction.
AP_CONFIRM_SYNC_LEVEL	AP_SYNCLEVEL	Action of CONFIRM or MC_CONFIRM verb before deallocation or change of direction.

Sync Point Backout Support

This section describes backout support for Sync Point conversations.

This section contains:

Additional Sync Point Return Codes

When a remote TP issues a **BACKOUT** verb, the backout is reported to the local TP as a new primary return code value, AP_BACKED_OUT, on the next (current) verb issued. The local TP is provided access to the sense code information contained in the Backout FMH-7 by setting the **secondary_rc** field as follows:

- AP_BO_NO_RESYNC for sense code 0x08240000
- AP_BO_RESYNC for sense code 0x08240001

This new return code will only be supplied on conversations with **synclevel** AP_SYNCPT, and therefore will not be presented to existing applications.

The verbs on which this new return code can be returned are:

CONFIRM

MC_CONFIRM

MC_PREPARE_TO_RECEIVE

MC_RECEIVE_AND_POST

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_SEND_DATA

MC_SEND_ERROR

PREPARE_TO_RECEIVE

RECEIVE_AND_POST

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

SEND_DATA

SEND_ERROR

Sending Backout on Sync Point Conversations

To send a Backout, an FMH-7 containing a sense code of 0x08240000 or 0x08240001 is sent on the session. This is done using the SEND_ERROR or MC_SEND_ERROR verb. To allow Host Integration Server 2000 to send the appropriate sense data, the **SEND_ERROR** and **MC_SEND_ERROR** verbs are modified as follows:

- A new field, **err_type**, is added to allow the TP to specify the type of error. The default is AP_PROG (0x00), which means existing TPs will continue to work unmodified.
- The err_type field in both verbs can take one of two new values, specifying the sense codes to be generated by Host Integration Server 2000:

  AP_BACKOUT_NO_RESYNC for sense code 0x08240000

  AP_BACKOUT_RESYNC for sense code 0x08240001

LUWID, Conversation Correlators, and Session Identifiers

The logical unit-of-work identifier (LUWID), conversation correlators, and session identifiers are important for all Sync Point operations and accounting purposes. The following sections describe how Host Integration Server and SNA Server 4.0 provide access to these components and, where appropriate, facilities to modify this information.

This section contains:

Generating and Setting LUWIDs

The LUWID is used to identify conversations that are part of a single Sync Point transaction. All conversations with the same LUWID are committed (or backed out) at the same time.

Host Integration Server and SNA Server assign two LUWIDs to a transaction program when the TP is started. For locally started TP's, this is when the TP_STARTED verb is issued. (In previous versions of SNA Server 2.*x* only one LUWID was assigned.) The first LUWID is the TP's protected LUWID. It is used by Host Integration Server 2000 as the LUWID for all synclevel AP_SYNCPT conversations allocated by the TP. When the TP issues an ALLOCATE or MC_ALLOCATE verb with a synclevel of AP_SYNCPT, Host Integration Server and SNA Server generate an Attach containing the TP's current protected LUWID.

The second LUWID is the TP's unprotected LUWID. It is used on all conversations allocated by the TP with a synclevel other than AP_SYNCPT.

For remotely initiated TPs, the incoming Attach may contain an LUWID for the TP—it is mandatory if the conversation has a synclevel of AP_SYNCPT. For Sync Point conversations, Host Integration Server and SNA Server save the LUWID as the TP's protected LUWID and generate a new unprotected LUWID for it. For conversations with a synclevel other than Sync Point (AP_SYNCPT), Host Integration Server and SNA Server save the LUWID as the TP's unprotected LUWID and generate a new protected LUWID.

Host Integration Server and SNA Server generate LUWIDs by concatenating the following:

- The fully qualified name of the local LU, preceded by a single byte indicating its length (exclusive of the length byte).
- A 6-byte LUW instance number, generated from the current date and time (modified to ensure uniqueness if necessary).
- A 2-byte LUW sequence number, initialized to 1.

If the fully qualified LU name component of the LUWID is not 17 bytes long, Host Integration Server and SNA Server do not add any padding between it and the LUW instance number. The application can determine the length of the LUWID, and the offsets within it of the LUW instance number and LUW sequence number, by examining the first byte of the LUWID, which indicates the length of the fully qualified LU name.

When Host Integration Server and SNA Server generate both a protected and an unprotected LUWID for a TP, the unprotected LUWID is created by incrementing the protected LUWID's instance number.

The protected LUWID needs to be changed by a TP for one of four reasons:

- When a transaction is backed out or committed, the LUWID sequence number must be incremented.
- If the transaction tree is split, a new LUWID must be generated for the TP.
- If the application uses multiple logical TPs to implement a transaction, each TP must have the same LUWID (different from that assigned by Host Integration Server or SNA Server).
- If the application is acting as a gateway from a non-SNA environment and LUWIDs are received by a means other than an Attach.

To allow a TP to set or generate new LUWIDs, a new verb, SET_TP_PROPERTIES, is provided by the APPC API. This verb allows the TP to either set its LUWIDs to an existing value, by providing the LUWIDs, or generate new ones and use them from then on. When a new LUWID is generated by Host Integration Server or SNA Server, it is guaranteed to be unique.

Note that it is the responsibility of the application (the Sync Point system component) to transmit the new LUWID PS header to the partner Sync Point system when the protected LUWID is changed. Similarly, when a new LUWID PS header is received, the application must inform the LU by issuing SET_TP_PROPERTIES.

Extracting LUWIDs

Both LUWIDs for a particular TP can be determined by issuing the GET_TP_PROPERTIES verb. The **GET_TP_PROPERTIES** verb returns the TP's unprotected LUWID in the **luw_id** field.

If the TP needs to access the protected LUWID, it must combine the opext member of the VCB with the value AP_EXTD_VCB using OR before issuing the verb. The protected LUWID will then be returned in the prot_luw_id field. If the opext field does not contain the AP_EXTD_VCB bit, the verb control block is presumed to end immediately before the prot_luw_id field.

The LUWID for a particular conversation can be determined by issuing a GET_ATTRIBUTES or MC_GET_ATTRIBUTES verb on the conversation. These verbs are modified as follows:

- A new field, **luw_id**, is added in which the LUWID is returned. The LUWID returned is the protected one if the conversation was allocated with **synclevel** field of the ALLOCATE or MC_ALLOCATE verb set to Sync Point (AP_SYNCPT); otherwise it is the unprotected one.
- Since the luw_id field cannot be incorporated within the existing verb control blocks, the TP must use a larger VCB structure. To indicate that the VCB is longer than usual, the opext field of the VCB must be combined with the value AP_EXTD_VCB using OR before calling APPC.
- The sync_level field of the GET_ATTRIBUTES or MC_GET_ATTRIBUTES verb can take an additional value, AP_SYNCPT, when the conversation was allocated with the synclevel field of the ALLOCATE or MC_ALLOCATE verb of Sync Point (AP_SYNCPT).

Session Identifiers

Host Integration Server and SNA Server maintain a unique identification for every LU 6.2 session it has with a remote LU. This 8-byte identifier is generated by Host Integration Server or SNA Server every time it starts a new session (or is received by Host Integration Server or SNA Server when a session is initiated remotely). The Sync Point resynchronization protocols require knowledge of the session identifier.

To provide this, the MC_GET_ATTRIBUTES and the GET_ATTRIBUTES verbs have been modified to return the session identifier of the session over which a particular conversation is allocated. The MC_GET_ATTRIBUTES and GET_ATTRIBUTES verbs can be used to retrieve this sess_id field of the VCB if the opext field of the VCB is combined with the value AP_EXTD_VCB using OR before calling APPC.

Configuration Changes for Sync Point Support

A new check box is added to the Local LU Configuration dialog box. When checked, this indicates that the local LU is able to participate in synclevel Sync Point sessions. Host Integration Server and SNA Server use this option to determine the synclevel BIND parameters it sends on BIND requests and responses.

This field is added to the Host Integration Server and SNA Server configuration file in a field that is no longer used by Host Integration Server or SNA Server. Existing configurations from earlier versions of SNA Server will therefore continue to work unmodified.

Accepting Incoming Attaches

The Sync Point support in Host Integration Server and SNA Server is intended for use only by gateway applications that implement the architected SNA Sync Point components, including Conversation-Protected Resource Manager (C-PRM). In a Sync Point implementation, it is necessary for C-PRM to be aware of all protected conversations, both locally initiated and remotely initiated. This can be achieved in Host Integration Server or SNA Server by C-PRM intercepting the conversation allocation and deallocation verbs and issuing them on behalf of the transaction program (TP). Note that since Host Integration Server and SNA Server do not allow TP or conversation identifiers to be shared across processes, this also means that the process containing C-PRM must also intercept all APPC verbs issued by the client TPs.

For locally initiated TPs, this is straightforward. However for incoming Attaches, the situation is made more complex by the requirement that the RECEIVE_ALLOCATE verb specify the name of the TP to be matched with the Attach.

In some implementations, this will not be an issue, as the gateway will be aware of the names of all the transactions passing through it. To support this situation, the RECEIVE_ALLOCATE verb has been enhanced as described in the following topic to permit the gateway to indicate that it can accept Sync Point conversations.

In other implementations, the gateway does not know the names of the transactions passing through it. This is particularly so when the gateway is providing a conversion between SNA and another communications protocol. In this case, Host Integration Server and SNA Server allow the gateway process to register itself as a Sync Point Attach Service, indicating that it is willing to accept incoming Attaches for any Sync Point conversation. In this case, the gateway must be implemented as a Sync Point Attach Manager.

This section contains:

- Sync Point Knows Transaction Names
- Sync Point Attach Manager
- Rejecting Remotely Initiated Conversations

Sync Point Knows Transaction Names

A Sync Point implementation that knows the names of all the transactions that can be supported (for example, through configuration of the gateway) may accept incoming Sync Point conversations by issuing a RECEIVE_ALLOCATE verb specifying the name of the transaction and indicating that it is willing to accept Sync Point conversations.

The RECEIVE_ALLOCATE verb was modified to allow a TP to specify that it can accept Sync Point conversations by adding a new syncpoint_rqd field to the VCB. When this field is set to AP_YES it indicates that the transaction program can accept Sync Point conversations from Host Integration Server or SNA Server. When this field is set to AP_NO (the default), it indicates that Sync Point conversations are not supported.

Sync Point Attach Manager

Instead of issuing separate RECEIVE_ALLOCATE verbs for each possible transaction name, a Sync Point implementation may instead register as the Sync Point Attach Manager for Host Integration Server or SNA Server. It does so by issuing a **RECEIVE_ALLOCATE** verb specifying a TP name consisting of all 0x00s.

When a Sync Point Attach Manager is registered, the following changes are effected in server's incoming Attach support on Host Integration Server or SNA Server:

- When an Attach message arrives for any TP name on a conversation with the **syncpoint_rqd** field of the VCB set to AP_YES, Host Integration Server 2000 matches it with the application that issued the special **RECEIVE_ALLOCATE** verb registering itself as the Sync Point Attach Manager.
- Any Attach message arriving for the Resynchronization TP (0x06F2) will automatically be routed to the Sync Point Attach Manager.
- If no RECEIVE_ALLOCATE has been issued for the Sync Point Attach Manager, or for the specific TP name, Host Integration Server or SNA Server will queue the Attach for a configured period of time. If no RECEIVE_ALLOCATE is issued in that time, the Attach will be rejected with a return code of TP_NOT_AVAILABLE_RETRY.
- If a RECEIVE_ALLOCATE is matched with the Attach message, the verb is returned to the TP with the tp_name field of the VCB set to the TP name contained in the Attach message.

Applications using this feature must adhere to two restrictions:

- All verbs issued on conversations started in this manner must be issued by the same process, as Host Integration Server or SNA Server cannot pass **tp_id**s between processes.
- Only a single process may register as the Sync Point Attach Manager on any server running Host Integration Server 2000 or SNA Server. If a second process attempts to register, its RECEIVE_ALLOCATE verb will return immediately with the primary return code set to AP_SYNCPOINT_MANAGER_ACTIVE.

Sync Point Attach Manager applications must reside on a Host Integration Server 2000 server. They may not be distributed across Host Integration Server or SNA Server clients. This restriction is imposed to ensure that only a single instance of Sync Point Services (SPS) and Conversation-Protected Resource Manager (C-PRM) exists for each LU on the Host Integration Server or SNA Server (which might not be the case if Sync Point Attach Managers were visible from multiple servers in the Host Integration Server or SNA Server domain).

The structure of the RECEIVE_ALLOCATE verb control block does not require modification to support this function.

Rejecting Remotely Initiated Conversations

In an environment where a Sync Point Attach Manager is receiving all Attach messages as described above, it may be necessary for it to reject an Attach for a particular TP name, either because the TP name is not valid or because there is another problem with the received Attach message. To enable the application to generate the correct return code at the initiating TP, the DEALLOCATE and MC_DEALLOCATE verbs are enhanced with new **deallocate_type** field values in the VCB that allow the application to specify the return code to be sent to the initiating TP. The new values for **deallocate_type** are:

AP_TP_NOT_AVAIL_RETRY

AP_TP_NOT_AVAIL_NO_RETRY

AP_TPN_NOT_RECOGNIZED

AP_PIP_DATA_NOT_ALLOWED

AP_PIP_DATA_INCORRECT

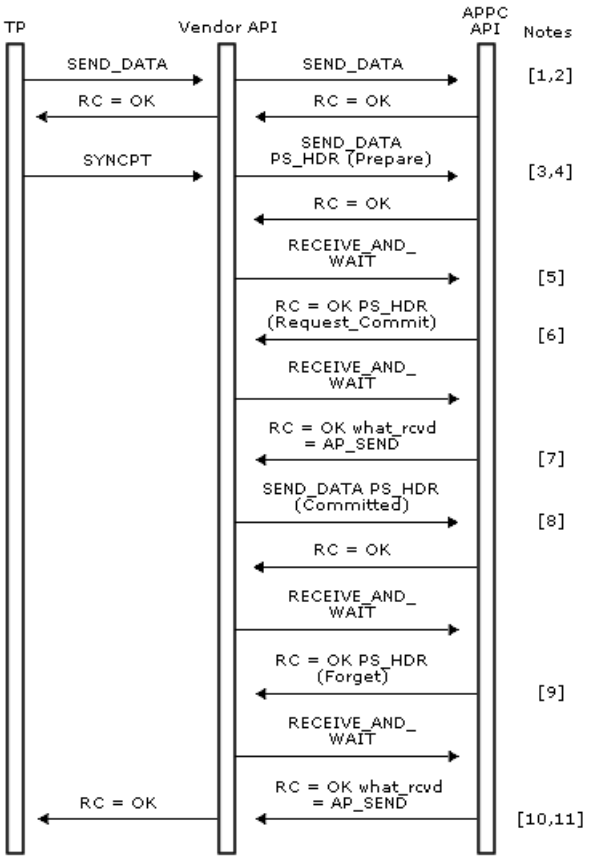
Sync Point Examples

This section contains example verb sequences for implementing the architected Sync Point verbs using the Sync Point facilities provided by Host Integration Server and SNA Server 4.0.

In the following figures, TP is the transaction program that requires Sync Point services. Vendor API is the vendor-supplied APPC API. This component provides the SPS and C-PRM components and a mapping between the vendor's APPC syntax and that of Host Integration Server or SNA Server. APPC API is the Host Integration Server or SNA Server APPC basic and mapped conversation interface.

This section contains:

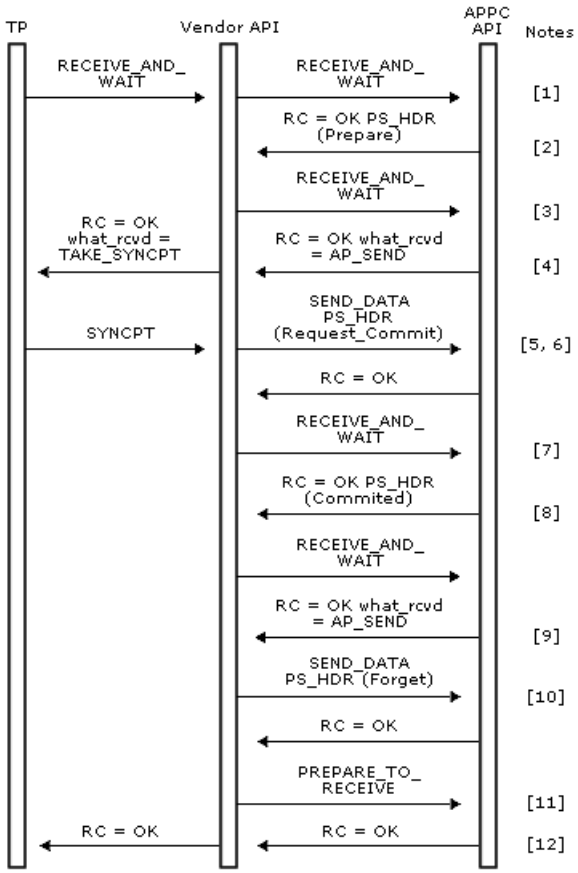
SYNCPT Verb Issued Locally



Notes

1. The transaction program issues a SEND_DATA or MC_SEND_DATA verb depending on whether a basic or mapped conversation is being used.
2. The SEND_DATA or MC_SEND_DATA VCB is passed transparently through the vendor API to Host Integration Server 2000. When the verb completes, the return code from Host Integration Server 2000 is returned to the transaction program.
3. The transaction program issues a SYNCPT verb to the vendor API.
4. The vendor API creates a PREPARE PS header and transmits it by issuing a SEND_DATA or MC_SEND_DATA verb. For a mapped conversation, the data_type field of the MC_SEND_DATA VCB must be set to AP_PS_HEADER.
5. On completion of the SEND_DATA or MC_SEND_DATA verb, the vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb.
6. The RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb completes with the what_rcvd field of the VCB with a value of AP_PS_HEADER. The data buffer is filled with the received REQUEST_COMMIT PS header.
7. Another RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb is issued to get send direction. Note that the vendor API can combine these two verbs into a single request by setting the rtn_status field of the VCB to AP_YES in order to receive status with data on the first RECEIVE_AND_WAIT. or MC_RECEIVE_AND_WAIT.
8. A COMMITTED PS header is then transmitted using a SEND_DATA or MC_SEND_DATA verb.
9. The Vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb to receive the FORGET PS header from the remote TP.
10. Another RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb is issued with the what_rcvd field of the VCB set to AP_SEND to get send direction (again the rtn_status RECEIVE_AND_WAIT field of the VCB can be set to AP_YES to combine these two verbs).
11. When send indication is received, the vendor API returns the SYNCPT verb to the local transaction program with an OK return code.

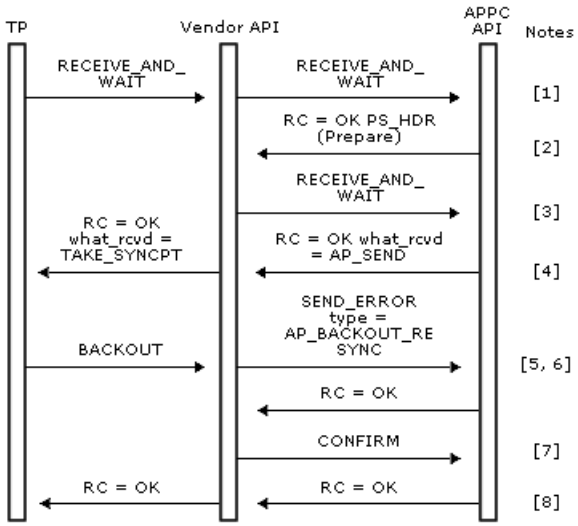
SYNCPT Verb Issued Remotely



Notes

1. The local TP issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb (depending on whether a basic or mapped conversation is being used) to receive data from the remote transaction program. The vendor API passes the verb transparently to Host Integration Server or SNA Server.
2. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with **what_rcvd** = AP_PS_HEADER. The data buffer contains a PREPARE PS header.
3. Another RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb is issued by the vendor API to receive the send indication from the remote TP.
4. The vendor API returns the transaction program's RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb with the what_rcvd field of the VCB set to TAKE_SYNCPT.
5. The transaction program issues a SYNCPT verb.
6. The vendor API generates a REQUEST_COMMIT PS header and transmits it using a SEND_DATA or MC_SEND_DATA verb. If the conversation is mapped, the MC_SEND_DATA verb is issued with the data_type field of the VCB set to AP_PS_HEADER.
7. The vendor API then issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb to give the remote TP direction to send.
8. The RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb completes with the what_rcvd field of the VCB set to AP_PS_HEADER. The data buffer contains a COMMITTED PS header.
9. Another RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb is issued to get permission to send.
10. A FORGET PS header is prepared and sent to the remote transaction program.
11. The FORGET is flushed and direction given to the remote transaction program by issuing a PREPARE_TO_RECEIVE or MC_PREPARE_TO_RECEIVE with the ptr_type field of the VCB set to AP_FLUSH.
12. When the PREPARE_TO_RECEIVE or MC_PREPARE_TO_RECEIVE verb completes, the vendor API returns the SYNCPT verb to the local transaction program.

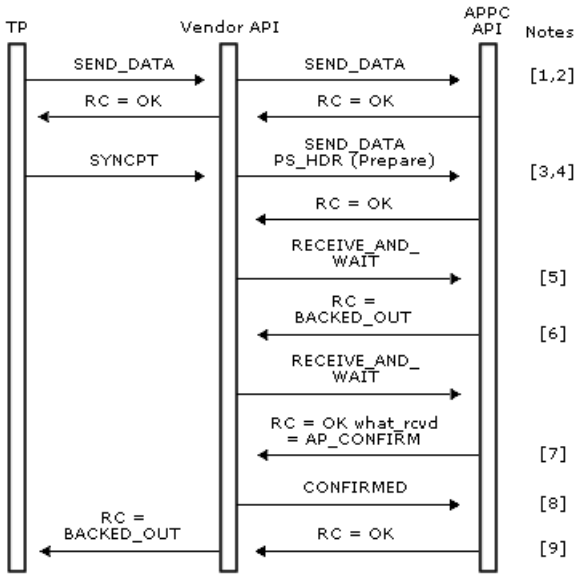
BACKOUT Verb Issued Locally



Notes

1. The local transaction program issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb (depending on whether a basic or mapped conversation is being used) to receive data from the remote transaction program. The vendor API passes the verb transparently to Host Integration Server or SNA Server.
2. The **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** verb completes with the **what_rcvd** field of the VCB set to AP_PS_HEADER. The data buffer contains a PREPARE PS header.
3. Another RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb is issued by the vendor API to receive the send indication from the remote TP.
4. The vendor API returns the transaction program's RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb with the what_rcvd field of the VCB set to TAKE_SYNCPT.
5. The transaction program issues a BACKOUT verb to back out the transaction.
6. The vendor API generates a SEND_ERROR or MC_SEND_ERROR verb of type BACKOUT_RESYNC to send the Backout sense code 0x08240001.
7. The vendor API then issues a CONFIRM or MC_CONFIRM verb to flush the SEND_ERROR or MC_SEND_ERROR verb and request a response from the remote transaction program.
8. The CONFIRM or MC_CONFIRM verb completes when the remote transaction program issues a CONFIRMED or MC_CONFIRMED verb. The vendor API then returns the BACKOUT verb to the local transaction program.

BACKOUT Verb Issued Remotely



Notes

1. The transaction program issues a SEND_DATA or MC_SEND_DATA verb depending on whether a basic or mapped conversation is being used.
2. The **SEND_DATA** or **MC_SEND_DATA** VCB is passed transparently through the vendor API to Host Integration Server or SNA Server. When the verb completes the return code from Host Integration Server or SNA Server is returned to the transaction program.
3. The transaction program issues a SYNCPT verb to the vendor API.
4. The vendor API creates a PREPARE PS header and transmits it by issuing a SEND_DATA or MC_SEND_DATA verb. For a mapped conversation, the data_type field of the MC_SEND_DATA VCB must be set to AP_PS_HEADER.
5. On completion of the SEND_DATA or MC_SEND_DATA verb, the vendor API issues a RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb.
6. The RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb returns with a return code of AP_BACKED_OUT, indicating that the remote transaction program issued a BACKOUT verb.
7. The vendor API issues another RECEIVE_AND_WAIT or MC_RECEIVE_AND_WAIT verb to receive the Confirm indication.
8. When the verb completes with the what_rcvd field of the VCB set to AP_CONFIRM, the vendor API issues a CONFIRMED or MC_CONFIRMED verb to acknowledge the BACKOUT verb.
9. The SYNCPT verb is returned to the transaction program with a BACKED_OUT return code when the CONFIRMED or MC_CONFIRMED verb completes.

Windows CSV Overview

Common service verbs (CSVs) are a set of programming functions provided by Microsoft® Host Integration Server 2000 and Microsoft® SNA Server. The CSVs provide convert, log, trace, and transfer services to applications.

The CSVs and information presented in this guide represent an evolving CSV API that is composed of IBM Extended Services for OS/2 version 1.0 and a set of Windows extensions that allow for registering and deregistering the application and that provide an asynchronous entry point for TRANSFER_MS_DATA.

This section describes the verbs available to you and explains how to use them with your applications. A detailed description of each verb is provided in the reference portion of the SDK.

The CSVs are as follows:

CONVERT
: Converts a character string from ASCII to EBCDIC or from EBCDIC to ASCII.

COPY_TRACE_TO_FILE
: Concatenates the contents of the individual application programming interface (API)/link service trace files to form a single trace file.

DEFINE_TRACE
: Enables or disables tracing for specific APIs.

GET_CP_CONVERT_TABLE
: Creates and returns a 256-byte conversion table to translate character strings from a source code page to a target code page.

LOG_MESSAGE
: For OS/2 only, takes a message from a message file, adds specified data to it, and records the message in the error log file. This verb optionally displays the message on the user's screen.

TRANSFER_MS_DATA
: Builds a Systems Network Architecture (SNA) request unit (RU) containing Network Management Vector Transport (NMVT) data. The verb can send the NMVT data to NetView for centralized problem diagnosis and resolution. The data is optionally logged in the event log for Microsoft® Windows 2000, Windows NT®, Windows® 98, Windows® 95, Windows® version 3.*x*, or MS-DOS®, and in the local audit log file for OS/2.

Host Integration Server and SNA Server Asynchronous Support

Asynchronous call completion returns the initial call immediately so the application can continue with other processes. An application that issues a call and does not regain control until the operation completes is not able to perform any other operations. This type of operation, referred to as blocking, is not suited to a server application designed to handle multiple requests from many clients.

Through **RegisterWindowsMessage** with "WinAsyncCSV" as the string, you pass a window handle by which you will be notified of call completion. You then make your call and when it completes, a message is posted to the window handle that you passed, notifying you that the call is complete.

Before Using Windows CSV

The following Windows extensions are of particular importance and should be reviewed before using Windows CSV:

WinAsyncCSV

Provides an asynchronous entry point for TRANSFER_MS_DATA only. If used for any other verb, the behavior will be synchronous. Use this extension instead of the blocking version of the verb if you run your application under Microsoft® Windows® version 3.*x*.

When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncCSV" as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call. The *lParam* argument contains the original verb control block (VCB) pointer and can be dereferenced to determine the final return code.

If the function returns successfully, a "WinAsyncCSV" message is posted to the application when the operation completes or the conversation is canceled.

WinCSVCleanup

Terminates and deregisters an application from a Windows CSV implementation.

> An application must call this function to deregister itself from the Windows CSV implementation.

WinCSVStartup

Allows an application to specify the version of Windows CSV required and to retrieve details of the specific CSV implementation.

> An application must call this function to register itself with a Windows CSV implementation before issuing any further Windows CSV calls.

Creating Specific NetView User Alerts

You can create NetView user alerts for users to send. Users identify the alerts by number; each number corresponds to a specific collection of information or requests that the user wants to send via NetView to a host operator.

Host Integration Server and SNA Server leave blank fields for the user alert information in the structure that is returned from the sepdcrec function. To create specific user alerts, create appropriate data structures and call the TRANSFER_MS_DATA verb to send the user alert to NetView.

Using CSVs in C Programs

CSVs are available to applications written in Microsoft C version 5.1 or later. A program written in C calls CSVs through the external function **WINCSV**.

Sample Programs

A collection of sample programs is delivered with the Host Integration Server Software Development Kit and the SNA Server Software Development Kit in the \SDK\SAMPLES directory on the SNA Server CD. For more information, see Sample APPC TPs in the SDK.

CSV Verb Control Block

The only parameter passed to the **WINCSV** function is the address of a VCB. The VCB is a structure made up of variables that identify the verb to be executed, supply information to be used by the verb, and contain information returned by the verb when execution is complete. Each verb has its own VCB structure, which is declared in the file WINCSV.H.

Bit Ordering

Bit 0 refers to the high-order bit in a byte or word. To set bit 0 on in a byte, use the bitwise **OR** operation (=) with a value of 128.

WINCSV Definition

The prototype definition of the **WINCSV** function is as follows:

```
extern void WINAPI WINCSV (LPCSV);
```

The VCB address parameter, a 32-bit pointer, is declared as a long integer and requires casting from a pointer to a long integer.

WINCSV.H File

Use the **#include** command to include the WINCSV.H file in any application that issues CSVs.

The WINCSV.H file, which is included with the Host Integration Server and SNA Server Software Development Kits, contains:

- The CSV function prototype.
- The structure declarations for the CSV VCBs.
- The **#define** statements that substitute meaningful symbolic constants for hexadecimal values supplied to and returned by CSVs.

If a **#define** statement pertains to a hexadecimal value that is longer than one byte, a comment shows how the hexadecimal value is stored in memory.

When setting or testing CSV parameters, use the symbolic constants defined by the WINCSV.H file. When examining trace files or the contents of memory, use the hexadecimal values.

Issuing a CSV

The procedure for issuing a CSV is shown in the following sample code that uses CONVERT.

To issue a CSV

1. Create a structure variable from the VCB structure that applies to the verb to be issued.

```
#include <wincsv.h>
    .
    .
struct convert  conv_block;
```

   The VCB structures are declared in the WINCSV.H file; one of these structures is named **CONVERT**.

2. Clear (set to zero) the variables within the structure.

```
memset( conv_block, '\0', sizeof( conv_block ) );
```

   This procedure is not required. However, it helps in debugging and reading the contents of memory. It also eliminates the possibility that future versions of a verb are sensitive to fields that are ignored in the current version.

3. Assign values to the required VCB variables.

```
conv_block.opcode = SV_CONVERT;
conv_block.direction = SV_ASCII_TO_EBCDIC;
conv_block.char_set = SV_AE;
conv_block.len = sizeof(tpstart_name);
conv_block.source = (LPBYTE) tpstart_name;
conv_block.target = (LPBYTE) tpstart.tp_name;
```

   The values SV_CONVERT, SV_ASCII_TO_EBCDIC, and SV_AE are symbolic constants representing integers. These constants are defined in the WINCSV.H file.

   The character array TPSTART_NAME contains an ASCII string to be converted to EBCDIC and placed in the character array TPSTART.TP_NAME.

4. Invoke the verb. The only parameter is a pointer to the address of the structure containing the VCB for the verb.

```
ACSSVC((LONG) &conv_block);
```

   You can also use the following statement:

```
ACSSVC_C((LONG) &conv_block);
```

5. Use the values returned by the verb.

```
if( conv_block.primary_rc == SV_OK ) {
/* other statements */
    .
    .
    .
```

Support for APPC Automatic Logon

This section describes the support for automatic logon for APPC applications available in Microsoft® Host Integration Server 2000 and Microsoft® SNA Server version 3.0 with Service Pack 1 or higher. This feature requires specific configuration by the network administrator: For more information on configuring this feature, see the SNA Server online documentation.

The APPC application must be invoked on the LAN side from a client of Host Integration Server or SNA Server. The client must be logged into a Windows 2000 or Windows NT® domain, but the client can be running on any operating system supported by the Host Integration Server or SNA Server APPC APIs.

The client application is coded to use "program" level security, with a special hard-coded APPC user name MS$SAME and password MS$SAME. When this session allocation flows from client to Host Integration Server or SNA Server, the server looks up the host account and password corresponding to the Windows 2000 or Windows NT account under which the client is logged in, and substitutes the host account information into the APPC attach message it sends to the host.

To use this feature for an APPC application, the **user_id** and **pwd** fields in the ALLOCATE or MC_ALLOCATE verbs must be hard-coded to this special string and **security** must be set to AP_PGM.

APPC Reference

This section of the Microsoft® Host Integration Server 2000 Developer's Guide provides information about the verbs, extensions, and return codes that make up the APPC programming interface.

This section contains:

APPC Management Verbs

This section describes the APPC management verbs:

ACTIVATE_SESSION

CNOS

DEACTIVATE_SESSION

DISPLAY

The management verbs allow you to establish APPC LU 6.2 session limits, obtain configuration information and current operating values for the SNA node, and activate or deactivate sessions. The description of each verb provides:

- A definition of the verb.
- The structure defining the VCB used by the verb. The structure is contained in the WINAPPC.H file. The length of each VCB field is in bytes. Fields beginning with **reserv** (for example, **reserv2**) are reserved.
- The parameters (VCB fields) supplied to and returned by APPC. A description of each parameter is provided, along with its possible values and other information.
- The conversation state(s) in which the verb can be issued.
- The state(s) to which the conversation can change upon return from the verb. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the verb.

Most parameters supplied to and returned by APPC are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the WINAPPC.H header file. For example, the **opcode** (operation code) member of the **mc_send_data** structure used by the **MC_SEND_DATA** verb is the hexadecimal value represented by the symbolic constant AP_M_SEND_DATA. Use only the symbolic constants when writing TPs.

ACTIVATE_SESSION

The **ACTIVATE_SESSION** verb requests Host Integration Server or SNA Server to activate a session between the local LU and a specified partner LU, using a specified mode. This verb completes either when the specified session has become active or when it has failed.

The following structure describes the verb control block used by the **ACTIVATE_SESSION** verb.

```
typedef struct activate_session {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   reserv3[8];
    unsigned char   lu_alias[8];
    unsigned char   plu_alias[8];
    unsigned char   mode_name[8];
    unsigned char   fqplu_name[17];
    unsigned char   polarity;
    unsigned char   session_id[8];
    unsigned long   conv_group_id;
    unsigned char   reserv4[1];
    unsigned char   type;
    HANDLE          deactivation_event;
    unsigned short* p_deactivation_status;
    unsigned char   reserv5[10];
} ACTIVATE_SESSION;
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_ACTIVATE_SESSION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3
A reserved field.

lu_alias
Supplied parameter. Provides the 8-byte ASCII name used locally for the LU. If the default local LU is to be used, fill this parameter with spaces.

plu_alias
Supplied parameter. Provides the 8-byte ASCII name used locally for the partner LU. If the default remote LU is to be used, fill this parameter with spaces. If the partner LU is to be specified with the fqplu_name parameter, fill this parameter with binary zeros.

mode_name
Supplied parameter. Specifies the EBCDIC (type A) mode name.

fqplu_name
Supplied parameter. Provides the partner LU name in EBCDIC (type A) when no **plu_alias** name is defined at the local node and the partner LU is located at a different node. This parameter is ignored if plu_alias is specified.

polarity
Supplied parameter. Specifies the polarity for the session. The possible values are AP_POL_EITHER, AP_POL_FIRST_SPEAKER, and AP_POL_BIDDER.

If AP_POL_EITHER is set, ACTIVATE_SESSION activates a first speaker session if available, otherwise a bidder session is activated.

If AP_POL_FIRST_SPEAKER is set, ACTIVATE_SESSION only succeeds if a session of the requested polarity is available.

If AP_POL_BIDDER is set, ACTIVATE_SESSION only succeeds if a session of the requested polarity is available.

session_id
Returned parameter. Provides the 8-byte identifier of the activate session.

conv_group_id
Returned parameter. Provides the conversation group identifier. This parameter can be specified on ALLOCATE and MC_ALLOCATE verbs to start conversations on this particular session.

reserv4
A reserved field.

type
Supplied parameter. Specifies the type of activation. Possible values are AP_ACT_ACTIVE and AP_ACT_PASSIVE.

If AP_ACT_ACTIVE is specified, then Host Integration Server or SNA Server will attempt to start the required session (by sending the BIND or INIT-SELF).

If AP_ACT_PASSIVE is specified, then Host Integration Server or SNA Server will not attempt to start the session and the verb will complete when the partner has started the session.

deactivation_event
Supplied parameter. Provides an event handle that APPC is to signal when the session is deactivated. The event handle should be obtained by calling either the **CreateEvent** or **OpenEvent** Win32® function.

p_deactivation_status
Returned parameter. A pointer to a value that is set when the deactivation event is signaled to provide completion status. The following values can be returned.
AP_SESSION_DEACTIVATED
AP_COMM_SUBSYSTEM_ABENDED

reserv5
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully. The secondary return code indicates the polarity of the established session. The following values can be returned.

AP_POL_FIRST_SPEAKER

AP_POL_BIDDER

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_INVALID_LU_ALIAS

Secondary return code; APPC cannot find the specified **lu_alias** among those defined.

AP_INVALID_PLU_ALIAS

Secondary return code; APPC did not recognize the specified **plu_alias**.

AP_INVALID_MODE_NAME

Secondary return code; APPC did not recognize the specified **mode_name**.

AP_INVALID_FQPLU_NAME

Secondary return code; APPC did not recognize the specified **fqplu_name**.

AP_INVALID_POLARITY

Secondary return code; APPC did not recognize the specified **polarity**.

AP_INVALID_TYPE

Secondary return code; APPC did not recognize the specified **type**.

AP_ACTIVATION_FAIL_NO_RETRY
Primary return code; the session could not be activated because of a condition that requires action (such as a configuration mismatch or a session protocol error).

AP_ACTIVATION_FAIL_RETRY
Primary return code; the session could not be activated because of a temporary condition (such as a link failure).

AP_SESSION_LIMITS_EXCEEDED
Primary return code; the session could not be activated because the session limits have been exceeded.

AP_SESSION_LIMITS_CLOSED
Primary return code; the session could not be activated because the session limits are closed (i.e. zero).
AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions occurred:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (local area network error occurred).
- The SnaBase at the TP's computer encountered an ABEND.
- The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

Remarks

This verb is supported using APPC only on Windows 2000, Windows NT, Windows 98, and Windows 95.

This verb supports both active and passive activation.

The active form of this verb results in Host Integration Server or SNA Server trying to initiate the session (by sending a BIND for independent LUs or an INIT-SELF for dependent LUs). The active form of this verb will also result in the following behavior.

- If the connection to the partner LU is inactive and is configured as on-demand, the Node will attempt to start the connection.
- If dynamic partnering is being used, the Node will set up the LU-LU/MODE partnership.
- If CNOS has not run, the Node will start CNOS (but will not change any of the session limits).

The passive form does not attempt to start the session, but completes when the LU is started by a BIND from its partner LU. For independent LUs, multiple passive ACTIVATE_SESSION verbs can be queued up for the same LU-LU/MODE, and complete in turn as new sessions are started.

This verb also includes a deactivation event, which is posted when the session is deactivated by any method other than a DEACTIVATE_SESSION verb (for example, an unsolicited UNBIND from its partner LU results in this event being posted).

CNOS

The **CNOS** (Change Number of Sessions) verb establishes APPC LU 6.2 session limits.

The following structure describes the verb control block used by the **CNOS** verb.

```
typedef struct cnos {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   key[8];
    unsigned char   lu_alias[8];
    unsigned char   plu_alias[8];
    unsigned char   fqplu_name[17];
    unsigned char   reserv3;
    unsigned char   mode_name[8];
    unsigned int    mode_name_select:1;
    unsigned int    set_negotiable:1;
    unsigned int    reserv4:6;
    unsigned int    reserv5:8;
    unsigned short  plu_mode_sess_lim;
    unsigned short  min_conwinners_source;
    unsigned short  min_conwinners_target;
    unsigned short  auto_act;
    unsigned int    drain_target:1;
    unsigned int    drain_source:1;
    unsigned int    responsible:1;
    unsigned int    reserv6:5;
    unsigned int    reserv7:8;
} CNOS;
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_CNOS.

reserv2
A reserved field.›

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

key
Supplied parameter. Specifies either the master or service key in ASCII, if the keylock feature has been secured.

lu_alias
Supplied parameter. Provides the 8-byte ASCII name used locally for the LU.

plu_alias
Supplied parameter. Provides the 8-byte ASCII name used locally for the partner LU.

fqplu_name
Supplied parameter. Provides the partner LU name in EBCDIC (type A) when no **plu_alias** name is defined at the local node and the partner LU is located at a different node.

mode_name
Supplied parameter. Specifies the EBCDIC (type A) mode name to be used when the value of **mode_name_select** is AP_ONE.

mode_name_select
Supplied parameter. Specifies the mode name select for which your program is setting or resetting the session limits and contention-winner polarities. Allowed values are AP_ALL or AP_ONE.

set_negotiable
Supplied parameter. Specifies whether APPC is to change the current setting for the maximum negotiable session limit. Allowed values are AP_YES and AP_NO.

reserv4
A 6-bit reserved field.

reserv5
An 8-bit reserved field.›
plu_mode_sess_lim
Supplied parameter. Specifies the session limit when the value for **set_negotiable** is YES. Allowed values are 0 to 32767.
min_conwinners_source
Supplied parameter. Specifies the number of sessions of which the LU is guaranteed to be the contention winner. Allowed values are 0 to 32767.
min_conwinners_target
Supplied parameter. Specifies the minimum number of sessions of which the target LU is guaranteed to be the contention winner. Allowed values are 0 to 32767.
auto_act
Supplied parameter. Specifies the number of the local LU's contention-winner sessions for APPC to activate automatically. Allowed values are 0 to 32767. See the Remarks section of this topic before using this parameter.
drain_target
Supplied parameter. Specifies whether the target LU can drain its waiting (outbound) allocation requests. Allowed values are AP_YES and AP_NO.
drain_source
Supplied parameter. Specifies whether the source LU can drain its waiting (outbound) allocation requests. Allowed values are AP_YES and AP_NO.
responsible
Supplied parameter. Specifies which LU is responsible for deactivating the sessions as a result of resetting the session limit for parallel-session connections. Allowed values are AP_SOURCE and AP_TARGET.
reserv6
A 5-bit reserved field.
reserv7
An 8-bit reserved field.›

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_CNOS_ACCEPTED

Secondary return code; APPC accepts the session limits and responsibility as specified.

AP_CNOS_NEGOTIATED

Secondary return code; APPC accepts the session limits and responsibility as negotiable by the partner LU. Values that can be negotiated are:

plu_mode_session_limit

min_conwinners_source

min_conwinners_target

responsible

drain_target

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE or MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CNOS_LOCAL_RACE_REJECT
Primary return code; APPC is currently processing a **CNOS** verb issued by a local LU.
AP_CNOS_PARTNER_LU_REJECT

Primary return code; the partner LU rejected a **CNOS** request from the local LU.

AP_CNOS_MODE_CLOSED

Secondary return code; the local LU cannot negotiate a nonzero session limit because the local maximum session limit at the partner LU is zero.

AP_CNOS_MODE_NAME_REJECT

Secondary return code; the partner LU does not recognize the specified mode name.

AP_CNOS_COMMAND_RACE_REJECT

Secondary return code; the local LU is currently processing a **CNOS** verb issued by the partner LU.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a local area network error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE or MC_ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** or **MC_ALLOCATE** request.

When **ALLOCATE** or **MC_ALLOCATE** produces this return code for an Host Integration Server or SNA Server system, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_KEY
Primary return code; the supplied key was incorrect.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_ALL_MODE_MUST_RESET

Secondary return code; APPC does not permit a nonzero session limit when the **mode_name_select** parameter indicates AP_ALL.

AP_AUTOACT_EXCEEDS_SESSLIM

Secondary return code; on the **CNOS** verb, the value for **auto_act** is greater than the value for **plu_mode_sess_lim**.

AP_BAD_LU_ALIAS

Secondary return code; APPC cannot find the specified **lu_alias** among those defined.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **plu_alias**.

AP_BAD_SNASVCMG_LIMITS

Secondary return code; your program specified invalid settings for **plu_mode_sess_lim**, **min_conwinners_source**, or **min_conwinners_target** when **mode_name** was supplied.

AP_CHANGE_SRC_DRAINS

Secondary return code; APPC does not permit **mode_name_select** (ONE) and **drain_source** (YES) when **drain_source** (NO) is currently in effect for the specified mode.

AP_CNOS_IMPLICIT_PARALLEL

Secondary return code; APPC does not permit a program to change the session limit for a mode other than the SNASVCMG mode for the implicit partner template when the template specifies parallel sessions. (The term "template" is used because many of the actual values are yet to be filled in.)

AP_CPSVCMG_MODE_NOT_ALLOWED

Secondary return code; the mode named CPSVCMG cannot be specified as the **mode_name** on the deactivate session verb.

AP_EXCEEDS_MAX_ALLOWED

Secondary return code; your program issued a **CNOS** verb, specifying a **plu_mode_sess_lim** number and **set_negotiable** (AP_NO).

AP_MIN_GT_TOTAL

Secondary return code; the sum of **min_conwinners_source** and **min_conwinners_target** specifies a number greater than **plu_mode_sess_lim**.

AP_MODE_CLOSED

Secondary return code; the local LU cannot negotiate a nonzero session limit because the local maximum session limit at the partner LU is zero.

AP_RESET_SNA_DRAINS

Secondary return code; SNASVCMG does not support the drain parameter values.

AP_SINGLE_NOT_SRC_RESP

Secondary return code; for a single-session **CNOS** verb, APPC permits only the local (source) LU to be responsible for deactivating sessions.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CANT_RAISE_LIMITS

Secondary return code; APPC does not permit setting session limits to a nonzero value unless the limits currently are zero.

AP_LU_DETACHED

Secondary return code; a command has reset the definition of the local LU before **CNOS** tried to specify the LU.

AP_SNASVCMG_RESET_NOT_ALLOWED

Secondary return code; your local program attempted to issue the **CNOS** verb for the mode named SNASVCMG, specifying a session limit of zero.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC verb from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

CNOS identifies an LU by alias alone. If the same local LU alias is used multiple times in a domain (for backup or other purposes) and that LU alias is specified through **CNOS**, the verb can flow to a different LU than the one intended.

If **CNOS** is not issued to set the mode session limit before a program issues its first APPC ALLOCATE, MC_ALLOCATE, SEND_CONVERSATION, or MC_SEND_CONVERSATION, or Common Programming Interface for Communications (CPI-C)

Allocate call for a given partner LU and mode, APPC will internally generate a session limit using the value from the mode definition.

When setting the limits for a parallel-session connection, the two LUs negotiate the mode session limits, drain settings, and responsibility values. APPC updates these parameters in **CNOS** to reflect the settings agreed to by both LUs during negotiation. Your program can issue DISPLAY to obtain the negotiated values for the mode session limit.

No **CNOS** negotiation occurs when setting the limits for a single session (that is, the two LUs do not negotiate drain settings or responsibility values). Therefore, coordinate the mode definition parameter settings between partner LUs using a single-session connection by defining a single session mode at each node.

As part of setting up the initial limits, **CNOS** also sets the guaranteed (that is, the minimum) number of contention-winner and contention-loser sessions and sets the automatic activation count for the source LU's contention-winner sessions. The action of **CNOS** normally affects only the group of sessions with the specified mode name between the source LU and the target LU. Alternatively, one **CNOS** can reset the session limits of all modes for a partner LU.

APPC enforces the new mode session limit and the contention-winner polarities until one side or the other changes them by issuing a subsequent **CNOS** verb. The **CNOS** transaction is invisible at the target LU's API, regardless of which LU is the target. The results of the **CNOS** transaction can be obtained using **DISPLAY**.

Setting a Session Limit to Zero

After **CNOS** raises the session limit above zero, it can reset the limit to zero only. It cannot set the session limit to a value that is not zero, and it cannot redistribute the number of sessions allocated as the contention winners and losers. Therefore, your program cannot change the mode session limits if the two LUs have already set the limits to a nonzero value, regardless of which LU initiated the **CNOS** transaction.

A program can change the session limits from a nonzero value, as long as the program first changes the session limit to zero. For example, if the session limit is 8, a program can change it to 6 by first issuing **CNOS** and changing the session limit to zero, and then issuing **CNOS** again and setting the session limit to 6.

APPC can activate one or more LU-LU sessions with the specified mode name as a result of initializing the session limit. You cannot use **CNOS** to activate sessions between two LUs on the same server. APPC deactivates all LU-LU sessions for the specified mode name (or for all mode names for a partner LU) as a result of resetting the session limit to zero. APPC deactivates each session as it becomes free and does not interrupt active conversations.

A separate value, the maximum negotiable session limit, is used in **CNOS** negotiations. If the **set_negotiable** value is AP_YES, the mode session limit value given in this **CNOS** verb also sets the maximum negotiable session limit.

The **lu_alias** and **plu_alias** parameters are 8-byte ASCII character strings. If the name is fewer than eight bytes, it must be padded on the right with ASCII spaces.

You can specify the SNA-defined mode name SNASVCMG for **mode_name**. Use this mode only in a **CNOS** transaction when the source LU and the target LU use parallel user sessions. However, when resetting the session limits to zero for the SNASVCMG PU 2.1 node, the session limits of all other modes between the two LUs must be reset first. The PU 2.1 mode name is a type A EBCDIC character string. A mode name consisting of all spaces is supported. The SNA-defined mode name CPSVCMG is not allowed.

When specifying **plu_mode_sess_lim**, if the mode session limit is currently greater than zero, the value of this parameter must be zero. **CNOS** can raise the limit above zero, but the next **CNOS** must set the value to zero. A single **CNOS** cannot change the mode session limit from one nonzero number to another.

When raising the mode session limit above zero for a parallel-session connection, the target LU can negotiate its parameter to a value greater than zero and less than the specified session limit. The specified or negotiated limit then becomes the new mode session limit and is returned in this field.

The value specified for this parameter must be greater than or equal to the sum of the values specified in the **CNOS** **min_conwinners_source** and **min_conwinners_target** parameters.

Do not reset the SNASVCMG session limit to zero until all other mode session limits between the two LUs are reset to zero and the count of active sessions for all modes (except SNASVCMG) for the partner LU is zero.

The mode session limit should be large enough to accommodate all active conversations in the mode for all TPs.

For **min_conwinners_source** and **min_conwinners_target**, the sum of both parameters cannot exceed the mode session limit. For single-session connections, these parameters specify the desired contention-winner sessions for the target and source LUs. For the SNASVCMG mode name (with a mode session limit of 2 or 1), the specified minimum number of contention-winner sessions for the target LU must be 1. For the source LU, with a mode session limit of 2, the number must be 1; with a mode session limit of 1, the number must be 0. APPC uses these parameters only when the mode session limit is set to a nonzero value.

APPC uses **auto_act** only when the mode session limit is set to a nonzero value. If the value is greater than the **min_conwinners_source** value, APPC uses the new minimum number of contention winners for the source LU as the autoactivation limit.

> The **auto_act** parameter can conflict with the on-demand definition of a connection. Autoactivations by either peer partner can re-establish sessions and connections, possibly resulting in a thrashing situation. Therefore, avoid specifying autoactivation between peer PU 2.1 nodes using on-demand connections.

Whether an LU deactivates a session immediately after the current conversation or after all queued conversations are complete depends on the **drain_source** and **drain_target** parameters.

If an LU is to drain its waiting (outbound) allocation requests, it continues to allocate conversations to active sessions. The responsible LU deactivates a session only when the conversation allocated to the session is deallocated and no request is waiting for allocation to any session with the specified mode name between the two LUs. The allocation of a waiting request takes precedence over the deactivation of a session.

If an LU is not to drain its waiting (outbound) allocation requests, the responsible LU deactivates a session as soon as the conversation allocated to the session is deallocated. If no conversation is allocated to the session, the responsible LU deactivates

the session immediately. However, this verb does not force deallocation of active conversations.

The **responsible** and **mode_name_select** parameters are interrelated as follows:

- APPC ignores the **responsible** parameter for mode names for which the session limit is currently zero if this **CNOS** verb specifies **mode_name_select** (AP_ALL).
- If **CNOS** specifies **mode_name_select** (AP_ONE) with a mode session limit of zero, and the current session limit for that mode name is already zero, the **responsible** parameter must specify the same LU (SOURCE or TARGET) that is currently responsible for deactivating sessions. APPC uses this parameter only when **CNOS** specifies a mode session limit of zero.

For parallel-session connections, the **drain_source** and **mode_name_select** parameters are interrelated as follows:

- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_source** (AP_YES), APPC ignores **drain_source** for those mode names for which the session limit is currently zero.
- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_source** (AP_NO), APPC accepts **drain_source** for all mode names. APPC ends draining for any mode currently draining its requests.
- If **CNOS** specifies **mode_name_select** (AP_ONE), and **drain_source** (AP_YES) is currently in effect, **drain_source** (AP_NO) directs APPC to end the draining at the source LU for requests for the specified mode name.
- If **CNOS** specifies **mode_name_select** (AP_ONE) and **drain_source** (AP_NO) is currently in effect, your program must specify **drain_source** (AP_NO) again.

For parallel-session connections, the **drain_target** parameter and the **mode_name_select** parameter are interrelated as follows:

- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_target** (AP_YES), APPC ignores **drain_target** for the mode names for which the session limit is currently zero.
- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_target** (AP_NO), APPC accepts **drain_target** for all mode names, regardless of the current session limit. Any draining of waiting (outbound) allocation requests at the target LU is ended.
- If **CNOS** specifies **mode_name_select** (AP_ONE) and **drain_target** (AP_YES) is currently in effect, **drain_target** (AP_NO) ends the target LU's draining.
- If **CNOS** specifies **mode_name_select** (AP_ONE) and **drain_target** (AP_YES), and **drain_target** (AP_NO) is currently in effect, the target LU can either accept **drain_target** (AP_YES) or negotiate the parameter to AP_NO. After the target LU accepts the **drain_target** (AP_YES) parameter, it can drain any remaining waiting (outbound) allocation requests.

DEACTIVATE_SESSION

The **DEACTIVATE_SESSION** verb requests Host Integration Server or SNA Server to deactivate a particular session between the local LU and a specified partner LU, or all sessions on a particular mode.

The following structure describes the verb control block used by the **DEACTIVATE_SESSION** verb.

```
typedef struct deactivate_session {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   reserv3[8];
    unsigned char   lu_alias[8];
    unsigned char   session_id[8];
    unsigned char   plu_alias[8];
    unsigned char   mode_name[8];
    unsigned char   type;
    unsigned char   reserv4[3];
    unsigned short  sense_data;
    unsigned char   fqplu_name[17];
    unsigned char   reserv5[19];
} DEACTIVATE_SESSION;
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_DEACTIVATE_SESSION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3
A reserved field.

lu_alias
Supplied parameter. Provides the 8-byte ASCII name used locally for the LU.

session_id
Supplied parameter. Provides the 8-byte identifier of the session to deactivate (returned on the ACTIVATE_SESSION verb). If this field is set to 8 binary zeros, Host Integration Server or SNA Server deactivates all sessions for the partner LU and mode.

plu_alias
Supplied parameter. Provides the 8-byte ASCII name used locally for the partner LU. If the default remote LU is to be used, fill this parameter with spaces. If the partner LU is to be specified with the fqplu_name parameter, fill this parameter with binary zeros.

mode_name
Supplied parameter. Specifies the EBCDIC (type A) mode name.

type
Supplied parameter. Specifies the type of deactivation. Possible values are:

AP_DEACT_CLEANUP

Deactivate the session immediately, without waiting for sessions to end.

AP_DEACT_NORMAL

Do not deactivate the session until all conversations using the session have ended.

sense_data
Returned parameter. Specifies the deactivation sense data for the session.

reserv4
A reserved field.

fqplu_name

Supplied parameter. Provides the partner LU name in EBCDIC (type A) when no **plu_alias** name is defined at the local node and the partner LU is located at a different node. This parameter is ignored if plu_alias is specified.

reserv5

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully. The secondary return code indicates the polarity of the established session. The following values can be returned.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error, specified by one of the following secondary return codes:

AP_INVALID_LU_ALIAS

Secondary return code; APPC cannot find the specified **lu_alias** among those defined.

AP_INVALID_PLU_ALIAS

Secondary return code; APPC did not recognize the specified **plu_alias**.

AP_INVALID_SESSION_ID

Secondary return code; APPC did not recognize the specified **session_id**.

AP_INVALID_MODE_NAME

Secondary return code; APPC did not recognize the specified **mode_name**.

AP_INVALID_FQPLU_NAME

Secondary return code; APPC did not recognize the specified **fqplu_name**.

AP_INVALID_TYPE

Secondary return code; APPC did not recognize the specified **type**.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions occurred:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a local area network error occurred).
- The SnaBase at the TP's computer encountered an ABEND.
- The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

Remarks

This verb is supported using APPC only on Windows 2000, Windows NT, Windows 98, and Windows 95.

DISPLAY

The **DISPLAY** verb returns configuration information and current operating values for the SNA node.

It is recommended that you use the GetAppcConfig Windows extension function to obtain system configuration information relating to APPC LUs. Users of 5250 emulators, in particular, should use the **GetAPPCConfig** Windows extension.

> **Note** Because of the nature of client/server architecture, the implementation of the **DISPLAY** on Host Integration Server 2000 and SNA Server contains important differences from the IBM Extended Services for OS/2 version 1.0 (IBM ES for OS/2 version 1.0) on which it was based. These differences are described in the following topics. For information on configuring **DISPLAY** in Host Integration Server 2000 Manager, see the Microsoft Host Integration Server 2000 online books.

> **Note** For applications that use the APPC **DISPLAY** verb in IBM ES for OS/2 version 1.0 compatibility mode and that do not use the Host Integration Server or SNA Server extensions for enumerating all active servers and connections, Host Integration Server and SNA Server will randomly choose a default **DISPLAY** connection, unless a specific default **DISPLAY** connection has been configured in Host Integration Server Manager or SNA Explorer. This connection is used as the basis for all **DISPLAY** requests. For information about specifying the default **DISPLAY** connection, see the Microsoft Host Integration Server 2000 online books.

The following structure describes the verb control block used by the **DISPLAY** verb.

```
struct display {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned long   init_sect_len;
    unsigned long   buffer_len;
    unsigned char FAR * buffer_ptr;
    unsigned long  num_sections;
    unsigned long  display_len;
    unsigned long  area_needed;
    unsigned char  sna_global_info;
    unsigned char  lu62_info;
    unsigned char  am_info;
    unsigned char  tp_info;
    unsigned char  sess_info;
    unsigned char  link_info;
    unsigned char  lu_0_3_info;
    unsigned char  gw_info;
    unsigned char  x25_physical_link_info;
    unsigned char  sys_def_info;
    unsigned char  adapter_info;
    unsigned char  lu_def_info;
    unsigned char  plu_def_info;
    unsigned char  mode_def_info;
    unsigned char  link_def_info;
    unsigned char  ms_info;
    struct sna_global_info_sect FAR * sna_global_info_ptr;
    struct lu62_info_sect FAR * lu62_info_ptr;
    struct am_info_sect FAR * am_info_ptr;
    struct tp_info_sect FAR * tp_info_ptr;
    struct sess_info_sect FAR * sess_info_ptr;
    struct link_info_sect FAR * link_info_ptr;
    struct lu_0_3_info_sect FAR * lu_0_3_info_ptr;
    struct gw_info_sect FAR * gw_info_ptr;
    struct x25_physical_link_info_sect FAR * x25_physical_link_info_ptr;
    struct sys_def_info_sect FAR * sys_def_info_ptr;
    struct adapter_info_sect FAR * adapter_info_ptr;
    struct lu_def_info_sect FAR * lu_def_info_ptr;
    struct plu_def_info_sect FAR * plu_def_info_ptr;
    struct mode_def_info_sect FAR * mode_def_info_ptr;
    struct link_def_info_sect FAR * link_def_info_ptr;
    struct ms_info_sect FAR * ms_info_ptr;
} DISPLAY;
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_DISPLAY.

reserv2
A reserved field, this value must be set to NULL.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

init_sect_len
Supplied parameter. Specifies the number of bytes in the initial section of the VCB, up to the beginning of information pointers. This parameter and the **num_sections** parameter must be set to specific values depending on the format being requested. See the notes below for details.

buffer_len
Supplied parameter. Specifies the length (0 to 65535 bytes) of the passed display data buffer.

buffer_ptr
Supplied parameter. Provides the address of the display data buffer that will contain the requested information.

num_sections
Supplied parameter. Specifies the maximum number of information sections that can be returned by the verb. This parameter and the **init_sect_len** parameter must be set to specific values depending on the format being requested. See the notes below for details.

display_len
Returned parameter. Provides the total number of bytes used that are returned into the display data buffer.

area_needed
Returned parameter. Provides the total number of bytes needed for all of the displayed data.

sna_global_info
Supplied parameter. Specifies if global information is requested. Allowed values are AP_YES and AP_NO.

lu62_info
Supplied parameter. Specifies if information on all active LUs, their partners, and their modes is requested. Allowed values are AP_YES and AP_NO.

am_info
Supplied parameter. Specifies if Attach Manager information on the defined TP is requested. Allowed values are AP_YES and AP_NO.

> **Note** This option is not supported by Host Integration Server or SNA Server and this parameter must be set to AP_NO.

tp_info
Supplied parameter. Specifies if information on the active TPs and any active conversations is requested. Allowed values are AP_YES and AP_NO.

> **Note** This option is not supported by Host Integration Server or SNA Server and this parameter must be set to AP_NO.

sess_info
Supplied parameter. Specifies if information on sessions is requested. Allowed values are AP_YES and AP_NO.

link_info
Supplied parameter. Specifies if information on the active SNA logical lines is requested. Allowed values are AP_YES and AP_NO.

lu_0_3_info
Supplied parameter. Specifies if information on logical units type 0, 1, 2, and 3 is requested. Allowed values are AP_YES and AP_NO.

gw_info
Supplied parameter. Specifies if information on the SNA gateway is requested. Allowed values are AP_YES and AP_NO.

x25_physical_link_info
Supplied parameter. Specifies if X.25 information is required. Allowed values are AP_YES and AP_NO.

> **Note** This option is not supported by Host Integration Server or SNA Server and this parameter must be set to AP_NO.

sys_def_info
Supplied parameter. Specifies if information about the default LU, node names, and default parameters for inbound and outbound implicit partners is requested. Allowed values are AP_YES and AP_NO.

adapter_info
Supplied parameter. Specifies if information about the configured communications adapters is requested. Allowed values are AP_YES and AP_NO. This parameter must be set to AP_NO when NS/2 format is requested.

lu_def_info
Supplied parameter. Specifies if information about the defined LUs is requested. Allowed values are AP_YES and AP_NO.

plu_def_info
Supplied parameter. Specifies if information about the defined partner LUs is requested. Allowed values are AP_YES and AP_NO.

mode_def_info
Supplied parameter. Specifies if information about the defined nodes is requested. Allowed values are AP_YES and AP_NO.

link_def_info
Supplied parameter. Specifies if information about the defined logical links is requested. Allowed values are AP_YES and AP_NO.

ms_info
Supplied parameter. Specifies if information about management services is requested. Allowed values are AP_YES and AP_NO. This parameter must be set to AP_NO when NS/2 format is requested.

sna_global_info_ptr
Returned parameter. Indicates the address of the beginning of SNA global information in the data buffer.

lu62_info_ptr
Returned parameter. Indicates the address of the beginning of LU 6.2 information in the data buffer.

am_info_ptr
Returned parameter. Indicates the address of the beginning of the Attach Manager information in the data buffer.

> **Note** This option is not supported by Host Integration Server or SNA Server.

tp_info_ptr
Returned parameter. Indicates the address of the beginning of TP information in the data buffer.

> **Note** This option is not supported by Host Integration Server or SNA Server.

sess_info_ptr
Returned parameter. Indicates the address of the beginning of session information in the data buffer.

link_info_ptr
Returned parameter. Indicates the address of the beginning of link information in the data buffer.

lu_0_3_info_ptr
Returned parameter. Indicates the address of the beginning of LU information in the data buffer.

gw_info_ptr
Returned parameter. Indicates the address of the beginning of gateway information in the data buffer.

x25_physical_link_info_ptr
Returned parameter. Indicates the address of the beginning of X.25 information in the data buffer.

> **Note** This option is not supported by Host Integration Server or SNA Server.

sys_def_info_ptr
Returned parameter. Indicates the address of the beginning of system default information in the data buffer.

adapter_info_ptr
Returned parameter. Indicates the address of the beginning of adapter information in the data buffer.

lu_def_info_ptr
Returned parameter. Indicates the address of the beginning of local LU definition information in the data buffer.

plu_def_info_ptr
Returned parameter. Indicates the address of the beginning of partner LU definition information in the data buffer.

mode_def_info_ptr
Returned parameter. Indicates the address of the beginning of mode definition information in the data buffer.

link_def_info_ptr
Returned parameter. Indicates the address of the beginning of link definition information in the data buffer.

ms_info_ptr
Returned parameter. Indicates the address of the beginning of management services information in the data buffer.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_DISPLAY_INVALID_CONSTANT

Secondary return code; the value supplied for NUM_SECTIONS or INIT_SEC_LEN is invalid.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_DISPLAY_INFO_EXCEEDS_LEN

Secondary return code; the returned **DISPLAY** information did not fit in the buffer.

AP_INVALID_DATA_SEGMENT

Secondary return code; the segment containing the data buffer is too small for the specified data length.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation has encountered an ABEND.
- The connection between the TP and the node type 2.1 has been broken (a LAN error).
- The SnaBase at the TP's computer has encountered an ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

DISPLAY identifies an LU by alias alone. If the same local LU alias is used multiple times in a domain (for backup or other purposes) and that LU alias is specified through **DISPLAY**, the verb can flow to a different LU than the one intended.

For the **DISPLAY** verb to return successfully, a specific connection must be defined in the Host Integration Server 2000 Manager or SNA Explorer program Display Verb dialog box. IBM originally defined the **DISPLAY** verb with the IBM OS/2 Extended Edition product which assumed a single connection. However, because Host Integration Server and SNA Server support multiple connections, the specific connection associated with the **DISPLAY** verb must be configured.

The **DISPLAY** verb requires a user-supplied buffer for the return of system information. If the buffer is not large enough, APPC returns the AP_DISPLAY_INFO_EXCEEDS_LEN return code, along with the size actually needed at the time of the request (in the **area_needed** parameter). One possible strategy for the use of this verb follows:

- If the **buffer_len** value is less than the **area_needed** value returned by APPC, and the required length is less than 64 kilobytes (K), then increase the size of the display buffer to equal or greater than the **area_needed** value.
- If the **area_needed** value is greater than 64K, you can choose to request each information section individually. Or, you can take the following steps:

    1. Process the information sections with complete information, whose total number displayed equals the total actual number.
    2. Choose a subset of the information sections you requested that contains incomplete information, and reissue the verb requesting those information sections.
    3. Repeat steps 1 and 2 as needed.

    Note If an individual information section is greater than 64K, then you cannot get all of the requested information from APPC.

The **DISPLAY** verb should not executed from different threads of the same process, since it is not thread-safe.

The **DISPLAY** verb returns AP_DISPLAY_INVALID_CONSTANT if the following values are not set for the supplied parameters for **init_sect_len** and **num_sections**:

	NS/2 format	**IBM EE format**	**NS/2 format (Windows 2000 and Windows NT only**	**IBM EE format (Windows 2000 and Windows NT only)**
init_sect_len	50	44	52	48
num_sections	16	9	16	9

The AP_DISPLAY_INVALID_CONSTANT is also returned when the following parameters are not set properly:

- **reserv2** must be set to NULL.
- **am_info** must be set to AP_NO.
- **tp_info** must be set to AP_NO.
- **adapter_info** must be set to AP_NO if NS/2 format is requested.
- **ms_info** must be set to AP_NO if NS/2 format is requested.

Host Integration Server and SNA Server Extensions

The Host Integration Server and SNA Server **DISPLAY** verb is compatible with the IBM ES for OS/2 version 1.0 **DISPLAY** verb. However, since IBM ES for OS/2 version 1.0 is a single-server system and Host Integration Server and SNA Server support multiple-server systems, the **DISPLAY** verb has been extended to allow the user to target a specific server running Host Integration Server or SNA Server by which the **DISPLAY** verb will be processed.

To direct a **DISPLAY** verb at a particular server running Host Integration Server or SNA Server, place the ASCII string CSEXTNID, followed by the computer name of the server running Host Integration Server or SNA Server at the start of the buffer pointed to by **buffer_ptr**. The computer name is a 32-byte ASCII string and can be zero or padded with spaces.

Because the local node identifier is configured on a per-node basis for IBM ES for OS/2 version 1.0 and can be different for each connection in Host Integration Server or SNA Server, Host Integration Server and SNA Server also allow you to specify an optional connection name. This is an 8-byte ASCII string, which is placed after the 32-byte computer name. Again, the string can be zero or padded with spaces. The following example illustrates the CSEXTNID extension:

```
csextnid computername 00000000000000000000 name
```

If you do not specify a connection name, Host Integration Server and SNA Server return information about the first connection configured for the Host Integration Server or SNA Server system.

If you do not specify a computer name, Host Integration Server and SNA Server will randomly choose a default **DISPLAY** computer and connection, unless a specific default **DISPLAY** connection has been configured on the server. These parameters can be configured with the Host Integration Server Manager or the Host Integration Server Administrator Client when using Host Integration Server 2000 or with the SNA Explorer or SNA Manager Client on SNA Server. **DISPLAY** will behave as if you specified the connection and the computer name of the server that owns the verb. For additional information about using default LUs, see the *Microsoft Host Integration Server 2000 online books*.

Host Integration Server and SNA Server also allow you to use **DISPLAY** to return a list of active servers. To do so, place the string CSEXTNIDCSLISTND in the **DISPLAY** buffer and set the supplied parameters **sna_global_info**, **lu62_info**, and so on, to AP_NO. The information is returned in the **DISPLAY** buffer in the following format:

```
#activenodes            - 2 bytes
  node_name 1           - 8 bytes
  box_name 1            - 32 bytes
  .
  node_name m
  box_name m
```

In the current version of Host Integration Server and SNA Server, **node_name** is always SNASERVR and **box_name** is the computer name of the server.

Differences by Information Type

Differences in the implementation of the **DISPLAY** verb between the Host Integration Server or SNA Server and IBM ES for OS/2 are described in this section by information type. For each information type, there is a topic that describes:

- The information defined by IBM ES for OS/2 version 1.0.
- The information returned by Host Integration Server 2000 and SNA Server 4.0.

> **Note** Host Integration Server and SNA Server do not support all of the information types supported by IBM ES for OS/2 version 1.0. If an information type is not listed in this section, it is not supported by Host Integration Server or SNA Server.

SNA Global Information

SNA global information is defined or returned as described here.

Defined by IBM ES for OS/2 Version 1.0

Information on SNA global information is provided in the **sna_global_info_sect** structure as defined below.

```
typedef struct sna_global_info_sect {
    unsigned char version;
    unsigned char release;
    unsigned char net_name[8];
    unsigned char pu_name[8];
    unsigned char node_id[4];
    type_product_set_id product_set_id;
    unsigned char alias_cp_name[8];
    unsigned char node_type;
    unsigned char cp_nau_addr;
    unsigned char corr_serv_disk;
    unsigned char reserved;
    unsigned char appc_version;
    unsigned char appc_release;
    unsigned char appc_fixlevel;
} SNA_GLOBAL_INFO_SECT;
```

Members

version
  Communications Manager Extended Edition version number.
release
  Communications Manager Extended Edition release number.
net_name
  Network name, first part of fully qualified control program (CP) name, in EBCDIC (type A).
pu_name
  PU name, second part of fully qualified CP name, in EBCDIC (type A).
node_id
  Four-byte hexadecimal exchange identifier.
product_set_id
  Computer product data.
alias_cp_name
  Node name (local name for CP) in ASCII.
node_type
  AP_NN, AP_EN, or AP_LEN.
cp_nau_addr
  CP NAU address where 0 means not used (an independent LU). Other legal values are 1 to 254.
corr_serv_disk
  Last four digits of corrective service disk number.
reserved
  Reserved field.
appc_version
  APPC version number.
appc_release
  APPC release number.
appc_fixlevel
  APPC fixlevel.

Returned by Host Integration Server and SNA Server

Information on SNA global information is provided in the **sna_global_info_sect** structure as defined below.

```
typedef struct sna_global_info_sect {
    unsigned char version;
    unsigned char release;
    unsigned char net_name[8];
```

```
    unsigned char pu_name[8];
    unsigned char node_id[4];
    type_product_set_id product_set_id;
    unsigned char alias_cp_name[8];
    unsigned char node_type;
    unsigned char cp_nau_addr;
    unsigned char corr_serv_disk;
    unsigned char reserved;
    unsigned char appc_version;
    unsigned char appc_release;
    unsigned char appc_fixlevel;
} SNA_GLOBAL_INFO_SECT;
```

Members

version
  Major operating system (OS) version number.
release
  Minor OS version number.
net_name
  Node network name in EBCDIC (type A).
pu_name
  PU name in EBCDIC (type A) associated with connection.
node_id
  Node identifier to send.
product_set_id
  Set to EBCDIC zeros.
alias_cp_name
  Node name, local name for the control program (CP), in ASCII.
node_type
  Set to AP_LEN.
cp_nau_addr
  CP NAU address where 0 means not used (an independent LU). Other legal values are 1 to 254.
corr_serv_disk
  Reserved field set to zero.
reserved
  Reserved field set to zero.
appc_version
  Host Integration Server or SNA Server major version number.
appc_release
  Host Integration Server or SNA Server minor version number.
appc_fixlevel
  Host Integration Server or SNA Server patchlevel.

Remarks

Host Integration Server and SNA Server return **version** and **release** as the major and minor OS version numbers from **GetVersion** (for Windows 2000, Windows NT, Windows 98, Windows 95, or Windows version 3.*x* systems) or **GetDosVersion** (for OS/2).

Because Host Integration Server 2000 and SNA Server have no information on the computer type, serial number, and manufacturer, **product_set_id** is set to EBCDIC zeros.

Host Integration Server and SNA Server do not support APPN node types, so the node type is returned as 1 (an AP_LEN node), and not 2 or 3 (AP_NN or AP_EN nodes), as defined by IBM ES for OS/2 version 1.0.

LU 6.2 Information

Information on LUs is provided in the **lu62_info_sect** structure as defined below.

```
typedef struct lu62_info_sect {
    unsigned long  lu62_init_sect_len;
    unsigned short num_lu62s;
    unsigned short total_lu62s;
} LU62_INFO_SECT;
```

Members

lu62_init_sect_len
Structure length.
num_lu62s
Number of configured LUs displayed.
total_lu62s
Total number of configured LUs.

For each configured LU, an **lu62_overlay** structure is provided as defined below.

```
typedef struct lu62_overlay {
    unsigned long  lu62_entry_len;
    unsigned long  lu62_overlay_len;
    unsigned char  lu_name[8];
    unsigned char  lu_alias[8];
    unsigned short num_plus;
    unsigned char  fqlu_name[17];
    unsigned char  default_lu;
    unsigned char  reserv3;
    unsigned char  lu_local_addr;
    unsigned short lu_sess_lim;
    unsigned char  max_tps;
    unsigned char  lu_type;
} LU62_OVERLAY;
```

Members

lu62_entry_len
Size of this LU entry.
lu62_overlay_len
This value contains **sizeof(**struct **lu62_overlay)**–**sizeof(lu62_entry_len)**.
lu_name
LU name (EBCDIC type A).
lu_alias
LU alias (ASCII).
num_plus
Number of partner LUs.
fqlu_name
Fully qualified LU name (EBCDIC type A).
default_lu
For local LU group, an LU equal to the **default_lu** is used if none is specified. Legal values are AP_NO and AP_YES.

On Host Integration Server and SNA Server, there is no concept of a default local LU. Therefore, the **default_lu** flag, which is set to AP_YES for the node in IBM ES for OS/2 version 1.0, is set to AP_NO for Host Integration Server and SNA Server.

lu_local_addr
NAU address, 0–254.
lu_sess_lim
Configured session limit, 0–255.
max_tps
Maximum number of TPs, 1–255.
lu_type

Always LU type 6.2.

For each configured LU, a **plu_62_overlay** structure for the partner LU is provided as defined below.

```
typedef struct plu62_overlay {
    unsigned long  plu62_entry_len;
    unsigned long  plu62_overlay_len;
    unsigned char  plu_alias[8];
    unsigned short num_modes;
    unsigned char  plu_un_name[8];
    unsigned char  fqplu_name[17];
    unsigned char  reserv3;
    unsigned char  plu_sess_lim;
    unsigned char  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned int   par_sess_supp:1;
    unsigned int   reserv4:7;
    unsigned int   def_already_ver:1;
    unsigned int   def_conv_sec:1;
    unsigned int   def_sess_sec:1;
    unsigned int   reserv5:5;
    unsigned int   act_already_ver:1;
    unsigned int   act_conv_sec:1;
    unsigned int   reserv6:6;
    unsigned int   implicit_part:1;
    unsigned int   reserv7:7;
} PLU62_OVERLAY;
```

Members

plu62_entry_len
Size of this partner LU entry.

plu62_overlay_len
This value contains **sizeof(**struct **plu62_overlay)**–**sizeof(plu62_entry_len)**.

plu_alias
Partner LU alias (ASCII).

num_modes
Number of modes.

plu_un_name
Partner LU uninterpreted name (EBCDIC).

fqplu_name
Fully qualified partner LU name (EBCDIC type A).

reserv3
Reserved field set to zero.

plu_sess_lim
Partner LU session limit, 0–255.

dlc_name
DLC name (ASCII).

adapter_num
DLC adapter number.

dest_addr_len
Length of destination adapter address.

dest_addr
Destination adapter address.

par_sess_supp
Bit 15 of a bitfield specifying parallel sessions. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

reserv4
Bits 8–14 of a bitfield specifying a reserved field set to zero.

def_already_ver
Bit 7 of a bitfield specifying whether the configured already verified option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

def_conv_sec

Bit 6 of a bitfield specifying whether the configured conversation security option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

def_sess_sec

Bit 5 of a bitfield specifying whether the configured session security option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

reserv5

Bits 0–4 of a bitfield specifying a reserved field set to zero.

act_already_ver

Bit 15 of a bitfield specifying whether the active already verified option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

act_conv_sec

Bit 14 of a bitfield specifying whether the active conversation security option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

reserv6

Bits 8–13 of a bitfield specifying a reserved field set to zero.

implicit_part

Bit 7 of a bitfield specifying whether this is an implicit partner. Valid values are AP_NO and AP_YES.

For partner LU group, **implicit_part** indicates the partner LU group was configured as an implicit primary logical unit (PLU).

reserv7

Bits 0–6 of a bitfield specifying a reserved field set to zero.

Remarks

Host Integration Server and SNA Server return information on all the configured LU 6.2s in the system, including the implicit PLU and all instances of implicit modes. IBM ES for OS/2 version 1.0 only returns information on those that are in use or have been in use.

For partner LU group, **implicit_part** indicates the partner LU group was configured as an implicit primary logical unit (PLU).

For mode group, **implicit_mode** bitfield returned in the mode_overlay structure indicates the mode group was configured as an implicit mode.

Session Information

Information on session information is provided in the **sess_info_sect** structure as defined below.

```
typedef struct sess_info_sect {
    unsigned long  sess_sect_len;
    unsigned short num_sessions;
    unsigned short total_sessions;
} SESS_INFO_SECT;
```

Members

sess_sect_len
The length of the initial session information section, including this parameter, up to the first session group. The length does not include any previous information sections.

num_sessions
The number of session groups returned by the DISPLAY verb into your program's buffer. This is the number of times the session group is repeated.

total_sessions
The total number of session groups. This number is the same as the number returned in the **num_sessions** member except when APPC has more information about session groups than it can place in the supplied buffer, in which case this number is larger.

For each session group, a **sess_overlay** structure for the session is provided as defined below.

```
typedef struct sess_overlay {
    unsigned long  sess_entry_len;
    unsigned long  reserv3;
    unsigned char  sess_id[8];
    unsigned long  conv_id[8];
    unsigned char  lu_alias[8];
    unsigned char  plu_alias[8];
    unsigned char  mode_name[8];
    unsigned short send_ru_size;
    unsigned short rcv_ru_size;
    unsigned short send_pacing_size;
    unsigned short rcv_pacing_size;
    unsigned char  link_id[12];
    unsigned char  daf;
    unsigned char  oaf;
    unsigned char  odai;
    unsigned char  sess_type;
    unsigned char  conn_type;
    unsigned char  reserv4;
    FPCID_OVERLAY  fpcid;
    unsigned char  cgid[4];
    unsigned char  fqlu_name[17];
    unsigned char  fqplu_name[17];
    unsigned char  pacing_type;
    unsigned char  reserv5;
 } SESS_OVERLAY;
```

Defined by IBM ES for OS/2 Version 1.0

Members

sess_entry_len
Size of this session group entry.

sess_id
The internal identifier of the session for which this information is displayed.

conv_id
The unique four-byte ID of the conversation currently using this session.

lu_alias
LU alias (ASCII).

plu_alias
Partner LU alias (ASCII).
mode_name
The name of the mode (EBCDIC).
send_ru_size
The maximum RU size used on this session and this **mode_name** for sending RUs.
rcv_ru_size
The maximum RU size used on this session and this **mode_name** for receiving RUs.
send_pacing_size
The size of the send pacing window on this session.
rcv_pacing_size
The size of the receive pacing window on this session.
link_id
Name of local logical link station.
daf
The destination address field for this session.
oaf
The origin address field for this session.
odai
The origin destination address indicator field for this session.
sess_type
The type of the session. The session type can be one of the following:

SSCP_PU_SESSION

This session is between a workstation physical unit and a host system services control point. This type of session exists if the local node contains a dependent LU, or if the session has been solicited in order to send alerts to the host.

SSCP_LU_SESSION

This session is between a dependent LU and a host system services control point.

LU_LU _SESSION

This session is between two LUs.

conn_type
Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

fq_pc_id
Fully qualified procedure correlation identifier of the session.
cgid
Unique identifier for the conversation group of the session.
fqlu_name
The fully-qualified LU name in EBCDIC (type A).
fqplu_name
The fully-qualified partner LU name in EBCDIC (type A).
pacing_type
The pacing type can be one of the following:

AP_FIXED

Fixed pacing.

AP_ADAPTIVE

Adaptive pacing.

Returned by Host Integration Server and SNA Server

Members

sess_entry_len
Size of this session group entry.
sess_id
The internal identifier of the session for which this information is displayed.
conv_id
The unique four-byte ID of the conversation currently using this session.
lu_alias
LU alias (ASCII).
plu_alias
Partner LU alias (ASCII).
mode_name
The name of the mode (EBCDIC).
mode_name
The name of the mode (EBCDIC).
send_ru_size
The maximum RU size used on this session and this **mode_name** for sending RUs.
rcv_ru_size
The maximum RU size used on this session and this **mode_name** for receiving RUs.
send_pacing_size
The size of the send pacing window on this session.
rcv_pacing_size
The size of the receive pacing window on this session.
link_id
Connection name.
daf
The destination address field for this session.
oaf
The origin address field for this session.
odai
The origin destination address indicator field for this session.
sess_type
The type of the session. The session type can be one of the following:

SSCP_PU_SESSION

This session is between a workstation physical unit and a host system services control point. This value is never returned by Host Integration Server or SNA Server.

SSCP_LU_SESSION

This session is between a dependent LU and a host system services control point.

LU_LU _SESSION

This session is between two LUs.

conn_type
Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

AP_BOTH_SESSION

fq_pc_id
Set to zero.

cgid

Set to zero.

type_of_pacing

The pacing type can be one of the following:

AP_FIXED

Fixed pacing.

AP_ADAPTIVE

Adaptive pacing. This value is never returned by Host Integration Server or SNA Server.

Active Link Information

Active link information is provided in the **link_info_sect** structure as defined below.

```
typedef struct link_info_sect {
    unsigned long  link_init_sect_len;
    unsigned short num_links;
    unsigned short total_links;
} LINK_INFO_SECT;
```

Members

link_init_sect_len
The length of the initial active link information section, including this parameter, up to the first link overlay group. The length does not include any previous information sections.

num_links
The number of active links returned by the DISPLAY verb into your program's buffer. This is the number of times the link overlay group is repeated.

total_sessions
The total number of active links. This number is the same as the number returned in the **num_links** member except when APPC has more information about active links than it can place in the supplied buffer, in which case this number is larger.

For each active link, a **link_overlay** structure for the active link is provided as defined below.

```
typedef struct link_overlay {
    unsigned long  link_entry_len;
    unsigned char  link_id[12];
    unsigned long  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned char  inbound_outbound;
    unsigned char  state;
    unsigned char  deact_link_flag;
    unsigned char  reserv3;
    unsigned short num_sessions;
    unsigned short ru_size;
    unsigned short reserv4;
    unsigned char  adj_fq_cp_name[17];
    unsigned char  adj_node_type;
    unsigned char  reserv5;
    unsigned char  cp_cp_sess_spt;
    unsigned char  conn_type;
    unsigned char  ls_role;
    unsigned char  line_type;
    unsigned char  tg_number;
    unsigned long  eff_capacity;
    unsigned char  conn_cost;
    unsigned char  byte_cost;
    unsigned char  propagation_delay;
    unsigned char  user_def_1;
    unsigned char  user_def_2;
    unsigned char  user_def_3;
    unsigned char  security;
    unsigned char  reserv6;
 } LINK_OVERLAY;
```

Defined by IBM ES for OS/2 Version 1.0

Members

link_entry_len
Size of this link entry.

link_id
Local logical link station name (EBCDIC).

dlc_name
Data link control (DLC) name set to one of the following:

ETHERAND

IBMTRNET

IBMPCNET

SDLC

TWINAX

X25DLC

adapter_num
Adapter number used by this link to connect to the adjacent node.

dest_addr_len
Length of the destination adapter address.

dest_addr
The destination adapter address.

inbound_outbound

state
The state of the link. The link state can be one of the following:

AP_CONALS_PND

The process to bring up the link has started but XID negotiation has not started.

AP_XID_PND

XID negotiation is in process.

AP_CONTACT_PND

XID negotiation has been completed but the final response from the DLC has not been received.

AP_CONTACTED

The link is fully functioning.

AP_DISC_PND

A request to disconnect the link has been issued to the DLC.

AP_DISC_RQ

The operator has requested that the link be disconnected.

deact_link_flag
Deactivate logical link.

num_sessions
Number of active sessions.

ru_size
RU size.

adj_fq_cp_name
Fully qualified **cp_name** in adjacent node.

adj_node_type
The adjacent node type (NN, EN, or LEN).

cp_cp_sess_spt
Specifies whether the link supports CP-CP sessions.

conn_type
Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

AP_BOTH_SESSION

ls_role
Specifies the link station role.
line_type
The line type.
tg_number
Transmission group number.
effective_capacity
Highest bit rate transmission effective capacity supported.
conn_cost
Relative cost per connection time using this link.
byte_cost
Relative cost of transmitting a byte over link.
propagation_delay
Indicates amount of time for signal to travel length of link. Set to one of the following:

AP_PROP_DELAY_MINIMUM

AP_PROP_DELAY_LAN

AP_PROP_DELAY_TELEPHONE

AP_PROP_DELAY_PKT_SWITCHED_NET

AP_PROP_DELAY_SATELLITE

AP_PROP_DELAY_MAXIMUM

user_def_1
User-defined TG characteristics.
user_def_2
User-defined TG characteristics.
user_def_3
User-defined TG characteristics.
security
The security value for this link. Set to one of the following:

AP_SEC_NONSECURE

AP_SEC_PUBLIC_SWITCHED_NETWORK

AP_SEC_UNDERGROUND_CABLE

AP_SEC_SECURE_CONDUIT

AP_SEC_GUARDED_CONDUIT

AP_SEC_ENCRYPTED

AP_SEC_GUARDED_RADIATION

Returned by Host Integration Server or SNA Server

Members

link_entry_len
Size of this link entry.
link_id
Connection name.
dlc_name
DLC name set to one of the following:

IBMTRNET

SDLC

DFT

X25DLC

adapter_num
Adapter number used by this link to connect to the adjacent node. Always set to zero.

dest_addr_len
Length of the destination adapter address.

dest_addr
The destination adapter address.

inbound_outbound

state
The state of the link. The link state can be one of the following:

AP_CONALS_PND

The process to bring up the link has started but XID negotiation has not started.

AP_XID_PND

XID negotiation is in process.

AP_CONTACT_PND

XID negotiation has been completed but the final response from the DLC has not been received.

AP_CONTACTED

The link is fully functioning.

AP_DISC_PND

A request to disconnect the link has been issued to the DLC.

AP_DISC_RQ

The operator has requested that the link be disconnected.

deact_link_flag
Deactivate logical link.

num_sessions
Number of active sessions.

ru_size
RU size.

adj_fq_cp_name
Fully qualified **cp_name** in adjacent node. Always set to EBCDIC spaces.

adj_node_type
The adjacent node type. Always set to AP_LEN.

cp_cp_sess_spt
Specifies whether the link supports CP-CP sessions. Always set to AP_NO.

conn_type
Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

ls_role
Specifies the link station role.

line_type
The line type.

tg_number
Transmission group number. Always set to zero.

effective_capacity
Highest bit rate transmission effective capacity supported. Always set to zero.

conn_cost
Relative cost per connection time using this link. Always set to zero.
byte_cost
Relative cost of transmitting a byte over link. Always set to zero.
propagation_delay
Indicates amount of time for signal to travel length of link. This parameter is always set to AP_PROP_DELAY_MAXIMUM.
user_def_1
User-defined TG characteristics. Always set to zero.
user_def_2
User-defined TG characteristics. Always set to zero.
user_def_3
User-defined TG characteristics. Always set to zero.
security
The security value for this link. Always set to AP_SEC_NONSECURE.

LU 0 to 3 Information

LU 0 to 3 information is provided in the **lu_0_3_info_sect** structure as defined below.

```
typedef struct lu_0_3_info_sect {
    unsigned long  lu_0_3_init_sect_len;
    unsigned short num_lu_0_3s;
} LU_0_3_ INFO_SECT;
```

Members

lu_0_3_init_sect_len
The length of the initial LU 0 to 3 information section, including this parameter, up to the first link overlay group. The length does not include any previous information sections.

num_links
The number of LU groups. This is the number of times the lu_0_3 overlay group is repeated.

For each configured LU, an **lu_0_3_overlay** structure for the LU is provided as defined below.

```
typedef struct lu_0_3_overlay {
    unsigned long  lu_0_3_entry_len;
    unsigned char  access_type;
    unsigned char  lu_type;
    unsigned char  lu_daf;
    unsigned char  lu_short_name;
    unsigned char  lu_long_name[8];
    unsigned char  sess_id[8];
    unsigned long  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned char  sscp_lu_sess_state;
    unsigned char  lu_lu_sess_state;
    unsigned char  link_id[12];
 } LU_0_3_OVERLAY;
```

Defined by IBM ES for OS/2 Version 1.0

Members

lu_3_3_entry_len
Size of this LU entry.

access_type
The access type (AP_3270 or AP_LUA).

lu_type
The LU type (AP_LU0, AP_LU1, AP_LU2, or AP_LU3).

lu_daf
The network addressable unit of the LU for which the information is displayed.

lu_short_name
The one-byte LU short name (ASCII).

lu_long_name
The eight-byte ASCII LU long name.

session_id
The LU-LU session ID.

dlc_name
DLC name set to one of the following:

ETHERAND

IBMTRNET

IBMPCNET

SDLC

TWINAX

X25DLC

adapter_number
The DLC adapter number for host link.
dest_addr_len
Length of the destination adapter address.
dest_addr
The destination adapter address.
sscp_lu_sess_state
Specifies the state of the SSCP-LU session.
lu_lu_sess_state
Specifies the state of the LU-LU session. The state can be one of the following:

AP_NOT_BOUND

The LU-LU session is not bound.

AP_BOUND

The LU-LU session is bound.

AP_BINDING

The LU-LU session is in the process of binding.

AP_UNBINDING

The LU-LU session is in the process of unbinding.

link_id
Name of local logical link station being used.

Returned by Host Integration Server and SNA Server

Members

lu_3_3_entry_len
Size of this LU entry.
access_type
The access type (AP_3270 or AP_LUA).
lu_type
The LU type (AP_LU0, AP_LU1, AP_LU2, or AP_LU3).
lu_daf
The network addressable unit of the LU for which the information is displayed.
lu_short_name
The one-byte ASCII LU short name.
lu_long_name
The eight-byte ASCII LU long name.
session_id
The LU-LU session ID.
dlc_name
DLC name set to one of the following:

IBMTRNET

SDLC

TWINAX

X25DLC

adapter_number
The DLC adapter number for host link. Always set to zero.
dest_addr_len
Length of the destination adapter address.
dest_addr
The destination adapter address.
sscp_lu_sess_state

Specifies the state of the SSCP-LU session.

lu_lu_sess_state

Specifies the state of the LU-LU session. The state can be one of the following:

AP_NOT_BOUND

The LU-LU session is not bound.

AP_BOUND

The LU-LU session is bound.

AP_BINDING

The LU-LU session is in the process of binding.

AP_UNBINDING

The LU-LU session is in the process of unbinding.

link_id

Name of connection.

System Default Information

System default information is defined or returned as described here.

Defined by IBM ES for OS/2 Version 1.0

Members

default_mode_name
Mode name used for undefined mode name is sent or received.
default_local_lu_name
Alias or local default LU.
implicit_partner_lu_support
Indicates if implicit partner LU support is enabled.
maximum_held_alerts
Number of alerts that will be held by NS/2 if there is no active link to a focal point.
default_tp_conversation_security_rqd
Specifies if conversation security is used for default TPs.
maximum_mc_ll_send_size
Maximum length of a logical record used on a mapped conversation for sending data to either the inbound or outbound implicit remote LU.
directory_for_inbound_attaches
Name of OS/2 directory used by Attach Manager.
default_tp_operation
Set to one of the following:

QUEUED_OPERATOR_STARTED

QUEUED_OPERATOR_PRELOADED

QUEUED_AM_STARTED

NONQUEUED_AM_STARTED

default_tp_program_type
Set to one of the following:

BACKGROUND

FULL_SCREEN

PRESENTATION_MANAGER

VIO_WINDOWABLE

Returned by Host Integration Server and SNA Server

Members

default_mode_name
Always set to NULL.
default_local_lu_name
Always set to spaces.
implicit_partner_lu_support
Always set to NO.
maximum_held_alerts
Always set to zero.
default_tp_conversation_security_rqd
Always set to NO.
maximum_mc_ll_send_size
Always set to 16384.
directory_for_inbound_attaches
Always returned * and indicates that the current path should be used.
default_tp_operation
Always set to QUEUED_AM_STARTED.
default_tp_program_type
Always set to FULL_SCREEN.

LU 6.2 Definition Information

There are no differences for this information type.

Partner Definition Information

Partner definition information is defined or returned as described here.

Defined by IBM ES for OS/2 Version 1.0

Members

maximum_mc_ll_send_size
Maximum length of a logical record used on a mapped conversation for sending data to the partner LU.
number_of_alternate_aliases
Specifies number of alternate aliases configured.

Returned by Host Integration Server and SNA Server

maximum_mc_ll_send_size
Always set to 16384.
number_of_alternate_aliases
Always set to zero.

Mode Definition Information

Mode definition information is defined or returned as described here.

Defined by IBM ES for OS/2 Version 1.0

Members

cos_name
Name of class of service.

Returned by Host Integration Server and SNA Server

Members

cos_name
Set to EBCDIC spaces.

Link Definition Information

Link definition information is provided in the **link_def_info_sect** structure as defined below.

```
typedef struct link_def_info_sect {
    unsigned long  link_def_init_sect_len;
    unsigned short num_link_def;
    unsigned short total_link_def;
} LINK_DEF_INFO_SECT;
```

Members

link_def_init_sect_len
The length of the initial link definition information section, including this parameter, up to the first link definition overlay group. The length does not include any previous information sections.

num_link_def
The number of link definitions returned by the DISPLAY verb into your program's buffer. This is the number of times the link definition overlay is repeated.

total_sessions
The total number of link definitions. This number is the same as the number returned in the **num_link_def** member except when APPC has more information about link definitions than it can place in the supplied buffer, in which case this number is larger.

For each link definition, a **link_def_overlay** structure for the link definition is provided as defined below.

```
typedef struct link_def_overlay {
    unsigned long  link_def_entry_len;
    unsigned char  link_name[8];
    unsigned char  adj_fq_cp_name[17];
    unsigned char  adj_node_type;
    unsigned long  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned char  preferred_nn_server;
    unsigned char  auto_act_link;
    unsigned char  tg_number;
    unsigned char  lim_res;
    unsigned char  solicit_sscp_session;
    unsigned char  initself;
    unsigned char  bind_support;
    unsigned char  ls_role;
    unsigned char  line_type;
    unsigned long  eff_capacity;
    unsigned char  conn_cost;
    unsigned char  byte_cost;
    unsigned char  propagation_delay;
    unsigned char  user_def_1;
    unsigned char  user_def_2;
    unsigned char  user_def_3;
    unsigned char  security;
    unsigned char  reserv;
 } LINK_OVERLAY;
```

Defined by IBM ES for OS/2 Version 1.0

Members

link_def_entry_len
Size of this link definition entry.

link_name
Local logical link station name (EBCDIC).

dlc_name
Data link control (DLC) name set to one of the following:

ETHERAND

IBMTRNET

IBMPCNET

SDLC

TWINAX

X25DLC

adj_fq_cp_name
Fully qualified **cp_name** in adjacent node.
adj_node_type
The adjacent node type (AP_ADJACENT_NN, AP_LEARN, or AP_LEN).
adapter_num
DLC adapter number used by this link.
dest_addr_len
Length of the destination adapter address.
dest_addr
The destination adapter address.
cp_cp_sess_spt
Specifies whether the link supports CP-CP sessions.
preferred_nn_server
Indicates if this is the preferred NN server.
auto_act_link
Indicates if the link should be automatically activated.
tg_number
Transmission group number.
lim_res
Indicates if this is a limited resource.
solicit_sscp_session
Indicates whether to solicit an SSCP session.
initself
Indicates if the node supports receiving INIT_SELF over this link.
bind_support
Indicates whether BIND support is available.
ls_role
Specifies the link station role.
line_type
The line type.
effective_capacity
Highest bit rate transmission effective capacity supported.
conn_cost
Relative cost per connection time using this link.
byte_cost
Relative cost of transmitting a byte over link.
propagation_delay
Indicates amount of time for signal to travel length of link. Set to one of the following:

AP_PROP_DELAY_MINIMUM

AP_PROP_DELAY_LAN

AP_PROP_DELAY_TELEPHONE

AP_PROP_DELAY_PKT_SWITCHED_NET

AP_PROP_DELAY_SATELLITE

AP_PROP_DELAY_MAXIMUM

user_def_1
User-defined TG characteristics.
user_def_2
User-defined TG characteristics.

user_def_3
User-defined TG characteristics.
security
The security value for this link. Set to one of the following:

AP_SEC_NONSECURE

AP_SEC_PUBLIC_SWITCHED_NETWORK

AP_SEC_UNDERGROUND_CABLE

AP_SEC_SECURE_CONDUIT

AP_SEC_GUARDED_CONDUIT

AP_SEC_ENCRYPTED

AP_SEC_GUARDED_RADIATION

Returned by Host Integration Server and SNA Server

Members

link_def_entry_len
Size of this link definition entry.
link_name
Local logical link station name (EBCDIC).
dlc_name
Data link control (DLC) name set to one of the following:

IBMTRNET

SDLC

DFT

X25DLC

adj_fq_cp_name
Fully qualified **cp_name** in adjacent node. Always set to EBCDIC spaces.
adj_node_type
The adjacent node type. Always set to AP_LEN.
adapter_num
DLC adapter number used by this link. Always set to zero.
dest_addr_len
Length of the destination adapter address.
dest_addr
The destination adapter address.
cp_cp_sess_spt
Specifies whether the link supports CP-CP sessions. Always set to AP_NO.
preferred_nn_server
Indicates if this is the preferred NN server.
auto_act_link
Indicates if the link should be automatically activated.
tg_number
Transmission group number. Always set to zero.
lim_res
Indicates if this is a limited resource.
solicit_sscp_session
Indicates whether to solicit an SSCP session.
initself
Indicates if the node supports receiving INIT_SELF over this link.
bind_support
Indicates whether BIND support is available.
ls_role
Specifies the link station role.
line_type
The line type.

effective_capacity
Highest bit rate transmission effective capacity supported. Always set to zero.
conn_cost
Relative cost per connection time using this link. Always set to zero.
byte_cost
Relative cost of transmitting a byte over link. Always set to zero.
propagation_delay

Indicates amount of time for signal to travel length of link. Set to one of the following: Always set to AP_PROP_DELAY_MAXIMUM.

user_def_1
User-defined TG characteristics. Always set to zero.
user_def_2
User-defined TG characteristics. Always set to zero.
user_def_3
User-defined TG characteristics. Always set to zero.
security
The security value for this link. Always set to AP_SEC_NONSECURE.

Management Services Information

Information on management services is provided in the **ms_info_sect** structure as defined below.

```
typedef struct ms_info_sect {
    unsigned long  ms_init_sect_len;
    unsigned char  held_mds_mu_alerts;
    unsigned char  held_nmvt_alerts;
    unsigned short num_fps;
    unsigned short total_fps;
    unsigned short num_ms_appls;
    unsigned short total_ms_appls;
    unsigned short num_act_trans;
    unsigned short total_act_trans;
} MS_INFO_SECT;
```

Members

ms_init_sect_len
The length of the initial MS information section, including this parameter, up to the first MS focal point group. The length does not include any previous information sections.

held_mds_mu_alerts
The number of management service MDS alerts being held that will be sent to the management service alert focal point (FP) when one becomes available.

held_nmvt_alerts
The number of management service NMVT alerts being held that will be sent to the management service alert focal point (FP) when one becomes available.

num_fps
The number of management service focal points (MS FPs) for which the information listed under MS Focal Point Group is returned. This is the number of times the information group is repeated.

total_fps
The total number of management service focal points for which APPC has information. This number is the same as the number returned in the **num_fps** member except when APPC has more information about management service focal points than it can place in the supplied buffer, in which case this number is larger.

num_ms_appls
The number of registered MS applications for which the information listed under Registered MS Application Group is returned. This is the number of times the information group is repeated.

total_ms_appls
The total number of registered MS applications for which APPC has information. This number is the same as the number returned in the **num_ms_appls** member except when APPC has more information about registered MS applications than it can place in the supplied buffer, in which case this number is larger.

num_act_trans
The number of MS active transactions for which the information listed under MS Active Transaction Group is returned. This is the number of times the information group is repeated.

total_act_trans
The number or MS active transactions for which APPC has information. This number is the same as the number returned in the **num_act_trans** member except when APPC has more information about registered MS active transactions than it can place in the supplied buffer, in which case this number is larger.

For each local and remore management service focal point group, an **ms_fp_overlay** structure for the focal point group is provided as defined below.

```
typedef struct ms_fp_overlay {
    unsigned long  ms_fp_entry_len;
    unsigned char  ms_appl_name[8];
    unsigned char  ms_category[4];
    unsigned char  fp_fq_cp_name[17];
    unsigned char  bkup_appl_name[8];
    unsigned char  bkup_fp_fq_cp_name[17];
    unsigned char  reserv1;
    unsigned char  fp_type;
    unsigned char  fp_status;
    unsigned char  fp_routing;
```

```
} MS_FP_OVERLAY;
```

Members

ms_fp_entry_len
Size of this management service focal point information entry.

ms_appl_name
The management service application name of the current active focal point (EBCDIC).

ms_category
The management service category.

fp_fq_cp_name
The fully qualified control point name of the node on which the current (active) management service focal point is located (EBCDIC). If the local node has no focal point, a value of all EBCDIC space characters (0x40) is returned.

bkup_appl_name
The management service application name of the backup focal point, if one is known (EBCDIC).

bkup_fp_fq_cp_name
The fully qualified control point name of the node on which the backup management service focal point is located, if one is known (EBCDIC). If the local node has no backup focal point, a value of all EBCDIC space characters (0x40) is returned.

fp_type
The type of the focal point for the local management service entry point node. The focal point type depends on how the focal point-end point relationship was established, and on whether the local node is configured as an NN, EN, or LEN node (an EN without CP-CP session support). The type can be one of the following:

AP_EXPLICIT_PRIMARY_FP

The current focal point type is explicit primary.

AP_BACKUP_FP

The current focal point type is backup.

AP_DEFAULT_PRIMARY_FP

The current focal point type is default primary.

AP_DOMAIN_FP

The current focal point type is domain.

AP_HOST_FP

The current focal point type is host.

AP_NO_FP

Currently the local node has no focal point.

fp_status
The status of the management service focal point. The status can be one of the following:

AP_NOT_ACTIVE

The focal point has been acquired, but has since become unavailable.

AP_ACTIVE

The remote focal point has been acquired and is available.

AP_PENDING

A request has been sent to a remote primary or backup focal point to acquire that FP, and its reply has not yet been received.

AP_NEVER_ACTIVE

The focal point has never been acquired, but one or more registered management service applications have requested focal point information.

fp_routing
The routing used to send unsolicited requests to the management service focal point when the local node is an EN. Note that requests from an NN are always sent directly to the focal point.

The routing can be one of the following:

AP_DEFAULT

Unsolicited management service requests destined for the focal point are sent from the EN to its serving NN for forwarding to the focal point.

AP_DIRECT

Unsolicited management service requests destined for the focal point are sent directly to the focal point.

Remarks

When a program registers an management service application name, it can request focal point information. When APPC acquires the focal point, it passes the program the focal point information, which includes the type of routing to use to send unsolicited management service requests to the focal point.

APPC TP Verbs

This section describes the APPC TP verbs:

GET_TP_PROPERTIES

SET_TP_PROPERTIES

TP_ENDED

TP_STARTED

The description of each verb provides:

- A definition of the verb.
- The structure defining the VCB used by the verb. The structure is contained in the WINAPPC.H file. The length of each VCB field is in bytes. Fields beginning with **reserv** (for example, **reserv2**) are reserved.
- The parameters (VCB fields) supplied to and returned by APPC. A description of each parameter is provided, along with its possible values and other information.
- The conversation state(s) in which the verb can be issued.
- The state(s) to which the conversation can change upon return from the verb. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the verb.

Most parameters supplied to and returned by APPC are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the WINAPPC.H header file. For example, the **opcode** (operation code) member of the **mc_send_data** structure used by the **MC_SEND_DATA** verb is the hexadecimal value represented by the symbolic constant AP_M_SEND_DATA. Use only the symbolic constants when writing TPs.

GET_TP_PROPERTIES

The **GET_TP_PROPERTIES** verb returns attributes of the TP and the current transaction.

The following structure describes the verb control block used by the **GET_TP_PROPERTIES** verb.

```
struct get_tp_properties {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned char   tp_name[64];
    unsigned char   lu_alias[8];
    unsigned char   luw_id[26];
    unsigned char   fqlu_name[17];
    unsigned char   reserve3[10];
    unsigned char   user_id[10];
    unsigned char   prot_luw_id[26];
    unsigned char   pwd[10];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_GET_TP_PROPERTIES.

opext
Supplied parameter. Specifies the verb operation extension. If the AP_EXTD_VCB bit is set, this indicates that the **get_tp_properties** structure includes the **prot_luw_id** member used for Sync Point support. Otherwise the verb control block ends immediately after the **user_id** member.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

tp_name
Returned parameter. Supplies the TP name of the TP that issued the verb. The name is returned as a 64-byte EBCDIC string, padded on the right with EBCDIC spaces.

lu_alias
Returned parameter. Supplies the alias name assigned to the local LU. It is returned as an 8-byte ASCII string padded on the right with ASCII spaces.

luw_id
Returned parameter. Supplies the unprotected logical unit-of-work identifier for the transaction in which the TP is participating. Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **luw_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct   luw_id_overlay {
    unsigned char  fqla_name_len;
    unsigned char  fqla_name[17];
    nsigned char   instance[6];
    unsigned char  sequence[2];
} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only).

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1, if Sync Point is not supported.)

If the **luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

fqlu_name
Returned parameter. Supplies the fully qualified name of the local LU. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. The name is padded on the right with EBCDIC spaces.

reserve3

A reserved field.

user_id
Supplied parameter. Indicates the **user_id** supplied by the initiating TP in the allocation request. The name is supplied as a 10-byte EBCDIC string, padded on the right with EBCDIC spaces.

prot_luw_id
Returned parameter. Contains the protected logical unit-of-work identifier for the transaction in which the TP is participating, if the conversation was allocated with **synclevel** Sync Point.

Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **prot_luw_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct   luw_id_overlay {
    unsigned char  fqla_name_len;
    unsigned char  fqla_name[17];
    nsigned char   instance[6];
    unsigned char  sequence[2];
} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only).

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1, if Sync Point is not supported.)

If the **prot_luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

pwd
Supplied parameter. Contains the password of the **user_id** of the initiating TP in the allocation request. The password is supplied as a 10-byte EBCDIC string, padded on the right with EBCDIC spaces.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE or MC_ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** or **MC_ALLOCATE** request.

When **ALLOCATE** or **MC_ALLOCATE** produces this return code for a system configured with multiple nodes using Microsoft® Host Integration Server 2000 or SNA Server 4.0, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY
Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb relates to the TP rather than a specification conversation, so the TP can issue the verb in any state. There is no state change.

The **luw_id** member contains fields for **fqla_name_len** (the length of the fully qualified LU name of the LU originating the TP), **fqla_name** (the fully qualified name of the LU originating the TP), **instance** (generated uniquely by the LU originating the TP), and **sequence** (always set to 1 and indicating the segment of unit-of-work).

SET_TP_PROPERTIES

The **SET_TP_PROPERTIES** verb allows a TP to set its logical unit-of-work identifiers (LUWIDs) to either an existing value, by providing the LUWIDs, or request that the SNA server generate new ones and use them from then on. When the LUWID is generated by the SNA server, it is guaranteed to be unique. This verb is used only if Sync Point support is enabled.

The following structure describes the verb control block used by the **SET_TP_PROPERTIES** verb.

```
struct set_tp_properties {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned char   set_prot_id;
    unsigned char   new_prot_id;
    unsigned char   prot_id[26];
    unsigned char   set_unprot_id;
    unsigned char   new_unprot_id;
    unsigned char   unprot_id[26];
    unsigned char   set_user_id;
    unsigned char   reserv3;
    unsigned char   user_id[10];
    unsigned char   reserv4[10];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_SET_TP_PROPERTIES.

opext
Supplied parameter. Specifies the verb operation extension. The AP_EXTD_VCB bit must be set to indicate that the **set_tp_properties** structure requires Sync Point support.

reserv2

A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

set_prot_id
Supplied parameter. Indicates whether the **prot_id** member should be modified. Legal values are AP_YES or AP_NO.

new_prot_id
Supplied parameter. Indicates whether Host Integration Server or SNA Server should use the supplied **prot_id** LUWID member or create a new LUWID. Legal values are AP_YES (create a new LUWID) or AP_NO (use the supplied LUWID).

prot_id
This member is the protected logical unit-of-work identifier for the transaction in which the TP is participating. It is ignored if **set_prot_id** is AP_NO. It is a supplied parameter if **new_unprot_id** is AP_NO or a returned parameter if **new_unprot_id** is AP_YES.

Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **prot_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct   luw_id_overlay {
    unsigned char  fqla_name_len;
```

```
    unsigned char  fqla_name[17];
    nsigned char   instance[6];
    unsigned char  sequence[2];
} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only).

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1 if Sync Point is not supported.)

If the **luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

set_unprot_id
Supplied parameter. Indicates whether the **unprot_id** member should be modified. Legal values are AP_YES or AP_NO.

new_unprot_id
Supplied parameter. Indicates whether Host Integration Server or SNA Server should use the supplied **unprot_id** LUWID member or create a new LUWID. Legal values are AP_YES (create a new LUWID) or AP_NO (use the supplied LUWID).

unprot_id
This member is the unprotected logical unit-of-work identifier for the transaction in which the TP is participating. It is ignored if **set_unprot_id** is AP_NO. It is a supplied parameter if **new_unprot_id** is AP_NO or a returned parameter if **new_unprot_id** is AP_YES.

Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **prot_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct   luw_id_overlay {
    unsigned char  fqla_name_len;
    unsigned char  fqla_name[17];
    nsigned char   instance[6];
    unsigned char  sequence[2];
} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only).

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1 if Sync Point is not supported.)

If the **luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

set_user_id

Supplied parameter. Indicates whether the **user_id** member should be modified. Legal values are AP_YES or AP_NO.

reserve3

A reserved field.

user_id

Supplied parameter. Indicates the **user_id** that should be used by the initiating TP in the allocation request. The name is a 10-byte EBCDIC string, padded on the right with EBCDIC spaces. This parameter is ignored if **set_user_id** is AP_NO.

reserve4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE or MC_ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** or **MC_ALLOCATE** request.

When **ALLOCATE** or **MC_ALLOCATE** produces this return code for an Host Integration Server or SNA Server system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY

Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb relates to the TP rather than a specification conversation, so the TP can issue the verb in any state. There is no state change.

The **prot_id** and **unprot_id** members contain fields for **fqla_name_len** (the length of the fully qualified LU name of the LU originating the TP), **fqla_name** (the fully qualified name of the LU originating the TP), **instance** (generated uniquely by the LU originating the TP), and **sequence** (always set to 1 and indicating the segment of unit-of-work).

It is the responsibility of the application (the Sync Point support component) to transmit the new LUWID PS header to the partner Sync Point support when the protected LUWID is changed. Similarly, when the new LUWID PS header is received, the application must inform the LU by issuing a **SET_TP_PROPERTIES** verb.

TP_ENDED

The **TP_ENDED** verb is issued by both the invoking and invoked TP, and notifies APPC that the TP is ending.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use the WinAsyncAPPC function rather than the blocking version of this call.

The following structure describes the verb control block used by the **TP_ENDED** verb.

```
struct tp_ended {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned char   type;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_TP_ENDED.

opext
Supplied parameter. Specifies the verb operation extension. This field is not used by the **TP_ENDED** verb.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

type
Supplied parameter. Specifies the type of termination to be performed. The following are allowed values:

- AP_HARD indicates that all active verbs for the TP are terminated; the session(s) being used by the conversation(s) are ended. Both the local TP and the partner TP can receive conversation failure return codes (AP_DEALLOC_ABEND for mapped conversations and AP_DEALLOC_ABEND_PROG for basic conversations).
- AP_SOFT indicates that the TP waits for all active verbs to complete; the session being used by the conversation remains active.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_TP_ID

Secondary return code; APPC did not recognize the **tp_id** as an assigned TP identifier.

AP_BAD_TYPE

Secondary return code; the specified **type** value was not recognized by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).

- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY
Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

In response to **TP_ENDED**, APPC frees the resources used by the TP. After this verb executes, the TP identifier is no longer valid; the TP cannot issue any more APPC conversation verbs.

The conversation can be in any state when the TP issues this verb.

If the conversation is in SEND state, **TP_ENDED** performs the function of DEALLOCATE or MC_DEALLOCATE with **dealloc_type** set to AP_FLUSH.

If the conversation is in a state other than RESET or SEND, **TP_ENDED** performs the function of **DEALLOCATE** or **MC_DEALLOCATE** with **dealloc_type** set to AP_ABEND (for a mapped conversation) or AP_ABEND_PROG (for a basic conversation).

After successful execution (**primary_rc** is AP_OK), there is no APPC state.

TP_STARTED

The **TP_STARTED** verb is issued by the invoking TP, and notifies APPC that the TP is starting.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use the WinAsyncAPPC function rather than the blocking version of this call.

The following structure describes the verb control block used by the **TP_STARTED** verb.

```
struct tp_started {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   lu_alias[8];
    unsigned char   tp_id[8];
    unsigned char   tp_name[64];
    unsigned char   syncpoint_rqd;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_TP_STARTED.

opext
Supplied parameter. Specifies the verb operation extension. If the AP_EXTD_VCB bit is set, this indicates that the **tp_started** structure includes the **syncpoint_rqd** member used for Sync Point support. Otherwise, the verb control block ends immediately after the **tp_name** member.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

lu_alias
Supplied parameter. Specifies the alias by which the local LU is known to the local TP.

The name must match an LU alias established during configuration. APPC checks the LU alias against the current Host Integration Server or SNA Server configuration file. Due to the client/server architecture used by Host Integration Server and SNA Server, however, this parameter is not validated until an ALLOCATE or MC_ALLOCATE is performed.

This parameter is an 8-byte ASCII character string. It can consist of the following ASCII characters:

- Uppercase letters
- Numerals from 0 through 9
- Spaces
- Special characters $, #, % and @

The first character of this string cannot be a space.

If the value of this parameter is fewer than eight bytes in length, pad it on the right with ASCII spaces (0x20).

To use an LU from the default LU pool, set this field to eight hexadecimal zeros. For more information, see Default LUs.

tp_id
Returned parameter. Identifies the newly-established TP.

tp_name
Supplied parameter. Specifies the name of the local TP.

Under the Host Integration Server and SNA Server implementation of APPC, this parameter is ignored when issued by **TP_STARTED**. However, this parameter is required if the program runs under the IBM ES for OS/2 version 1.0 implementation of APPC.

This parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of the following EDCDIC characters:

- Uppercase and lowercase letters
- Numerals from 0 through 9
- Special characters $, #, @, and period (.)

If the TP name is fewer than 64 bytes in length, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention for a service TP name is up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F.

syncpoint_rqd
This optional parameter is only applicable if the AP_EXTD_VCB bit is set in the **opext** parameter and Sync Point services are required.

- AP_YES if Sync Point is required.
- AP_NO if Sync Point is not required.

Return Codes

AP_OK
Primary return code; the verb executed successfully.
AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE or MC_ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** or **MC_ALLOCATE** request.

When **ALLOCATE** or **MC_ALLOCATE** produces this return code for a system configured with multiple nodes using Host Integration Server or SNA Server, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_TP_BUSY
Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The

operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

In response to **TP_STARTED**, APPC generates a TP identifier for the invoking TP. This identifier is a required parameter for subsequent APPC verbs issued by the invoking TP.

This must be the first APPC verb issued by the invoking TP. Consequently, no prior APPC state exists.

If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RESET.

Default LUs

Any LU can be configured to be in a pool of default local LUs available for use by invoking TPs.

For a user or group who will be using TPs, 5250 emulators, and/or APPC applications, you can assign a default local APPC LU and a default remote APPC LU. If the invoking TP specifies the LU alias that it uses (in TP_STARTED), that LU alias must match a local APPC LU alias on the supporting SNA server. If the invoking TP leaves the LU alias blank in **TP_STARTED**, one of two methods for designating a default LU must be carried out on the supporting SNA server:

- Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which **TP_STARTED** is issued).

  —or—

- Designate one or more LUs as members of the default outgoing local APPC LU pool. The SNA server first attempts to determine the default local APPC LU of the associated user or group, then attempts to assign an available LU from the default outgoing local APPC LU pool; if these attempts fail, the SNA server rejects the request.

In AS/400 environments, the ability to assign default APPC LUs to users or groups is especially useful because it gives the administrator centralized control over these LU assignments. In such environments, for each user or group, assign both a default local APPC LU and a default remote APPC LU. Assigning a default local APPC LU for each user fulfills the normal AS/400 procedure of assigning local LUs on a per-user basis. Assigning a default remote APPC LU is equivalent to assigning a default AS/400 for the user to connect to, since the remote LU designates the AS/400. By making these assignments, the administrator can centrally control the default AS/400 that a 5250 emulator user connects to.

For more information, see the *Microsoft Host Integration Server 2000 online books*.

APPC Conversation Verbs

This section describes the APPC conversation verbs. The description of each verb provides:

- A definition of the verb.
- The structure defining the VCB used by the verb. The structure is contained in the WINAPPC.H file. The length of each VCB field is in bytes. Fields beginning with reserv (for example, reserv2) are reserved.
- The parameters (VCB fields) supplied to and returned by APPC. A description of each parameter is provided, along with its possible values and other information.
- The conversation state(s) in which the verb can be issued.
- The state(s) to which the conversation can change upon return from the verb. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the verb.

Mapped conversation verbs are preceded by an **MC_** designator. For example, the mapped conversation verb **MC_ALLOCATE** corresponds to the basic conversation verb **ALLOCATE**.

Most parameters supplied to and returned by APPC are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the WINAPPC.H header file. For example, the **opcode** (operation code) member of the **mc_send_data** structure used by the **MC_SEND_DATA** verb is the hexadecimal value represented by the symbolic constant AP_M_SEND_DATA. Use only the symbolic constants when writing TPs.

ALLOCATE

The **ALLOCATE** verb is issued by the invoking TP. It allocates a session between the local LU and partner LU and (in conjunction with RECEIVE_ALLOCATE) establishes a conversation between the invoking TP and the invoked TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **ALLOCATE** verb.

```
struct allocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned long    conv_type;
    unsigned char    synclevel;
    unsigned char    reserv3[2];
    unsigned char    rtn_ctl;
    unsigned char    reserv4;
    unsigned long    conv_group_id;
    unsigned long    sense_data;
    unsigned char    plu_alias[8];
    unsigned char    mode_name[8];
    unsigned char    tp_name[64];
    unsigned char    security;
    unsigned char    reserv5[11];
    unsigned char    pwd[10];
    unsigned char    user_id[10];
    unsigned short   pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char    reserv7;
    unsigned char    fqplu_name[17];
    unsigned char    reserv8[8];
    unsigned long    proxy_user;
    unsigned long    proxy_domain;
    unsigned char    reserv9[16];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_ALLOCATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION. If the AP_EXTD_VCB bit is set, this indicates that an extended version of the verb control block is used. In this case, the **ALLOCATE** structure includes Sync Point support or privileged proxy feature support.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id
Returned parameter. Identifies the conversation established between the two TPs.

conv_type
Supplied parameter. Used only by **ALLOCATE** to specify the type of conversation to allocate and is either AP_BASIC_CONVERSATION or AP_MAPPED_CONVERSATION.

If **ALLOCATE** establishes a mapped conversation, the local TP must issue basic-conversation verbs and provide its own mapping layer to convert data records to logical records and logical records to data records. The partner TP can issue basic-conversation verbs and provide the mapping layer, or it can use mapped-conversation verbs (if the partner TP is using an implementation of APPC that supports mapped-conversation verbs). For more information, see your IBM SNA manual(s).

synclevel
Supplied parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE specifies that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL specifies that the TPs can use confirmation processing in this conversation.
- AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

reserv3
A reserved field.

rtn_ctl
Supplied parameter. Specifies when the local LU, acting on a session request from the local TP, should return control to the local TP. For information about sessions, see About Transaction Programs.

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns control to the TP.
- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs, (as documented in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOCATED specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOCATED specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id** or encounters one of the errors documented in Return Codes in this topic. If a session is not available, the TP waits for it to become free.

Note that AP_IMMEDIATE is the only value for **rtn_ctl** that will never cause a new session to start. For values other than AP_IMMEDIATE, if an appropriate session is not immediately available, Microsoft® Host Integration Server or SNA Server will try to start one. This will cause the on-demand connection to be activated.

reserv4
A reserved field.

conv_group_id
Supplied/returned parameter. Specifies the identifier of the conversation group from which the session should be allocated. The **conv_group_id** is required only if **rtn_ctl** is set to WHEN_CONV_GROUP_ALLOC. When **rtn_ctl** specifies a different value and the **primary_rc** is AP_OK, this is a returned value.

sense_data
Returned parameter. Indicates an allocation error (retry or no-retry) and contains sense data.

plu_alias
Supplied parameter. Specifies the alias by which the partner LU is known to the local TP.

The **plu_alias** must match the name of a partner LU established during configuration.

The parameter is an 8-byte ASCII character string. It can consist of the following ASCII characters:

- Uppercase letters
- Numerals 0 through 9
- Spaces
- Special characters $, #, %, and @

The first character of this string cannot be a space.

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

If you want to specify the partner LU with the **fqplu_name** parameter, fill this parameter with binary zeros.

For a user or group using TPs, 5250 emulators, and/or APPC applications, the system administrator can assign default local and remote LUs. In this case, the field is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information on default LUs, see the *Microsoft Host Integration Server 2000 online books*.

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration.

The value of **mode_name** must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or a special character.

Do not use SNASVCMG in a mapped conversation. SNASVCMG is a reserved **mode_name** used internally by APPC. Using this name in a basic conversation is not recommended.

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by **ALLOCATE** in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **tp_name** is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the type AE EBCDIC character set.

security

Supplied parameter. Provides the information that the partner LU requires to validate access to the invoked TP.

Based on the conversation security established for the invoked TP during configuration, use one of the following values:

- AP_NONE for an invoked TP that uses no conversation security.
- AP_PGM for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters.
- AP_PROXY_PGM for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password. Pointers must be set up for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.
- AP_PROXY_SAME for a TP that has been invoked using privileged proxy with a valid user identifier and password supplied by the proxy, which in turn invokes another TP. Pointers must be set up for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.

For example, assume that TP A invokes TP B with a valid user identifier and password supplied by the privileged proxy, and TP B in turn invokes TP C. If TP B specifies the value AP_PROXY_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

- AP_PROXY_STRONG for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password provided by the privileged proxy mechanism. Pointers must be set up for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields. AP_PROXY_STRONG differs from AP_PROXY_PGM in

that AP_PROXY_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.

- AP_SAME for a TP that has been invoked with a valid user identifier and password, which in turn invokes another TP.

For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

When AP_SAME is used in an Allocate verb, your application must always provide values for the **user_id** and **pwd** parameters in the verb control block. Depending on the properties negotiated between the SNA server and the peer LU, the **ALLOCATE** verb will send one of 3 kinds of Attach (FMH-5) messages, in this order of precedence:

1. If the LUs have negotiated "already verified" security, then the Attach sent by the SNA server will not include the contents of the **pwd** parameter field specified in the VCB.
2. If the LUs have negotiated "persistent verification" security, then the Attach sent by the SNA server will include the **pwd** parameter specified in the VCB, but only when the Attach is the first for the specified **user_id** parameter since the start of the LU-LU session, and will omit the **pwd** parameter on all subsequent Attaches (issued by your application or any other application using this LU-LU-mode triplet).
3. If the LUs have not negotiated either of the above, then the Attach sent by the SNA server will omit both the **user_id** and **pwd** parameters on all Attaches.

   Your application cannot tell which mode of security has been negotiated between the LUs, nor can it tell whether the **ALLOCATE** verb it is issuing is the first for that LU-LU-mode triplet. So your application must always set the **user_id** and **pwd** parameter fields in the VCB when **security** is set to AP_SAME.

   For more information on persistent verification and already verified security, see the SNA Formats Guide, section "FM Header 5: Attach (LU 6.2)".

- AP_STRONG for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters. AP_STRONG differs from AP_PGM in that AP_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.

  If the APPC automatic logon feature is to be used, **security** must be set to AP_PGM. See the Remarks section for details.

reserv5
A reserved field.

pwd
Supplied parameter. Specifies the password associated with **user_id**.

The **pwd** parameter is required only if **security** is set to AP_PGM or AP_SAME. It must match the password for **user_id** that was established during configuration.

The **pwd** parameter is a 10-byte EBCDIC character string and is case-sensitive. It can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **pwd** character string must be hard-coded to MS$SAME. See the Remarks section for details.

user_id
Supplied parameter. Specifies the user identifier required to access the partner TP. It is required only if the security parameter is set to AP_PGM or AP_SAME.

The **user_id** parameter is a 10-byte EBCDIC character string and is case-sensitive. It must match one of the user identifiers configured for the partner TP.

The parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **user_id** is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **user_id** character string must be hard-coded to MS$SAME. See the Remarks section for details.

pip_dlen
Supplied parameter. Specifies the length of the program initialization parameters (PIP) to be passed to the partner TP. The range is from 0 through 32767.

pip_dptr
Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the general data stream (GDS) format. For more information, see *SNA LU6.2 Reference: Peer Protocols* published by IBM.

For Microsoft® Windows NT®, Windows 95, Windows 98, and Windows version 3.*x*, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For OS/2, the PIP data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The PIP data buffer must fit entirely on the segment.

reserv7
A reserved field.

fqplu_name
Supplied parameter. Specifies the fully qualified name of the partner LU. This must match the fully qualified name of the local LU defined in the remote node. The parameter consists of two type A EBCDIC character strings for the NETID and the LU name of the partner LU. The names are separated by an EBCDIC period (.).

This name must be provided if no **plu_alias** is specified. It can consist of the following EBCDIC characters:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

reserv8
A reserved field.

proxy_user
Supplied parameter. Specifies a LPWSTR pointing to a UNICODE string containing the user name to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

proxy_domain
Supplied parameter. Specifies a LPWSTR pointing to a UNICODE string containing the domain name of the user to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

reserv9
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL
Primary return code; the supplied parameter **rtn_ctl** specified immediate (AP_IMMEDIATE) return of control to the TP, and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_SYNC_LEVEL

Secondary return code; the value specified for **sync_level** was invalid.

AP_BAD_TP_ID

Secondary return code; the value specified for **tp_id** was invalid.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **partner_lu_alias**.

AP_BAD_CONV_TYPE (for a basic conversation)

Secondary return code; the value specified for **conv_type** was invalid.

AP_NO_USE_OF_SNASVCMG (for a mapped conversation)

Secondary return code; SNASVCMG is not a valid value for **mode_name**.

AP_INVALID_DATA_SEGMENT

Secondary return code; the PIP data was longer than the allocated data segment, or the address of the PIP data buffer was wrong.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for system configured with multiple nodes using Host Integration Server or SNA Server, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

ALLOCATE can establish either a basic or mapped conversation.

The conversation state is RESET when the TP issues this verb. After successful execution (**primary_rc** is AP_OK), the state changes to SEND. If the verb does not execute, the state remains unchanged.

Several parameters of **ALLOCATE** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

To send the **ALLOCATE** request immediately, the invoking TP can issue FLUSH or CONFIRM immediately after **ALLOCATE**. Otherwise, the **ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

By issuing **CONFIRM** after **ALLOCATE**, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

Host Integration Server and SNA Server support a feature called password substitution. This is a security feature supported by the latest version of the OS/400 operating system (V3R1) which encrypts any password that flows between two nodes on an Attach message. A password flows on an Attach whenever someone invokes an APPC transaction program specifying a user identifier and password. For example, this happens whenever anyone logs on to an AS/400.

Support for password substitution is indicated by setting bit 5 in byte 23 of the BIND request to 1 (which indicates that password substitution is supported). If the remote system sets this bit in the BIND response, the SNA server automatically encrypts the LU 6.2 conversation security password included in the FMH-5 Attach message. APPC applications using Host Integration Server or SNA Server automatically take advantage of this feature by setting the **security** field of the VCB to AP_PGM or AP_STRONG in the **ALLOCATE** request.

If an APPC application wants to force an encrypted password to flow, the application can specify AP_STRONG for the **security** field in the VCB in the **ALLOCATE** request. This option is implemented as defined in OS/400 V3R1, and is documented in the OS/400 CPIC programmer reference as CM_SECURITY_PROGRAM_STRONG, where the LU 6.2 **pwd** (password) field is encrypted before it flows over the physical network.

The password substitution features is currently only supported by OS/400 V3R1 or later. If the remote system does not support this feature, the SNA server will UNBIND the session with the sense code of 10060006. The two nodes negotiate whether or not they support this feature in the BIND exchange. Host Integration Server and SNA Server set a bit in the BIND, and also adds some random data on the BIND for encryption. If the remote node supports password substitution, it sets the same bit in the BIND response, and adds some (different) random data for decryption.

Host Integration Server 2000, SNA Server version 4.0, and SNA Server version 3.0 with Service Pack 1 or later and support

automatic logon for APPC applications. This feature requires specific configuration by the network administrator: The APPC application must be invoked on the LAN side from a client of Host Integration Server 2000. The client must be logged into a Windows 2000 or Windows NT domain, but the client can be running on any operating system supported by the Host Integration Server or SNA Server APPC APIs.

The client application is coded to use "program" level security, with a special hard-coded APPC user name MS$SAME and password MS$SAME. When this session allocation flows from client to SNA server, the server looks up the host account and password corresponding to the Windows 2000 or Windows NT account under which the client is logged in, and substitutes the host account information into the APPC attach message it sends to the host.

It is illegal for the remote node to set the bit specifying password substitution and not add the random data.

According to IBM, there are implementations of LU 6.2 password substitution that do not support password substitution but do echo the password substitution bit back to Host Integration Server 2000, without specifying any random data. When they do this, the SNA server will UNBIND the session with the sense code 10060006.This sense code is interpreted as:

- 1006 = Required field or parameter missing.
- 0006 = A required subfield of a control vector was omitted.

Host Integration Server and SNA Server should also log an Event 17 (APPC session activation failure: BIND negative response sent).

The correct solution is for the failing implementation to be fixed. However, as a short-term workaround, the following Host Integration Server or SNA Server service registry setting can be set:

HKEY_LOCAL_MACHINE\\SYSTEM\CurrentControlSet\Services\snaservr\parameters\NOPWDSUB: REG_SZ: YES

When this parameter is specified in the registry, password substitution support will be disabled.

Several updates have been made to Host Integration Server and SNA Server to allow a privileged APPC application to open an APPC conversation using the Single Signon feature on behalf of any defined Windows NT user. This is referred to as the privileged proxy feature. An extension has been added to the APPC **ALLOCATE** verb to invoke this feature.

An APPC application becomes privileged by being started in a Windows NT user account that is a member of a special Windows NT group. When a Host Security Domain is configured, Host Integration Server 2000 Manager will define a second Windows NT group for use with the host security features of Host Integration Server 2000. If the user account under which the actual client is running is a member of this second Windows NT group, the client is privileged to initiate an APPC conversation on behalf of any user account defined in the Host Account Cache.

The following illustrates how the privileged proxy feature works:

The Host Integration Server 2000 administrator creates a Host Security Domain called APP. Host Integration Server 2000 Manager now creates two Windows NT groups. The first group is called APP and the second is called APP_PROXY for this example. Users that are assigned to the APP group are enabled for single signon. Users assigned to the APP_PROXY group are privileged proxies. The administrator adds the Windows NT user AppcUser to the APP_PROXY group using the Users button on the Host Security Domain property dialog box in Host Integration Server 2000 Manager.

The administrator then sets up an APPC application on the Host Integration Server 2000 to run as a Windows NT service called APPCAPP and that service has been setup to operate under the AppcUser user account. When APPCAPP runs, it opens an APPC session via an ALLOCATE verb using the extended VCB format and specifies the Windows NT username of the desired user, UserA (for example).

The SNA service sees the session request coming from a connection that is a member of the Host Security Domain APP. The Client/Server interface tells the SNA service that the actual client is AppcUser.

The SNA service checks to see if AppcUser is a member of the APP_PROXY group. Because AppcUser is a member of APP_PROXY, the SNA service inserts the Username/Password for UserA in the APPC Attach (FMH-5) command and sends it off to the partner TP.

In order to support the privileged proxy feature, the APPC application must implement the following program logic:

The APPC application must determine the Windows NT user ID and domain name that it wishes to impersonate.

The APPC application must set the following parameters before calling the **ALLOCATE** verb:

Enable the use of the extended ALLOCATE verb control block structure by setting the AP_EXTD_VCB flag in the **opext** field.

Set **security** to AP_PROXY_SAME, AP_PROXY_PGM or AP_PROXY_STRONG.

Set up the pointers for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name

of the user to be impersonated.

> **Note** The application does not need to set up the **user_id** and **pwd** fields in the **ALLOCATE** VCB.

When the APPC application performs the above steps and issues the **ALLOCATE** verb, the Host Integration Server 2000 server will perform a lookup in the host security domain for the specified Windows NT user and set the user ID and password fields in the FMH-5 Attach message sent to the remote system.

CONFIRM

The **CONFIRM** verb sends the contents of the local LU's send buffer and a confirmation request to the partner TP.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **CONFIRM** verb.

```
struct confirm {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_CONFIRM.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id
Returned parameter. Identifies the conversation established between the two TPs.

rts_rcvd
Returned parameter. Indicates whether the partner TP issued REQUEST_TO_SEND which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state operating on Microsoft® Windows NT®, Windows 95, or Windows 98, the local TP can use PREPARE_TO_RECEIVE, RECEIVE_AND_WAIT, or RECEIVE_AND_POST.

To change to RECEIVE state operating on Windows 3.x, the local TP can use **PREPARE_TO_RECEIVE** or **RECEIVE_AND_WAIT**.

To change to RECEIVE state operating on OS/2, the local TP can use **RECEIVE_AND_POST**.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_CONFIRM_ON_SYNC_LEVEL_NONE

Secondary return code; the local TP attempted to use **CONFIRM** in a conversation with a synchronization level of AP_NONE.

The synchronization level, established by ALLOCATE, must be AP_CONFIRM_SYNC_LEVEL.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state.

AP_CONFIRM_NOT_LL_BDY

Secondary return code; the conversation for the local TP was in SEND state, and the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.

- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer has encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, Windows 98, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

In response to **CONFIRM**, the partner TP normally issues CONFIRMED to confirm that it has received the data without error. (If the partner TP encounters an error, it issues SEND_ERROR or abnormally deallocates the conversation.)

The TP can issue **CONFIRM** only if the conversation's synchronization level, established by ALLOCATE, is AP_CONFIRM_SYNC_LEVEL.

The conversation must be in SEND state when the TP issues this verb. State changes, summarized in the following table, are based on the value of the **primary_rc**.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET

AP_COMM_SUBSYSTEM_ABENDED AP_COMM_SUBSYSTEM_NOT_LOADED	RESET RESET
AP_CONV_FAILURE_RETRY AP_CONV_FAILURE_NO_RETRY	RESET RESET
AP_DEALLOC_ABEND AP_DEALLOC_ABEND_PROG AP_DEALLOC_ABEND_SVC AP_DEALLOC_ABEND_TIMER	RESET RESET RESET RESET
AP_PROG_ERROR_PURGING AP_SVC_ERROR_PURGING	RECEIVE RECEIVE

CONFIRM waits for a response from the partner TP. A response is generated by one of the following verbs in the partner TP:

- CONFIRMED
- SEND_ERROR
- DEALLOCATE with dealloc_type set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER
- TP_ENDED

By issuing **CONFIRM** after ALLOCATE, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**. For more information, see the *Microsoft Host Integration Server 2000 online books*.

Several parameters of **ALLOCATE** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

To send the **ALLOCATE** request immediately, the invoking TP can issue FLUSH or **CONFIRM** immediately after **ALLOCATE**. Otherwise, the **ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

CONFIRMED

The **CONFIRMED** verb responds to a confirmation request from the partner TP. It informs the partner TP that the local TP has not detected an error in the received data. Because the TP issuing the confirmation request waits for a confirmation, **CONFIRMED** synchronizes the processing of the two TPs.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **CONFIRMED** verb.

```
struct confirmed {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_CONFIRMED.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd
Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND, which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRMED_BAD_STATE

Secondary return code; the conversation is not in CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation must be in one of the following states when the TP issues this verb:

- CONFIRM
- CONFIRM_SEND
- CONFIRM_DEALLOCATE

The new state is determined by the old state—the state of the conversation when the local TP issued **CONFIRMED**. The old state is indicated by the value of the **what_rcvd** parameter of the preceding receive verb. The following state changes are possible:

Old state	New state

CONFIRM	RECEIVE
CONFIRM_SEND	SEND
CONFIRM_DEALLOCATE	RESET

Confirmation Requests

A confirmation request is issued by one of the following verbs in the partner TP:

- CONFIRM
- PREPARE_TO_RECEIVE if **ptr_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by ALLOCATE) is AP_CONFIRM_SYNC_LEVEL
- DEALLOCATE if **dealloc_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by **ALLOCATE**) is AP_CONFIRM_SYNC_LEVEL
- SEND_DATA if type is set to AP_SEND_DATA_CONFIRM and the conversation's synchronization level (established by **ALLOCATE**) is AP_CONFIRM_SYNC_LEVEL

A confirmation request is received by the local TP through the **what_rcvd** parameter of one of the following verbs:

- RECEIVE_IMMEDIATE
- RECEIVE_AND_WAIT
- RECEIVE_AND_POST

CONFIRMED is issued by the local TP only if **what_rcvd** contains one of the following values:

- AP_CONFIRM_WHAT_RECEIVED
- AP_CONFIRM_SEND
- AP_CONFIRM_DEALLOCATE

If the **rtn_status** parameter is set to AP_YES, **what_rcvd** can also contain the following values:

- AP_DATA_COMPLETE_CONFIRM
- AP_DATA_COMPLETE_CONFIRM_SEND
- AP_DATA_COMPLETE_CONFIRM_DEALL

For basic conversations, **what_rcvd** can also contain the following values:

- AP_DATA_CONFIRM
- AP_DATA_CONFIRM_SEND
- AP_DATA_CONFIRM_DEALLOCATE

DEALLOCATE

The **DEALLOCATE** verb deallocates a conversation between two TPs.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC function rather than the blocking version of this call.

The following structure describes the verb control block used by the **DEALLOCATE** verb.

```
struct deallocate {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        tp_id[8];
    unsigned long        conv_id;
    unsigned char        reserv3;
    unsigned char        dealloc_type;
    unsigned short       log_dlen;
    unsigned char FAR *  log_dptr;
    void                 (WINAPI *callback)();
    void                 *correlator;
    unsigned char        reserv4[4];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_DEALLOCATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3
A reserved field.

dealloc_type
Supplied parameter. Specifies how to perform the deallocation.

Using one of the following values deallocates the conversation abnormally:

- AP_ABEND_PROG
- AP_ABEND_SVC
- AP_ABEND_TIMER

If the conversation is in SEND state when the local TP issues **DEALLOCATE**, APPC sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation. If the conversation is in RECEIVE or PENDING_POST state, APPC purges any incoming data before deallocating the conversation.

An application or service TP should specify AP_ABEND_PROG when it encounters an error preventing the successful completion of a transaction.

A service TP should specify AP_ABEND_SVC when it encounters an error caused by its partner service TP (for example, a format error in control information sent by the partner service TP). A service TP should specify AP_ABEND_TIMER when it encounters an error requiring immediate deallocation (for example, an operator ending the program prematurely).

AP_FLUSH sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation. This value is allowed only if the conversation is in SEND state.

AP_SYNC_LEVEL uses the conversation's synchronization level (established by ALLOCATE) to determine how to deallocate the conversation. This value is allowed only if the conversation is in SEND state.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation.

If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC deallocates the conversation. If, however, the partner TP reports an error, the conversation remains allocated.

log_dlen

Supplied parameter. Specifies the number of bytes of data to be sent to the error log file. The range is from 0 through 32767.

You can set this parameter to a number greater than zero if **dealloc_type** is set to AP_ABEND_PGM, AP_ABEND_SVC, or AP_ABEND_TIMER. Otherwise, this parameter must be zero.

log_dptr

Supplied parameter. Provides the address of the data buffer containing error information. The data is sent to the local error log and to the partner LU.

This parameter is used by **DEALLOCATE** if **log_dlen** is greater than zero.

For Microsoft® Windows NT®, Windows 95, Windows 98, and Windows 3.x, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For OS/2, the log data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The log data buffer must fit entirely on the segment.

The TP must format the error data as a GDS error log variable. For more information, see your IBM SNA manual(s).

callback

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member, indicating support for Sync Point. This parameter is the address of a user-supplied callback function. If this field is NULL, no notification will be provided.

The prototype of the callback routine is as follows:

```
void WINAPI callback_proc(
struct appc_hdr *vcb,
unsigned char tp_id[8],
unsigned long conv_id,
unsigned short type,
void *correlator
);
```

The callback procedure can take any name, since the address of the procedure is passed to the APPC DLL. The parameters passed to the function are as follows:

vcb

A pointer to the **DEALLOCATE** verb control block that caused the conversation to be deallocated.

tp_id

The TP identifier of the TP that owned the deallocated conversation.

conv_id

The conversation identifier of the deallocated conversation.

type

The type of the message flow that caused the callback to be invoked. Possible values are:

AP_DATA_FLOW

Normal data flow on the session.

AP_UNBIND

The session was unbound normally.

AP_FAILURE

The session terminated due to an outage.

correlator

This value is the **correlator** specified on the **DEALLOCATE** verb.

correlator
Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member, indicating support for the Sync Point API. This correlator field allows the TP to specify a value it can use to correlate a call to the callback function with, for example, its own internal data structures. This value is returned to the TP as one of the parameters of the callback routine when it is invoked.

reserv4
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_DEALLOC_BAD_TYPE

Secondary return code; the **dealloc_type** parameter was not set to a valid value.

AP_DEALLOC_LOG_LL_WRONG

Secondary return code; the LL field of the GDS error log variable did not match the actual length of the log data.

AP_INVALID_DATA_SEGMENT

Secondary return code; the error data for the log file was longer than the segment allocated to contain the error data, or the address of the error data buffer was wrong.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_DEALLOC_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state, and the TP attempted to flush the send buffer and send a confirmation request. This attempt occurred because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_CONFIRM_SYNC_LEVEL.

AP_DEALLOC_FLUSH_BAD_STATE

Secondary return code; the conversation was not in SEND state and the TP attempted to flush the send buffer. This attempt occurred because the value of **dealloc_type** was AP_FLUSH or because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_NONE. In either case, the conversation must be in SEND state.

AP_DEALLOC_NOT_LL_BDY

Secondary return code; the conversation was in SEND state, and the TP did not finish sending a logical record. The **dealloc_type** parameter was set to AP_SYNC_LEVEL or AP_FLUSH.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the

allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for an Host Integration Server 2000 system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, Windows 98, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

Depending on the value of the **dealloc_type** parameter, the conversation can be in one of the states indicated in the following table when the TP issues **DEALLOCATE**.

dealloc_type	**Allowed state**
AP_FLUSH	SEND
AP_SYNC_LEVEL	SEND
AP_ABEND	Any except RESET
AP_ABEND_PROG	Any except RESET
AP_ABEND_SVC	Any except RESET

AP_ABEND_TIMER	Any except RESET

State changes, summarized in the following table, are based on the value of the **primary_rc**.

primary_rc	New state
AP_OK	RESET
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

Before deallocating the conversation, this verb performs the equivalent of one of the following:

- FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the conversation identifier is no longer valid.

LU 6.2 Sync Point can use an optimization of the message flows known as implied forget. When the protocol specifies that a FORGET PS header is required, the next data flow on the session implies that a FORGET has been received. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However, it is possible that the last message to flow is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. To provide the TP with this notification, the **DEALLOCATE** verb is modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a DLC outage.

The **DEALLOCATE** verb also contains a correlator field member that is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

The TP can use the *type* parameter passed to the callback function to determine whether the message flow indicates an implied forget has been received.

Note that the **DEALLOCATE** verb will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

Host Integration Server 2000 allows TPs to deallocate conversations immediately after sending data by specifying the **type** parameter on SEND_DATA as AP_SEND_DATA_DEALLOC_*. However, the **SEND_DATA** verbs do not contain the implied forget callback function. TPs wishing to receive implied forget notification must issue **DEALLOCATE** explicitly.

FLUSH

The **FLUSH** verb sends the contents of the local LU's send buffer to the partner LU (and TP). If the send buffer is empty, no action takes place.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **FLUSH** verb.

```
struct flush {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_FLUSH.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_FLUSH_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.

- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

Data processed by SEND_DATA accumulates in the local LU's send buffer until one of the following happens:

- The local TP issues **FLUSH** (or other verb that flushes the LU's send buffer).
- The buffer is full.

The request generated by ALLOCATE is also buffered.

The conversation must be in SEND state when the TP issues this verb.

There is no state change.

GET_ATTRIBUTES

The **GET_ATTRIBUTES** verb returns the attributes of the conversation.

The following structure describes the verb control block used by the **GET_ATTRIBUTES** verb.

```
struct get_attributes {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    sync_level;
    unsigned char    mode_name[8];
    unsigned char    net_name[8];
    unsigned char    lu_name[8];
    unsigned char    lu_alias[8];
    unsigned char    plu_alias[8];
    unsigned char    plu_un_name[8];
    unsigned char    reserv4[2];
    unsigned char    fqplu_name[17];
    unsigned char    reserv5;
    unsigned char    user_id[10];
    unsigned long    conv_group_id;
    unsigned char    conv_corr_len;
    unsigned char    conv_corr[8];
    unsigned char    reserv6[13];
NOTE: The following fields are present when the high bit of opext is set (opext & AP_EXTD_VCB
) != 0.
    unsigned char    luw_id[26];
    unsigned char    sess_id[8];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_GET_ATTRIBUTES.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Reserv3
A reserved field.

sync_level
Returned parameter. Specifies the level of synchronization processing for the conversation. This parameter determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE indicates that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL indicates that TPs can use confirmation processing in this conversation.

- AP_SYNCPT indicates that TPs can use Sync Point Level 2 confirmation processing in this conversation.

mode_name
Returned parameter. Specifies the name of a set of networking characteristics. It is a type A EBCDIC character string.
net_name
Returned parameter. Specifies the name of the SNA network containing the local LU used by this TP. It is a type A EBCDIC character string.
lu_name
Returned parameter. Provides the name of the local LU.
lu_alias
Returned parameter. Provides the alias by which the local LU is known to the local TP. It is an ASCII character string.
plu_alias
Returned parameter. Provides the alias by which the partner LU is known to the local TP. It is an ASCII character string.
plu_un_name
Returned parameter. Specifies the uninterpreted name of the partner LU — the name of the partner LU as defined to the system services control point (SSCP). It is a type AE EBCDIC character string. This parameter is returned only if the local LU is dependent.
Reserv4
A reserved field.
fqplu_name
Returned parameter. Provides the fully qualified name of the partner LU. It is a type A EBCDIC character string. The field contains the network name, an EBCDIC period, and the partner-LU name.
Reserv5
A reserved field.
user_id
Returned parameter. Specifies the user identifier sent by the invoking TP through ALLOCATE to access the invoked TP (if applicable). It is a type AE EBCDIC character string. The field contains the user identifier if the following conditions are true:

- The invoked TP requires conversation security.
- **GET_ATTRIBUTES** was issued by the invoked TP.

Otherwise, the field contains spaces.

conv_group_id
Returned parameter. Specifies the conversation group identifier for the session to which the conversation has been allocated. This is also returned on ALLOCATE and RECEIVE_ALLOCATE.
Conv_Corr_len
Returned parameter. Specifies the length of the conversation correlator identifier that is returned.
Conv_corr
Returned parameter. Specifies the conversation correlator identifier (if any) that the source LU assigns to identify the conversation, which is unique for the source/partner LU pair. It is sent by the source LU on the allocation request.

The following fields are present when the high bit of **opext** is set (**opext** & AP_EXTD_VCB) != 0.These fields are only present when when using Sync Point Level 2 support.

Reserv6
A reserved field.
Luw_id
Logical unit-of-work identifier.
Sess_id
Session identifier.

Return Codes

AP_OK
Primary return code; the verb executed successfully.
AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

GET_LU_STATUS

The **GET_LU_STATUS** verb returns the status of a particular LU. This conversation verb is only available when Sync Point conversations are supported.

The following structure describes the verb control block used by the **GET_LU_STATUS** verb.

```
struct get_type {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned char    plu_alias[8];
    unsigned short   active_sess;
    unsigned char    zero_sess;
    unsigned char    reserv3[7];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_GET_LU_STATUS.
opext
This field is unused by the **GET_LU_STATUS** verb.
reserv2
A reserved field.
primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.
secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.
tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.
plu_alias
Supplied parameter. Provides the identifier for the LU about which this TP is inquiring. The value of this parameter was returned by MC_ALLOCATE or ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.
active_sess
Returned parameter. Supplies the number of active sessions on this LU.
zero_sess
Returned parameter. Indicates whether a zero session is on this LU. Values are AP_YES or AP_NO.
reserv3
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.
AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_LU_ALIAS

Secondary return code; the value of **plu_alias** did not match any LUs assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

GET_STATE

The **GET_STATE** verb returns the state of a particular conversation.

The following structure describes the verb control block used by the **GET_STATE** verb.

```
struct get_state {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    conv_state;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_GET_STATE.

opext
This field is unused by the **GET_STATE** verb.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the identifier for the conversation about which this TP is inquiring. The value of this parameter was returned by MC_ALLOCATE or ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

conv_state
Returned parameter. Indicates the state of the conversation. The **conv_state** parameter can be one of the following values:

AP_RESET_STATE

The conversation is in the RESET state.

AP_SEND_STATE

The conversation is in the SEND state.

AP_RECEIVE_STATE

The conversation is in the RECEIVE state.

AP_CONFIRM_STATE

The conversation is in the CONFIRM state.

AP_CONFIRM_SEND_STATE

The conversation is in the CONFIRM_SEND state.

AP_CONFIRM_DEALL_STATE

The conversation is in the CONFIRM_DEALLOCATE state.

AP_PEND_POST_STATE

The conversation has a POST verb pending.

AP_PEND_DEALL_STATE

The conversation has a DEALLOCATE verb pending.

AP_END_CONV_STATE

The conversation is in the END_CONVERSATION state.

AP_SEND_PENDING_STATE

The conversation is in the SEND_PENDING state.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state when the TP issues this verb.

There is no state change.

GET_TYPE

The **GET_TYPE** verb returns the conversation type (basic or mapped) of a particular conversation so the TP can decide whether to use basic or mapped conversation verbs.

The following structure describes the verb control block used by the **GET_TYPE** verb.

```
struct get_type {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    conv_type;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_GET_TYPE.

opext
This field is unused by the **GET_TYPE** verb.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the identifier for the conversation about which this TP is inquiring. The value of this parameter was returned by MC_ALLOCATE or ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

conv_type
Returned parameter. Supplies the type of conversation, either AP_BASIC_CONVERSATION or AP_MAPPED_CONVERSATION.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

MC_ALLOCATE

The **MC_ALLOCATE** verb is issued by the invoking TP. It allocates a session between the local LU and partner LU and (in conjunction with RECEIVE_ALLOCATE) establishes a conversation between the invoking TP and the invoked TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_ALLOCATE** verb.

```
struct mc_allocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    synclevel;
    unsigned char    reserv4[2];
    unsigned char    rtn_ctl;
    unsigned char    reserv5;
    unsigned long    conv_group_id;
    unsigned long    sense_data;
    unsigned char    plu_alias[8];
    unsigned char    mode_name[8];
    unsigned char    tp_name[64];
    unsigned char    security;
    unsigned char    reserv6[11];
    unsigned char    pwd[10];
    unsigned char    user_id[10];
    unsigned short   pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char    reserv7;

};
```

Members

opcode
Supplied parameter. Specifies the verb operation code; AP_M_ALLOCATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION. If the AP_EXTD_VCB bit is set, this indicates that an extended version of the verb control block is used. In this case, the **MC_ALLOCATE** structure includes Sync Point support or privileged proxy feature support.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id
Returned parameter. Identifies the conversation established between the two TPs.

reserv3
A reserved field.
synclevel
Supplied parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE specifies that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL specifies that the TPs can use confirmation processing in this conversation.
- AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

reserv4
A reserved field.
rtn_ctl
Supplied parameter. Specifies when the local LU, acting on a session request from the local TP, should return control to the local TP. For information about sessions, see About Transaction Programs.

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns control to the TP.
- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs, (as documented in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOC specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOC specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id** or encounters one of the errors documented in Return Codes in this topic. If a session is not available, the TP waits for it to become free.

Note that AP_IMMEDIATE is the only value for **rtn_ctl** that will never cause a new session to start. For values other than AP_IMMEDIATE, if an appropriate session is not immediately available, Microsoft® Host Integration Server 2000 will try to start one. This will cause the on-demand connection to be activated.

reserv5
A reserved field.
conv_group_id
Supplied/returned parameter. Specifies the identifier of the conversation group from which the session should be allocated. The **conv_group_id** is required only if **rtn_ctl** is set to WHEN_CONV_GROUP_ALLOC. When **rtn_ctl** specifies a different value and the **primary_rc** is AP_OK, this is a returned value.
sense_data
Returned parameter. Indicates an allocation error (retry or no-retry) and contains sense data.
plu_alias
Supplied parameter. Specifies the alias by which the partner LU is known to the local TP.

The **plu_alias** must match the name of a partner LU established during configuration.

The parameter is an 8-byte ASCII character string. It can consist of the following ASCII characters:

- Uppercase letters
- Numerals 0 through 9
- Spaces
- Special characters $, #, %, and @

The first character of this string cannot be a space.

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

If you want to specify the partner LU with the **fqplu_name** parameter, fill this parameter with binary zeros.

For a user or group using TPs, 5250 emulators, and/or APPC applications, the system administrator can assign default local and remote LUs. In this case, the field is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information on default LUs, see the *Microsoft Host Integration Server 2000 online books*.

mode_name
Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration.

The value of **mode_name** must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or a special character.

Do not use SNASVCMG in a mapped conversation. SNASVCMG is a reserved **mode_name** used internally by APPC.

tp_name
Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by **MC_ALLOCATE** in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **tp_name** is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the type AE EBCDIC character set.

security
Supplied parameter. Provides the information that the partner LU requires to validate access to the invoked TP.

Based on the conversation security established for the invoked TP during configuration, use one of the following values:

- AP_NONE for an invoked TP that uses no conversation security.
- AP_PGM for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters.
- AP_PROXY_PGM for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password. Pointers must be set up for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.
- AP_PROXY_SAME for a TP that has been invoked using privileged proxy with a valid user identifier and password supplied by the proxy, which in turn invokes another TP. Pointers must be set up for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.

  For example, assume that TP A invokes TP B with a valid user identifier and password supplied by the privileged proxy, and TP B in turn invokes TP C. If TP B specifies the value AP_PROXY_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

- AP_PROXY_STRONG for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password provided by the privileged proxy mechanism. Pointers must be set up for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields. AP_PROXY_STRONG differs from AP_PROXY_PGM in that AP_PROXY_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.
- AP_SAME for a TP that has been invoked with a valid user identifier and password, which in turn invokes another TP.

  For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

When AP_SAME is used in an **MC_ALLOCATE** verb, your application must always provide values for the **user_id** and **pwd** parameters in the verb control block. Depending on the properties negotiated between Host Integration Server 2000 and the peer LU, the MC_ALLOCATE verb will send one of 3 kinds of Attach (FMH-5) messages, in this order of precedence:

1. If the LUs have negotiated "already verified" security, then the Attach sent by Host Integration Server 2000 will not include the contents of the pwd parameter field specified in the VCB.
2. If the LUs have negotiated "persistent verification" security, then the Attach sent by Host Integration Server 2000 will include the pwd parameter specified in the VCB, but only when the Attach is the first for the specified user_id parameter since the start of the LU-LU session, and will omit the pwd parameter on all subsequent Attaches (issued by your application or any other application using this LU-LU-mode triplet).
3. If the LUs have not negotiated either of the above, then the Attach sent by Host Integration Server 2000 will omit both the user_id and pwd parameters on all Attaches.

   Your application cannot tell which mode of security has been negotiated between the LUs, nor can it tell whether the **MC_ALLOCATE** verb it is issuing is the first for that LU-LU-mode triplet. So your application must always set the **user_id** and **pwd** parameter fields in the VCB when **security** is set to AP_SAME.

   For more information on persistent verification and already verified security, see the SNA Formats Guide, section "FM Header 5: Attach (LU 6.2)".

- AP_STRONG for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters. AP_STRONG differs from AP_PGM in that AP_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.

  If the APPC automatic logon feature is to be used, **security** must be set to AP_PGM. See the Remarks section for details.

reserv6
A reserved field.

pwd
Supplied parameter. Specifies the password associated with **user_id**.

The **pwd** parameter is required only if **security** is set to AP_PGM or AP_SAME. It must match the password for **user_id** that was established during configuration.

The **pwd** parameter is a 10-byte EBCDIC character string and is case-sensitive. It can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **pwd** character string must be hard-coded to MS$SAME. See the Remarks section for details.

user_id
Supplied parameter. Specifies the user identifier required to access the partner TP. It is required only if the security parameter is set to AP_PGM or AP_SAME.

The **user_id** parameter is a 10-byte EBCDIC character string and is case-sensitive. It must match one of the user identifiers configured for the partner TP.

The parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **user_id** is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **user_id** character string must be hard-coded to MS$SAME. See the Remarks section for details.

pip_dlen
Supplied parameter. Specifies the length of the program initialization parameters (PIP) to be passed to the partner TP. The range

is from 0 through 32767.

pip_dptr

Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the general data stream (GDS) format. For more information, see your IBM SNA manual(s).

For Windows NT, Windows 95, Windows 98, and Windows 3.x, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For OS/2, the PIP data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The PIP data buffer must fit entirely on the segment.

reserv7

A reserved field.

fqplu_name

Supplied parameter. Specifies the fully qualified name of the partner LU. This must match the fully qualified name of the local LU defined in the remote node. The parameter consists of two type A EBCDIC character strings for the NETID and the LU name of the partner LU. The names are separated by an EBCDIC period (.).

This name must be provided if no **plu_alias** is specified. It can consist of the following EBCDIC characters:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

reserv8

A reserved field.

proxy_user

Supplied parameter. Specifies a LPWSTR pointing to a UNICODE string containing the user name to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

proxy_domain

Supplied parameter. Specifies a LPWSTR pointing to a UNICODE string containing the domain name of the user to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

reserv9

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate (AP_IMMEDIATE) return of control to the TP, and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_SYNC_LEVEL

Secondary return code; the value specified for **sync_level** was invalid.

AP_BAD_TP_ID

Secondary return code; the value specified for **tp_id** was invalid.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **partner_lu_alias**.

AP_NO_USE_OF_SNASVCMG

Secondary return code; SNASVCMG is not a valid value for **mode_name**.

AP_INVALID_DATA_SEGMENT

Secondary return code; the PIP data was longer than the allocated data segment, or the address of the PIP data buffer was wrong.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **MC_ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **MC_ALLOCATE**, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for an Host Integration Server 2000 system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

MC_ALLOCATE establishes a mapped conversation.

The conversation state is RESET when the TP issues this verb. After successful execution (**primary_rc** is AP_OK), the state changes to SEND. If the verb does not execute, the state remains unchanged.

Several parameters of **MC_ALLOCATE** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

To send the **MC_ALLOCATE** request immediately, the invoking TP can issue MC_FLUSH or MC_CONFIRM immediately after **MC_ALLOCATE**. Otherwise, the **MC_ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

By issuing **MC_CONFIRM** after **MC_ALLOCATE**, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **MC_ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

Host Integration Server 2000 supports a feature called password substitution. This is a security feature supported by the latest version of the OS/400 operating system (V3R1) which encrypts any password that flows between two nodes on an Attach message. A password flows on an Attach whenever someone invokes an APPC transaction program specifying a user identifier and password. For example, this happens whenever anyone logs on to an AS/400.

Support for password substitution is indicated by setting bit 5 in byte 23 of the BIND request to 1 (which indicates that password substitution is supported). If the remote system sets this bit in the BIND response, Host Integration Server 2000 automatically encrypts the LU 6.2 conversation security password included in the FMH-5 Attach message. Host Integration Server 2000 APPC applications automatically take advantage of this feature by setting the **security** field of the VCB to AP_PGM or AP_STRONG in the **MC_ALLOCATE** request.

If an APPC application wants to force an encrypted password to flow, the application can specify AP_STRONG for the **security** field in the VCB in the **MC_ALLOCATE** request. This option is implemented as defined in OS/400 V3R1, and is documented in the OS/400 CPIC programmer reference as CM_SECURITY_PROGRAM_STRONG, where the LU 6.2 **pwd** (password) field is encrypted before it flows over the physical network.

The password substitution features is currently only supported by OS/400 V3R1 or later. If the remote system does not support this feature, Host Integration Server 2000 will UNBIND the session with the sense code of 10060006. The two nodes negotiate whether or not they support this feature in the BIND exchange. Host Integration Server 2000 sets a bit in the BIND, and also adds some random data on the BIND for encryption. If the remote node supports password substitution, it sets the same bit in the BIND response, and adds some (different) random data for decryption.

SNA Server version 3.0 with Service Pack 1 or later and SNA Server version 4.0 support automatic logon for APPC applications. This feature requires specific configuration by the network administrator: The APPC application must be invoked on the LAN side from a client of Host Integration Server 2000. The client must be logged into a Windows NT domain, but can be any platform that supports Host Integration Server 2000's APPC APIs.

The client application is coded to use "program" level security, with a special hard-coded APPC user name MS$SAME and password MS$SAME. When this session allocation flows from client to Host Integration Server 2000, the Host Integration Server 2000 server looks up the host account and password corresponding to the Windows NT account under which the client is logged in, and substitutes the host account information into the APPC attach message it sends to the host.

Note It is illegal for the remote node to set the bit specifying password substitution and not add the random data.

According to IBM, there are implementations of LU 6.2 password substitution that do not support password substitution but do echo the password substitution bit back to Host Integration Server 2000, without specifying any random data. When they do this, Host Integration Server 2000 will UNBIND the session with the sense code 10060006.This sense code is interpreted as:

- 1006 = Required field or parameter missing.
- 0006 = A required subfield of a control vector was omitted.

Host Integration Server 2000 should also log an Event 17 (APPC session activation failure: BIND negative response sent).

The correct solution is for the failing implementation to be fixed. However, as a short-term workaround, the following Host Integration Server 2000 SNA Service registry setting can be set:

HKEY_LOCAL_MACHINE\\SYSTEM\CurrentControlSet\Services\snaservr\parameters\NOPWDSUB: REG_SZ: YES

When this parameter is specified in the registry, Host Integration Server 2000's password substitution support will be disabled.

Several updates have been made to Host Integration Server 2000 to allow a privileged APPC application to open an APPC conversation using the Single Signon feature on behalf of any defined Windows NT user. This is referred to as the privileged proxy feature. An extension has been added to the APPC **MC_ALLOCATE** verb to invoke this feature.

An APPC application becomes privileged by being started in a Windows NT user account that is a member of a special Windows NT group. When a Host Security Domain is configured, Host Integration Server 2000 Manager will define a second Windows NT group for use with the host security features of Host Integration Server 2000. If the user account under which the actual client is running is a member of this second Windows NT group, the client is privileged to initiate an APPC conversation on behalf of any user account defined in the Host Account Cache.

The following describes how the privileged proxy feature works:

The Host Integration Server 2000 administrator creates a Host Security Domain called APP. Host Integration Server 2000 Manager now creates two Windows NT groups. The first group is called APP and the second is called APP_PROXY for this example. Users that are assigned to the APP group are enabled for single signon. Users assigned to the APP_PROXY group are privileged proxies. The administrator adds the Windows NT user AppcUser to the APP_PROXY group using the Users button on the Host Security Domain property dialog box in Host Integration Server 2000 Manager.

The administrator then sets up an APPC application on the Host Integration Server 2000 server to run as a Windows NT service called APPCAPP and that service has been setup to operate under the AppcUser user account. When APPCAPP runs, it opens an APPC session via an ALLOCATE verb using the extended VCB format and specifies the Windows NT username of the desired user, UserA (for example).

The SNA Service sees the session request coming from a connection that is a member of the Host Security Domain APP. The Client/Server interface tells the SNA Service that the actual client is AppcUser.

The SNA Service checks to see if AppcUser is a member of the APP_PROXY group. Because AppcUser is a member of APP_PROXY, the SNA Service inserts the Username/Password for UserA in the APPC Attach (FMH-5) command and sends it off to the partner TP.

In order to support the privileged proxy feature, the APPC application must implement the following program logic:

The APPC application must determine the Windows NT user ID and domain name that it wishes to impersonate.

The APPC application must set the following parameters before calling the **MC_ALLOCATE** verb:

Enable the use of the extended **MC_ALLOCATE** verb control block structure by setting the AP_EXTD_VCB flag in the **opext** field.

Set **security** to AP_PROXY_SAME, AP_PROXY_PGM or AP_PROXY_STRONG.

Set up the pointers for **proxy_user** and **proxy_domain** to point to UNICODE strings containing the user name and domain name of the user to be impersonated.

The application does not need to set up the **user_id** and **pwd** fields in the **MC_ALLOCATE** VCB.

When the APPC application performs the above steps and issues the **MC_ALLOCATE** verb, the Host Integration Server 2000 server will perform a lookup in the host security domain for the specified Windows NT user and set the user ID and password fields in the FMH-5 Attach message sent to the remote system.

MC_CONFIRM

The **MC_CONFIRM** verb sends the contents of the local LU's send buffer and a confirmation request to the partner TP.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_CONFIRM** verb.

```
struct mc_confirm {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_CONFIRM.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id
Returned parameter. Identifies the conversation established between the two TPs.

rts_rcvd
Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND, which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state operating on Microsoft® Windows NT®, Windows 95, or Windows 98, the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

To change to RECEIVE state operating on Windows 3.x, the local TP can use **MC_PREPARE_TO_RECEIVE** or **MC_RECEIVE_AND_WAIT**.

To change to RECEIVE state operating on OS/2, the local TP can use **MC_RECEIVE_AND_POST**.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_CONFIRM_ON_SYNC_LEVEL_NONE

Secondary return code; the local TP attempted to use **MC_CONFIRM** in a conversation with a synchronization level of AP_NONE. The synchronization level, established by MC_ALLOCATE, must be AP_CONFIRM_SYNC_LEVEL.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state.

AP_CONFIRM_NOT_LL_BDY

Secondary return code; the conversation for the local TP was in SEND state, and the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **MC_ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer has encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

In response to **MC_CONFIRM**, the partner TP normally issues MC_CONFIRMED to confirm that it has received the data without error. (If the partner TP encounters an error, it issues MC_SEND_ERROR or abnormally deallocates the conversation.)

The TP can issue **MC_CONFIRM** only if the conversation's synchronization level, established by MC_ALLOCATE, is AP_CONFIRM_SYNC_LEVEL.

The conversation must be in SEND state when the TP issues this verb. State changes, summarized in the following table, are based on the value of the **primary_rc**.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET
AP_COMM_SUBSYSTEM_ABENDED AP_COMM_SUBSYSTEM_NOT_LOADED	RESET RESET
AP_CONV_FAILURE_RETRY AP_CONV_FAILURE_NO_RETRY	RESET RESET
AP_DEALLOC_ABEND AP_DEALLOC_ABEND_PROG AP_DEALLOC_ABEND_SVC AP_DEALLOC_ABEND_TIMER	RESET RESET RESET RESET
AP_PROG_ERROR_PURGING AP_SVC_ERROR_PURGING	RECEIVE RECEIVE

MC_CONFIRM waits for a response from the partner TP. A response is generated by one of the following verbs in the partner TP:

- MC_CONFIRMED
- MC_SEND_ERROR
- MC_DEALLOCATE with dealloc_type set to AP_ABEND
- TP_ENDED

By issuing **MC_CONFIRM** after MC_ALLOCATE, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **MC_ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**. For more information, see the *Microsoft Host Integration Server 2000 online books*.

Several parameters of **MC_ALLOCATE** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

To send the **MC_ALLOCATE** request immediately, the invoking TP can issue MC_FLUSH or **MC_CONFIRM** immediately after **MC_ALLOCATE**. Otherwise, the **MC_ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

MC_CONFIRMED

The **MC_CONFIRMED** verb responds to a confirmation request from the partner TP. It informs the partner TP that the local TP has not detected an error in the received data. Because the TP issuing the confirmation request waits for a confirmation, **MC_CONFIRMED** synchronizes the processing of the two TPs.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_CONFIRMED** verb.

```
struct mc_confirmed {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_CONFIRMED.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd
Returned parameter.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRMED_BAD_STATE

Secondary return code; the conversation is not in CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation must be in one of the following states when the TP issues this verb:

- CONFIRM
- CONFIRM_SEND
- CONFIRM_DEALLOCATE

The new state is determined by the old state — the state of the conversation when the local TP issued **MC_CONFIRMED**. The old state is indicated by the value of the **what_rcvd** parameter of the preceding receive verb. The following state changes are possible:

Old state	**New state**
CONFIRM	RECEIVE
CONFIRM_SEND	SEND

CONFIRM_DEALLOCATE	RESET

Confirmation Requests

A confirmation request is issued by one of the following verbs in the partner TP:

- MC_CONFIRM
- MC_PREPARE_TO_RECEIVE if **ptr_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL
- MC_DEALLOCATE if **dealloc_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by **MC_ALLOCATE**) is AP_CONFIRM_SYNC_LEVEL
- MC_SEND_DATA if **type** is set to AP_SEND_DATA_CONFIRM and the conversation's synchronization level (established by **MC_ALLOCATE**) is AP_CONFIRM_SYNC_LEVEL

A confirmation request is received by the local TP through the **what_rcvd** parameter of one of the following verbs:

- MC_RECEIVE_IMMEDIATE
- MC_RECEIVE_AND_WAIT
- MC_RECEIVE_AND_POST for Windows NT, Windows 95, Windows 98, , and OS/2

MC_CONFIRMED is issued by the local TP only if **what_rcvd** contains one of the following values:

- AP_CONFIRM_WHAT_RECEIVED
- AP_CONFIRM_SEND
- AP_CONFIRM_DEALLOCATE

If the **rtn_status** parameter is set to AP_YES, **what_rcvd** can also contain the following values:

- AP_DATA_COMPLETE_CONFIRM
- AP_DATA_COMPLETE_CONFIRM_SEND
- AP_DATA_COMPLETE_CONFIRM_DEALL

MC_DEALLOCATE

The **MC_DEALLOCATE** verb deallocates a conversation between two TPs.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC function rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_DEALLOCATE** verb.

```
struct mc_deallocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    dealloc_type;
    unsigned char    reserv4[2];
    unsigned char    reserv5[4];
    void             (WINAPI *callback)();
    void             *correlator;
    unsigned char    reserv6[4];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_DEALLOCATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3
A reserved field.

dealloc_type
Supplied parameter. Specifies how to perform the deallocation.

For **MC_DEALLOCATE**, use AP_ABEND to deallocate the conversation abnormally. If the conversation is in SEND state when the local TP issues **MC_DEALLOCATE**, APPC sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation. If the conversation is in RECEIVE or PENDING_POST state, APPC purges any incoming data before deallocating the conversation.

A TP should specify AP_ABEND when it encounters an error preventing the successful completion of a transaction.

AP_FLUSH sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation. This value is allowed only if the conversation is in SEND state.

AP_SYNC_LEVEL uses the conversation's synchronization level (established by MC_ALLOCATE) to determine how to deallocate the conversation. This value is allowed only if the conversation is in SEND state.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the

partner TP before deallocating the conversation.

If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC deallocates the conversation. If, however, the partner TP reports an error, the conversation remains allocated.

callback

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member indicating support for Sync Point. This parameter is the address of a user-supplied callback function. If this field is NULL, no notification will be provided.

The prototype of the callback routine is as follows:

```
void WINAPI callback_proc(
struct appc_hdr *vcb,
unsigned char tp_id[8],
unsigned long conv_id,
unsigned short type,
void *correlator
);
```

The callback procedure can take any name, since the address of the procedure is passed to the APPC DLL. The parameters passed to the function are as follows:

vcb

A pointer to the **MC_DEALLOCATE** verb control block that caused the conversation to be deallocated.

tp_id

The TP identifier of the TP that owned the deallocated conversation.

conv_id

The conversation identifier of the deallocated conversation.

type

The type of the message flow that caused the callback to be invoked. Possible values are:

AP_DATA_FLOW Normal data flow on the session.

AP_UNBIND The session was unbound normally.

AP_FAILURE The session terminated due to an outage.

correlator

This value is the **correlator** specified on the **MC_DEALLOCATE** verb.

correlator

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member indicating support for the Sync Point API. This correlator field allows the TP to specify a value it can use to correlate a call to the callback function with, for example, its own internal data structures. This value is returned to the TP as one of the parameters of the callback routine when it is invoked.

reserv4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_DEALLOC_BAD_TYPE

Secondary return code; the **dealloc_type** parameter was not set to a valid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_DEALLOC_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state, and the TP attempted to flush the send buffer and send a confirmation request. This attempt occurred because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_CONFIRM_SYNC_LEVEL.

AP_DEALLOC_FLUSH_BAD_STATE

Secondary return code; the conversation was not in SEND state and the TP attempted to flush the send buffer. This attempt occurred because the value of **dealloc_type** was AP_FLUSH or because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_NONE. In either case, the conversation must be in SEND state.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued **MC_DEALLOCATE** with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

Depending on the value of the **dealloc_type** parameter, the conversation can be in one of the states indicated in the following table when the TP issues **MC_DEALLOCATE**.

Dealloc_type	**Allowed state**
AP_FLUSH	SEND
AP_SYNC_LEVEL	SEND
AP_ABEND	Any state except RESET
AP_ABEND_PROG	Any state except RESET
AP_ABEND_SVC	Any state except RESET
AP_ABEND_TIMER	Any state except RESET

State changes, summarized in the following table, are based on the value of the **primary_rc**.

Primary_rc	**New state**
AP_OK	RESET
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET

AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE

Before deallocating the conversation, this verb performs the equivalent of one of the following:

- MC_FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- MC_CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the conversation identifier is no longer valid.

LU 6.2 Sync Point can use an optimization of the message flows known as implied forget. When the protocol specifies that a FORGET PS header is required, the next data flow on the session implies that a FORGET has been received. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However, it is possible that the last message to flow is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. In order to provide the TP with this notification, the **MC_DEALLOCATE** verb is modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a DLC outage.

The **MC_DEALLOCATE** verb also contains a correlator field member that is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

The TP can use the *type* parameter passed to the callback function to determine whether the message flow indicates an implied forget has been received.

Note that the **MC_DEALLOCATE** verb will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

Host Integration Server 2000 allows TPs to deallocate conversations immediately after sending data by specifying the **type** parameter on MC_SEND_DATA as AP_SEND_DATA_DEALLOC_*. However, the **MC_SEND_DATA** verbs do not contain the implied forget callback function. TPs wishing to receive implied forget notification must issue **MC_DEALLOCATE** explicitly.

MC_FLUSH

The **MC_FLUSH** verb sends the contents of the local LU's send buffer to the partner LU (and TP). If the send buffer is empty, no action takes place.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_FLUSH** verb.

```
struct mc_flush {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_FLUSH.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_FLUSH_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.

- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

Data processed by MC_SEND_DATA accumulates in the local LU's send buffer until one of the following happens:

- The local TP issues **MC_FLUSH** (or other verb that flushes the LU's send buffer).
- The buffer is full.

The request generated by MC_ALLOCATE is also buffered.

The conversation must be in SEND state when the TP issues this verb.

There is no state change.

MC_GET_ATTRIBUTES

The **MC_GET_ATTRIBUTES** verb returns the attributes of the conversation.

The following structure describes the verb control block used by the **MC_GET_ATTRIBUTES** verb.

```
struct mc_get_attributes {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    sync_level;
    unsigned char    mode_name[8];
    unsigned char    net_name[8];
    unsigned char    lu_name[8];
    unsigned char    lu_alias[8];
    unsigned char    plu_alias[8];
    unsigned char    plu_un_name[8];
    unsigned char    reserv4[2];
    unsigned char    fqplu_name[17];
    unsigned char    reserv5;
    unsigned char    user_id[10];
    unsigned long    conv_group_id;
    unsigned char    conv_corr_len;
    unsigned char    conv_corr[8];
    unsigned char    reserv6[13];
NOTE: The following fields are present when the high bit of opext is set (opext & AP_EXTD_VCB
) != 0.
    unsigned char    luw_id[26];
    unsigned char    sess_id[8];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_GET_ATTRIBUTES.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

sync_level
Returned parameter. Specifies the level of synchronization processing for the conversation. This parameter determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

AP_NONE indicates that confirmation processing will not be used in this conversation.

AP_CONFIRM_SYNC_LEVEL indicates that TPs can use confirmation processing in this conversation.

AP_SYNCPT indicates that TPs can use Sync Point Level 2 confirmation processing in this conversation.

mode_name
Returned parameter. Specifies the name of a set of networking characteristics. It is a type A EBCDIC character string.

net_name
Returned parameter. Specifies the name of the SNA network containing the local LU used by this TP. It is a type A EBCDIC character string.

lu_name
Returned parameter. Provides the name of the local LU.

lu_alias
Returned parameter. Provides the alias by which the local LU is known to the local TP. It is an ASCII character string.

plu_alias
Returned parameter. Provides the alias by which the partner LU is known to the local TP. It is an ASCII character string.

plu_un_name
Returned parameter. Specifies the uninterpreted name of the partner LU — the name of the partner LU as defined to the system services control point (SSCP). It is a type AE EBCDIC character string. This parameter is returned only if the local LU is dependent.

fqplu_name
Returned parameter. Provides the fully qualified name of the partner LU. It is a type A EBCDIC character string. The field contains the network name, an EBCDIC period, and the partner-LU name.

user_id
Returned parameter. Specifies the user identifier sent by the invoking TP through MC_ALLOCATE to access the invoked TP (if applicable). It is a type AE EBCDIC character string. The field contains the user identifier if the following conditions are true:

- The invoked TP requires conversation security.
- **MC_GET_ATTRIBUTES** was issued by the invoked TP.

Otherwise, the field contains spaces.

conv_group_id
Returned parameter. Specifies the conversation group identifier for the session to which the conversation has been allocated. This is also returned on MC_ALLOCATE and RECEIVE_ALLOCATE.

conv_corr_len
Returned parameter. Specifies the length of the conversation correlator identifier that is returned.

conv_corr
Returned parameter. Specifies the conversation correlator identifier (if any) that the source LU assigns to identify the conversation, which is unique for the source/partner LU pair. It is sent by the source LU on the allocation request.

> **Note** The following fields are present when the high bit of **opext** is set (**opext** & AP_EXTD_VCB) != 0.These fields are only present when when using Sync Point Level 2 support.

luw_id
Logical unit-of-work identifier.

sess_id
Session identifier.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

MC_POST_ON_RECEIPT

The **MC_POST_ON_RECEIPT** verb allows the application to register to receive a notification when data or status arrives at the local LU without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state. This verb is only supported on Microsoft® Windows NT® and Microsoft® Windows® 95 by Microsoft® SNA Server version 3.0 with Service Pack 1 or later and by SNA Server version 4.0.

When the TP issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied, the Win32® event specified by the **sema** parameter is signalled and the verb completes. Then the TP looks at the return code in the verb control block to determine whether or not any data or status notification has arrived at the local LU and issues an MC_RECEIVE_IMMEDIATE or MC_RECEIVE_AND_WAIT verb to actually receive the data or status notification.

The **MC_POST_ON_RECEIPT** verb implements both the **POST_ON_RECEIPT** and **TEST** verbs as described in the IBM Transaction Programmer's manual for LU Type 6.2.

The following structure describes the verb control block used by the **MC_POST_ON_RECEIPT** verb.

```
struct mc_post_on_receipt {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv1;
    unsigned char    primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned short   reserv2;
    unsigned char    reserv3;
    unsigned char    reserv4;
    unsigned short   max_len;
    unsigned short   reserv5;
    unsigned char *  reserv6;
    unsigned char    reserv7[5];
    unsigned long    sema;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_POST_ON_RECEIPT.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv1
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv2
A reserved field.

reserv3
A reserved field.

reserv4
A reserved field.

max_len
Supplied parameter. Specifies the length of data that triggers APPC to post a notification to the TP.

reserv5
A reserved field.
reserv6
A reserved field.
reserv7
A reserved field.
sema
Supplied parameter. Specifies the handle of a Win32 event. The event should have been created by the TP and the TP is responsible for ensuring that it is reset before a call is made and after the verb completes.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_DATA

Secondary return code; data is available for the program to receive.

AP_NOT_DATA

Secondary return code; information other than data is available for the program to receive.

AP_CANCELLED
Primary return code; the verb was canceled.
AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the **sema** parameter was not set to a valid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.
AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE.
- The partner TP has encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

AP_DEALLOC_NORMAL
Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_CONFIRM_SYNC_LEVEL
- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

AP_PROG_ERROR_NO_TRUNC
Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC
Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was truncated.

AP_SVC_ERROR_NO_TRUNC
Primary return code; the partner TP (or partner LU) issued MC_SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP was not truncated.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued MC_SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE,

PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC

Primary return code; the partner TP (or partner LU) issued MC_SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been truncated.

Remarks

While an **MC_POST_ON_RECEIPT** verb is outstanding, the following verbs can be issued on the same conversation:

GET_ATTRIBUTES

GET_TYPE

MC_DEALLOCATE

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_REQUEST_TO_SEND

MC_SEND_ERROR

MC_TEST_RTS

TP_ENDED

Issuing any of the following verbs prior to completion of the asynchronous **MC_POST_ON_RECEIPT** verb causes the **MC_POST_ON_RECEIPT** verb to be canceled (the Win32 event is signaled and the primary return code in the verb control block is set to AP_CANCELLED).

MC_DEALLOCATE

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_SEND_ERROR

TP_ENDED

MC_PREPARE_TO_RECEIVE

The **MC_PREPARE_TO_RECEIVE** verb changes the state of the conversation for the local TP from SEND to RECEIVE.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_PREPARE_TO_RECEIVE** verb.

```
struct mc_prepare_to_receive {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    primary_rc;
    unsigned short   reserv2;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    ptr_type;
    unsigned char    locks;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_PREPARE_TO_RECEIVE.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

ptr_type
Supplied parameter. Specifies how to perform the state change.

Use AP_FLUSH to send the contents of the local LU's send buffer to the partner LU (and TP) before changing the conversation's state to RECEIVE.

The AP_SYNC_LEVEL value uses the conversation's synchronization level (established by **MC_ALLOCATE**) to determine how to perform the state change.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before changing the conversation's state to RECEIVE. If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC changes the conversation's state to RECEIVE. If, however, the partner TP reports an error, the state changes to RECEIVE or RESET. See the Remarks in this topic.

locks
Supplied parameter. Specifies when APPC should return control to the local TP.

Use this parameter only if **ptr_type** is set to AP_SYNC_LEVEL and the synchronization level of the conversation, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. (Otherwise, the parameter is ignored.)

- AP_LONG indicates that APPC returns control to the local TP when the confirmation and subsequent data from the partner TP arrive at the local LU. (This method results in more efficient use of the network but requires a longer time to return control to the local TP.)

- AP_SHORT indicates that APPC returns control to the local TP when the confirmation from the partner TP arrives at the local LU.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_P_TO_R_INVALID_TYPE

Secondary return code; the **ptr_type** parameter was not set to a valid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_P_TO_R_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_P_TO_R_NOT_LL_BDY

Secondary return code; the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Microsoft® Windows NT®, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

Before changing the conversation state, this verb performs the equivalent of one of the following:

- MC_FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- MC_CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the local TP can receive data.

The conversation must be in SEND state when the TP issues this verb.

State changes, summarized in the following table, are based on the value of **primary_rc**.

primary_rc	New state
AP_OK	RECEIVE
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

The conversation does not change to SEND state for the partner TP until the partner TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_SEND
- AP_CONFIRM_SEND and replies with MC_CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **MC_CONFIRMED**
- AP_DATA_CONFIRM_SEND and replies with **MC_CONFIRMED**

The receive verbs are MC_RECEIVE_AND_POST (Windows NT, Windows 95, Windows 98, and OS/2), MC_RECEIVE_IMMEDIATE, and MC_RECEIVE_AND_WAIT.

MC_RECEIVE_AND_POST

The **MC_RECEIVE_AND_POST** verb receives application data and status information asynchronously. This allows the local TP to proceed with processing while data is still arriving at the local LU.

MC_RECEIVE_AND_POST is only supported under the Microsoft® Windows NT®, Microsoft® Windows® 95, and OS/2 operating systems. For similar functionality under the Windows version 3.*x* graphical environment, use MC_RECEIVE_AND_WAIT in conjunction with WinAsyncAPPC. Specifically, while an asynchronous **MC_RECEIVE_AND_POST** is outstanding, the following verbs can be issued on the same conversation:

- GET_TYPE
- MC_GET_ATTRIBUTES
- MC_REQUEST_TO_SEND
- MC_SEND_ERROR
- MC_TEST_RTS
- TP_ENDED

This allows an application to use an asynchronous **MC_RECEIVE_AND_POST** to receive data. While the **MC_RECEIVE_AND_POST** is outstanding, it can still use **MC_SEND_ERROR** and **REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support. For information on how a TP receives data and how to use this verb, see Remarks in this topic.

The following structure describes the verb control block used by the **MC_RECEIVE_AND_POST** verb.

```
struct mc_receive_and_post {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       reserv4;
    unsigned char       rts_rcvd;
    unsigned char       reserv5;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char FAR * sema;
    unsigned char       reserv6;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_AND_POST.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the

invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Indicates whether data or conversation status was received.

- AP_CONFIRM_DEALLOCATE indicates that the partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by MC_ALLOCATE, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues MC_CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP issued MC_PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**, and begins to send data.
- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP issued MC_CONFIRM. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**.
- AP_DATA_COMPLETE indicates, for **MC_RECEIVE_AND_POST**, that the local TP has received a complete data record or the last part of a data record. Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_POST** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data. Otherwise, the local TP examines status information.

  If **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED, see the description of the value (in this section) for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to the MC_DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates, for **MC_RECEIVE_AND_POST**, that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record). Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_POST** (or issues another receive verb) to receive the next part of the record.
- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses MC_SEND_DATA to begin sending data.

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The data is the last data record before the status indicator.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND.

- AP_YES indicates that the partner TP issued **MC_REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

max_len

Supplied parameter. Specifies the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

The value must not exceed the length of the buffer to contain the received data. The offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

dlen

Returned parameter. Specifies the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Provides the address of the buffer to contain the data received by the local LU.

For the Windows NT, Windows 95, and Windows 98 operating systems, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the **DosAllocSeg** function with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

sema
Supplied parameter. Provides the address of the semaphore that APPC is to clear when the asynchronous receiving operation is finished. On OS/2, the **sema** parameter is either a RAM or system semaphore. On Windows NT, Windows 95, and Windows 98 the **sema** parameter is an event handle obtained by calling either the **CreateEvent** or **OpenEvent** Win32® function.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DEALLOC_NORMAL
Primary return code; the partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_FLUSH or AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE.

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the address of the RAM semaphore or system semaphore handle was invalid.

> APPC cannot trap all invalid semaphore handles. If the TP passes a bad RAM semaphore handle, a protection violation results.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_POST_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_RCV_AND_POST_NOT_LL_BDY

Secondary return code; the conversation was in SEND state; the TP began but did not finish sending a logical record.

AP_CANCELED

Primary return code; the local TP issued one of the following verbs, which canceled **MC_RECEIVE_AND_POST**:

MC_DEALLOCATE with **dealloc_type** set to AP_ABEND

MC_SEND_ERROR

TP_ENDED

Issuing one of these verbs causes the semaphore to be cleared.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC
Primary return code; the partner TP issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received is one data record.

The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it. The receive verbs are **MC_RECEIVE_AND_POST** (Windows NT, Windows 95, Windows 98, , and OS/2), MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE.

1. The local TP issues the receive verb again. This has one of the following effects:

    - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
    - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The following procedure shows tasks performed by the local TP in using **MC_RECEIVE_AND_POST**.

To use MC_RECEIVE_AND_POST

1. For the Windows NT, Windows 95, and Windows 98 operating systems, the TP retrieves the WinAsyncAPPC message number by calling the **RegisterWindowMessage** API or allocating a semaphore. The **sema** field should be set to NULL if the application expects to be notified through the Windows message mechanism.

APPC sends the Windows message or clears the semaphore when the local TP finishes receiving data.

For the OS/2 operating system, the TP uses the **DosSemSet** function to set the semaphore pointed to by **sema**.

The semaphore will remain set while the local TP receives data asynchronously. APPC will clear the semaphore when the local TP finishes receiving data.

1. The TP issues MC_RECEIVE_AND_POST.
2. The TP checks the value of **primary_rc**.

If **primary_rc** is AP_OK, the receive buffer (pointed to by **dptr**) is asynchronously receiving data from the partner TP. While receiving data asynchronously, the local TP can:

- Perform tasks not related to this conversation.
- Issue MC_REQUEST_TO_SEND.
- Gather information about this conversation by issuing GET_TYPE, MC_GET_ATTRIBUTES, or MC_TEST_RTS.
- Prematurely cancel **MC_RECEIVE_AND_POST** by issuing MC_DEALLOCATE with **dealloc_type** set to AP_ABEND; MC_SEND_ERROR; or TP_ENDED.

If, however, **primary_rc** is not AP_OK, **MC_RECEIVE_AND_POST** has failed. In this case, the local TP does not perform the next two tasks.

1. For the Windows NT, Windows 95, and Windows 98 operating systems, when the TP finishes receiving data asynchronously, APPC issues the WinAsyncAPPC Windows message or clears the semaphore.

For the OS/2 operating system, the TP uses the **DosSemWait** function to wait for APPC to clear the semaphore pointed to by **sema**. When the TP finishes receiving data asynchronously, APPC clears the semaphore. To prevent the local TP from waiting, have it test the semaphore (invoking **DosSemWait** with **Timeout** set to zero) until APPC clears the semaphore.

1. The TP checks the new value of **primary_rc**.

If **primary_rc** is AP_OK, the local TP can examine the other returned parameters and manipulate the asynchronously received data.

If **primary_rc** is not AP_OK, only **secondary_rc** and **rts_rcvd** (request-to-send received) are meaningful.

Conversation State Effects

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing **MC_RECEIVE_AND_POST** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to PENDING_POST state; the local TP is ready to receive information from the partner TP asynchronously.

The conversation changes states twice:

- Upon initial return of the verb, if **primary_rc** contains AP_OK, the conversation changes to PENDING_POST state.
- After completion of the verb, the state changes depending on the value of the following:

The **primary_rc** parameter

The **what_rcvd** parameter if **primary_rc** is AP_OK

The following table shows the new state associated with each value of **what_rcvd** when **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	SEND

AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table shows the new state associated with each value of **primary_rc** other than AP_OK.

primary_rc	**New state**
AP_CANCELED	No change
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE
AP_PROG_ERROR_TRUNC	RECEIVE
AP_SVC_ERROR_TRUNC	RECEIVE

MC_RECEIVE_AND_WAIT

The **MC_RECEIVE_AND_WAIT** verb receives any data that is currently available from the partner TP. If no data is currently available, the local TP waits for data to arrive.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call. To allow full use to be made of the asynchronous support, asynchronously issued **MC_RECEIVE_AND_WAIT** verbs have been altered to act like MC_RECEIVE_AND_POST verbs. Specifically, while an asynchronous **MC_RECEIVE_AND_WAIT** is outstanding, the following verbs can be issued on the same conversation:

- GET_TYPE
- MC_GET_ATTRIBUTES
- MC_REQUEST_TO_SEND
- MC_SEND_ERROR
- MC_TEST_RTS
- TP_ENDED

This allows an application, and in particular, a 5250 emulator, to use an asynchronous **MC_RECEIVE_AND_WAIT** to receive data. While the **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **MC_SEND_ERROR** and **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support.

The following structure describes the verb control block used by the **MC_RECEIVE_AND_WAIT** verb.

```
struct mc_receive_and_wait {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       reserv4;
    unsigned char       rts_rcvd;
    unsigned char       reserv5;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv6[5];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_AND_WAIT.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Specifies the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd
Returned parameter. Indicates whether data or conversation status was received.

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued MC_DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues MC_CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP has issued MC_PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **MC_CONFIRMED** and begins to send data.
- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued MC_CONFIRM. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**.
- AP_DATA_COMPLETE indicates, for **MC_RECEIVE_AND_WAIT**, that the local TP has received a complete data record or the last part of a data record. Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_WAIT** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information, if **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED.

  See Return Codes in this topic for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to MC_DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record). Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_WAIT** (or issues another receive verb) to receive the next part of the record.
- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses MC_SEND_DATA to begin sending data.

rtn_status
Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The data is the last data record before the status indicator.

rts_rcvd
Returned parameter. Contains the request-to-send indicator.

- AP_YES indicates that the partner TP has issued MC_REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

max_len
Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Windows NT, Windows 95, and Windows 98 operating systems and the Windows graphical environment, this value must not exceed the length of the buffer to contain the received data.

For the OS/2 operating system, the offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

By issuing **MC_RECEIVE_AND_WAIT** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen
Returned parameter. Indicates the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Provides the address of the buffer to contain the data received by the local TP.

For the Windows NT, Windows 95, and Windows 98 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the **DosAllocSeg** function with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

For the Windows environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_CONFIRM_SYNC_LEVEL
- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_WAIT_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single

conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC
Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received is one data record.

The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

The receive verbs are MC_RECEIVE_AND_POST (Windows NT, Windows 95, Windows 98, , and OS/2 operating systems), **MC_RECEIVE_AND_WAIT**, and MC_RECEIVE_IMMEDIATE.

1. The local TP issues the receive verb again. This has one of the following effects:

    - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
    - If the partner TP has finished sending data or is waiting for confirmation, status information (available through the **what_rcvd** parameter) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing the Verb in SEND State

Issuing **MC_RECEIVE_AND_WAIT** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to RECEIVE state; the local TP waits for the partner TP to send data.

State Change

The new conversation state is determined by the following factors:

- The state the conversation is in when the TP issues the verb.
- The **primary_rc** parameter.
- The **what_rcvd** parameter if **primary_rc** contains AP_OK.

Verb Issued in SEND State

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is AP_OK.

what_rcvd	New state
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	No change
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is not AP_OK.

primary_rc	New state
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE

Verb Issued in RECEIVE State

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is AP_OK.

what_rcvd	New state
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is not AP_OK.

primary_rc	New state

AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	No change
AP_PROG_ERROR_NO_TRUNC	No change
AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change

MC_RECEIVE_IMMEDIATE

The **MC_RECEIVE_IMMEDIATE** verb receives any data currently available from the partner TP. If no data is available, the local TP does not wait. To avoid blocking the conversation, the Microsoft® Windows NT®, Microsoft® Windows® 95, and Windows version 3.*x* systems can issue MC_RECEIVE_AND_WAIT in conjunction with WinAsyncAPPC. For OS/2 systems, use MC_RECEIVE_AND_POST.

The following structure describes the verb control block used by the **MC_RECEIVE_IMMEDIATE** verb.

```
struct mc_receive_immediate {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       reserv4;
    unsigned char       rts_rcvd;
    unsigned char       reserv5;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv6[5];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_IMMEDIATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd
Returned parameter. Contains information received with the incoming data:

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued MC_DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues MC_CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP has issued MC_PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**, and begins to send data.
- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued MC_CONFIRM. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**.
- AP_DATA_COMPLETE indicates, for **MC_RECEIVE_IMMEDIATE** in mapped conversations, that the local TP has received a complete data record or the last part of a data record. Upon receiving this value, the local TP normally reissues

MC_RECEIVE_IMMEDIATE or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

Otherwise, the local TP examines status information if **primary_rc** contains AP_OK and **what_rcvd** contains any of these values:

AP_SEND

AP_CONFIRM_SEND

AP_CONFIRM_DEALLOCATE

AP_CONFIRM_WHAT_RECEIVED

See the description of the value in Return Codes in this topic for the next action the local TP normally takes.

If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to MC_DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates for **MC_RECEIVE_IMMEDIATE** in mapped conversations that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record). Upon receiving this value, the local TP normally reissues **MC_RECEIVE_IMMEDIATE** (or issues another receive verb) to receive the next part of the record.
- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses MC_SEND_DATA to begin sending data.

rtn_status
Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The data is the last data record before the status indicator.

rts_rcvd
Returned parameter. Contains the request-to-send indicator. Possible values are:

- AP_YES indicates that the partner TP has issued MC_REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

max_len
Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Windows NT, Windows 95, and Windows 98 operating systems and the Windows graphical environment, this value must not exceed the length of the buffer to contain the received data.

For the OS/2 operating system, the offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

By issuing **MC_RECEIVE_IMMEDIATE** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen
Returned parameter. Provides the number of bytes of data received. Data is stored in a buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr
Supplied parameter. Address of the buffer to contain the data received by the local TP.

For the Windows NT, Windows 95, and Windows 98 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_UNSUCCESSFUL
Primary return code; no data is immediately available from the partner TP.

AP_DEALLOC_NORMAL
Primary return code; the partner TP has deallocated the conversation without requesting confirmation. The partner TP issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_IMMD_BAD_STATE

Secondary return code; the conversation was not in RECEIVE state.

AP_ALLOCATION_ERROR

Secondary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, Windows 98, , and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received is one data record.

The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

The receive verbs are MC_RECEIVE_AND_POST (Windows NT, Windows 95, Windows 98, , and OS/2 operating systems), MC_RECEIVE_AND_WAIT, and **MC_RECEIVE_IMMEDIATE**.

1. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE state when the TP issues this verb.

The new state is determined by **primary_rc**. If **primary_rc** is AP_OK, the new state is determined by **what_rcvd**.

The following table details the state changes when the **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when the **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET

AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	No change
AP_PROG_ERROR_NO_TRUNC	No change
AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change
AP_UNSUCCESSFUL	No change

MC_RECEIVE_LOG_DATA

The **MC_RECEIVE_LOG_DATA** verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another buffer (that is, until the TP issues another **MC_RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all). This verb is only supported on Microsoft® Windows NT® and Microsoft® Windows® 95 by Microsoft® SNA Server version 3.0 with Service Pack 1 or later and by SNA Server version 4.0.

Note that the TP itself is responsible for allocating and freeing the buffer. After the buffer has been passed to APPC, the TP should either issue another **MC_RECEIVE_LOG_DATA** specifying a new buffer or a zero-length buffer, or wait until the conversation has finished before freeing the original buffer.

When an FMH7 is received, APPC copies any associated error log general data stream (GDS) into the buffer. If there is no associated error log variable, the buffer is zeroed out. It is up to the TP to check the buffer whenever a return code from a receive verb indicates that an error has been received.

The following structure describes the verb control block used by the **MC_RECEIVE_LOG_DATA** verb.

```
struct mc_receive_log_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv1;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      log_dlen;
    unsigned char FAR * log_dptr;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_LOG_DATA.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

‹reserv1
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

log_dlen
Supplied parameter. Specifies the maximum length of log data that APPC can place in the buffer (that is, the buffer size). The range is from 0 through 65535. Note that a length of zero here indicates that any previous **MC_RECEIVE_LOG_DATA** verb should be cancelled.

log_dptr
Supplied parameter. Specifies the address of the buffer that APPC will use to store the log data.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

MC_REQUEST_TO_SEND

The **MC_REQUEST_TO_SEND** verb notifies the partner TP that the local TP wants to send data.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_REQUEST_TO_SEND** verb.

```
struct mc_request_to_send {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_REQUEST_TO_SEND.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_R_T_S_BAD_STATE

Secondary return code; the conversation is not in an allowed state when the TP issued this verb.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any of the following states when the TP issues this verb:

CONFIRM

PENDING_POST (OS/2)

RECEIVE

There is no state change.

The request-to-send notification is received by the partner program through the **rts_rcvd** parameter of the following verbs:

- MC_CONFIRM
- MC_RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2 operating systems)
- MC_RECEIVE_AND_WAIT
- MC_RECEIVE_IMMEDIATE
- MC_SEND_DATA

- MC_SEND_ERROR

It is also indicated by a **primary_rc** of AP_OK on MC_TEST_RTS.

Request-to-send notification is sent to the partner TP immediately; APPC does not wait until the send buffer fills up or is flushed. Consequently, the request-to-send notification may arrive out of sequence. For example, if the local TP is in SEND state and issues MC_PREPARE_TO_RECEIVE followed by **MC_REQUEST_TO_SEND**, the partner TP, in RECEIVE state, may receive the request-to-send notification before it receives the send notification. For this reason, request-to-send can be reported to a TP through a receive verb.

In response to this request, the partner TP can change the conversation to:

- RECEIVE state by issuing **MC_PREPARE_TO_RECEIVE** or MC_RECEIVE_AND_WAIT.
- PENDING_POST state by issuing MC_RECEIVE_AND_POST.

The partner TP can also ignore the request-to-send.

The conversation state changes to SEND for the local TP when the local TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_CONFIRM_SEND and replies with MC_CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **MC_CONFIRMED**
- AP_SEND

The receive verbs are MC_RECEIVE_AND_POST (Microsoft® Windows NT®, Windows 95, and OS/2 operating systems), MC_RECEIVE_IMMEDIATE, and MC_RECEIVE_AND_WAIT.

MC_SEND_CONVERSATION

The **MC_SEND_CONVERSATION** verb allocates a session between the local LU and partner LU, sends data on the session, and then deallocates the session.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_SEND_CONVERSATION** verb.

```
struct mc_send_conversation {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3[8];
    unsigned char       rtn_ctl;
    unsigned char       reserv4;
    unsigned long       conv_group_id;
    unsigned long       sense_data;
    unsigned char       plu_alias[8];
    unsigned char       mode_name[8];
    unsigned char       tp_name[64];
    unsigned char       security;
    unsigned char       reserv6[11];
    unsigned char       pwd[10];
    unsigned char       user_id[10];
    unsigned short      pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char       reserv6;
    unsigned char       fqplu_name[17];
    unsigned char       reserv7[8];
    unsigned short      dlen;
    unsigned char FAR * dptr;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_SEND_CONVERSATION.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id
Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

rtn_ctl
Supplied parameter. Specifies how APPC should select a session to allocate for the conversation and when the local LU should return control to the local TP. The allowed values are:

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns

control to the TP.

- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs (as described in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOC specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOC specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id** or encounters one of the errors described in Return Codes in this topic. If the session is not available, the TP waits for it to become free.

conv_group_id

Supplied/returned parameter. Used as a supplied parameter when **rtn_ctl** is WHEN_CONV_GROUP_ALLOC to specify the identity of the conversation group from which the session should be allocated. When **rtn_ctl** specifies a different value, and the **primary_rc** is AP_OK, this is a returned value. The purpose of this parameter is to provide a TP with the assurance that the same session will be reallocated and therefore the conversations conducted over the session will occur in the same sequence that they were initiated.

sense_data

Returned parameter. If the primary and secondary return codes indicate an allocation error (retry or no-retry), an SNA-defined sense code is returned.

plu_alias

Supplied parameter. Specifies the alias by which the partner LU is known to the local TP. This parameter must match the name of a partner LU established during configuration. The parameter is an 8-byte, type G ASCII character set that includes:

- Uppercase letters
- Numerals 0 to 9
- Spaces
- Special characters $, #, %, and @

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration. This parameter must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set, including all EBCDIC spaces. These characters are:

- Uppercase letters
- Numerals 0 to 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or special character.

In a mapped conversation, the name cannot be SNASVCMG (a reserved mode name used internally by APPC).

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by MC_ALLOCATE in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte, case-sensitive, EBCDIC character string. This parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the TP name is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the EBCDIC AE character set.

security
Supplied parameter. Specifies the information the partner LU requires in order to validate access to the invoked TP.

- AP_NONE specifies that the invoked TP uses no conversation security.
- AP_PGM specifies that the invoked TP uses conversation security and requires a user identifier and password. Use **user_id** and **pwd** to supply this information.
- AP_SAME specifies that the invoked TP, invoked with a valid user identifier and password, in turn invokes another TP.

For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator indicates to TP C not to require the password (if TP C is configured to accept an already-verified indicator).

pwd
Supplied parameter. Specifies the password associated with **user_id**. This parameter is required only if the security parameter is set to AP_PGM and must match the password for **user_id** that was established during configuration.

This parameter is a 10-byte, case-sensitive, EBCDIC character string. It can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

user_id
Supplied parameter. Specifies the user identifier required to access the partner TP. This parameter is required only if the security parameter is set to AP_PGM and must match one of the user identifiers configured for the partner TP.

The parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the user identifier is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

pip_dlen
Supplied parameter. Specifies the length of the PIP to be passed to the partner TP. The range for this parameter is from 0 through 32767.

pip_dptr
Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the GDS format. For more information, see your IBM SNA manual(s).

For the Microsoft® Windows NT® and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area.

For the OS/2 operating system, use a shared, unnamed segment for the data buffer. To allocate the segment, issue the function call **DosAllocSeg** with the shared indicator equal to 1. The data buffer must be entirely within the data segment.

fqplu_name
Supplied parameter. Specifies the fully qualified name of the local LU. This parameter must match the fully qualified name of the local LU defined in the remote node. The parameter is made up of two type A EBCDIC character strings (each of up to eight characters), which are the network name (NETID) and the LU name of the partner LU. The names are separated by an EBCDIC period (.). The NETID can be omitted, and if this is the case, the period should also be omitted.

This name must be provided if no **plu_alias** is provided.

Type A EBCDIC characters contain:

- Uppercase letters
- Numerals 0 to 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

dlen

Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range for this parameter is from 0 through 65535.

dptr

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Windows NT and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, use a shared, unnamed segment for the data buffer. To allocate the segment, issue the function call **DosAllocSeg** with the shared indicator equal to 1. The data buffer must be entirely within the data segment.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate return of the control to the TP (AP_IMMEDIATE), and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code, APPC did not recognize the supplied **partner_lu_alias**.

AP_NO_USE_OF_SNASVCMG

Secondary return code; SNASVCMG is not a valid value for **mode_name**.

AP_INVALID_DATA_SEGMENT

Secondary return code; the PIP data or application data was longer than the allocated data segment, or the address of a data buffer was wrong.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb is issued by the invoking TP to conduct an entire conversation with the remote TP. If the remote TP rejects either the conversation initiation or the data, the invoking TP will not receive notification of the rejection.

The conversation state is RESET when the TP issues this verb. There is no state change.

Several parameters of **MC_SEND_CONVERSATION** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

Normally, the value of **mode_name** must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU. If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

MC_SEND_DATA

The **MC_SEND_DATA** verb places data in the local LU's send buffer for transmission to the partner TP.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_SEND_DATA** verb.

```
struct mc_send_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
    unsigned char       data_type;
    unsigned short int  dlen;
    unsigned char FAR * dptr ;
    unsigned char       type;
    unsigned char       reserv4;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_SEND_DATA.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd
Returned parameter. Provides the request-to-send-received indicator.

- AP_YES indicates that the partner TP has issued MC_REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST (Microsoft® Windows NT®, Windows 95, and OS/2 operating systems).
- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

data_type
Supplied parameter. Specifies the type of data to be sent if Sync Point is supported. Valid parameters are:

AP_APPLICATION

AP_USER_CONTROL_DATA

AP_PS_HEADER

dlen
Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range is from 0 through 65535.

dptr
Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Windows NT and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For OS/2, the data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

type
Supplied parameter. Allows a TP to send data and perform other functions within one API call. For example, you can combine **MC_SEND_DATA** with **type** set to CONFIRM to accomplish the same objective as issuing **MC_SEND_DATA** followed by MC_CONFIRM.

- AP_SEND_DATA_CONFIRM corresponds to **MC_SEND_DATA** followed by **MC_CONFIRM**.
- AP_SEND_DATA_FLUSH corresponds to **MC_SEND_DATA** followed by MC_FLUSH.
- AP_SEND_DATA_DEALLOC_ABEND corresponds to **MC_SEND_DATA** followed by MC_DEALLOCATE with a **dealloc_type** of AP_ABEND.
- AP_SEND_DATA_DEALLOC_FLUSH corresponds to **MC_SEND_DATA** followed by **MC_DEALLOCATE** with a **dealloc_type** of AP_FLUSH.
- AP_SEND_DATA_DEALLOC_SYNC_LEVEL corresponds to **MC_SEND_DATA** followed by **MC_DEALLOCATE** with a **dealloc_type** of AP_SYNC_LEVEL.
- AP_SEND_DATA_P_TO_R_FLUSH corresponds to **MC_SEND_DATA** followed by MC_PREPARE_TO_RECEIVE with a **ptr_type** of AP_FLUSH.
- AP_SEND_DATA_P_TO_R_SYNC_LEVEL corresponds to **MC_SEND_DATA** followed by **MC_PREPARE_TO_RECEIVE** with a **ptr_type** of AP_SYNC_LEVEL and **locks** set to AP_SHORT.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_SEND_DATA_INVALID_TYPE

Secondary return code; the specified type was not recognized by APPC.

AP_SEND_DATA_CONFIRM_SYNC_NONE

Secondary return code; the **type** CONFIRM is not permitted for a conversation that was allocated with a **sync_level** of NONE.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_SEND_DATA_NOT_SEND_STATE

Secondary return code; the local TP issued **MC_SEND_DATA**, but the conversation was not in SEND state.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The conversation must be in SEND state when the TP issues this verb. State changes, based on **primary_rc**, are summarized in the following table.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

MC_SEND_DATA may wait indefinitely because the partner TP has not issued a receive verb. If this occurs, the send buffer may

fill up.

The data collected in the local LU's send buffer is transmitted to the partner LU (and partner TP) when one of the following occurs:

- The send buffer fills up.
- The local TP issues MC_FLUSH, MC_CONFIRM, or MC_DEALLOCATE (or other verb that flushes the LU's send buffer).

MC_SEND_ERROR

The **MC_SEND_ERROR** verb notifies the partner TP that the local TP has encountered an application-level error.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **MC_SEND_ERROR** verb.

```
struct mc_send_error {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
    unsigned char       err_type;
    unsigned char       err_dir;
    unsigned char       reserv4;
    unsigned char       reserv5[2];
    unsigned char       reserv6[4];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_SEND_ERROR.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd
Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND. Possible values include:

- AP_YES indicates that the partner TP has issued **MC_REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.
- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

err_type
For a mapped conversation, this parameter is supplied if Sync Point is supported. Valid values are:

AP_PROG

AP_BACKOUT_NO_RESYNC

AP_BACKOUT_RESYNC

err_dir

Supplied parameter. Indicates whether the error is with data just received or with data that is about to be sent. Use this parameter only when the conversation is in SEND_PENDING state. The parameter is ignored otherwise. The following are allowed values:

- AP_RCV_DIR_ERROR indicates that the TP issued **MC_SEND_ERROR** after detecting an error associated with the data just received.
- AP_SEND_DIR_ERROR indicates that the TP issued **MC_SEND_ERROR** after detecting an error associated with data it was going to send. For example, the TP encountered an error while reading data from the disk drive.

reserv3
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_ERROR_DIRECTION

Secondary return code; the specified **err_dir** was not recognized by APPC.

AP_SEND_ERROR_BAD_TYPE

Secondary return code; the value of **err_type** was invalid.

AP_SEND_ERROR_LOG_LL_WRONG

Secondary return code; the LL field of the error log GDS variable did not match the actual length of the data.

The following return codes can be generated when **MC_SEND_ERROR** is issued in any allowed state:

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This may occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

The following return codes can be generated only if **MC_SEND_ERROR** is issued in SEND state:

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_DEALLOC_ABEND
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

The following return code can be generated only if **MC_SEND_ERROR** is issued in RECEIVE state:

AP_DEALLOC_NORMAL
Primary return code; this return code does not indicate an error.

The partner TP issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

Remarks

The conversation can be in any state except RESET when the TP issues this verb. The conversation state must be SEND_PENDING if **err_dir** is used.

The local TP sends the error notification immediately to the partner TP; it does not hold the information in the local LU's send buffer.

Upon successful execution of this verb, the conversation is in SEND state for the local TP and in RECEIVE state for the partner TP.

The new state is determined by **primary_rc**. Possible state changes are summarized in the following table.

primary_rc	New state
AP_OK	SEND
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

If the conversation is in RECEIVE state when the TP issues **MC_SEND_ERROR**, incoming data is purged by APPC. This data includes:

- Data sent by MC_SEND_DATA.
- Return code indicators.
- Confirmation requests.
- Deallocation requests.

APPC does not purge an incoming request-to-send indicator. APPC replaces purged incoming return code indicators with other return codes. The primary return code AP_OK replaces the following purged return code indicators:

AP_PROG_ERROR_NO_TRUNC

AP_PROG_ERROR_PURGING

AP_PROG_ERROR_TRUNC

AP_SVC_ERROR_NO_TRUNC

AP_SVC_ERROR_PURGING

AP_SVC_ERROR_TRUNC

The primary return code AP_DEALLOC_NORMAL replaces the following purged return code indicators:

AP_ALLOCATION_ERROR

AP_ALLOCATION_FAILURE_NO_RETRY

AP_ALLOCATION_FAILURE_RETRY

AP_CONVERSATION_TYPE_MISMATCH

AP_DEALLOC_ABEND

AP_DEALLOC_ABEND_PROG

AP_DEALLOC_ABEND_SVC

AP_DEALLOC_ABEND_TIMER

AP_PIP_NOT_ALLOWED

AP_PIP_NOT_SPECIFIED_CORRECTLY

AP_SECURITY_NOT_VALID

AP_SYNC_LEVEL_NOT_SUPPORTED

AP_TP_NAME_NOT_RECOGNIZED

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

AP_TRANS_PGM_NOT_AVAIL_RETRY

When the conversation is in SEND_PENDING state, APPC reports the following return codes to the partner TP based on the value in **err_dir**:

AP_PROG_ERROR_PURGING
  The local TP issued **MC_SEND_ERROR** with RECEIVE as the **err_dir**.
AP_PROG_ERROR_NO_TRUNC
  The local TP issued **MC_SEND_ERROR** with SEND as the **err_dir**.

MC_TEST_RTS

The **MC_TEST_RTS** verb determines whether a request-to-send notification has been received from the partner TP.

The following structure describes the verb control block used by the **MC_TEST_RTS** verb.

```
struct mc_test_rts {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_TEST_RTS.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL
Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID
Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

MC_TEST_RTS_AND_POST

The **MC_TEST_RTS_AND_POST** verb allows an application, typically a 5250 emulator, to request asynchronous notification when a partner TP requests send direction. It is not supported on Microsoft® MS-DOS® platforms.

The following structure describes the verb control block used by the **MC_TEST_RTS_AND_POST** verb.

```
struct mc_test_rts_and_post {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
    unsigned long       handle;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_M_TEST_RTS_AND_POST.

opext
Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3
A reserved field.

handle
Supplied parameter. On Microsoft® Windows NT® and Microsoft® Windows® 95 this field provides the event handle to set. On Windows 3.x, this field provides the Windows handle to receive the completion message. On OS/2, this field provides the address of the semaphore APPC is to clear when the asynchronous operation is finished.

Return Codes from Initial Verb

AP_OK
Primary return code; the verb executed successfully. Note particularly that a return code of AP_OK from the initial verb does not indicate that **MC_REQUEST_TO_SEND** verb received from the partner TP. It simply indicates that the facility to receive asynchronous notification has been registered.

AP_UNSUCCESSFUL
Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Return Codes from Asynchronous Completion

AP_OK
Primary return code; the request-to-send notification has been received from the partner TP.
AP_CANCELLED
The outstanding **TEST_RTS_AND_POST** verb has been terminated. This will occur if the underlying conversation has been deallocated or an AP_TP_ENDED has been issued.
Note that as with **RECEIVE_AND_POST**, the TP is still responsible for correctly terminating the conversation and possibly terminating the TP. Issuing another verb, such as **RECEIVE_IMMEDIATE,** at this point will indicate the reason for the conversation failure.

Remarks

The conversation can be in any state except RESET when the TP issues this verb. There is no state change.

A common feature of many APPC applications, such as 5250 emulators, is a requirement to detect a partner's request to send.

Currently, this can be done by polling the APPC interface to detect the partner's request. For example, an application can occasionally issue one of the following verbs:

- **MC_TEST_RTS**
- **MC_RECEIVE_IMMEDIATE** and check the **rts_rcvd** field
- **MC_SEND_DATA** of zero bytes, again checking the **rts_rcvd** field.

Some of the problems associated with this polling approach are:

- The application must continually interrupt its main work to poll APPC.
- The partner's request is not detected as soon as it becomes available.
- These approaches are processor-intensive.

The **MC_TEST_RTS_AND_POST** verb allows an application running on Windows NT, Windows 95, Windows 3.*x*, or OS/2, typically a 5250 emulator, to request asynchronous notification when the partner TP requests send direction.

An APPC application typically issues the **MC_TEST_RTS_AND_POST** verb while in SEND state and then continues with its main processing. A request for send direction from the partner TP is indicated asynchronously to the application. After dealing with the partner's request, the application typically returns to SEND state, reissues **MC_TEST_RTS_AND_POST**, and continues.

The **MC_TEST_RTS_AND_POST** verb completes synchronously and the return code AP_OK indicates that a request for asynchronous notification has been registered. It is important to emphasize that this does not indicate that request-to-send was received from the partner TP.

When the partner's request to send is received, the asynchronous event completion occurs. It is important to note that this may be before the completion of the local TP's original **MC_TEST_RTS_AND_POST** verb. This will be the case if the partner's request to send was received before the local TP's **MC_TEST_RTS_AND_POST** verb was issued, or while the local TP's **MC_TEST_RTS_AND_POST** verb was being processed.

POST_ON_RECEIPT

The **POST_ON_RECEIPT** verb allows the application to register to receive a notification when data or status arrives at the local LU without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state. This verb is only supported on Microsoft® Windows NT® and Microsoft® Windows® 95 by Microsoft® SNA Server version 3.0 with Service Pack 1 or later and by SNA Server version 4.0.

When the TP issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied the Win32® event specified by the **sema** parameter is signalled and the verb completes. Then the TP looks at the return code in the verb control block to determine whether or not any data or status notification has arrived at the local LU and issues a RECEIVE_IMMEDIATE or RECEIVE_AND_WAIT verb to actually receive the data or status notification.

The **POST_ON_RECEIPT** verb implements both the **POST_ON_RECEIPT** and **TEST** verbs as described in the IBM Transaction Programmer's manual for LU Type 6.2.

The following structure describes the verb control block used by the **POST_ON_RECEIPT** verb.

```
struct post_on_receipt {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv1;
    unsigned char    primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned short   reserv2;
    unsigned char    fill;
    unsigned char    reserv4;
    unsigned short   max_len;
    unsigned short   reserv5;
    unsigned char *  reserv6;
    unsigned char    reserv7[5];
    unsigned long    sema;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_POST_ON_RECEIPT.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv1
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv2
A reserved field.

fill
Supplied parameter. Specifies how the local TP receives data. The following values are allowed:

AP_BUFFER

Specifies that APPC should post a notification when the number of data bytes specified by **max_len** have arrived at the local LU, the end of the data has been reached, or information other than data is received.(such as a conversation status, a confirmation,

or a syncpoint request).

AP_LL

Specifies that APPC should post a notification when a complete or truncated logical record is received, when a portion of a logical record is received which is at least equal in length to the length specified by **max_len**, or when information other than data is received.

reserv4
A reserved field.
max_len
Supplied parameter. Specifies the length of data that triggers APPC to post a notification to the TP.
reserv5
A reserved field.
reserv6
A reserved field.
reserv7
A reserved field.
sema
Supplied parameter. Specifies the handle of a Win32 event. The event should have been created by the TP and the TP is responsible for ensuring that it is reset before a call is made and after the verb completes.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_DATA

Secondary return code; data is available for the program to receive.

AP_NOT_DATA

Secondary return code; information other than data is available for the program to receive.

AP_CANCELLED
Primary return code; the verb was canceled.
AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the **sema** parameter was not set to a valid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.
AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_DEALLOC_NORMAL
Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued DEALLOCATE with **dealloc_type** set to one of the following:

- AP_CONFIRM_SYNC_LEVEL
- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

AP_PROG_ERROR_NO_TRUNC
Primary return code; the partner TP has issued SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC
Primary return code; the partner TP has issued SEND_ERROR while the conversation was in SEND state. Data was truncated.

AP_SVC_ERROR_NO_TRUNC
Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP was not truncated.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC
Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been truncated.

Remarks

While a **POST_ON_RECEIPT** verb is outstanding, the following verbs can be issued on the same conversation:

GET_ATTRIBUTES

GET_TYPE

DEALLOCATE

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

REQUEST_TO_SEND

SEND_ERROR

TEST_RTS

TP_ENDED

Issuing any of the following verbs prior to completion of the asynchronous **POST_ON_RECEIPT** verb causes the **POST_ON_RECEIPT** verb to be canceled (the Win32 event is signaled and the primary return code in the verb control block is set to AP_CANCELLED).

DEALLOCATE

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

SEND_ERROR

TP_ENDED

PREPARE_TO_RECEIVE

The **PREPARE_TO_RECEIVE** verb changes the state of the conversation for the local TP from SEND to RECEIVE.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **PREPARE_TO_RECEIVE** verb.

```
struct prepare_to_receive {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    primary_rc;
    unsigned short   reserv2;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    ptr_type;
    unsigned char    locks;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_PREPARE_TO_RECEIVE.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

ptr_type
Supplied parameter. Specifies how to perform the state change.

Use AP_FLUSH to send the contents of the local LU's send buffer to the partner LU (and TP) before changing the conversation's state to RECEIVE.

The AP_SYNC_LEVEL value uses the conversation's synchronization level (established by **ALLOCATE**) to determine how to perform the state change.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before changing the conversation's state to RECEIVE. If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC changes the conversation's state to RECEIVE. If, however, the partner TP reports an error, the state changes to RECEIVE or RESET. See the Remarks in this topic.

locks
Supplied parameter. Specifies when APPC should return control to the local TP.

Use this parameter only if **ptr_type** is set to AP_SYNC_LEVEL and the synchronization level of the conversation, established by ALLOCATE, is AP_CONFIRM_SYNC_LEVEL. (Otherwise, the parameter is ignored.)

Use AP_LONG to indicate that APPC returns control to the local TP when the confirmation and subsequent data from the partner TP arrive at the local LU. (This method results in more efficient use of the network but requires a longer time to return control to the local TP.)

Use AP_SHORT to indicate that APPC returns control to the local TP when the confirmation from the partner TP arrives at the local LU.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_P_TO_R_INVALID_TYPE

Secondary return code; the **ptr_type** parameter was not set to a valid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_P_TO_R_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_P_TO_R_NOT_LL_BDY

Secondary return code; the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued a SEND_ERROR verb with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

Before changing the conversation state, this verb performs the equivalent of one of the following:

- FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the local TP can receive data.

The conversation must be in SEND state when the TP issues this verb.

State changes, summarized in the following table, are based on the value of **primary_rc**.

primary_rc	**New state**
AP_OK	RECEIVE
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

The conversation does not change to SEND state for the partner TP until the partner TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_SEND
- AP_CONFIRM_SEND and replies with CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **CONFIRMED**
- AP_DATA_CONFIRM_SEND and replies with **CONFIRMED**

The receive verbs are RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2), RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT.

RECEIVE_ALLOCATE

The **RECEIVE_ALLOCATE** verb is issued by the invoked TP to confirm that the invoked TP is ready to begin a conversation with the invoking TP that issued ALLOCATE or MC_ALLOCATE.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **RECEIVE_ALLOCATE** verb.

```
struct receive_allocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_name[64];
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    sync_level;
    unsigned char    conv_type;
    unsigned char    user_id[10];
    unsigned char    lu_alias[8];
    unsigned char    plu_alias[8];
    unsigned char    mode_name[8];
    unsigned char    reserv3[2];
    unsigned long    conv_group_id;
    unsigned char    fqplu_name[17];
    unsigned char    pip_incoming;
    unsigned char    syncpoint_rqd;
    unsigned char    reserv4[3];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_RECEIVE_ALLOCATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_name
Supplied parameter. Provides the name of the local TP. The value of **tp_name** must match the TP name configured through registry or environment variables. APPC matches the **RECEIVE_ALLOCATE** verb's **tp_name** parameter with the TP name specified by the incoming allocate, which is generated by MC_ALLOCATE or ALLOCATE in the invoking TP.

This parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of characters from the type AE EBCDIC character set:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, and period (.)

If **tp_name** is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the type AE EBCDIC character set.

tp_id

Returned parameter. Identifies the local TP.

conv_id

Returned parameter. Provides the conversation identifier. It identifies the conversation APPC has established between the two partner TPs.

sync_level

Returned parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE specifies that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL specifies that the TPs can use confirmation processing in this conversation.
- AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

conv_type

Returned parameter. Specifies the type of conversation chosen by the partner TP, using MC_ALLOCATE or ALLOCATE. The following are possible values:

AP_BASIC_CONVERSATION

AP_MAPPED_CONVERSATION

user_id

Returned parameter. Provides the user identifier specified by the partner TP, using **MC_ALLOCATE** or **ALLOCATE** (if the partner TP set the **MC_ALLOCATE** or **ALLOCATE** verb's security parameter to AP_PGM or AP_SAME). It is a type AE EBCDIC character string.

lu_alias

Returned parameter. Provides the alias by which the local LU is known to the local TP. It is an ASCII character string.

plu_alias

Returned parameter. Provides the alias by which the partner LU (which initiated the incoming allocate) is known to the local TP. It is an ASCII character string.

mode_name

Returned parameter. Provides the mode name specified by **MC_ALLOCATE** or **ALLOCATE** in the partner TP. It is the name of a set of networking characteristics defined during configuration. The **mode_name** is a type A EBCDIC character string.

reserv3

A reserved field.

conv_group_id

Conversation group identifier.

fqplu_name

This returned parameter provides the fully qualified LU name.

pip_incoming

This optional supplied and returned parameter is applicable only if Sync Point services are required.

For the supplied parameter:

AP_YES if TP does accept PIP data.

AP_NO if TP does not accept PIP data.

For the returned parameter:

AP_YES if PIP data is available.

AP_NO if PIP data is not available.

syncpoint_rqd

This parameter indicates if Sync Point services are required.

AP_YES if Sync Point is required.

AP_NO if Sync Point is not required.

reserv4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_UNDEFINED_TP_NAME

Secondary return code; the TP name was not configured correctly.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_ALLOCATE_NOT_PENDING

Secondary return code; APPC did not find an incoming allocate (from the invoking TP) to match the value of **tp_name**, supplied by **RECEIVE_ALLOCATE**. **RECEIVE_ALLOCATE** waited for the incoming allocate and eventually timed out.

AP_INVALID_PROCESS

Secondary return code; the process issuing **RECEIVE_ALLOCATE** was different from the one started by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This must be the first APPC verb issued by the invoked TP. The initial state is RESET. If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RECEIVE.

In response to this verb, APPC establishes a conversation between the two TPs and generates a TP identifier for the invoked TP and a conversation identifier. These identifiers are required parameters for subsequent APPC verbs.

If the invoked TP issues **RECEIVE_ALLOCATE** and a corresponding incoming allocate (resulting from MC_ALLOCATE or ALLOCATE issued by the invoking TP) is not present, the invoked TP waits until the incoming allocate arrives or the verb times out. The time-out value is set by the system administrator.

RECEIVE_AND_POST

The **RECEIVE_AND_POST** verb receives application data and status information asynchronously. This allows the local TP to proceed with processing while data is still arriving at the local LU.

RECEIVE_AND_POST is only supported under the Microsoft® Windows NT®, Microsoft® Windows® 95, and OS/2 operating systems. For similar functionality under the Windows version 3.*x* graphical environment, use RECEIVE_AND_WAIT in conjunction with WinAsyncAPPC. Specifically, while an asynchronous **RECEIVE_AND_POST** is outstanding, the following verbs can be issued on the same conversation:

DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)

GET_ATTRIBUTES

GET_TYPE

REQUEST_TO_SEND

SEND_ERROR

TEST_RTS

TP_ENDED

This allows an application to use an asynchronous **RECEIVE_AND_POST** to receive data. While the **RECEIVE_AND_POST** is outstanding, it can still use **SEND_ERROR** and **REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support. For information on how a TP receives data and how to use this verb, see Remarks in this topic.

The following structure describes the verb control block used by the **RECEIVE_AND_POST** verb.

```
struct receive_and_post {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       fill;
    unsigned char       rts_rcvd;
    unsigned char       reserv4;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char FAR * sema;
    unsigned char       reserv5;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_AND_POST.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd
Returned parameter. Indicates whether data or conversation status was received. Possible values are listed following the **Members** section.

rtn_status
Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The **fill** parameter specifies BUFFER or LL, and the data is the last logical record before the status indicator.

fill
Supplied parameter. Specifies how the local TP receives data.

Use AP_BUFFER to indicate that the local TP receives data until the number of bytes specified by **max_len** is reached or until end of data. Data is received without regard for the logical-record format.

Use AP_LL to indicate that data is received in logical-record format. The data received can be:

- A complete logical record.
- A **max_len** byte portion of a logical record.
- The end of a logical record**.**

rts_rcvd
Returned parameter. Indicates whether the partner TP issued REQUEST_TO_SEND. Possible values are:

- AP_YES indicates that the partner TP issued **REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

max_len
Supplied parameter. Specifies the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

The value must not exceed the length of the buffer to contain the received data. The offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

dlen
Returned parameter. Specifies the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr
Supplied parameter. Provides the address of the buffer to contain the data received by the local LU.

For the Windows NT and Windows 95 operating systems, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the **DosAllocSeg** function with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

sema
Supplied parameter. Provides the address of the semaphore that APPC is to clear when the asynchronous receiving operation is finished. On OS/2, the **sema** parameter is either a RAM or system semaphore. On Windows NT and Windows 95, the **sema** parameter is an event handle obtained by calling either the **CreateEvent** or **OpenEvent** Win32® function.

Values returned by the what_rcvd parameter

- AP_CONFIRM_DEALLOCATE indicates that the partner TP issued DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by ALLOCATE, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP issued PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value,

the local TP normally issues **CONFIRMED**, and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP issued CONFIRM. Upon receiving this value, the local TP normally issues **CONFIRMED**.
- AP_DATA indicates that this value can be returned by **RECEIVE_AND_POST** if **fill** is set to AP_BUFFER. The local TP received data until **max_len** or the end of the data was reached. For more information, see Remarks in this topic.
- AP_DATA_COMPLETE indicates, for **RECEIVE_AND_POST**, that the local TP has received a complete data record or the last part of a data record.

  For **RECEIVE_AND_POST** with **fill** set to AP_LL, this value indicates that the local TP has received a complete logical record or the end of a logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_POST** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information.

  If **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED, see the description of the value (in this section) for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to the DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates, for **RECEIVE_AND_POST**, that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record).

  For **RECEIVE_AND_POST** with **fill** set to AP_LL, this value indicates that the local TP has received an incomplete logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_POST** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses SEND_DATA to begin sending data.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.
AP_DATA_COMPLETE_CONFIRM_SEND
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.
AP_DATA_COMPLETE_CONFIRM
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.
AP_DATA_COMPLETE_CONFIRM_DEALL
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.
AP_DATA_SEND
Primary return code; this is a combination of AP_DATA and AP_SEND.
AP_DATA_CONFIRM_SEND
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_SEND.
AP_DATA_CONFIRM
Primary return code; this is a combination of AP_DATA and AP_CONFIRM.
AP_DATA_CONFIRM_DEALLOCATE
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_DEALLOCATE.
AP_DEALLOC_NORMAL
Primary return code; the partner TP issued DEALLOCATE with **dealloc_type** set to AP_FLUSH or AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE.

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the address of the RAM semaphore or system semaphore handle was invalid.

> APPC cannot trap all invalid semaphore handles. If the TP passes a bad RAM semaphore handle, a protection violation results.

AP_RCV_AND_POST_BAD_FILL

Secondary return code; the **fill** parameter was set to an invalid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_POST_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_RCV_AND_POST_NOT_LL_BDY

Secondary return code; the conversation was in SEND state; the TP began but did not finish sending a logical record.

AP_CANCELED
Primary return code; the local TP issued one of the following verbs, which canceled **RECEIVE_AND_POST**:

DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER

SEND_ERROR

TP_ENDED

Issuing one of these verbs causes the semaphore to be cleared.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the

partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC
Primary return code; the partner TP issued SEND_ERROR with **err_type** set to AP_PROG while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC
Primary return code; in SEND state, after sending an incomplete logical record, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. The local TP may have received the first part of the logical record through a receive verb.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_NO_TRUNC
Primary return code; while in SEND state, the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC. Data was not truncated.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC
Primary return code; in SEND state, after sending an incomplete logical record, the partner TP (or partner LU) issued **SEND_ERROR**. The local TP may have received the first part of the logical record.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received can be:

   - One logical record.
   - A buffer of data received independent of its logical-record format.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it. The receive verbs are **RECEIVE_AND_POST** (Windows NT, Windows 95, and OS/2), RECEIVE_AND_WAIT, and RECEIVE_IMMEDIATE.

2. The local TP issues the receive verb again. This has one of the following effects:

- If the partner TP has sent more data, the local TP begins to receive a new unit of data.
- If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The following procedure shows tasks performed by the local TP in using **RECEIVE_AND_POST**.

To use RECEIVE_AND_POST

1. For the Windows NT and Windows 95 operating systems, the TP retrieves the WinAsyncAPPC message number by calling the **RegisterWindowMessage** API or allocating a semaphore. The **sema** field should be set to NULL if the application expects to be notified through the Windows message mechanism.

   APPC sends the Windows message or clears the semaphore when the local TP finishes receiving data.

   For the OS/2 operating system, the TP uses the **DosSemSet** function to set the semaphore pointed to by **sema**.

   The semaphore will remain set while the local TP receives data asynchronously. APPC will clear the semaphore when the local TP finishes receiving data.

2. The TP issues RECEIVE_AND_POST.
3. The TP checks the value of primary_rc.

   If **primary_rc** is AP_OK, the receive buffer (pointed to by **dptr**) is asynchronously receiving data from the partner TP. While receiving data asynchronously, the local TP can:

   - Perform tasks not related to this conversation.
   - Issue REQUEST_TO_SEND.
   - Gather information about this conversation by issuing GET_TYPE, GET_ATTRIBUTES, or TEST_RTS.
   - Prematurely cancel **RECEIVE_AND_POST** by issuing DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER; SEND_ERROR; or TP_ENDED.

   If, however, **primary_rc** is not AP_OK, **RECEIVE_AND_POST** has failed. In this case, the local TP does not perform the next two tasks.

4. For the Windows NT and Windows 95 operating systems, when the TP finishes receiving data asynchronously, APPC issues the WinAsyncAPPC Windows message or clears the semaphore.

   For the OS/2 operating system, the TP uses the **DosSemWait** function to wait for APPC to clear the semaphore pointed to by **sema**. When the TP finishes receiving data asynchronously, APPC clears the semaphore. To prevent the local TP from waiting, have it test the semaphore (invoking **DosSemWait** with **Timeout** set to zero) until APPC clears the semaphore.

5. The TP checks the new value of **primary_rc**.

   If **primary_rc** is AP_OK, the local TP can examine the other returned parameters and manipulate the asynchronously received data.

   If **primary_rc** is not AP_OK, only **secondary_rc** and **rts_rcvd** (request-to-send received) are meaningful.

Conversation State Effects

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing **RECEIVE_AND_POST** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to PENDING_POST state; the local TP is ready to receive information from the partner TP asynchronously.

The conversation changes states twice:

- Upon initial return of the verb, if **primary_rc** contains AP_OK, the conversation changes to PENDING_POST state.
- After completion of the verb, the state changes depending on the value of the following:

  The **primary_rc** parameter

  The **what_rcvd** parameter if **primary_rc** is AP_OK

The following table shows the new state associated with each value of **what_rcvd** when **primary_rc** is AP_OK.

what_rcvd	New state
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table shows the new state associated with each value of **primary_rc** other than AP_OK.

primary_rc	New state
AP_CANCELED	No change
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE
AP_PROG_ERROR_TRUNC	RECEIVE
AP_SVC_ERROR_TRUNC	RECEIVE

End of Data for a Basic Conversation

If the local TP issues **RECEIVE_AND_POST** and sets **fill** to AP_BUFFER, the receipt of data ends when **max_len** or the end of the data is reached. The end of the data is indicated by either **primary_rc** with a value other than AP_OK (for example, AP_DEALLOC_NORMAL), or by **what_rcvd** with one of the following values:

AP_SEND

AP_CONFIRM_SEND

AP_CONFIRM_DEALLOCATE

AP_CONFIRM_WHAT_RECEIVED

AP_DATA_CONFIRM_SEND

AP_DATA_CONFIRM_DEALLOCATE

AP_DATA_CONFIRM

To determine if the end of the data has been reached, the local TP reissues **RECEIVE_AND_POST**. If the new **primary_rc** contains AP_OK and **what_rcvd** contains AP_DATA, the end of the data has not been reached. If, however, the end of the data has been reached, **primary_rc** or **what_rcvd** will indicate the cause of the end of the data.

Troubleshooting

The local TP can wait indefinitely if one of the following situations occurs:

- For the Windows NT and Windows 95 operating systems, the local TP issues a **RECEIVE_AND_POST** request, but either the partner TP has not sent data or the initial **primary_rc** is not AP_OK.

- For the OS/2 operating system, the local TP issues a **DosSemWait** function call, but either the partner TP has not sent data or the initial **primary_rc** is not AP_OK.

This is because APPC will not issue the Windows message or clear the semaphore.

When a condition resulting in one of the following **primary_rc** parameters occurs, APPC does not clear the semaphore:

AP_INVALID_SEMAPHORE_HANDLE

AP_INVALID_VERB_SEGMENT

AP_STACK_TOO_SMALL

To test **what_rcvd**, issue **RECEIVE_AND_POST** with **max_len** set to zero, so that the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

RECEIVE_AND_WAIT

The **RECEIVE_AND_WAIT** verb receives any data that is currently available from the partner TP. If no data is currently available, the local TP waits for data to arrive.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call. To allow full use to be made of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** verbs have been altered to act like RECEIVE_AND_POST verbs. Specifically, while an asynchronous **RECEIVE_AND_WAIT** is outstanding, the following verbs can be issued on the same conversation:

DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)

GET_ATTRIBUTES

GET_TYPE

REQUEST_TO_SEND

SEND_ERROR

TEST_RTS

TP_ENDED

This allows an application, and in particular, a 5250 emulator, to use an asynchronous **RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** and **REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support.

The following structure describes the verb control block used by the **RECEIVE_AND_WAIT** verb.

```
struct receive_and_wait {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       fill;
    unsigned char       rts_rcvd;
    unsigned char       reserv4;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv5[5];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_AND_WAIT.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Specifies the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd
Returned parameter. Indicates whether data or conversation status was received. Possible values are listed in the table following the Members section.

rtn_status
Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The **fill** parameter specifies BUFFER or LL, and the data is the last logical record before the status indicator.

fill
Supplied parameter. Used in a basic conversation to specify how the local TP receives data. The following are allowed values:

- AP_BUFFER specifies that the local TP receives data until the number of bytes specified by **max_len** is reached or until the end of the data. Data is received without regard for the logical-record format.
- AP_LL specifies that data is received in logical-record format. The data received can be a complete logical record, a **max_len** byte portion of a logical record, or the end of a logical record.

rts_rcvd
Returned parameter. Contains the request-to-send indicator. Possible values are:

- AP_YES indicates that the partner TP has issued REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

max_len
Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Microsoft® Windows NT® and Windows 95 operating systems and the Windows graphical environment, this value must not exceed the length of the buffer to contain the received data.

For the OS/2 operating system, the offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

By issuing **RECEIVE_AND_WAIT** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen
Returned parameter. Indicates the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr
Supplied parameter. Provides the address of the buffer to contain the data received by the local TP.

For the Windows NT and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the **DosAllocSeg** function with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

For the Windows environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Values returned by the what_rcvd member

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP has issued PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this

value, the local TP normally issues **CONFIRMED** and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued CONFIRM. Upon receiving this value, the local TP normally issues **CONFIRMED**.
- AP_DATA can be returned in a basic conversation by **RECEIVE_AND_WAIT** if **fill** is set to AP_BUFFER. The local TP received data until **max_len** or end of data was reached. For more information, see "**RECEIVE_AND_WAIT** End of Data" at the end of this topic.
- AP_DATA_COMPLETE indicates, for **RECEIVE_AND_WAIT**, that the local TP has received a complete data record or the last part of a data record.

  For **RECEIVE_AND_WAIT** with **fill** set to AP_LL, this value indicates that the local TP has received a complete logical record or the end of a logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_WAIT** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information, if **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED.

  See Return Codes in this topic for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates, for **RECEIVE_AND_WAIT**, that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record).

  For **RECEIVE_AND_WAIT** with **fill** set to AP_LL, this value indicates that the local TP has received an incomplete logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_WAIT** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses SEND_DATA to begin sending data.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.
AP_DATA_COMPLETE_CONFIRM_SEND
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.
AP_DATA_COMPLETE_CONFIRM
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.
AP_DATA_COMPLETE_CONFIRM_DEALL
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.
AP_DATA_SEND
Primary return code; this is a combination of AP_DATA and AP_SEND.
AP_DATA_CONFIRM_SEND
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_SEND.
AP_DATA_CONFIRM
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_WHAT_RECEIVED.
AP_DATA_CONFIRM_DEALLOCATE
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_DEALLOCATE.
AP_DEALLOC_NORMAL
Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued DEALLOCATE with **dealloc_type** set to one of the following:

AP_CONFIRM_SYNC_LEVEL

AP_FLUSH

AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_RCV_AND_WAIT_BAD_FILL

Secondary return code; for basic conversations, **fill** was set to an invalid value.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_WAIT_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_RCV_AND_WAIT_NOT_LL_BDY

Secondary return code; for basic conversations, the conversation was in SEND state; the TP began but did not finish sending a logical record.

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued SEND_ERROR with **err_type** set to AP_PROG while the conversation was in

SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC
Primary return code; in SEND state, after sending an incomplete logical record, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. The local TP may have received the first part of the logical record through a receive verb.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_NO_TRUNC
Primary return code; while in SEND state, the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC. Data was not truncated.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_NO_TRUNC
Primary return code; while in SEND state, after sending an incomplete logical record, the partner TP (or partner LU) issued **SEND_ERROR**. The local TP may have received the first part of the logical record.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received can be:

   - One logical record.
   - A buffer of data received independent of its logical-record format.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

   The receive verbs are RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2 operating systems), **RECEIVE_AND_WAIT**, and RECEIVE_IMMEDIATE.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through the **what_rcvd** parameter) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing the Verb in SEND State

Issuing **RECEIVE_AND_WAIT** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to RECEIVE state; the local TP waits for the partner TP to send data.

State Change

The new conversation state is determined by the following factors:

- The state the conversation is in when the TP issues the verb.
- The **primary_rc** parameter.
- The **what_rcvd** parameter if **primary_rc** contains AP_OK.

Verb Issued in SEND State

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is AP_OK.

what_rcvd	New state
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	No change
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is not AP_OK.

primary_rc	New state
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE

Verb Issued in RECEIVE State

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is AP_OK.

what_rcvd	New state
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND

AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	No change
AP_PROG_ERROR_NO_TRUNC	No change
AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change

RECEIVE_AND_WAIT End of Data

In basic conversations, if the local TP issues **RECEIVE_AND_WAIT** and sets **fill** to AP_BUFFER, the receipt of the data ends when **max_len** or the end of the data is reached. The end of the data is indicated by either:

- A **primary_rc** parameter with a value other than AP_OK (for example, AP_DEALLOC_NORMAL).
- A **what_rcvd** parameter with one of the following values:

  AP_SEND

  AP_CONFIRM_SEND

  AP_CONFIRM_DEALLOCATE

  AP_CONFIRM_WHAT_RECEIVED

  AP_DATA_CONFIRM_SEND

  AP_DATA_CONFIRM_DEALLOCATE

  AP_DATA_CONFIRM

To determine if the end of the data has been reached, the local TP reissues **RECEIVE_AND_WAIT**. If the new **primary_rc** contains AP_OK and **what_rcvd** contains AP_DATA, the end of the data has not been reached. If, however, the end of the data has been reached, **primary_rc** or **what_rcvd** will indicate the cause of the end of the data.

RECEIVE_AND_WAIT waits for data or an indicator to be sent by the partner TP. If you need the local TP to operate continuously, use RECEIVE_IMMEDIATE instead.

RECEIVE_IMMEDIATE

The **RECEIVE_IMMEDIATE** verb receives any data currently available from the partner TP. If no data is available, the local TP does not wait. To avoid blocking the conversation, the Microsoft® Windows NT®, Microsoft® Windows® 95, and Windows version 3.*x* systems can issue RECEIVE_AND_WAIT in conjunction with WinAsyncAPPC. For OS/2 systems, use RECEIVE_AND_POST.

The following structure describes the verb control block used by the **RECEIVE_IMMEDIATE** verb.

```
struct receive_immediate {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       fill;
    unsigned char       rts_rcvd;
    unsigned char       reserv4;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv5[5];
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_IMMEDIATE.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd
Returned parameter. Contains information received with the incoming data. Possible values are listed in the table following the Members section.

rtn_status
Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

Use AP_NO to specify that indicators should be returned individually on separate invocations of the verb.

Use AP_YES to specify that indicators should be returned together, provided both are available. Both can be returned when:

- The receive buffer is large enough to hold all of the data that precedes the status indicator.
- The **fill** parameter specifies either BUFFER or LL, and the data is the last logical record before the status indicator.

fill
Supplied parameter. Specifies the manner in which the local TP receives data. It is used only for **RECEIVE_IMMEDIATE**.

Use AP_BUFFER to indicate that the local TP receives data until the number of bytes specified by **max_len** is reached or until

end of data. Data is received without regard for the logical-record format.

Use AP_LL to indicate that data is received in logical-record format. The data received can be a complete logical record, a **max_len** byte portion of a logical record, or the end of a logical record.

rts_rcvd
Returned parameter. Contains the request-to-send indicator. Possible values are:

- AP_YES indicates that the partner TP has issued REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

max_len
Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Windows NT and Windows 95 operating systems and the Windows graphical environment, this value must not exceed the length of the buffer to contain the received data.

For the OS/2 operating system, the offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

By issuing **RECEIVE_IMMEDIATE** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen
Returned parameter. Provides the number of bytes of data received. Data is stored in a buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr
Supplied parameter. Address of the buffer to contain the data received by the local TP.

For the Windows NT and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

Values returned by the what_rcvd member

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP has issued PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **CONFIRMED**, and begins to send data.
- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued CONFIRM. Upon receiving this value, the local TP normally issues **CONFIRMED**.
- AP_DATA is returned for basic conversations by **RECEIVE_IMMEDIATE** if **fill** is set to AP_BUFFER. The local TP received data until **max_len** or end of data was reached. For more information, see "**RECEIVE_IMMEDIATE** End of Data" at the end of this topic.
- AP_DATA_COMPLETE indicates, for **RECEIVE_IMMEDIATE** with **fill** set to AP_LL in basic conversations, that the local TP has received a complete logical record or the end of a logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_IMMEDIATE** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information if **primary_rc** contains AP_OK and **what_rcvd** contains any of these values:

  AP_SEND

  AP_CONFIRM_SEND

  AP_CONFIRM_DEALLOCATE

  AP_CONFIRM_WHAT_RECEIVED

  See the description of the value in Return Codes in this topic for the next action the local TP normally takes.

If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates for **RECEIVE_IMMEDIATE** in mapped conversations that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record).

  For **RECEIVE_IMMEDIATE** with **fill** set to AP_LL in basic conversations, this value indicates that the local TP has received an incomplete logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_IMMEDIATE** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses SEND_DATA to begin sending data.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.
AP_DATA_COMPLETE_CONFIRM_SEND
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.
AP_DATA_COMPLETE_CONFIRM
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.
AP_DATA_COMPLETE_CONFIRM_DEALL
Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.
AP_DATA_SEND
Primary return code; this is a combination of AP_DATA and AP_SEND.
AP_DATA_CONFIRM_SEND
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_SEND.
AP_DATA_CONFIRM
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_WHAT_RECEIVED.
AP_DATA_CONFIRM_DEALLOCATE
Primary return code; this is a combination of AP_DATA and AP_CONFIRM_DEALLOCATE.
AP_UNSUCCESSFUL
Primary return code; no data is immediately available from the partner TP.
AP_DEALLOC_NORMAL
Primary return code; the partner TP has deallocated the conversation without requesting confirmation. The partner TP issued DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_RCV_IMMD_BAD_FILL

Secondary return code for a basic conversation; the **fill** parameter was set to an invalid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_IMMD_BAD_STATE

Secondary return code; the conversation was not in RECEIVE state.

AP_ALLOCATION_ERROR

Secondary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued SEND_ERROR with **err_type** set to AP_PROG while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC

Primary return code; in SEND state, after sending an incomplete logical record, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. The local TP may have received the first part of the logical record through a receive verb.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_NO_TRUNC
Primary return code; while in SEND state, the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC. Data was not truncated.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC
Primary return code; in SEND state, after sending an incomplete logical record, the partner TP (or partner LU) issued **SEND_ERROR**. The local TP may have received the first part of the logical record.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received can be:

   - One logical record.
   - A buffer of data received independent of its logical-record format.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

   The receive verbs are RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2 operating systems), RECEIVE_AND_WAIT, and **RECEIVE_IMMEDIATE**.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE state when the TP issues this verb.

The new state is determined by **primary_rc**. If **primary_rc** is AP_OK, the new state is determined by **what_rcvd**.

The following table details the state changes when the **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when the **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET

AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	No change
AP_PROG_ERROR_NO_TRUNC	No change
AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change
AP_UNSUCCESSFUL	No change

RECEIVE IMMEDIATE End of Data

In basic conversations, if the local TP issues **RECEIVE_IMMEDIATE** and sets **fill** to AP_BUFFER, the receipt of the data ends when **max_len** or the end of the data is reached. The end of the data is indicated by either:

- A **primary_rc** parameter with a value other than AP_OK (for example, AP_DEALLOC_NORMAL).
- A **what_rcvd** parameter with one of the following values:

  AP_SEND

  AP_CONFIRM_SEND

  AP_CONFIRM_DEALLOCATE

  AP_CONFIRM_WHAT_RECEIVED

  AP_DATA_CONFIRM_SEND

  AP_DATA_CONFIRM_DEALLOCATE

  AP_DATA_CONFIRM

To determine if the end of the data has been reached, the local TP reissues **RECEIVE_IMMEDIATE**. If the new **primary_rc** parameter contains AP_OK and **what_rcvd** contains AP_DATA, the end of the data has not been reached. If, however, the end of the data has been reached, **primary_rc** or **what_rcvd** will indicate the cause of the end of the data.

RECEIVE_LOG_DATA

The **RECEIVE_LOG_DATA** verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another one (that is, until the TP issues another **RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all). This verb is only supported on Microsoft® Windows NT® and Microsoft® Windows® 95 by Microsoft® SNA Server version 3.0 with Service Pack 1 or later and by SNA Server version 4.0.

Note that the TP itself is responsible for allocating and freeing the buffer. After the buffer has been passed to APPC, the TP should either issue another **RECEIVE_LOG_DATA** specifying a new buffer or a zero-length buffer, or wait until the conversation has finished before freeing the original buffer.

When an FMH7 is received, APPC copies any associated error log general data stream (GDS) into the buffer. If there is no associated error log variable, the buffer is zeroed out. It is up to the TP to check the buffer whenever a return code from a receive verb indicates that an error has been received.

The following structure describes the verb control block used by the **RECEIVE_LOG_DATA** verb.

```
struct receive_log_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv1;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      log_dlen;
    unsigned char FAR * log_dptr;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_LOG_DATA.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv1
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

log_dlen
Supplied parameter. Specifies the maximum length of log data that APPC can place in the buffer (that is, the buffer size). The range is from 0 through 65535. Note that a length of zero here indicates that any previous **RECEIVE_LOG_DATA** verb should be cancelled.

log_dptr
Supplied parameter. Specifies the address of the buffer that APPC will use to store the log data.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

REQUEST_TO_SEND

The **REQUEST_TO_SEND** verb notifies the partner TP that the local TP wants to send data.

For the Windows version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **REQUEST_TO_SEND** verb.

```
struct request_to_send {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_REQUEST_TO_SEND.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_R_T_S_BAD_STATE

Secondary return code; the conversation is not in an allowed state when the TP issued this verb.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.

- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any of the following states when the TP issues this verb:

CONFIRM

PENDING_POST (OS/2)

RECEIVE

There is no state change.

The request-to-send notification is received by the partner program through the **rts_rcvd** parameter of the following verbs:

- CONFIRM
- RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2 operating systems)
- RECEIVE_AND_WAIT
- RECEIVE_IMMEDIATE
- SEND_DATA
- SEND_ERROR

It is also indicated by a **primary_rc** of AP_OK on TEST_RTS.

Request-to-send notification is sent to the partner TP immediately; APPC does not wait until the send buffer fills up or is flushed. Consequently, the request-to-send notification may arrive out of sequence. For example, if the local TP is in SEND state and issues PREPARE_TO_RECEIVE followed by **REQUEST_TO_SEND**, the partner TP, in RECEIVE state, may receive the request-to-send notification before it receives the send notification. For this reason, request-to-send can be reported to a TP through a receive verb.

In response to this request, the partner TP can change the conversation to:

- RECEIVE state by issuing **PREPARE_TO_RECEIVE** or **RECEIVE_AND_WAIT**.
- PENDING_POST state by issuing **RECEIVE_AND_POST**.

The partner TP can also ignore the request-to-send.

The conversation state changes to SEND for the local TP when the local TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_CONFIRM_SEND and replies with CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **CONFIRMED**
- AP_DATA_CONFIRM_SEND and replies with **CONFIRMED**
- AP_SEND

The receive verbs are RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2 operating systems), RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT.

SEND_CONVERSATION

The **SEND_CONVERSATION** verb allocates a session between the local LU and partner LU, sends data on the session, and then deallocates the session.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **SEND_CONVERSATION** verb.

```
struct send_conversation {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3[8];
    unsigned char       rtn_ctl;
    unsigned char       reserv4;
    unsigned long       conv_group_id;
    unsigned long       sense_data;
    unsigned char       plu_alias[8];
    unsigned char       mode_name[8];
    unsigned char       tp_name[64];
    unsigned char       security;
    unsigned char       reserv6[11];
    unsigned char       pwd[10];
    unsigned char       user_id[10];
    unsigned short      pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char       reserv6;
    unsigned char       fqplu_name[17];
    unsigned char       reserv7[8];
    unsigned short      dlen;
    unsigned char FAR * dptr;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_SEND_CONVERSATION.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id
Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

rtn_ctl
Supplied parameter. Specifies how APPC should select a session to allocate for the conversation and when the local LU should return control to the local TP. The allowed values are:

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns

control to the TP.

- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs (as described in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOC specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOC specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id** or encounters one of the errors described in Return Codes in this topic. If the session is not available, the TP waits for it to become free.

conv_group_id

Supplied/returned parameter. Used as a supplied parameter when **rtn_ctl** is WHEN_CONV_GROUP_ALLOC to specify the identity of the conversation group from which the session should be allocated. When **rtn_ctl** specifies a different value, and the **primary_rc** is AP_OK, this is a returned value. The purpose of this parameter is to provide a TP with the assurance that the same session will be reallocated and therefore the conversations conducted over the session will occur in the same sequence that they were initiated.

sense_data

Returned parameter. If the primary and secondary return codes indicate an allocation error (retry or no-retry), an SNA-defined sense code is returned.

plu_alias

Supplied parameter. Specifies the alias by which the partner LU is known to the local TP. This parameter must match the name of a partner LU established during configuration. The parameter is an 8-byte, type G ASCII character set that includes:

- Uppercase letters
- Numerals 0 to 9
- Spaces
- Special characters $, #, %, and @

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration. This parameter must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set, including all EBCDIC spaces. These characters are:

- Uppercase letters
- Numerals 0 to 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or special character.

Using the name SNASVCMG (a reserved mode name used internally by APPC) in a basic conversation is not recommended.

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by ALLOCATE in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte, case-sensitive, EBCDIC character string. This parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the TP name is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention for naming a service TP is up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the EBCDIC AE character set.

security
Supplied parameter. Specifies the information the partner LU requires in order to validate access to the invoked TP.

- AP_NONE specifies that the invoked TP uses no conversation security.
- AP_PGM specifies that the invoked TP uses conversation security and requires a user identifier and password. Use **user_id** and **pwd** to supply this information.
- AP_SAME specifies that the invoked TP, invoked with a valid user identifier and password, in turn invokes another TP.

For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator indicates to TP C not to require the password (if TP C is configured to accept an already-verified indicator).

pwd
Supplied parameter. Specifies the password associated with **user_id**. This parameter is required only if the security parameter is set to AP_PGM and must match the password for **user_id** that was established during configuration.

This parameter is a 10-byte, case-sensitive, EBCDIC character string. It can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

user_id
Supplied parameter. Specifies the user identifier required to access the partner TP. This parameter is required only if the security parameter is set to AP_PGM and must match one of the user identifiers configured for the partner TP.

The parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the user identifier is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

pip_dlen
Supplied parameter. Specifies the length of the PIP to be passed to the partner TP. The range for this parameter is from 0 through 32767.

pip_dptr
Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the GDS format. For more information, see your IBM SNA manual(s).

For the Microsoft® Windows NT® and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area.

For the OS/2 operating system, use a shared, unnamed segment for the data buffer. To allocate the segment, issue the function call **DosAllocSeg** with the shared indicator equal to 1. The data buffer must be entirely within the data segment.

fqplu_name
Supplied parameter. Specifies the fully qualified name of the local LU. This parameter must match the fully qualified name of the local LU defined in the remote node. The parameter is made up of two type A EBCDIC character strings (each of up to eight characters), which are the network name (NETID) and the LU name of the partner LU. The names are separated by an EBCDIC period (.). The NETID can be omitted, and if this is the case, the period should also be omitted.

This name must be provided if no **plu_alias** is provided.

Type A EBCDIC characters contain:

- Uppercase letters
- Numerals 0 to 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

dlen

Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range for this parameter is from 0 through 65535.

dptr

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Windows NT and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, use a shared, unnamed segment for the data buffer. To allocate the segment, issue the function call **DosAllocSeg** with the shared indicator equal to 1. The data buffer must be entirely within the data segment.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate return of the control to the TP (AP_IMMEDIATE), and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **partner_lu_alias**.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb is issued by the invoking TP to conduct an entire conversation with the remote TP. If the remote TP rejects either the conversation initiation or the data, the invoking TP will not receive notification of the rejection.

The conversation state is RESET when the TP issues this verb. There is no state change.

Several parameters of **SEND_CONVERSATION** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

Normally, the value of **mode_name** must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU. If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

SEND_DATA

The **SEND_DATA** verb places data in the local LU's send buffer for transmission to the partner TP.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **SEND_DATA** verb.

```
struct send_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
    unsigned char       data_type;
    unsigned short int  dlen;
    unsigned char FAR * dptr ;
    unsigned char       type;
    unsigned char       reserv4;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_SEND_DATA.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd
Returned parameter. Provides the request-to-send-received indicator.

- AP_YES indicates that the partner TP has issued REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use PREPARE_TO_RECEIVE, RECEIVE_AND_WAIT, or RECEIVE_AND_POST (Windows NT, Windows 95, and OS/2 operating systems).
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

data_type
Supplied parameter. Specifies the type of data to be sent if Sync Point is supported. Valid parameters are:

AP_APPLICATION

AP_USER_CONTROL_DATA

AP_PS_HEADER

dlen
Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range is from 0 through 65535.

dptr
Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Microsoft® Windows NT® and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For OS/2, the data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The data buffer must fit entirely on the data segment.

type
Supplied parameter. Allows a TP to send data and perform other functions within one API call. For example, you can combine **SEND_DATA** with **type** set to CONFIRM to accomplish the same objective as issuing **SEND_DATA** followed by CONFIRM.

- AP_SEND_DATA_CONFIRM corresponds to **SEND_DATA** followed by **CONFIRM**.
- AP_SEND_DATA_FLUSH corresponds to **SEND_DATA** followed by FLUSH.
- AP_SEND_DATA_DEALLOC_ABEND corresponds to **SEND_DATA** followed by DEALLOCATE with a **dealloc_type** of AP_ABEND_PROG.
- AP_SEND_DATA_DEALLOC_FLUSH corresponds to **SEND_DATA** followed by **DEALLOCATE** with a **dealloc_type** of AP_FLUSH.
- AP_SEND_DATA_DEALLOC_SYNC_LEVEL corresponds to **SEND_DATA** followed by **DEALLOCATE** with a **dealloc_type** of AP_SYNC_LEVEL.
- AP_SEND_DATA_P_TO_R_FLUSH corresponds to **SEND_DATA** followed by PREPARE_TO_RECEIVE with a **ptr_type** of AP_FLUSH.
- AP_SEND_DATA_P_TO_R_SYNC_LEVEL corresponds to **SEND_DATA** followed by **PREPARE_TO_RECEIVE** with a **ptr_type** of AP_SYNC_LEVEL and **locks** set to AP_SHORT.

reserv4
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_LL

Secondary return code; the logical record length field of a logical record contained an invalid value—0x0000, 0x0001, 0x8000, or 0x8001. See About Transaction Programs for information on logical records.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_SEND_DATA_INVALID_TYPE

Secondary return code; the specified type was not recognized by APPC.

AP_SEND_DATA_CONFIRM_SYNC_NONE

Secondary return code; the **type** CONFIRM is not permitted for a conversation that was allocated with a **sync_level** of NONE.

AP_STATE_CHECK
Primary return code; the verb did not execute because it was issued in an invalid state.

AP_SEND_DATA_NOT_SEND_STATE

Secondary return code; the local TP issued **SEND_DATA**, but the conversation was not in SEND state.

AP_SEND_DATA_NOT_LL_BDY

Secondary return code; the TP started but did not finish sending a logical record. This occurs only when the **type** parameter is one of the following:

AP_SEND_DATA_CONFIRM

AP_SEND_DATA_DEALLOC_FLUSH

AP_SEND_DATA_DEALLOC_SYNC_LEVEL

AP_SEND_DATA_P_TO_R_FLUSH

AP_SEND_DATA_P_TO_R_SYNC_LEVEL

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued a **SEND_ERROR** verb with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

The conversation must be in SEND state when the TP issues this verb. State changes, based on **primary_rc**, are summarized in the following table.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

SEND_DATA may wait indefinitely because the partner TP has not issued a receive verb. If this occurs, the send buffer may fill up.

The data collected in the local LU's send buffer is transmitted to the partner LU (and partner TP) when one of the following occurs:

- The send buffer fills up.
- The local TP issues FLUSH, CONFIRM, or DEALLOCATE (or other verb that flushes the LU's send buffer).

SEND_ERROR

The **SEND_ERROR** verb notifies the partner TP that the local TP has encountered an application-level error.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use WinAsyncAPPC rather than the blocking version of this call.

The following structure describes the verb control block used by the **SEND_ERROR** verb.

```
struct send_error {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
    unsigned char       err_type;
    unsigned char       err_dir;
    unsigned char       reserv3;
    unsigned short      log_dlen;
    unsigned char FAR * log_dptr;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_SEND_ERROR.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd
Returned parameter. Indicates whether the partner TP issued REQUEST_TO_SEND. Possible values include:

- AP_YES indicates that the partner TP has issued **REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use PREPARE_TO_RECEIVE, RECEIVE_AND_WAIT, or RECEIVE_AND_POST.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

err_type
Supplied parameter. Indicates the type of the error being reported — application program or service program.

AP_PROG indicates that the error is to be reported to an end-user application program. This value causes APPC to send one of the following return codes to the partner TP:

AP_PROG_ERROR_NO_TRUNC

AP_PROG_ERROR_PURGING

AP_PROG_ERROR_TRUNC

AP_SVC indicates that the error is to be reported to a service program. This value causes APPC to send one of the following return codes to the partner TP:

AP_SVC_ERROR_NO_TRUNC

AP_SVC_ERROR_PURGING

AP_SVC_ERROR_TRUNC

err_dir
Supplied parameter. Indicates whether the error is with data just received or with data that is about to be sent. Use this parameter only when the conversation is in SEND_PENDING state. The parameter is ignored otherwise. The following are allowed values:

- AP_RCV_DIR_ERROR indicates that the TP issued **SEND_ERROR** after detecting an error associated with the data just received.
- AP_SEND_DIR_ERROR indicates that the TP issued **SEND_ERROR** after detecting an error associated with data it was going to send. For example, the TP encountered an error while reading data from the disk drive.

reserv3
A reserved field.

log_dlen
Supplied parameter for basic conversations; specifies the number of bytes of data to be sent to the error log file. The range is from 0 through 32767.

A length of zero indicates that there is no error log data.

log_dptr
Supplied parameter for basic conversations; specifies the address of the data buffer containing error information. The data is sent to the local error log and to the partner LU.

This parameter is used by **SEND_ERROR** if **log_dlen** is greater than zero.

For the Microsoft® Windows NT® and Windows 95 operating systems and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the log data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with **Flags** equal to 1. The log data buffer must fit entirely on the segment.

The TP must format the error data as a GDS error log variable. For more information, see your IBM SNA manual(s).

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_ERROR_DIRECTION

Secondary return code; the specified **err_dir** was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the error data for the log file was longer than the segment allocated to contain the error data, or the address of the error data buffer was wrong.

AP_SEND_ERROR_BAD_TYPE

Secondary return code; the value of **err_type** was invalid.

AP_SEND_ERROR_LOG_LL_WRONG

Secondary return code; the LL field of the error log GDS variable did not match the actual length of the data.

The following return codes can be generated when **SEND_ERROR** is issued in any allowed state:

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY
Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY
Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This may occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

The following return codes can be generated only if **SEND_ERROR** is issued in SEND state:

AP_ALLOCATION_ERROR
Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_PROG_ERROR_PURGING
Primary return code; while in RECEIVE, PENDING, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

The following return codes can be generated only if **SEND_ERROR** is issued in SEND state:

AP_DEALLOC_ABEND_PROG
Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER
Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING
Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST (Windows NT, Windows 95, and OS/2 only), CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

The following return code can be generated only if **SEND_ERROR** is issued in RECEIVE state:

AP_DEALLOC_NORMAL
Primary return code; this return code does not indicate an error.

The partner TP issued DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

Remarks

The conversation can be in any state except RESET when the TP issues this verb. The conversation state must be SEND_PENDING if **err_dir** is used.

The local TP sends the error notification immediately to the partner TP; it does not hold the information in the local LU's send buffer.

Upon successful execution of this verb, the conversation is in SEND state for the local TP and in RECEIVE state for the partner TP.

The new state is determined by **primary_rc**. Possible state changes are summarized in the following table.

primary_rc	New state
AP_OK	SEND
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

If the conversation is in RECEIVE state when the TP issues **SEND_ERROR**, incoming data is purged by APPC. This data includes:

- Data sent by SEND_DATA.
- Return code indicators.
- Confirmation requests.
- Deallocation requests.

APPC does not purge an incoming request-to-send indicator. APPC replaces purged incoming return code indicators with other return codes. The primary return code AP_OK replaces the following purged return code indicators:

AP_PROG_ERROR_NO_TRUNC

AP_PROG_ERROR_PURGING

AP_PROG_ERROR_TRUNC

AP_SVC_ERROR_NO_TRUNC

AP_SVC_ERROR_PURGING

AP_SVC_ERROR_TRUNC

The primary return code AP_DEALLOC_NORMAL replaces the following purged return code indicators:

AP_ALLOCATION_ERROR

AP_ALLOCATION_FAILURE_NO_RETRY

AP_ALLOCATION_FAILURE_RETRY

AP_CONVERSATION_TYPE_MISMATCH

AP_DEALLOC_ABEND

AP_DEALLOC_ABEND_PROG

AP_DEALLOC_ABEND_SVC

AP_DEALLOC_ABEND_TIMER

AP_PIP_NOT_ALLOWED

AP_PIP_NOT_SPECIFIED_CORRECTLY

AP_SECURITY_NOT_VALID

AP_SYNC_LEVEL_NOT_SUPPORTED

AP_TP_NAME_NOT_RECOGNIZED

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

AP_TRANS_PGM_NOT_AVAIL_RETRY

When the conversation is in SEND_PENDING state, APPC reports the following return codes to the partner TP based on the value in **err_dir**:

AP_PROG_ERROR_PURGING
The local TP issued **SEND_ERROR** with RECEIVE as the **err_dir**.
AP_PROG_ERROR_NO_TRUNC
The local TP issued **SEND_ERROR** with SEND as the **err_dir**.
AP_SVC_ERROR_PURGING
The local TP issued **SEND_ERROR** with RECEIVE as the **err_dir.**
AP_SVC_ERROR_NO_TRUNC
The local TP issued **SEND_ERROR** with SEND as the **err_dir**.

TEST_RTS

The **TEST_RTS** verb determines whether a request-to-send notification has been received from the partner TP.

The following structure describes the verb control block used by the **TEST_RTS** verb.

```
struct test_rts {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_TEST_RTS.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3
A reserved field.

Return Codes

AP_OK
Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL
Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID
Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED
Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED
Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.
AP_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.
AP_STACK_TOO_SMALL
Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.
AP_CONV_BUSY
Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.
AP_THREAD_BLOCKING
Primary return code; the calling thread is already in a blocking call.
AP_UNEXPECTED_DOS_ERROR
Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

TEST_RTS_AND_POST

The **TEST_RTS_AND_POST** verb allows an application, typically a 5250 emulator, to request asynchronous notification when a partner TP requests send direction. It is not supported on Microsoft® MS-DOS® platforms.

The following structure describes the verb control block used by the **TEST_RTS_AND_POST** verb.

```
struct test_rts {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
    unsigned long       handle;
};
```

Members

opcode
Supplied parameter. Specifies the verb operation code, AP_B_TEST_RTS_AND_POST.

opext
Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id
Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id
Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3
A reserved field.

handle
Supplied parameter. On Microsoft® Windows NT® and Microsoft® Windows® 95 this field provides the event handle to set. On Windows 3.x, this field provides the Windows handle to receive the completion message. On OS/2, this field provides the address of the semaphore APPC is to clear when the asynchronous operation is finished.

Return Codes from Initial Verb

AP_OK
Primary return code; the verb executed successfully. Note particularly that a return code of AP_OK from the initial verb does not indicate that **REQUEST_TO_SEND** verb received from the partner TP. It simply indicates that the facility to receive asynchronous notification has been registered.

AP_UNSUCCESSFUL
Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code, the value of **handle** was invalid.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications subsystem could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft® Host Integration Server 2000 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Return Codes from Asynchronous Completion

AP_OK

Primary return code; the request-to-send notification has been received from the partner TP.

AP_CANCELLED

The outstanding **TEST_RTS_AND_POST** verb has been terminated. This will occur if the underlying conversation has been deallocated or an AP_TP_ENDED has been issued.

Note that as with **RECEIVE_AND_POST**, the TP is still responsible for correctly terminating the conversation and possibly terminating the TP. Issuing another verb, such as **RECEIVE_IMMEDIATE,** at this point will indicate the reason for the conversation failure.

The conversation can be in any state except RESET when the TP issues this verb. There is no state change.

A common feature of many APPC applications, such as 5250 emulators, is a requirement to detect a partner's request to send. Currently, this can be done by polling the APPC interface to detect the partner's request. For example, an application can occasionally issue one of the following verbs:

- **TEST_RTS**

Remarks

- **RECEIVE_IMMEDIATE** and check the **rts_rcvd** field
- **SEND_DATA** of zero bytes, again checking the **rts_rcvd** field.

Some of the problems associated with this polling approach are:

- The application must continually interrupt its main work to poll APPC.
- The partner's request is not detected as soon as it becomes available.
- These approaches are processor-intensive.

The **TEST_RTS_AND_POST** verb allows an application running on Windows NT, Windows 95, Windows 3.*x*, or OS/2, typically a 5250 emulator, to request asynchronous notification when the partner TP requests send direction.

An APPC application typically issues the **TEST_RTS_AND_POST** verb while in SEND state and then continues with its main processing. A request for send direction from the partner TP is indicated asynchronously to the application. After dealing with the partner's request, the application typically returns to SEND state, reissues **TEST_RTS_AND_POST**, and continues.

The **TEST_RTS_AND_POST** verb completes synchronously and the return code AP_OK indicates that a request for asynchronous notification has been registered. It is important to emphasize that this does not indicate that request-to-send was received from the partner TP.

When the partner's request to send is received, the asynchronous event completion occurs. It is important to note that this may be before the completion of the local TP's original **TEST_RTS_AND_POST** verb. This will be the case if the partner's request to send was received before the local TP's **TEST_RTS_AND_POST** verb was issued, or while the local TP's **TEST_RTS_AND_POST** verb was being processed.

APPC Extensions for the Windows Environment

This section describes API extensions to Windows APPC that allow asynchronous communication. Asynchronous communication occurs when a function returns before the request completes. The application is notified later when the request is completed.

Under Microsoft® Windows®3.x, one method is are available for asynchronous communication using the APPC API:

- Message posting using window handles.

Under Microsoft Windows 98, and Windows® 95, two methods are available for asynchronous communication using the APPC API:

- Message posting using window handles.
- Waiting on Win32® events.

Under Microsoft Windows 2000 and Windows NT®, three methods are available for asynchronous communication using the APPC API:

- Message posting using window handles.
- Waiting on Win32 events.
- Using Win32 IO completion ports.

The first method uses messages posted to a window handle to notify an application of verb completion. This method using window handles and messages is supported on Microsoft Windows 3.x with the exception of real mode Windows 3.0. There is one such window for each APPC application, independent of the number of conversations. Each APPC conversation can have one asynchronous verb outstanding at any time. When a verb completes, the posting to the window takes as parameters the asynchronous task handle returned by the original call and a pointer to the verb control block which has completed, containing the return codes of the verb.

The extensions using window handles and message posting described in this section (WinAsyncAPPC) have been designed for all implementations and versions of Microsoft Windows from version 3.0 through the latest versions of Windows 2000, Windows NT, Windows 98, and Windows 95. They provide compatibility for Windows programming and optimum application performance in the 16-bit Windows operating environment.

A second method using Win32 events for notification is supported. The extensions using Win32 events described in this section (WinAsyncAPPCEx) operate only on Windows 2000, Windows NT, Windows 98, and Windows 95. and offer optimum application performance in the 32-bit Windows operating environment. If an event has been registered with the conversation, then an application can call the Win32 **WaitForSingleObject** or **WaitForMultipleObjects** function to wait to be notified of the completion of the verb.

A third method using Win32 I/O completion ports for notification is supported on Windows 2000 and Windows NT. The extensions using I/O completion ports described in this section (WinAsyncAPPCIOCP) operate only on Windows 2000 and Windows NT, and offer optimum application performance in the 32-bit Windows operating environment. If an I/O completion port has been created using **CreateIoCompletionPort**, then an application can call the Win32 **GetQueuedCompletionStatus** function to wait to be notified of the completion of the verb.

Windows APPC allows multithreaded Windows-based processes. A process contains one or more threads of execution. The 16-bit Windows environment is not multithreaded. In this instance, a task corresponds to a process with a single thread. All references to threads in this document refer to actual threads in multithreaded Windows environments.

This section provides, for each extension, a definition of the function, syntax, returns, and remarks for using the function.

WinAsyncAPPC

The **WinAsyncAPPC** function provides an asynchronous entry point for all of the APPC verbs. Use this function instead of the blocking versions of the verbs if you run your application and want to use message posting using Windows handles for asynchronous verb completion. This function is supported on Windows 3.x

```
HANDLE WINAPI WinAsyncAPPC(
    HANDLE hWnd,
    long lpVcb
);
```

Parameters

hWnd
A window handle that will be used for message posting to notify an application when an APPC verb completes.
lpVcb
Pointer to the verb control block

Return Values

The return value specifies whether the asynchronous request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

When this function returns with a successful value, this does not indicate that the APPC call will ultimately return successfully. It only indicates that it was possible for the APPC library to attempt the APPC call asynchronously using message posting for notification.

Remarks

For an example of how to use this verb in TPs, see the send and receive sample TP (SENDRECV.C located in the APPC folder) included in the SDK.

APPC verbs used in basic conversations that can block are as follows:

- ALLOCATE
- CONFIRM
- CONFIRMED
- DEALLOCATE
- FLUSH
- PREPARE_TO_RECEIVE
- RECEIVE_ALLOCATE
- RECEIVE_AND_WAIT
- REQUEST_TO_SEND
- SEND_CONVERSATION
- SEND_DATA
- SEND_ERROR
- TP_ENDED
- TP_STARTED

APPC verbs used in mapped conversations that can block are as follows:

- MC_ALLOCATE
- MC_CONFIRM
- MC_CONFIRMED
- MC_DEALLOCATE
- MC_FLUSH
- MC_PREPARE_TO_RECEIVE
- MC_RECEIVE_AND_WAIT
- MC_REQUEST_TO_SEND
- MC_SEND_CONVERSATION

- MC_SEND_DATA
- MC_SEND_ERROR

When using the synchronous or asynchronous versions of a verb, an application can only have one outstanding function in progress on a conversation at a time. An attempt to initiate a second function results in the error code AP_CONV_BUSY.

> The exceptions to the preceding paragraph are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT. To allow full use of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT** verbs have been altered to act like the **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** verbs. Specifically, while an asynchronous version of one of these verbs is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES or MC_GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND or MC_REQUEST_TO_SEND
- SEND_ERROR or MC_SEND_ERROR
- TEST_RTS or MC_TEST_RTS
- TP_ENDED

This allows an application, in particular, a 5250 emulator, to use an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** or **MC_SEND_ERROR** and **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support.

When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncAPPC" as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call. The *lParam* argument contains the original VCB pointer and can be dereferenced to determine the final return code.

As part of the Windows APPC definition, WinAPPCCancelAsyncRequest allows an application to cancel any asynchronous APPC action; but terminates the related conversation or TP as appropriate. Any outstanding operations return with AP_CANCELED as the return code.

If the function returns successfully, a **WinAsyncAPPC** message is posted to the application when the operation completes or the conversation is canceled.

WinAsyncAPPCEx

The **WinAsyncAPPCEx** function provides an asynchronous entry point for all of the APPC verbs. Use this function instead of the blocking versions of the verbs to allow multiple sessions to be handled on the same thread using events. This verb is only supported on Microsoft® Windows 2000, Windows NT®, Windows® 98, and Windows® 95, and uses Win32® events.

```
HANDLE WINAPI WinAsyncAPPCEx(
    HANDLE event_handle,
    long lpVcb
);
```

Parameters

event_handle
Handle used for event notification using Win32 events.
lpVcb
Pointer to the verb control block

Return Values

The return value specifies whether the asynchronous resolution request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

When this function returns with a successful value, this does not indicate that the APPC call will ultimately return successfully. It only indicates that it was possible for the APPC library to attempt the APPC call asynchronously using events for notification.

Remarks

This function is intended for use with **WaitForSingleObject** or **WaitForMultipleObjects** in the Win32 API. These functions are described in the "Reference" section of the Microsoft® Platform SDK documentation.

For an example of how to use this verb in multithreaded TPs, see the multithreaded send and receive sample TPs (MRCV.C MSEND.C, and MSENDRCV.C located in the MSENDRCV folder) included in the SDK.

APPC verbs used in basic conversations that can block are as follows:

- ALLOCATE
- CONFIRM
- CONFIRMED
- DEALLOCATE
- FLUSH
- PREPARE_TO_RECEIVE
- RECEIVE_ALLOCATE
- RECEIVE_AND_WAIT
- REQUEST_TO_SEND
- SEND_CONVERSATION
- SEND_DATA
- SEND_ERROR
- TP_ENDED
- TP_STARTED

APPC verbs used in mapped conversations that can block are as follows:

- MC_ALLOCATE
- MC_CONFIRM
- MC_CONFIRMED
- MC_DEALLOCATE
- MC_FLUSH
- MC_PREPARE_TO_RECEIVE
- MC_RECEIVE_AND_WAIT
- MC_REQUEST_TO_SEND

- MC_SEND_CONVERSATION
- MC_SEND_DATA
- MC_SEND_ERROR
- RECEIVE_ALLOCATE
- TP_ENDED
- TP_STARTED

When using the synchronous or asynchronous versions of a verb, an application can only have one outstanding function in progress on a conversation at a time. An attempt to initiate a second function results in the error code AP_CONV_BUSY.

> The exceptions to the preceding paragraph are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT. To allow full use of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT** verbs have been altered to act like the **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** verbs. Specifically, while an asynchronous version of one of these verbs is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES or MC_GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND or MC_REQUEST_TO_SEND
- SEND_ERROR or MC_SEND_ERROR
- TEST_RTS or MC_TEST_RTS
- TP_ENDED

This allows an application, in particular, a server application, to use an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** or **MC_SEND_ERROR** and **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support, and in particular, for support of multiple conversations on the same thread.

When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the APPC primary return code and secondary return code in the verb control block for any error conditions.

WinAsyncAPPCIOCP

The **WinAsyncAPPCIOCP** function provides an asynchronous entry point for all of the APPC verbs. Use this function instead of the blocking versions of the verbs to allow multiple sessions to be handled on the same thread using I/O completion ports. This verb is only supported on Microsoft® Windows 2000 and Windows NT®, and uses Win32® I/O completion ports.

```
HANDLE WINAPI WinAsyncAPPCIOCP(
    APPC_IOCP_INFO *iocp_handle,
    long lpVcb
);
```

Parameters

iocp_handle
A pointer to an APPC_IOCP_INFO structure used for passing I/O completion port information.
lpVcb
Pointer to the verb control block

The APPC_IOCP_INFO structure has the following prototype:

```
typedef struct {
    HANDLE APPC_CompletionPort;
    DWORD APPC_NumberOfBytesTransferred;
    DWORD APPC_CompletionKey;
    LPOVERLAPPED APPC_pOverlapped;
} APPC_IOCP_INFO;
```

APPC_CompletionPort

This supplied parameter is the HANDLE returned by the call to the **CreateIoCompletionPort**.function when the I/O completion port is created. The I/O completion port must be created before calling the **WinAsyncAPPCIOCP** function.
When the verb completes, the APPC Library calls the **PostQueuedCompletionStatus** with the remaining fields in the structure as inputs, and these fields are simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

APPC_NumberOfBytesTransferred

This supplied parameter is ignored. When the APPC verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with this field as an input, and the value returned for the *dwNumberOfBytesTransferred* is simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

APPC_CompletionKey

This supplied parameter is ignored. When the APPC verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with this field as an input, and the value returned for the *dwCompletionKey* is simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

APPC_pOverlapped

This supplied parameter is ignored. When the APPC verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with this field as an input, and the value returned for the *lpOverlapped* is simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

Return Values

The return value specifies whether the asynchronous resolution request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

When this function returns with a successful value, this does not indicate that the APPC call will ultimately return successfully. It only indicates that it was possible for the APPC library to attempt the APPC call asynchronously using an I/O completion port for notification.

Remarks

This function is intended for use with **CreateIoCompletionPort** and **GetQueuedCompletionStatus** in the Win32 API. These functions are described in the "Reference" section of the Microsoft® Platform SDK documentation.

For an example of how to use this verb in multithreaded TPs, see the multithreaded receive sample TP (MRCVIO located in the

SNA\MSENDRCV folder) using I/O completion ports included in the Host Integration Server 2000 SDK.

APPC verbs used in basic conversations that can block are as follows:

- ALLOCATE
- CONFIRM
- CONFIRMED
- DEALLOCATE
- FLUSH
- PREPARE_TO_RECEIVE
- RECEIVE_ALLOCATE
- RECEIVE_AND_WAIT
- REQUEST_TO_SEND
- SEND_CONVERSATION
- SEND_DATA
- SEND_ERROR
- TP_ENDED
- TP_STARTED

APPC verbs used in mapped conversations that can block are as follows:

- MC_ALLOCATE
- MC_CONFIRM
- MC_CONFIRMED
- MC_DEALLOCATE
- MC_FLUSH
- MC_PREPARE_TO_RECEIVE
- MC_RECEIVE_AND_WAIT
- MC_REQUEST_TO_SEND
- MC_SEND_CONVERSATION
- MC_SEND_DATA
- MC_SEND_ERROR
- RECEIVE_ALLOCATE
- TP_ENDED
- TP_STARTED

When using the synchronous or asynchronous versions of a verb, an application can only have one outstanding function in progress on a conversation at a time. An attempt to initiate a second function results in the error code AP_CONV_BUSY.

> The exceptions to the preceding paragraph are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT. To allow full use of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT** verbs have been altered to act like the **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** verbs. Specifically, while an asynchronous version of one of these verbs is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES or MC_GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND or MC_REQUEST_TO_SEND
- SEND_ERROR or MC_SEND_ERROR
- TEST_RTS or MC_TEST_RTS
- TP_ENDED

This allows an application, in particular, a server application, to use an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** or **MC_SEND_ERROR** and **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support, and in particular, for support of multiple conversations on the same thread.

When the asynchronous operation is complete, the application is notified through the **GetQueuedCompletionStatus** function. Upon I/O completion, examine the APPC primary return code and secondary return code in the verb control block for any error conditions.

WinAPPCCancelAsyncRequest

The **WinAPPCCancelAsyncRequest** function cancels an outstanding WinAsyncAPPC-based request.

```
int WINAPI WinAPPCCancelAsyncRequest(
    HANDLE hAsyncTaskID
);
```

Parameters

hAsyncTaskID
Supplied parameter. Specifies the asynchronous task to be canceled.

Return Values

The return value specifies whether the asynchronous request was canceled. If the value is zero, the request was canceled. Otherwise, the value is one of the following:

WAPPCINVALID
An error code indicating that the specified asynchronous task identifier was invalid.
WAPPCALREADY
An error code indicating that the asynchronous routine being canceled has already completed.

Remarks

An asynchronous task previously initiated by issuing one of the **WinAsyncAPPC**, **WinAsyncAPPCEx**, or **WinAsyncAPPCIOCP** functions can be canceled prior to completion by issuing the **WinAPPCCancelAsyncRequest** function, specifying the asynchronous task identifier as returned by the initial function in *hAsyncTaskID*.

If the outstanding verb relates to a conversation (for example, SEND_DATA or RECEIVE_AND_WAIT), the verb is purged and the session is closed. If the verb relates to a TP (for example, RECEIVE_ALLOCATE or TP_STARTED), the TP is ended. In both cases, while the implementation closes conversations and sessions as cleanly as possible, it does not flush send buffers, wait for confirmations, and so on. This call is synchronous, and after the processing described above is complete, a completion message is posted for the canceled verb.

If an attempt to cancel an existing asynchronous **WinAsyncAPPC** routine fails with an error code of WAPPCALREADY, one of two things has occurred. Either the original routine has already completed and the application has dealt with the resulting message, or the original routine has already completed and the resulting message is still waiting in the application window queue.

WinAPPCCancelBlockingCall

The **WinAPPCCancelBlockingCall** function cancels any outstanding blocking operation for its thread. Any outstanding blocked call canceled will cause an error code of WAPPCCANCEL to be generated.

```
BOOL WINAPI WinAPPCCancelBlockingCall(void);
```

Return Values

The return value specifies whether the cancellation request was successful. If the value is zero, the request was canceled. Otherwise, the value is the following:

WAPPCINVALID
An error code indicating that there is no outstanding blocking call.

Remarks

If the outstanding verb relates to a conversation (for example, SEND_DATA or RECEIVE_AND_WAIT), the verb is purged and the session is closed. If the verb relates to a TP (for example, RECEIVE_ALLOCATE or TP_STARTED), the TP is ended. In both cases, while the implementation brings down conversations and sessions as cleanly as possible, it does not flush send buffers, wait for confirmations, and so on. This call is synchronous and after the processing described above is complete, the function is finished.

In Microsoft® Windows 2000, Windows NT®, Microsoft® Windows® 98, and Microsoft® Windows® 95, a multithreaded application can have multiple blocking operations outstanding, but only one per thread. To distinguish between multiple outstanding calls, **WinAPPCCancelBlockingCall** cancels the outstanding operation on the current, or calling, application thread if one exists; otherwise, it fails. By default in Windows 2000, Windows NT, Windows 98, and Windows 95, Windows APPC suspends the calling application thread while an operation is outstanding. As a result, the thread on which the blocking operation was initiated will not regain control (and therefore, will not be able to issue a call to **WinAPPCCancelBlockingCall**) unless a blocking hook is registered for the thread using WinAPPCSetBlockingHook. This condition does not apply to Microsoft® Windows® version 3*.x* since applications only have one effective thread and the default blocking hook is registered by default.

WinAPPCCleanup

The **WinAPPCCleanup** function terminates and deregisters an application from a Windows APPC implementation.

```
BOOL WINAPI WinAPPCCleanup(void);
```

Return Values

The return value specifies whether the deregistration was successful. If the value is nonzero, the application was successfully deregistered. The application was not deregistered if a value of zero is returned.

Remarks

Use **WinAPPCCleanup** to indicate deregistration of a Windows APPC application from a Windows APPC implementation.

Conversations that are still active will be terminated and TPs ended. This function is equivalent to issuing TP_ENDED(HARD) on all TPs owned by the application.

See Also

WinAPPCStartup

WinAPPCIsBlocking

The **WinAPPCIsBlocking** function determines if a thread is executing while waiting for a previous blocking call to finish.

```
BOOL WINAPI WinAPPCIsBlocking(void);
```

Return Values

The return value specifies the outcome of the function. If the value is nonzero, there is an outstanding blocking call awaiting completion. A zero indicates the absence of an outstanding blocking call.

Remarks

Although a call issued on a blocking function appears to an application as though it blocks, the Windows APPC DLL has to relinquish the processor to allow other applications to run. This means that it is possible for the application that issued the blocking call to be re-entered, depending on the message(s) it receives. In this instance, the **WinAPPCIsBlocking** call can be used to determine whether the application task currently has been re-entered while waiting for an outstanding blocking call to finish. Note that Windows APPC prohibits more than one outstanding blocking call per thread.

The Windows APPC DLL prohibits more than one blocking call per thread and returns AP_THREAD_BLOCKING if this occurs.

See Also

WinAPPCSetBlockingHook, WinAPPCUnhookBlockingHook, WinAPPCCancelBlockingCall

WinAPPCStartup

The **WinAPPCStartup** function allows an application to specify the version of Windows APPC required and to retrieve details of the specific Windows APPC implementation. An application must call this function to register itself with a Windows APPC implementation before issuing any further Windows APPC calls.

```
int WINAPI WinAPPCStartup(
    WORD wVersionRequired,
    LPWAPPCDATA lpAPPCData
);

typedef struct {
    WORD wVersion;
    char szDescription[WAPPCDESCRIPTION_LEN+1];
} WAPPCDATA, FAR * LPWAPPCDATA;

where WAPPCDESCRIPTION_LEN is defined as 127
```

Parameters

wVersionRequired
Specifies the version of Windows APPC support required. The high-order byte specifies the minor version (revision) number; the low-order byte specifies the major version number. The current version of the Windows APPC API is 1.0.

lpAPPCData
Pointer to a returned structure containing a Windows APPC version number and a description of the Windows APPC implementation.

Return Values

The return value specifies whether the application was registered successfully and whether the Windows APPC implementation can support the specified version number. If the value is zero, it was registered successfully and the specified version can be supported. Otherwise, the return value is one of the following:

WAPPCSYSNOTREADY
The underlying network subsystem is not ready for network communication.

WAPPCVERNOTSUPPORTED
The version of Windows APPC support requested is not provided by this particular Windows APPC implementation.

WAPPCINVALID
The Windows APPC version specified by the application is not supported by this DLL.

Remarks

To support future Windows APPC implementations and applications that may have functionality differences from Windows APPC version 1.0, a negotiation takes place in **WinAPPCStartup**. An application passes to **WinAPPCStartup** the Windows APPC version that it can use. If this version is lower than the lowest version supported by the Windows APPC DLL, the DLL cannot support the application and **WinAPPCStartup** fails. If the version is not lower, however, the call succeeds and returns the highest version of Windows APPC supported by the DLL. If this version is lower than the lowest version supported by the application, the application either fails its initialization or attempts to find another Windows APPC DLL on the system.

This negotiation allows both a Windows APPC DLL and a Windows APPC application to support a range of Windows APPC versions. An application can successfully use a DLL if there is any overlap in the versions. The following table illustrates how **WinAPPCStartup** works in conjunction with different application and DLL versions.

Application versions	DLL versions	To WinAPPCStartup	From WinAPPCStartup	Result
1.0	1.0	1.0	1.0	Use 1.0
1.0, 2.0	1.0	2.0	1.0	Use 1.0
1.0	1.0, 2.0	1.0	2.0	Use 1.0
1.0	2.0, 3.0	1.0	WAPPCINVALID	Fail
2.0, 3.0	1.0	3.0	1.0	App Fails
1.0, 2.0, 3.0	1.0, 2.0, 3.0	3.0	3.0	Use 3.0
1.0	1.0	4.0	1.0	App Fails
1.0, 2.0, 3.0, 4.0	1.0, 2.0, 3.0, 4.0	4.0	4.0	Use 4.0

Details of the actual Windows APPC implementation are described in the **WAPPCDATA** structure defined as follows that is

returned by **WinAPPCStartup**:

```
typedef struct tagWAPPCDDATA { WORD wVersion;
char szDescription[WAPPCDESCRIPTION_LEN+1];
} WAPPCDATA, FAR *LPWAPPCDATA;
```

The structure members are as follows:

wVersion
The highest APPC version number supported by the Windows APPC DLL.
szDescription
A descriptive string describing the WinAPPC implementation.

After it makes its last Windows APPC call, an application should call the WinAPPCCleanup routine.

Each Windows APPC implementation must make a **WinAPPCStartup** call before issuing any other Windows APPC calls.

WinAPPCSetBlockingHook

The **WinAPPCSetBlockingHook** function allows a Windows APPC implementation to block APPC function calls by means of a new function. This call is used by Microsoft® Windows® version 3.*x* applications to make blocking calls without blocking the rest of the system. By default in Microsoft® Windows NT®, Windows 95, and Windows 98, blocking calls suspend the calling application's thread until the request is finished. Therefore, if a single-threaded application is targeted at both Windows 2000, Windows NT, Windows 98, Windows 95, and Windows version 3.*x*, and relies on this functionality, it should register a blocking hook even if the default hook will suffice.

```
FARPROC WINAPI WinAPPCSetBlockingHook (
    FARPROC lpBlockFunc
);
```

Parameters

lpBlockFunc
Specifies the procedure instance address of the blocking function to be installed.

Return Values

The return value points to the procedure instance of the previously installed blocking function. The application or library that calls **WinAPPCSetBlockingHook** should save this return value so that it can be restored if needed. (If nesting is not important, the application can simply discard the value returned by **WinAPPCSetBlockingHook** and eventually use WinAPPCUnhookBlockingHook to restore the default mechanism.)

Remarks

A Windows APPC implementation has a default mechanism by which blocking APPC functions are implemented. This function gives the application the ability to execute its own function at blocking time in place of the default function.

The default blocking function is equivalent to:

```
BOOL DefaultBlockingHook (void)  {
    MSG msg;
    /* get the next message if any */
    if ( PeekMessage (&msg,0,0,PM_NOREMOVE)  )  {
        if ( msg.message = = WM_QUIT  )
            return FALSE;   // let app process WM_QUIT
        PeekMessage (&msg,0,0,PM_REMOVE) ;
        TranslateMessage (&msg) ;
        DispatchMessage (&msg) ;
    }
    /* TRUE if no WM_QUIT received */
    return TRUE;
}
```

A blocking function must return FALSE if it receives a WM_QUIT message so Windows APPC can return control to the application to process the message and terminate gracefully. Otherwise, the function should return TRUE.

This function is implemented on a per-thread basis. It provides for a particular thread to replace the blocking mechanism without affecting other threads.

The **WinAPPCSetBlockingHook** function is provided to support those applications that require more complex message processing—for example, those employing the multiple document interface (MDI) model.

See Also

WinAPPCIsBlocking, WinAPPCCancelBlockingCall

WinAPPCUnhookBlockingHook

The **WinAPPCUnhookBlockingHook** function removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism.

```
BOOL WINAPI WinAPPCUnhookBlockingHook(void);
```

Return Values

The return value specifies the outcome of the function. It is nonzero if the default mechanism is successfully reinstalled. The value is zero if the mechanism did not reinstall.

WinAPPCSetBlockingHook

Host Integration Server 2000 Enhancements to the Windows Environment

This section describes the Microsoft® Host Integration Server 2000-specific extensions to Windows APPC and the Common Service Verb (CSV) API.

The GetAppcConfig function takes a local LU and returns the remote LUs that are accessible to the user through that LU. If left blank, and a default local LU has been configured, the user's default local LU will be used. In all instances, if one of the returned remote LUs is the user's default, this is indicated as such. For more information on configuring default local and remote LUs, see the *Microsoft Host Integration Server 2000 online books*. The call is asynchronous and completion is normally signaled by the posting of a Windows message. However, an alternative completion mechanism is provided for console applications.

The GetAppcReturnCode and GetCsvReturnCode functions convert the primary and secondary return codes in the verb control block (VCB) to a printable string. These functions provide a standard set of error strings for use by applications.

For each extension, this section provides a definition of the function, syntax, returns, and remarks for using the function.

GetAppcConfig

The **GetAppcConfig** function provides an asynchronous entry point for retrieving the remote systems to which a particular local LU can connect.

```
HANDLE WINAPI GetAppcConfig(
    HANDLE hWnd,
    LPSTR pLocalLu,
    LPSTR pMode,
    LPINT pNumRemLu,
    INT iMaxRemLu,
    PSTR pRemLu,
    LPINT pAsyncRetCode
);
```

Parameters

hWnd
Supplied parameter. Contains the handle of the window that is to receive an asynchronous completion message when the call has completed. If non-null, the completion message will be posted to this window handle. In this case, *pAsyncRetCode* (the last parameter) must be null. Asynchronous message completion is the recommended approach for a Windows applications to use this function.

pLocalLu
Supplied parameter. Specifies the address of a buffer containing the local LU name for which information is returned. This local LU name must be specified as follows:

- Nonpadded
- Null-terminated
- ASCII string
- Maximum length of eight bytes (excluding the terminator)

To request that the user's default local LU be used, the buffer should contain eight spaces followed by a null.

pMode
Supplied parameter. Specifies the address of a buffer containing the mode name for which information is returned. In Microsoft® SNA Server version 3.0 and later this parameter is not used, but for compatibility with earlier versions of SNA Server a mode name must be specified as follows:

- Nonpadded
- Null-terminated
- ASCII string
- Maximum length of eight bytes (excluding the terminator)

pNumRemLu
Supplied parameter. Specifies the address of an integer variable that when the function completes will contain the number of remote LUs that would have been returned, had the buffer specified by *pRemLu* been large enough to accommodate all of the remote LUs.

iMaxRemLu
Supplied parameter. Specifies the number of remote LU names that can be held by the buffer indicated by *pRemLu*.

pRemLu
Supplied parameter. Specifies the address of the buffer that will hold the remote LU names after the function completes. The information will be returned as an array of strings. Each remote LU name will be stored in the buffer as follows:

- Nonpadded
- Null-terminated
- ASCII string
- Maximum length of eight bytes (excluding the terminator)

The strings start every nine bytes in the buffer, and thus (*pRemLu* + (*i*–1)*9) gives the start of the *i*th string. In the case where the buffer is too small to hold all the names, only *iMaxRemLu* strings will be returned.

pAsyncRetCode

Supplied parameter. Specifies the address of an integer variable used to store the return code from this function, if the supplied address is non-null. The return codes will be the same as those returned by an asynchronous completion message. While the call is completing, the value of the this variable will be APPC_CFG_PENDING. When this asynchronous call is completed, the value of this variable will contain some return code other than APPC_CFG_PENDING.

This variable is used by polling for completion when asynchronous message completion to a window handle is not used.

Note that if *pAsyncRetCode* is used, *hWnd* must be null.

Return Values

The meaning of the immediate return value depends on whether or not the asynchronous request was accepted. To test for acceptance, evaluate the expression:

(<*Returned Handle*> & APPC_CFG_SUCCESS)

If the expression is FALSE, the request was rejected. The return value is then one of the synchronous return codes in the following list. If the expression is TRUE, the request was accepted, and one of the following cases will apply.

- If *hWnd* was non-null, a completion message will arrive in the following form:

Message parameter	**Description**
hWnd	The handle of the target window. This value is the same as the value passed in hWnd on the initial call.
uMsg	Matches the number returned by a call to **RegisterWindowMessage**, with WinAppcCfg used as the identifying string. This string is available by the **#define WIN_APPC_CFG_COMPLETION_MSG**.
wParam	Matches the HANDLE returned from the initial call. It is used as a correlator.
lParam	Contains one of the asynchronous return codes in the following list.

- If *pAsyncRetCode* was non-null, then the specified integer variable will be set to APPC_CFG_PENDING. After this function completes asynchronously, its value will change to one of the asynchronous return codes listed below.

Synchronous Return Codes

APPC_CFG_ERROR_NO_APPC_INIT

The Windows APPC library needs to be initialized by a call to WinAPPCStartup before calling **GetAPPCConfig** and this has not been done.

APPC_CFG_ERROR_INVALID_HWND

The handle passed in *hWnd* was non-null, yet not a valid window handle.

APPC_CFG_ERROR_BAD_POINTER

The *hWnd* parameter was null, indicating that completion was signaled by setting the integer variable pointed to by *pAsyncRetCode*, but *pAsyncRetCode* was not a valid pointer.

APPC_CFG_ERROR_UNCLEAR_COMPLETION_MODE

Both *hWnd* and *pAsyncCompletion* were non-null, so **GetAPPCConfig** was unable to decide how completion should be signaled.

APPC_CFG_ERROR_TOO_MANY_REQUESTS

Too many **GetAPPCConfig** calls are already being processed (currently, this indicates 16 requests are outstanding). Try the call again after a delay. For the Microsoft® Windows® version 3.*x* system, you must yield during this period.

APPC_CFG_ERROR_GENERAL_FAILURE

An unexpected error occurred, probably of a system nature.

Asynchronous Return Codes

APPC_CFG_SUCCESS_NO_DEFAULT_REMOTE

The configuration information has been retrieved, and either no default remote LU was defined or it was not accessible by the specified local LU.

APPC_CFG_SUCCESS_DEFAULT_REMOTE

The configuration information has been retrieved, and there is a default remote LU that is accessible by the specified local LU.

APPC_CFG_ERROR_NO_DEFAULT_LOCAL_LU

An attempt was made to retrieve remote LUs partnered with the default local LU, but no default local LU was configured.

APPC_CFG_ERROR_BAD_LOCAL_LU

The local LU specified is either not configured, or is not valid for the calling verb.

APPC_CFG_ERROR_GENERAL_FAILURE

An unexpected error occurred, probably of a system nature.

Remarks

WinAPPCStartup must be called before using **GetAPPCConfig**.

Whether an error code represents success or failure can be determined by evaluating either (*RetCode&* APPC_CFG_SUCCESS) to test for success or (*RetCode&* APPC_CFG_FAILURE) to test for failure.

The following code fragment shows how a console application can test completion:

```
while (*pAsyncRetCode == APPC_CFG_PENDING)
{
    sleep(250);
}
```

GetAppcReturnCode

The **GetAppcReturnCode** function converts the primary and secondary return codes in the verb control block to a printable string. This function provides a standard set of error strings for use by APPC applications such as 5250 emulators.

```
int WINAPI GetAppcReturnCode(
    struct appc_hdr FAR * vpb,
    UINT buffer_length,
    unsigned char FAR * buffer_addr
);
```

Parameters

vpb
Supplied parameter. Specifies the address of the verb control block.

buffer_length
Supplied parameter. Specifies the length of the buffer pointed to by *buffer_addr*. The recommended length is 256.

buffer_addr
Supplied parameter. Specifies the address of the buffer that will hold the formatted, null-terminated string.

Return Values

The **GetAppcReturnCode** function returns a positive value on success that indicates the length of the error string passed back in *buffer_addr*.

A return value of zero indicates an error. On Microsoft® Windows 2000, Windows NT®, Windows® 98, and Windows® 95, a call to **GetLastError** provides the actual error return code as follows:

0x20000001
The parameters are invalid; the function could not read from the specified verb control block or could not write to the specified buffer.

0x20000002
The specified buffer is too small.

0x20000003
The APPC string library APPCSTR.DLL (for Windows) or APPCST32.DLL (for Windows 2000, Windows NT, Windows 98, and Windows 95) could not be loaded.

Remarks

The descriptive error string returned in *buffer_addr* does not terminate with a new line character (**\n**).

The descriptive error strings are contained in APPCSTR.DLL (for Windows version 3.*x*) or APPCST32.DLL (for Windows 2000, Windows NT, Windows 98, and Windows 95) and can be customized for different languages.

GetCsvReturnCode

The **GetCsvReturnCode** function converts the primary and secondary return codes in the verb control block to a printable string. This function provides a standard set of error strings for use by applications using CSVs.

```
int WINAPI GetCsvReturnCode(
    struct csv_hdr FAR * vpb,
    UINT buffer_length,
    unsigned char FAR * buffer_addr
);
```

Parameters

vpb
Supplied parameter. Specifies the address of the verb control block.

buffer_length
Supplied parameter. Specifies the length of the buffer pointed to by *buffer_addr*. The recommended length is 256.

buffer_addr
Supplied parameter. Specifies the address of the buffer that will hold the formatted, null-terminated string when the function completes.

Return Values

The **GetCsvReturnCode** function returns a positive value on success that indicates the length of the error string passed back in *buffer_addr*.

A return value of zero indicates an error. On Microsoft® Windows 2000, Windows NT®, Windows 98, and Windows 95, a call to **GetLastError** provides the actual error return code as follows:

0x20000001
The parameters are invalid; the function could not read from the specified verb parameter block or could not write to the specified buffer.

0x20000002
The specified buffer is too small.

0x20000003
The CSV string library CSVSTR.DLL (for Microsoft® Windows® version 3.*x*) or CSVST32.DLL (for Windows NT, Windows 95, and Windows 98) could not be loaded.

Remarks

The descriptive error string returned in *buffer_addr* does not terminate with a newline character (**\n**).

The descriptive error strings are contained in CSVSTR.DLL (for Windows version 3.*x*) or CSVST32.DLL (for Windows NT, Windows 95, and Windows 98) and can be customized for different languages.

Common Service Verbs

This section describes each of the CSVs and provides:

- A definition of the verb.
- The structure that defines the VCB used by the verb. The structure is declared in the WINCSV.H file.
- The parameters (VCB fields) supplied to and returned by the verb. A description of each parameter is provided, along with its possible values and other information.
- Additional information describing the use of the verb.

Most parameters supplied to and returned by CSVs are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the header file WINCSV.H. For example, the **opcode** (operation code) parameter for CONVERT is the hexadecimal value represented by the symbolic constant SV_CONVERT. Use only the symbolic constants when programming CSVs.

CONVERT

The **CONVERT** verb translates an ASCII character string to EBCDIC or an EBCDIC character string to ASCII. The string to be converted is called the source string. The converted string is called the target string.

The following structure describes the verb control block used by the **CONVERT** verb.

```
struct convert {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        direction;
    unsigned char        char_set;
    unsigned short       len;
    unsigned char FAR * source;
    unsigned char FAR * target;
};
```

Members

opcode
Supplied parameter. The verb identifying the operation code, SV_CONVERT.

opext
A reserved field.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

direction
Supplied parameter. Specifies the direction of the conversion. To convert from ASCII to EBCDIC, use SV_ASCII_TO_EBCDIC. To convert from EBCDIC to ASCII, use SV_EBCDIC_TO_ASCII.

char_set
Supplied parameter. Specifies the character set to use in converting the source string. Allowed values include SV_A (type A character set), SV_AE (type AE character set), and SV_G (user-defined type G character set).

len
Supplied parameter. Specifies the number of characters to be converted.

This length plus the offset from the beginning of the source or target buffer must not exceed the segment boundary.

source
Supplied parameter. Specifies the address of the buffer containing the character string to be converted.

target
Supplied parameter. Specifies the address of the buffer to contain the converted character string.

This buffer can overlap or coincide with the buffer pointed to by the **source** parameter. In this case, the converted data string overwrites the source data string.

Return Codes

SV_OK
Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK
Primary return code; the verb did not execute because of a parameter error.

SV_CONVERSION_ERROR

Secondary return code; one or more characters in the source string were not found in the conversion table. These characters were converted to nulls (0x00). The verb still executed.

SV_INVALID_CHARACTER_SET

Secondary return code; the **char_set** parameter contained an invalid value.

SV_INVALID_DATA_SEGMENT

Secondary return code; the data buffer containing the source or target string did not fit in one segment, or the target segment was not a read/write segment. This applies only to the Microsoft® Windows 2000, Microsoft® Windows NT®, Microsoft® Windows® 98, Microsoft® Windows® 95, Microsoft® Windows version 3.*x*, and OS/2 operating systems.

SV_INVALID_DIRECTION

Secondary return code; the direction contained an invalid value.

SV_INVALID_FIRST_CHARACTER

Secondary return code; the first character of a type A source string was invalid.

SV_TABLE_ERROR

Secondary return code; one of the following occurred:

- The file containing the user-written type G conversion table was not specified by the environment variable **CSVTBLG**.
- The table was not in the correct format.
- The file specified by the **CSVTBLG** variable was not found.

SV_COMM_SUBSYSTEM_NOT_LOADED
Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_INVALID_VERB
Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT
Primary return code; the VCB extended beyond the end of the data segment.

SV_UNEXPECTED_DOS_ERROR
Primary return code; one of the following conditions occurred:

- The Microsoft® Windows 2000, Microsoft® Windows NT, Microsoft® Windows 98, Microsoft® Windows 95, Microsoft® Windows version 3.*x*, Microsoft® MS-DOS®, or OS/2 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.
- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.
- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

Remarks

The type A character set consists of:

- Uppercase letters.
- Numerals 0 through 9.
- Special characters $, #, @, and space.

This character set is supported by a system-supplied type A conversion table.

The first character of the source string must be an uppercase letter or the special character $, #, or @. Spaces are allowed only in trailing positions. Lowercase ASCII letters are translated to uppercase EBCDIC letters when the direction is ASCII to EBCDIC.

The type AE character set consists of:

- Uppercase letters.
- Lowercase letters.
- Numerals 0 through 9.
- Special characters $, #, @, period, and space.

This character set is supported by a system-supplied type AE conversion table.

The first character of the source string can be any character in the character set, except the space. Spaces are allowed only in trailing positions.

During conversion, embedded blanks (including blanks in the first position) are converted to 0x00. Although such a conversion will complete, CONVERSION_ERROR is returned as the secondary return code, indicating that the CSV library has completed an irreversible conversion on the supplied data.

For Windows 2000 or Windows NT, a description of **COMTBLG** should point to the Windows 2000 or Windows NT registry under **\SnaBase\Parameters\Client**. For Windows version 3.*x*, the fully qualified file name for a type G conversion table must be the **COMTBLG**=*filename* entry of the [WNAP] section in the WIN.INI file. Entries in this section of the WIN.INI file are used in all places where MS-DOS and OS/2 use environment variables. (If the file is not found, the system returns the parameter check SV_TABLE_ERROR.)

The data for a type G conversion table must be an ASCII file 32 lines long. Each line must consist of 32 hexadecimal digits, representing 16 characters, and be terminated by a carriage return and line feed. The first 16 lines (256 characters) specify the EBCDIC characters to which ASCII characters are converted; the remaining 16 lines specify the ASCII characters to which EBCDIC characters are converted.

The hexadecimal digits A through F can be either uppercase or lowercase. However, you may want to make these digits uppercase to ensure compatibility with IBM ES for OS/2 version 1.0.

> **Note** You can use GET_CP_CONVERT_TABLE to build a type G user-written conversion table in memory, and then store the table in a file.

COPY_TRACE_TO_FILE

The **COPY_TRACE_TO_FILE** verb concatenates individual API/link service trace files to form a single file.

The following structure describes the verb control block used by the **COPY_TRACE_TO_FILE** verb.

```
struct copy_trace_to_file {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        reserv3[8];
    unsigned char        file_name[64];
    unsigned char        file_option;
    unsigned char        reserv4[12];
};
```

Members

opcode
Supplied parameter. The verb identifying the operation code, SV_COPY_TRACE_TO_FILE.

opext
A reserved field.

reserv2
A reserved field.

primary_rc
Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc
Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3
A reserved field.

file_name
Supplied parameter. Specifies the name of the file to which trace data is to be copied. This parameter is a 64-byte character string, and it can include a path. If the name is fewer than 64 bytes, use spaces to pad it on the right.

file_option
Supplied parameter. Specifies the output file copy option:

- Use SV_NEW to copy the trace only if the specified file does not already exist.
- Use SV_OVERWRITE to copy the trace to an existing file, overwriting the current data. The size of the file is increased if necessary; and the file is created if it does not already exist.

reserv4
The address at which supplied data resides.

Return Codes

SV_OK
Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK
