XNA Game Studio 3.1

Microsoft XNA Game Studio 3.1 is a set of tools based on supported versions of Microsoft Visual Studio tools that allow students and hobbyists to build games for Microsoft Windows, the Microsoft Xbox 360 video game and entertainment system, and Microsoft Zune. XNA Game Studio also includes the XNA Framework, which is a set of managed libraries based on the Microsoft .NET Framework 2.0 that are designed for game development. This documentation collection contains technology overviews, tutorials, and reference material related to XNA Game Studio.

General Questions

Is XNA Game Studio 3.1 Supported on Windows 7 Beta?

XNA Game Studio 3.1 has been tested on Windows 7 Beta. Support for the final release of Windows 7 is expected after it becomes available.

How do I file bugs or make suggestions?

- Sign up for Microsoft Connect at <http://connect.microsoft.com> and click the **XNA Game Studio** connection under available connections.
- After you sign up, you can file a bug or make a suggestion by selecting [Feedback](#) on the **Connect: XNA Game Studio** page.

Is Visual Studio supported with XNA Game Studio?

Yes. XNA Game Studio is designed to install custom extensions to supported versions of Microsoft Visual Studio tools, such as Microsoft Visual Studio 2008 Professional Edition, Microsoft Visual Studio 2008 Standard Edition, and Microsoft Visual C# 2008 Express Edition.

For a complete list of supported editions, see [Microsoft Visual Studio 2008](#) and [Microsoft Visual C# Express Edition](#).

Can I use an earlier version of an XNA Game Studio game project with XNA Game Studio 3.1?

XNA Game Studio 3.1 supports both 3.0 and 3.1 projects, and it includes support for upgrading projects from 3.0 to 3.1.

For more information, please see [Upgrading XNA Game Studio Projects](#).

Can I target Windows, Xbox 360 and/or Zune platforms with the same solution?

Yes. See [Developing Cross-Platform Games](#) for details on how to create and manage games for multiple platforms. This includes information on converting a game project meant for one platform into one to run on another platform, such as a Windows game project into an Xbox 360 console and/or a Zune game project, keeping all projects in the same solution.

Do I need a connection to Xbox LIVE to play my XNA Framework game?

XNA Game Studio Connect requires a connection to Xbox LIVE at all times.

If I have written a multiplayer game, must the player with the XNA Creators Club membership sign in first?

In the event that multiple people wish to play a local multiplayer XNA Framework game, it is essential that the player with a valid XNA Creators Club membership sign in first before launching XNA Game Studio Connect. After launch, additional profiles can then sign in to play.

If multiple profiles on a single Xbox 360 console have a valid XNA Creators Club membership, the connection settings that are used by XNA Game Studio Connect will always default to player one.

How do I distribute my game?

See [Sharing and Distributing Your Game](#).

My computer cannot connect to my Xbox 360 console. What should I do?

This may indicate issues with your network settings, connection key, file names, or file system. Please see [Troubleshooting Xbox 360 Game Deployment](#) for detailed descriptions of these issues.

My computer cannot connect to my Zune device. What should I do?

This may indicate issues with your physical connection, Zune settings or state. Please see [Troubleshooting Zune Game](#)

[Deployment](#) for detailed descriptions of these issues.

What do I do to fix the error message "NoSuitableGraphicsDeviceException was unhandled"?

Check the inner exception for more detail on why the graphics device could not be created. XNA Game Studio thoroughly checks why the graphics device could not be created and reports these checks in the inner exception.

If **NoSuitableGraphicsDeviceException** does not have an inner exception, it is likely that your graphics card does not have a DirectX 9 driver, that it does not support Shader Model 1.1, or that the hardware acceleration slider is not set to **Full** in your settings.

To determine the version of DirectX installed on the computer

1. Click **Start**, and then click **Run**.
2. In the **Open** box, type **dxdiag**, and then click **OK**.

The **System** tab will display information about the version of DirectX that is installed on the computer.

To set hardware acceleration to Full on Windows XP

1. Right-click the desktop, and then click **Properties** on the menu.
2. Click the **Settings** tab, and then click **Advanced**.
3. Click the **Troubleshoot** tab.
4. Move the **Hardware Acceleration** slider until it is set to **Full**.
5. Click **OK**, and then click **Close**.

To set hardware acceleration to Full on Windows Vista

1. Right-click the desktop, and then click **Personalize** on the displayed context menu.
2. Click **Display Settings**
3. Click **Advanced Settings....**
4. Click the **Troubleshoot** tab.
5. Click the **Change Settings** button, then move the **Hardware Acceleration** slider until it is set to **Full**.

Note that for display adapters that do not allow hardware acceleration to be changed, the **Change Settings** button may be disabled.

6. Click **OK** on the three open dialog boxes.

To determine which shader models are supported

Please see [How To: Check for Shader Model 2.0 Support](#) for information about how to programmatically query the shader capabilities of the graphics card.

How do I playback video with XNA Game Studio?

The XNA Framework supports video playback for purposes such as opening splash and logo scenes, cut scenes, or in-game video displays.

For more information, please see [How To: Play Video](#) and [How To: Play a Video in 3D space](#).

Why does my application work from my local computer, but throw SecurityException when I move it to a shared network folder?

This is a security feature of the Common Language Runtime (CLR). Applications that are run from locations other than the local system have greater security restrictions than applications run locally. Running XNA Game Studio titles from a shared network folder is not supported.

What shader models does XNA Game Studio support?

XNA Game Studio supports all the DirectX 9 shader models (versions 1.x, 2.x, and 3.0) on Windows, along with some variants. For a full list of supported shaders, see the [ShaderProfile](#) enumeration.

On Xbox 360, XNA Game Studio supports Shader Model 2.0 and an extended variant of 3.0 customized for the Xbox 360.

Some starter kits may have more restrictive requirements.

Can I use the delay sign feature for my Xbox 360 game?

Use of delay signing can prevent the game from running on the Xbox 360, because the console uses strong name verification. Under strong name verification, the assemblies will not load until the signing process is complete.

When debugging, sometimes my full-screen game crashes and I am unable to return to Visual Studio. What can I do besides rebooting my computer?

When a program takes over the graphics device, sometimes it is unable to properly return the graphics device to Windows after a crash. Try the following:

1. Press the **Windows** button or CTRL+ESC to bring up the **Start** menu.

Sometimes this will restore the task bar, allowing you to bring up Visual Studio.

2. Press ALT+TAB to return focus to Visual Studio, then SHIFT+F5 to stop the program you are debugging.

Sometimes you may have to press ALT+TAB a few times to return the focus to Visual Studio before pressing SHIFT+F5.

3. Press CTRL+ALT+DELETE to attempt to bring up the Windows Security window.

If the Windows Security window comes up, you can use Task Manager to end the task running your game and return to Visual Studio.

If those steps are unsuccessful, the only option might be to reboot the computer.

3D Graphics

How do I create lighting and material effects in XNA Game Studio?

Lights and materials are implemented in XNA Game Studio with effects. To implement lighting or material effects, create an effect that contains the desired vertex or pixel color transformation. The actions of a simple effect are encapsulated in the [BasicEffect](#) class, which provides functionality for applying lights and materials, and setting world, view, and projection transformations. You may choose to use [BasicEffect](#) for simple functionality or create your own effects using the [Effect](#) class.

How do I create my own effects?

For a sample of a simple effect using the [Effect](#) class that sets the diffuse color of a vertex, see [How To: Create and Apply Custom Effects](#).

What is an effect file?

An effect is a combination of vertex and pixel shader code grouped together to encapsulate a particular rendering technique. Effects can be written in either high-level shader language (HLSL) or assembly code.

An effect file contains effect code. You may see effect files with an .fx extension that contain HLSL code. Effects in HLSL or assembly code must be compiled to a binary format before they can be used in an application.

For overviews of HLSL and the effect file format, see the [HLSL Shaders](#) and [Effects](#) DirectX Programming Guides on MSDN. Complete reference documentation for HLSL, shader ASM, and the effect file format is available in the [Direct3D API Reference](#).

After drawing using Graphics.SpriteBatch, why do my 3D objects draw incorrectly?

By default, [SpriteBatch.Begin](#) does not save your current render state, and will change certain render state properties that may make 3D objects render incorrectly. You can choose to either reset the render state yourself after the call to [SpriteBatch.End](#), or call [SpriteBatch.Begin](#) and pass in [SaveStateMode.SaveState](#), which will restore the render state after sprites are drawn.

Can I use PIX for Windows from the DirectX SDK with an XNA framework game?

Yes. PIX sees XNA Framework games as just another DirectX game and will expose information about the DirectX calls made by your XNA Framework game, including shader rendering. To use PIX with an XNA Framework game, start a New Experiment in PIX and enter your game executable path into the Program Path edit box. Then choose the information you want to gather and push Start Experiment.

For more information on how to use PIX, see the DirectX SDK documentation.

Input

Can I map the Xbox Guide button on the Xbox 360 Controller to an action?

No. The **Xbox Guide** button is reserved.

My mouse cursor is not visible. How can I make it visible?

Mouse support is available only for Windows. Set the [Game.IsMouseVisible](#) property to **true**.

The Xbox 360 Controller does not work properly in Windows. How can I correct this?

For the Xbox 360 Controller to work correctly in Windows, you need to install the latest Xbox 360 Controller driver. You can download this driver from [Microsoft Hardware Download Gaming Software](#).

Audio

Can I load and play a wave file from the Audio API without using the XACT tool?

Yes, make a call to the [Play](#) method. For more information, see [How To: Play a Sound](#).

How can I get more information on using XACT?

For an easy guide to adding sound files to an XACT project and playing them, see [How To: Add a Sound File to Your Game Using XACT](#) and [How To: Play a Sound Using XACT](#). For detailed information on how to author audio in the XACT tool, including information on categories, variables, and other advanced features, see [XACT Audio Authoring](#).

Why does calling GetCue from SoundBank never return a cue?

In your XACT project, you may have set a sound bank property called **IncludeCueNames** to **false**. For each sound bank in your project, this property must be set to **true**. Open XACT, load your project, and click each of your sound banks in the project tree view. Check the value of **IncludeCueNames** in the property pane as you click each sound bank. If any of these values are set to **false**, set them to **true** and rebuild your project.

Math

What coordinate system does the XNA Framework use?

The XNA Framework uses a right-handed coordinate system.

Storage

Why do I get an exception when I try to use Storage classes?

One possible reason is that one of your operating system folders — especially %_NTDrive%\Documents and Settings\ — is mapped to a network drive. Storing player data or running titles from a network location is not supported in this release.

Note

For answers to more questions about XNA Game Studio and the XNA Framework, see XNA Creators Club Online .

Zune Touch-Screen and Accelerometer Support

XNA Game Studio provides support for developing applications that use input gathered from the built-in touch screen and accelerometer of the Zune HD device.

Concepts

[Zune HD Input Overview](#)

Provides an overview of the touch screen and accelerometer input features for the Zune HD device.

Tasks

[Platformer: Adding Touch Support](#)

Extends the base Platformer starter kit code by adding touch screen and accelerometer support for input.

Reference

[Accelerometer Class](#)

Provides methods for interacting with the 3-axis accelerometer of a Zune device.

[AccelerometerCapabilities Structure](#)

Provides properties for accessing the capabilities of an accelerometer.

[AccelerometerState Structure](#)

Provides information on the current state of the accelerometer device and a helper function for rotational computation.

[TouchCollection Structure](#)

Provides methods and properties for accessing state information for the touch screen of a Zune device.

[TouchLocation Structure](#)

Provides methods and properties for interacting with a touch location on a touch screen device.

[TouchPanel Class](#)

Provides methods for retrieving touch panel device information.

[TouchPanelCapabilities Structure](#)

Provides access to information about the touch pad device.

Avatars

Avatars are three-dimensional animated characters. The Xbox Dashboard uses avatars to represent gamers who are signed in to the local console, and players in the gamers' friends lists and LIVE Party chats. Titles can also use avatars in games, both to represent gamers and to represent other characters in the game.

Concepts

[Programming with Avatars](#)

Discusses the support for avatars in XNA Game Studio applications targeting the Xbox 360 console.

Tasks

[How To: Render and Animate an Avatar Using AvatarRenderer.](#)

Demonstrates how to render and animate a gamer's avatar using the [AvatarRenderer](#) class and a standard animation.

Reference

[AvatarAnimation](#)

Provides methods and properties for animating an avatar using standard animations (for example, celebrate).

[AvatarDescription](#)

Provides access to the methods and properties of the description data for an avatar.

[AvatarExpression](#)

Contains the various components of the avatar's face, such as the left and right eyebrows.

[AvatarRenderer](#)

Provides properties and methods for rendering a standard avatar.

[SignedInGamer.AvatarChanged](#)

Occurs when a gamer's avatar changes.

[SignedInGamer.Avatar](#)

Description data for the avatar that represents the gamer.

[AvatarAnimationPreset](#)

Defines standard animations for avatars.

[AvatarBone](#)

Defines a list of the useful bones of the avatar model.

[AvatarEyebrow](#)

Defines the standard animation textures for an avatar's eyebrows.

[AvatarEye](#)

Defines the standard animation textures for an avatar's eyes.

[AvatarMouth](#)

Defines the standard animation textures for an avatar's mouth.

Xbox LIVE Party

Xbox LIVE Party enables gamers to communicate, even when each gamer is not playing the same game in the same multiplayer session. LIVE Party supports up to an eight-way group voice chat for gamers. It does not matter what each gamer is doing on his or her Xbox 360 at the time—playing games, watching videos, listening to music, or browsing the Marketplace. LIVE Party chat keeps gamers connected before, during, and after a gameplay session, persisting across title switches. Furthermore, LIVE Party chat provides easy and quick ways for gamers to get into multiplayer games together.

Tasks

[How To: Add LIVE Party Support](#)

Describes how to add LIVE Party support to Xbox LIVE Indie Games.

Reference

[LocalNetworkGamer.SendPartyInvites](#)

Sends game invitations to all party members that are not in the current game session.

[SignedInGamer.PartySize](#)

Gets the current party size.

[LocalNetworkGamer.SendPartyInvites](#)

Sends game invitations to all party members that are not in the current game session.

Video

XNA Game Studio now supports the ability to play back video that can be used for such purposes as opening splash and logo scenes, cut scenes, or in-game video displays.

This set of XNA Framework APIs supports the following features:

- Full screen video playback
- Video playback to simple textures in game
- Control of playback such as pause/resume and stop
- Retrieve properties of the video, such as playback time, size, and frame rate
- Determine the type and usage of the audio track, such as if it has music, dialog, or music and dialog
- Play back multiple video streams at the same time

Tasks

[How To: Play Video](#)

Demonstrates how to use the [VideoPlayer](#) to play back videos.

[How To: Play a Video in 3D space](#)

Demonstrates how to use the [VideoPlayer](#) to playback videos on the surface of a quad.

Reference

[Video](#)

Represents a video.

[VideoPlayer](#)

Provides methods and properties to playback, pause, resume, and stop video. [VideoPlayer](#) also exposes repeat, volume, and

play position information.

[VideoSoundtrackType](#)

Type of sounds in a video

Audio Enhancements

This version of XNA Game Studio has a new usage pattern of **SoundEffect.Play**. Sound instances created by **Play** calls are disposed automatically when playback ends, and **SoundEffect.Play** returns a Boolean to indicate success or failure.

Tasks

[How To: Apply Basic 3D Positional Effects to a SoundEffect](#)

Demonstrates how to apply 3D positioning effects to SoundEffects.

[How To: Change the Pitch or Volume of a Sound](#)

Demonstrates how to change pitch and volume of a playing sound.

Content Pipeline Enhancements

This changes the semantics of the Content Pipeline, making it much easier to add custom types.

Reference

[ContentSerializerRuntimeTypeAttribute](#)

A custom [Attribute](#) that specifies the corresponding run-time type of this object.

[ContentSerializerTypeVersionAttribute](#)

A custom [Attribute](#) that specifies the corresponding run-time type version of this object.

[ContentTypeWriter.CanDeserializeIntoExistingObject](#)

Determines if deserialization into an existing object is possible.

New Conceptual Content

Graphics

[The XNA Rendering Pipeline](#)

Provides a high-level view of the graphics rendering pipeline for XNA games.

[What Is a Model Bone?](#)

A model bone is a matrix that represents the position of a mesh relative to other bones in a 3D model.

Changes to the Development Environment and Tools

Visual Studio Changes

XNA Game Studio 3.1 supports both 3.0 and 3.1 projects, and it includes support for upgrading projects from 3.0 to 3.1.

Tasks

[Upgrading XNA Game Studio Projects](#)

Describes supported and unsupported XNA Game Studio project versions, provides guides for upgrade scenarios, and offers advice on troubleshooting upgrade issues.

[Troubleshooting Upgrades](#)

Describes common issues with upgrading XNA Game Studio projects.

XACT Update

XNA Game Studio 3.1 includes support for XACT3. XACT 3 has a number of new features, including the following.

Ability to enable a filter on every track.

XACT3 now exposes a filter on every track, letting the sound designer set the filter type and parameters (filter width and the cutoff/center frequency). The filter can be set directly on a track or it can be attached to an RPC. Sound designers either can set specific filter parameters or they can specify a range. When setting a range, they can select a random value for the parameter each time the track is played.

Support for the xWMA compression format.

XACT3 now supports xWMA decoding in software on both Xbox 360 and Windows. xWMA uses the WMA bitstream format in a lightweight wrapper, and it can provide 1.5–2× the compression compared with XMA at similar quality. xWMA is very useful for types of content, such as dialog or music, for which you can afford a small CPU hit to achieve much greater compression. A quality setting similar to XMA's allows you to increase or decrease compression to adjust sound performance.

Changes to the XNA Framework API

Getting Started with XNA Game Studio

XNA Game Studio is an integrated development environment designed to make it easier to develop games for Microsoft Windows, Xbox 360 platforms, and Zune devices. XNA Game Studio extends supported versions of Microsoft Visual Studio tools to support the XNA Framework. The XNA Framework is a managed-code class library that contains functionality targeted specifically to game development tasks. In addition, XNA Game Studio includes tools for incorporating graphical and audio content into your game.

The XNA Framework is designed to be similar to the .NET Framework in terms of its design patterns and idioms. With XNA Game Studio, you are able to incorporate functionality in your game from both the XNA Framework and the .NET Framework. Use the XNA Framework for game-specific tasks such as graphics rendering and managing input, and use the .NET Framework for more general programming tasks.

Documentation Roadmap

Describes the documentation for XNA Game Studio.

The XNA Game Studio documentation is divided into the following major sections:

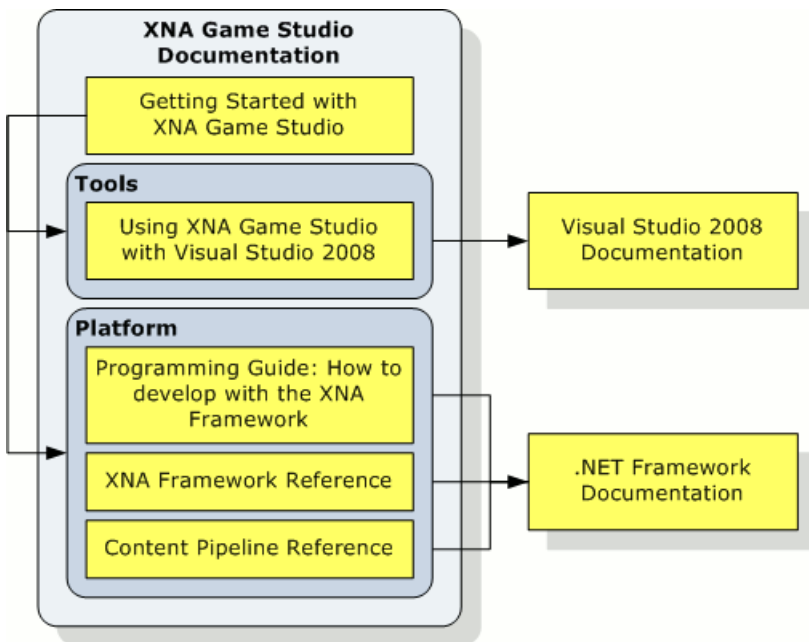

- [Getting Started with XNA Game Studio](#): This section describes how to set up and use XNA Game Studio with Microsoft Visual Studio 2008 and the .NET Framework. It includes information about setting up your Xbox 360 or Zune device to work with Game Studio.

This section links to many topics in the Using XNA Game Studio, Programming Guide, and Reference sections.

- [Using XNA Game Studio](#): This section provides greater detail about working with the Visual Studio Tools and IDE, including how to set up projects for specific platforms, how to work with cross-platform titles, and how to share and distribute your game.
- [Programming Guide](#): This section provides detail about game programming with Game Studio. It describes how to use the XNA Framework classes to implement different features of your game. It is divided into sections based on the feature type, such as graphics, audio, networking, and LIVE programming.
- Reference: The reference section provides even greater detail about the XNA Framework. It is divided into two sub-sections, the [XNA Framework Class Library](#) and [Content Pipeline Class Library](#).

The XNA Game Studio documentation builds upon the existing documentation provided with Microsoft Visual Studio 2008 and the [Microsoft .NET Framework](#). It links to these sets of documentation, where appropriate. You should have access to both of these sets of documentation.

The following diagram shows the relationship between these sections of the documentation, the Visual Studio 2008 documentation, and Microsoft .NET Framework:

Supported Operating Systems and Hardware

Describes the operating systems that fully support XNA Game Studio, and the computing hardware you need to use XNA Game Studio.

Supported Operating Systems

The following operating systems fully support XNA Game Studio.

Operating system	Supported versions
Windows XP	<ul style="list-style-type: none"> • Home Edition • Professional • Media Center Edition • Tablet PC Edition
Windows Vista	<ul style="list-style-type: none"> • Home Basic • Home Premium • Business • Enterprise • Ultimate

Remarks

- XNA Game Studio 3.1 has been tested on Windows 7 Release Candidate. Support for the Windows 7 operating system is expected after the final release.
- Windows Vista Service Pack 1 (or the latest service pack) is supported, but is not required, for XNA Game Studio.
- Windows XP requires, at a minimum, Service Pack 2.
- Although XNA Game Studio itself is available only in English and Japanese, it is supported under any of the available language settings on Windows.
- Administrator permissions are not required to run XNA Game Studio, but they are to install it. For Windows Vista, elevated administrator permissions are required.
- Although the setup program for XNA Game Studio will complete on the Windows Server 2003 and Windows Server 2008 operating systems, XNA Game Studio is not officially supported on these operating systems, and the XNA Game Studio software may not work as expected.

Hardware Requirements

To run XNA Framework games on a computer running a Windows operating system, you need a graphics card that supports, at a minimum, Shader Model 1.1, and DirectX 9.0c. We recommend using a graphics card that supports Shader Model 2.0 because some samples and starter kits may require it.

Ensure your graphics card is using the latest driver. Check with your hardware vendor or access [Microsoft Update](#) to find the latest version of a driver.

Other hardware requirements for XNA Game Studio are identical to those for Visual Studio 2008. For more information, see the [Visual Studio documentation](#).

Required Software

Describes the software required to use XNA Game Studio 3.1.

XNA Game Studio 3.1

To download XNA Game Studio 3.1 itself, go to the [Creators Club Online](#).

Important

You must uninstall previous versions of XNA Game Studio before you install XNA Game Studio 3.1. However, you can install multiple versions of the XNA Framework Redistributable at the same time.

Visual Studio 2008

XNA Game Studio leverages the Visual Studio 2008 development environment, extending it for game development. You can use XNA Game Studio with any supported versions of Visual Studio 2008 tools. Click one of the following links for more information about using XNA Game Studio with Visual Studio 2008.

- [Microsoft Visual C# Express Edition](#)
- [Microsoft Visual Studio 2008](#)

Note

Only members of the Visual Studio 2008 product line support XNA Game Studio 3.1. XNA Game Studio 3.1 is not compatible with Visual Studio 2005 or any previous editions.

XNA Creators Club

To develop games for Xbox 360, you need a membership in the XNA Creators Club. You can get an XNA Creators Club membership from Xbox LIVE Marketplace, or at XNA Creators Club Online: [Sign in](#) and [Membership](#).

XNA Creators Club and Xbox LIVE Membership Requirements

There are two types of online multiplayer games available when you create a networked game with XNA Game Studio: system link game sessions and LIVE sessions. These two forms of online multiplayer gaming describe whether the multiplayer gaming session is on the local area network (system link games), or if the gaming session is advertised and found through the LIVE service. With system link games, you can search the local area network to find the gaming sessions. With LIVE sessions, you can use the LIVE service to find available game sessions. Use the *searchProperties* argument of [NetworkSession.Find](#) to specify the parameters used to search for an available game session—a game session that uses either system or the LIVE service.

Developing and testing a networked game requires at least two machines, but you only need one Xbox 360 console and one Creators Club membership to test network code for the Xbox 360. This is because XNA Framework supports cross-platform system links so developers can run one instance of a game on an Xbox 360, and a second on a Windows-based computer. This functionality helps creators debug their titles without having to purchase a second console. It is also possible for more than one Windows-based development computer to connect several machines in a system link session without any memberships required.

Memberships are required for a player on a Windows-based computer and an Xbox 360 console in a network session, depending on the session type that has been created.

	Xbox 360 console	Windows-based development computer	Zune
Run an XNA Framework Game	LIVE Silver membership + Premium XNA Creators Club membership	No memberships required	No memberships required
Use System Link for Local Area Network gameplay	LIVE Silver membership + Premium XNA Creators Club membership	No memberships required	No memberships required
Sign in to Xbox LIVE and Games for Windows - LIVE Servers	LIVE Silver membership + Premium XNA Creators Club membership	LIVE Silver membership + Premium XNA Creators Club membership	Not available on Zune

Use LIVE to connect to other machines over the Internet while the game is in development	LIVE Gold membership + Premium XNA Creators Club membership	LIVE Silver membership + Premium XNA Creators Club membership	Not available on Zune
⚠Caution			
XNA Framework components that interact with Games for Windows - LIVE require an XNA Creators Club membership. If for any reason a LIVE profile without a Creators Club membership is set to auto sign in to a Windows-based computer, the game will be unable to connect to the LIVE service. Furthermore, the XNA Framework gamer services components, including the Guide, will be unavailable. To disable auto sign in for a LIVE profile on a Windows-based computer, disconnect from the network, launch an XNA Framework game, and then open the Guide.			

Please note the following.

- If you are running an XNA Framework Game on the Microsoft Windows operating system on a dual-core AMD processor, and the game contacts the Xbox LIVE servers or otherwise uses the Gamer Services extensions, you may experience unpredictable behavior such as a hanging of the game process. To work around this issue, you should install the **AMD Dual-Core Optimizer** from AMD on the computer on which you are running the game. Currently, the optimizer is available at the following location.

[AMD Dual-Core Optimizer](#)

Zune Client Version

When developing games for Zune, the Zune client needs to be running at least the 3.0 version of the firmware.

Additional Required Software Installed by XNA Game Studio 3.1 Setup

The XNA Game Studio Setup program also installs the following required software:

DirectX Runtime

XNA Game Studio Setup installs the DirectX runtime, which is required to use the XNA Framework Game API.

Microsoft Cross-Platform Audio Creation Tool

XNA Game Studio Setup installs multiple versions of the Microsoft Cross-Platform Audio Creation Tool (XACT). You can use XACT to author audio content for your game. Games written using the 3.1 XNA Framework are required to use XACT 3 projects, which are not backwards compatible. Games written using the 3.0 XNA Framework are required to use XACT 2 projects. For more information about upgrading your projects in regard to XACT, [Upgrading XNA Game Studio Projects](#).

Games for Windows - LIVE

XNA Game Studio Setup installs Microsoft Games for Windows – LIVE Redistributable, version 2.0.687.0. This software provides support for various gamer services such as retrieving player preferences for local accounts, as well as programmatically displaying various LIVE Guide user interface screens.

How To: Configure Help to Use Online Content

Describes how to configure the Visual Studio Help system to use online Help content if such content is available.

Configuring Visual Studio Help

To configure Visual Studio Help to use online content

1. On the **Tools** menu, click **Options**.

The **Options** dialog box appears.

2. In the tree view control in the left pane of the **Options** dialog box, click the **Help** node beneath the **Environment** node.

You may need to check the **Show all settings** checkbox to make the **Help** node visible.

3. Click the **Online** node beneath the **Help** node.

You may need to click the plus sign next to the **Help** node to make the **Online** node visible.

4. In the set of options labeled **When loading Help content**, select **Try online first, then local**.

5. Click **OK**.

Third-Party Firewall Settings

The XNA Game Studio setup program adjusts Windows Firewall settings to allow the XnaTransX.exe application to send and receive network traffic. This is necessary for your Windows-based development computer to communicate with the Xbox 360 console. Similarly, the setup program adjusts Windows Firewall settings for the XnaLiveProxy.exe application to enable network communications for networked games.

If you are using a firewall product other than Windows Firewall—that is, a third-party firewall setting—you will need to configure this firewall to allow XnaTransX.exe and XnaLiveProxy.exe to send and receive network traffic. Some firewall products enable you to unblock entire applications, some enable you to unblock specific ports, and some, such as Windows Firewall, enable you to do both.

To unblock the entire XnaTransX.exe application, specify the following executable:

```
<install dir>\Common Files\Microsoft Shared\XNA\XnaTrans\v3.1\XnaTransX.exe
```

For the XnaLiveProxy.exe application, specify the following executable:

```
<install dir>\Microsoft XNA\XNA Game Studio\v3.1\Bin\XnaLiveProxy.exe
```

Note

In the above paths, <install dir> refers to the directory beneath which XNA Game Studio is installed. By default, this directory is %ProgramFiles%.

To unblock specific ports, configure your firewall using the following information.

Application	Port	Protocol	Inbound or Outbound
XnaTransX.exe	1001	TCP	outbound
XnaTransX.exe	1001	UDP	inbound/outbound
XnaTransX.exe	3825	UDP	inbound/outbound
XnaTransX.exe	3835	UDP	inbound/outbound
XnaLiveProxy.exe	1000	UDP	inbound/outbound
XnaLiveProxy.exe	3074	UDP	inbound/outbound

Firewall Settings for Connectivity to Xbox LIVE

You may also need to unblock ports on firewall devices between your Xbox 360 console and the external network to allow the console to connect to the Xbox LIVE service. For more information, see the following Knowledge Base article: [Xbox 360: Port settings for Xbox LIVE](#)

Connecting to Your Xbox 360 Console with XNA Game Studio 3.1

Describes how to use XNA Game Studio Connect to connect and deploy a game to your Xbox 360 console.

XNA Game Studio makes it easy for you to create games for both your Windows-based computer and your Xbox 360 console. By joining the XNA Creators Club as a premium member and downloading XNA Game Studio, you can begin developing for your Windows-based computer. To begin developing for Xbox 360, follow these additional steps.

This guide assumes you have installed a supported version of Visual Studio tools and XNA Game Studio already. You must install these products before you connect to an Xbox 360 console. For information about installing these products, see [Setup and System Requirements](#).

- [Step 1: Sign In to Xbox LIVE](#)
- [Step 2: Download XNA Game Studio Connect](#)
- [Step 3: Connect Your Xbox 360 Console and Windows-Based Computer](#)
- [Step 4: Create and Deploy an Xbox 360 Project](#)
- [What's Next?](#)

Step 1: Sign In to Xbox LIVE

Turn on your Xbox 360 console, and sign in to Xbox LIVE. At the very least, you will need a Silver Xbox LIVE membership, an XNA Creators Club premium membership, and a hard drive for your Xbox 360 console to be able to develop games for Xbox 360 using XNA Game Studio. While you are in XNA Game Studio Connect or playing an XNA Game Studio game, you need to be connected to Xbox LIVE.

Connections between your Xbox 360 console and XNA Game Studio require a premium membership in XNA Creators Club. To sign up, visit the [XNA Creators Club Web site](#).

Step 2: Download XNA Game Studio Connect

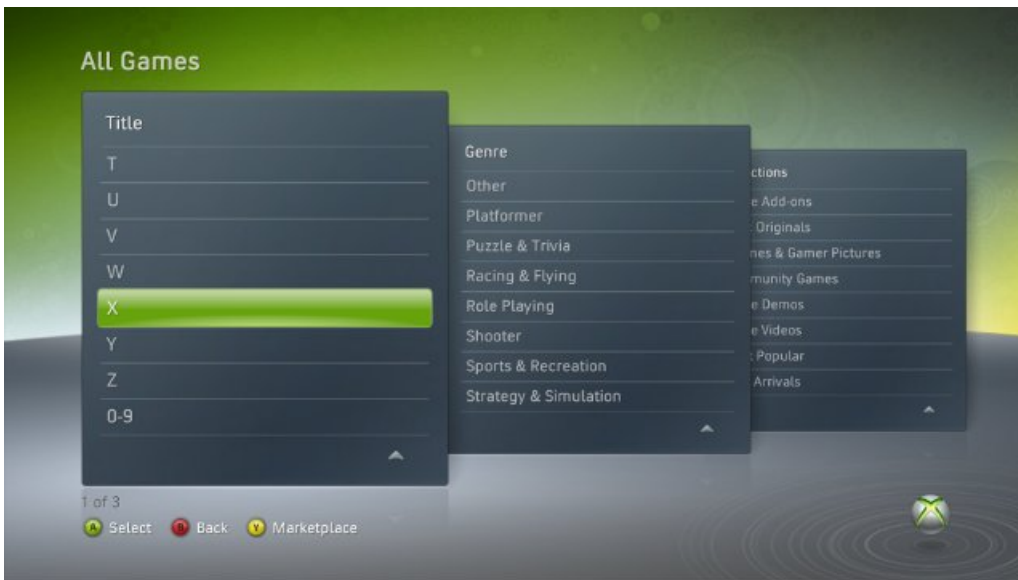

You must download XNA Game Studio Connect from Xbox LIVE Marketplace, and install it on the Xbox 360 console. Go to the Xbox LIVE Marketplace to find XNA Game Studio Connect. To download XNA Game Studio Connect, choose one of the following options:

Browsing to All Games using the Guide

- From the Guide, navigate to the **Marketplace** blade.
- Select **Game Marketplace**, then **All Games**. This brings you to the **All Games** screen.
- Continue with *Downloading XNA Game Studio Connect from the All Games screen*, below.

Browsing to All Games using the New Xbox Experience (NXE) UI

- Navigate to **Game Marketplace**, and select **Explore Game Content**. Press **A** on the controller.
- Select **Browse**, and press **A**. This brings you to the **All Games** screen.
- Continue with *Downloading XNA Game Studio Connect from the All Games screen*, below.

Once you've arrived at the **All Games** screen from either the Guide or NXE, use the following procedure to download XNA Game Studio Connect.

Downloading XNA Game Studio Connect from the All Games screen

- From **All Games**, browse to the **Genre** screen, and select **Other**.

Note

You can also do this by scrolling down the **Title** list, and selecting **X**.

- Scroll to **XNA Creators Club**, and press **A**.
- From the **XNA Creators Club** pane, select **All Downloads**, then **XNA Game Studio Connect**.
- Press the **A** controller button, and select **Confirm Download** to begin downloading.

Step 3: Connect Your Xbox 360 Console and Windows-Based Computer

When you develop games for Xbox 360, you develop them on your Windows-based computer, then transfer them over your local network to your Xbox 360 console. This requires that your Windows-based computer and Xbox 360 console share the same subnet. Most home networking layouts support this configuration. If your console and computer share a router or hub, it is likely that they share the same subnet.

With your computer and console on the same subnet, follow these steps to set up a connection between your computer and your console.

Step 3A. On Your Xbox 360 Console, Generate a Connection Key:

1. From the Xbox Dashboard, go to **My Xbox**, select **Game Library**, and press the **A** controller button.

Also, you have the option of using the Xbox Guide: select the **Games** tab, then **Game Library**, and press the **A** controller button.

2. From the **Game Library**, go to the **Collections** tab, select **Community Games**, and press **A**.
3. Select **XNA Game Studio Connect**, and press **A**.
4. Select **Launch**, and press **A**.

The XNA Game Studio Connect screen appears.

5. If the XNA Game Studio Connect screen displays a connection key, continue to step 3B.

If the connection key does not appear, you can generate a new key by pressing the **X** controller button.

If the connection key does not appear, the Xbox console could already be connected to this Windows-based computer. XNA Game Studio allows multiple connection keys for multiple users on multiple computers. For more information, see [Using XNA Game Studio Device Center](#). To add a new connection key to the list of connection keys recognized by this Xbox 360 console, press **X**. To reset all connection keys and generate a new connection key to connect to this Xbox 360 console, press **Y**.

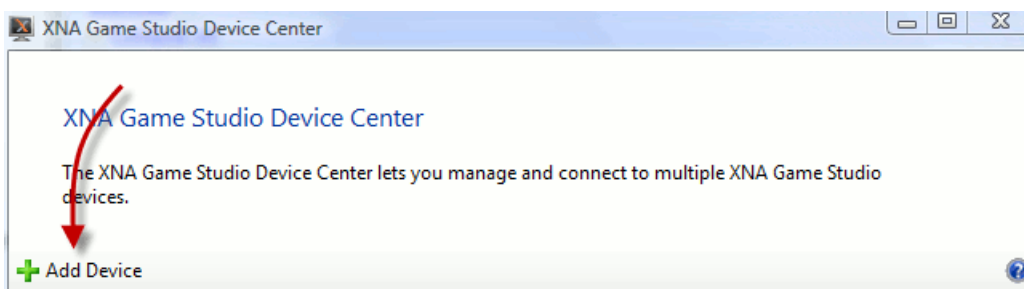

Step 3B. On Your Windows-Based Computer, Enter the Connection Key and Initiate the Connection

1. From the **Start** menu, select **Programs**, select **XNA Game Studio 3.1**, and launch the **XNA Game Studio Device Center**.

Note

You can also use the **XNA Game Studio Device Management** toolbar to directly launch XNA Game Studio Device Center and add a device. Visual Studio 2008 displays the **XNA Game Studio Device Management** toolbar by default when an Xbox 360 game is open in Visual Studio.

2. Click **Add Device**.

3. Select the type of device you're adding. In this case, click **Xbox 360**.

4. Enter a name for this Xbox 360 console, and click **Next**.

Give your Xbox 360 console a name.

Please choose a name for your Xbox 360 console. This will be used to identify the Xbox 360 console in the XNA Game Studio Device Center.

Xbox 360 Name:

This name serves only to identify your Xbox 360 console to XNA Game Studio. The name does not need to correspond to any other computer or Xbox 360 name.

5. Enter the connection key that is displayed in XNA Game Studio Connect on the Xbox 360.

Type your Connection Key

You can find the Connection Key displayed on the XNA Game Studio Connect screen on your Xbox 360 console.

The Connection Key looks similar to this:

XXXXX-XXXXX-XXXXX-XXXXX-XXXXX

Type your connection key (dashes will be added automatically):

Note

The connection key might be somewhat hard to read on a standard television screen. The following guide should help you identify specific letters and numbers:

- The number "1" has a small tick at its top left; the capital letter "l" does not.
- The capital letter "B" has a straight line on the left; the number "8" does not.
- The number "3," sometimes mistaken for a "B," also has no straight side on the left.
- The number "0" and the capital letter "O" are so similar that XNA Game Studio Connect treats these characters as the same. Therefore, the number "0" and the capital letter "O" are interchangeable.

If the connection key is still too difficult to read, press **X** on the Xbox 360 controller to generate a new connection key.

6. Once you are sure that the two keys match, click **Next** on the **XNA Game Studio Devices** dialog box.

XNA Game Studio Device Center will test the connection with the Xbox 360 console.

If the connection is successful, the XNA Game Studio Device Center on the Windows-based computer will display "Successfully connected to the Xbox 360 console." XNA Game Studio Connect on the Xbox 360 console will display "Waiting for computer connection," followed by the name you have chosen for your Xbox 360 console in the XNA Game Studio Device Center.

If the XNA Game Studio Device Center fails to connect to the Xbox 360 console, click **Try again** to edit the connection key and try again. If the connection continues to fail, make a careful note of the error message displayed at the bottom of the **XNA Game Studio Devices** dialog box. This error message can help you or a technician diagnose the cause of the connection failure, if it did not result from mismatched keys. For more information about troubleshooting a failed connection, see [Troubleshooting Xbox 360 Game Deployment](#).

7. Click **Finish**.

The name you gave to your Xbox 360 console will be listed in the XNA Game Studio Device Center. From now on, your computer and your console can connect to each other easily.

Step 4: Create and Deploy an Xbox 360 Project

Try out the Xbox 360 console by deploying a simple, blank XNA Game Studio game to it.

1. On your Windows-based computer, at the main Visual Studio screen, select the **File** menu, and then click **New Project**.

- From **Project types**, expand the **Visual C#**, and click **XNA Game Studio 3.1**.
- In **Templates**, select **Xbox 360 Game (3.1)**, and then click **OK**.

At this point, you should bring up XNA Game Studio Connect to prepare the Xbox 360 console to receive content from the Windows-based computer.

- From the Xbox Dashboard, go to **My Xbox**, select **Game Library**, and press **A** on the controller.
You can also use the Guide: select the **Games** tab, select **Game Library**, and then press **A**.
- From the **Game Library**, go to the **Collections** tab, select **Community Games**, and press **A**.
- Select **XNA Game Studio Connect**, and press **A**.
- Select **Launch**, and press **A**.

The XNA Game Studio Connect screen appears.

- On your Windows-based computer, with your new project open, press the F5 key.

The project will build, deploy necessary files to the Xbox 360 console, and run.

At this point, you should see a simple display on your console—just a blue screen. If you see this screen, you have successfully deployed a game to your Xbox 360 console. You can now deploy and play any game you create on your console.

- To stop the game and return to the main screen of XNA Game Studio Connect, either press the **BACK** button on your Xbox 360 gamepad, or press SHIFT+F5 to stop debugging on your computer.

If the deployment fails, you may need to check your network settings. See [Troubleshooting Xbox 360 Game Deployment](#) for more information.

What's Next?

You have successfully deployed your first Xbox 360 game. This game, like every game you deploy, will now appear in the **Recent Games** tab in the **Game Library** on your Xbox 360 console. It can also be found by selecting **Community Games** in the **Collections** tab in your **Game Library**. Using **Game Library**, you can play any of the games you have deployed to your Xbox 360 console. From **Game Library**, you can also delete games you do not want to keep.

Once your game is loaded onto the hard disk so that it appears in the **Recent Games** tab of the **Game Library** on your Xbox 360 console, it can be transferred to a memory unit if one is installed. From **System Settings** on your Xbox 360 console, the **Memory** selection enables you to transfer a game from the hard disk to the memory unit. The memory unit can then be installed on any other Xbox 360 console and played or copied.

Important

Only XNA Framework games built and deployed with XNA Game Studio 3.0 and later can be transferred to a memory unit. If you wish to transfer a game developed under an earlier version of XNA Game Studio, you must convert, build, and deploy the project using the current version of XNA Game Studio.

A good next step would be to try some of the tutorials. The code used in the tutorials works on both Windows-based computers and on the Xbox 360 console, so you can try either platform to get a feel for how to develop for both. Start with [Tutorial 1: Displaying a 3D Model on the Screen](#) for your first taste of game development.

Connecting to your Zune Device with XNA Game Studio

Describes the steps necessary to connect and deploy a game to your Zune device using XNA Game Studio Connect.

XNA Game Studio allows you to easily create games for your Zune device, Windows-based computer, and Xbox 360 console. Follow this guide to develop games for the Zune platform topic.

Note

This guide assumes you have already installed a supported version of Visual Studio and XNA Game Studio. You must install these products before you connect to a Zune device. For information about installing these products, see [Setup and System Requirements](#).

- [Step 1: Update Your Zune Device Firmware](#)
- [Step 2: Add Your Zune in the XNA Game Studio Device Center](#)
- [Step 3: Create and Deploy a Zune Project](#)
- [What's Next?](#)

Step 1: Update Your Zune Device Firmware

XNA Game Studio is supported on Zune devices running firmware version 3.0 or later. If your device does not already have firmware version 3.0 or later, you'll need to update your Zune firmware to the most current version.

To determine Zune device firmware version

- On the Zune device, select **settings | about | zune**.

The firmware version will be displayed.

If you have a version older than 3.0, you'll need to update your Zune.

To update your Zune device

1. Make sure you have the current version of the Zune software installed on your desktop computer.
 - If you are a new Zune customer, visit <http://www.zune.net/setup> and install the Zune software for your computer.
 - If you already have the Zune software installed on your computer, check for updates. From the Zune software, click **Settings | GENERAL | CHECK FOR UPDATES**.
2. Use the Zune sync cable to connect the Zune device to your computer. Connect the sync cable to a USB port on the computer, not a USB hub.

Note

If the Zune device battery is critically low, we recommend that you charge your Zune device before you continue. For more information about how to charge your Zune device, see the following Microsoft Knowledge Base article: [How to charge the battery in your Zune device](#).

3. Open the Zune software on your desktop computer while the Zune device is still connected to your computer.

The Zune software searches the Internet for the latest version of the firmware. If a newer version of the Zune device firmware is available, you will get a notice to update your device.

Note

Do not move or disconnect the Zune device until the update is complete. The update may take several minutes. During this time, the Zune device may restart several times. Please be patient.

You can also manually check for new device updates, if desired. To do so: from the Zune software on your desktop computer, click **Settings | device | DEVICE UPDATE**.

For more information about updating your Zune device, or to troubleshoot issues with updating, please see the following Microsoft Knowledge Base article: [How to update your Zune device](#).

After you update your Zune firmware to version 3.0 or later, you won't need to perform this step again.

Step 2: Add Your Zune in the XNA Game Studio Device Center

Once you add your Zune to the XNA Game Studio Device Center, XNA Game Studio will be able to connect to your Zune so that you can deploy and debug games.

To add your Zune to the XNA Game Studio Device Center

1. Use the Zune sync cable to connect the Zune device to your computer.
2. Start the device center by clicking **Start, All Programs, Microsoft XNA Game Studio 3.1**, and then click **XNA Game Studio Device Center**.
3. Click **Add Device**, and then click **Zune**.

The device center will display a list of connected Zune devices.

4. In the list of connected Zunes, click the one that you want to add.
5. Click **Next**.

The Zune you selected will be added to the list of devices in the device center.

6. Close the XNA Game Studio Device Center.

Note

If you are having trouble connecting to your Zune device, or the device is not showing up in the device center, close the Zune client desktop software (if it is running).

You can also configure the Zune desktop software so it won't launch automatically when a Zune device is connected. This setting is located under **settings | device | SYNC OPTIONS**.

Step 3: Create and Deploy a Zune Project

Now you can try out Zune development by deploying a simple, blank XNA Game Studio game.

To deploy a simple, blank XNA Game Studio game

1. On your Windows-based computer, at the main Visual Studio screen, click **File | New Project** (or **File | New | Project**, depending on your Visual Studio configuration).
2. From **Project types**, expand **Visual C#** and click **XNA Game Studio 3.1**.
3. In **Visual Studio installed templates**, click **Zune Game (3.1)**, and then click **OK**.
4. On your Windows-based computer, with your new project open, press the F5 key.

The project will build. It launches XNA Game Studio Connect on the Zune device, deploys the project and other necessary files to the Zune, and then launches the game.

At this point, you should see a simple display on your Zune: a light blue screen. If you see this screen, you have successfully deployed a game to your Zune. You can now deploy and play any game you dream and build.

5. To stop the game and return to the main screen of XNA Game Studio Connect, either:
 - Press the **BACK** button on your Zune.
 - or-
 - Stop debugging by pressing SHIFT+F5 on your computer.

Note

When an XNA Framework game exits on the Zune, the Zune device reboots. This behavior is by design—it ensures that game and run-time resources are completely cleaned up after a game exits.

Note

Holding down the Back button for 2 seconds forces the currently executing game to exit, regardless of the game's normal exit semantics.

What's Next?

You have successfully deployed your first Zune game. This game, like the other games you deploy to your Zune, will appear under **games** on your Zune device. Using the **games** menu, you can play or delete the games you have deployed to your Zune.

A good next step would be to try the 2D tutorial [Your First Game: Microsoft XNA Game Studio in 2D](#). The code in the 2D tutorial works on Zune, Windows-based computers, and on the Xbox 360 console, so you can try any or all of the platforms to get a feel for developing on each.

For an overview of Zune-specific features and programming concepts, see [Zune Programming Considerations](#).

Note

See the *Supported Platforms* section on individual reference pages to check for Zune support. If Zune is not on the supported platforms list, the API is not supported. If listed, there is support for the API.

Your First Game: Microsoft XNA Game Studio in 2D

Describes the steps necessary to create a simple sprite-based game by using XNA Game Studio.

Note

A sprite is a simple 2D graphic (such as a bitmap) that is displayed on the screen using a call to [SpriteBatch.Draw](#).

- [The Complete Sample](#)
- [Step 1: Install Your Software](#)
- [Step 2: Create a New Project](#)
- [Step 3: View the Code](#)
- [Step 4: Add a Sprite](#)
- [Step 5: Make the Sprite Move and Bounce](#)
- [Step 6: Explore!](#)

The Complete Sample

The code in this tutorial illustrates the technique described in the text. A complete code sample for this tutorial is available for you to download, including full source code and any additional supporting files required by the sample.

[Download MyFirstGame_Tutorial_Sample.zip](#).

Step 1: Install Your Software

Before you begin, make sure that you have installed all the necessary software, including a supported version of Microsoft Visual Studio tools and XNA Game Studio. See [Required Software](#) for a list of required programs.

Step 2: Create a New Project

1. From the **Start** menu, click **All Programs**, click the **XNA Game Studio 3.1** folder, and then click your supported version of Microsoft Visual Studio tools.
2. When the Start Page appears, click the **File** menu, and then click **New Project**.
A dialog box appears with a tree list on the left pane, marked Project Types.
3. Select the **XNA Game Studio 3.1** tree node underneath the **Visual C#** node.
A set of available projects appears in the right pane.
4. In the right pane of the dialog box that appears, click **Windows Game (3.1)**, and then type a title for your project (such as "MyFirstGame") in the **Name** box.
5. Type a path where you'd like to save your project in the **Location** box, and then click **OK**.

After creating a new project, you'll be presented with the code view of your game.

Step 3: View the Code

Some of the hard work has already been done for you. If you build and run your game now, the [GraphicsDeviceManager](#) will set up your screen size and render a blank screen. Your game will run and update all by itself. It's up to you to insert your own code to make the game more interesting.

Much of the code to start and run your game has already been written for you. You can insert your own code now.

- The [Initialize](#) method is where you can initialize any assets that do not require a [GraphicsDevice](#) to be initialized.
- The [LoadContent](#) method is where you load any necessary game assets such as models and textures.
- The [UnloadContent](#) method is where any game assets can be released. Generally, no extra code is required here, as assets will be released automatically when they are no longer needed.
- The [Update](#) loop is the best place to update your game logic: move objects around, take player input, decide the outcome of collisions between objects, and so on.
- The [Draw](#) loop is the best place to render all of your objects and backgrounds on the screen.

Step 4: Add a Sprite

The next step is to add a graphic that can be drawn on the screen. Use a small graphics file, such as a small .bmp or .jpg file. Be creative—you can even make your own. You can even skip ahead a bit and make a sprite that "hides" parts that should not be seen (such as edges or corners) so that it looks even better.

Once you have a graphic picked out on your computer, follow these steps.

1. Make sure you can see the Solution Explorer for your project on the right side of the window. If you cannot see it, click the **View** menu, and then click **Solution Explorer**.

When it appears, you will see files associated with your project in a tree structure. Inside the tree, you will see a node named **Content**.

2. Right-click the **Content** node, click **Add**, click **Existing Item**, and then browse to your graphic.

If you can't see any files, make sure you change the **Files of type** selection box to read **Texture Files**.

3. Click the graphic file, and then click **Add**.

An entry for the graphic file will appear in Solution Explorer.

4. Click the entry for the graphic in the Solution Explorer. If you do not see the entry, ensure the **Content** node is expanded by clicking the small plus sign (+) to the left of the node, then click on the entry that appears underneath the **Content** node.

When you add a graphic file, it is automatically added to the XNA Framework Content Pipeline, which will allow you to quickly and easily load the graphic into your game.

In the **Properties** window below Solution Explorer, look for the "Asset Name" property. Note the name; you'll use it in your code to load the graphic so it can be displayed in your game.

5. If the **Properties** window is not visible, press F4, or click the **View** menu, and then click **Properties Window**.

Now, you must write code that loads and displays the sprite on the screen. You can use the instructions in [How To: Draw a Sprite](#), or follow along here.

6. Back in the Code view of your game, find the `LoadContent` method, and add the following lines in and above the method so it looks similar to this:

C#

```
// This is a texture we can render.
Texture2D myTexture;

// Set the coordinates to draw the sprite at.
Vector2 spritePosition = Vector2.Zero;

protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    myTexture = Content.Load<Texture2D>("mytexture");
}
```

Make sure the call to `ContentManager.Load` is using the "Asset Name" you saw in the Properties window in the previous step. This code will load and prepare your graphic to be drawn, and will reload your graphic if the graphics device is reset (such as in the case of the game window being resized).

7. Now, add code to the `Draw` loop so it looks like this:

C#

```
protected override void Draw(GameTime gameTime)
{
    graphics.GraphicsDevice.Clear(Color.CornflowerBlue);

    // Draw the sprite.
```

```

        spriteBatch.Begin(SpriteBlendMode.AlphaBlend);
        spriteBatch.Draw(myTexture, spritePosition, Color.White);
        spriteBatch.End();

        base.Draw(gameTime);
    }

```

This code draws the sprite on the screen each frame.

Notice the parameter passed by the `Begin` method, `SpriteBlendMode.AlphaBlend`. This parameter tells the `Draw` method to use the alpha channel of the source color to create a transparency effect so that the destination color appears through the source color. For more information, see [What is Color Blending](#).

8. Build and run your game.

The sprite appears.

Now, it's time to give it some motion.

Step 5: Make the Sprite Move and Bounce

- Change the lines of code in and below the `Update` method to read this way:

C#

```

// Store some information about the sprite's motion.
Vector2 spriteSpeed = new Vector2(50.0f, 50.0f);

protected override void Update(GameTime gameTime)
{
    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back ==
        ButtonState.Pressed)
        this.Exit();

    // Move the sprite around.
    UpdateSprite(gameTime);

    base.Update(gameTime);
}

void UpdateSprite(GameTime gameTime)
{
    // Move the sprite by speed, scaled by elapsed time.
    spritePosition +=
        spriteSpeed * (float)gameTime.ElapsedGameTime.TotalSeconds;

    int MaxX =
        graphics.GraphicsDevice.Viewport.Width - myTexture.Width;
    int MinX = 0;
    int MaxY =
        graphics.GraphicsDevice.Viewport.Height - myTexture.Height;
    int MinY = 0;

    // Check for bounce.
    if (spritePosition.X > MaxX)
    {
        spriteSpeed.X *= -1;
        spritePosition.X = MaxX;
    }

    else if (spritePosition.X < MinX)

```

```
{
    spriteSpeed.X *= -1;
    spritePosition.X = MinX;
}

if (spritePosition.Y > MaxY)
{
    spriteSpeed.Y *= -1;
    spritePosition.Y = MaxY;
}

else if (spritePosition.Y < MinY)
{
    spriteSpeed.Y *= -1;
    spritePosition.Y = MinY;
}
}
```

This adds a little bit of logic that will move the sprite around each frame and cause the sprite to change direction if it hits the edges of the game window.

- Build and run your game.

The sprite moves across the screen and changes direction when it encounters the edges of the game window.

Step 6: Explore!

From here, you can do just about anything. If you're ready to jump into a more complex example, including 3D graphics, input, and audio, see [Going Beyond: XNA Game Studio in 3D](#).

Here are some more ideas to extend this sample:

- Experiment with the call to [SpriteBatch.Draw](#). Change the *Color* parameter to tint the sprite. See [How To: Tint a Sprite](#).
- Add a second sprite, and use [BoundingBox](#) objects to allow the sprites to collide with one another. (See [How To: Detect Whether Two Models Collide](#).)
- Use [Keyboard](#), [Mouse](#), or [GamePad](#) to make the sprite respond to movements of an input device. (See [Input Overview](#).)
- Create some audio events so that the sprite makes sounds as it moves. (See [How To: Add a Sound File to Your Game Using XACT](#) and [How To: Play a Sound Using XACT](#).)
- Instead of a sprite, use a 3D primitive that moves around in 3D space. (See [How To: Draw Points, Lines, and Other 3D Primitives](#).)

Going Beyond: XNA Game Studio in 3D

This multipart tutorial takes you through the first steps of creating your own 3D game using XNA Game Studio.

In XNA Game Studio, it is easier than ever to create games for Windows and for Xbox 360. This tutorial highlights how to load 2D and 3D resources into your game using the XNA Framework Content Pipeline; how to take user input from an Xbox 360 Controller; and how to use the Microsoft Cross-Platform Audio Creation Tool (XACT) to create audio for your game. Each step of the way, you'll have something to see or hear so you will know you are making progress.

Note

The code displayed in each section will work on both Xbox 360 and Windows, but not on Zune. Zune devices do not support 3D graphics, and XACT is not available on Zune. To set up your Xbox 360 console to work with XNA Game Studio, see [Connecting to Your Xbox 360 Console with XNA Game Studio 3.1](#).

Introduction

In [Your First Game: Microsoft XNA Game Studio in 2D](#), you saw a simple example that used the XNA Framework Content Pipeline to load a sprite, represented by a [Texture2D](#) object. You also used the XNA Framework to draw the sprite on the screen. This tutorial goes beyond that simple sample to help introduce you to many concepts that XNA Game Studio makes easy, so you can focus on making fun, interactive games.

This first tutorial will introduce you to the Content Pipeline in a little more detail, and will introduce you to some of the XNA Framework API calls you will use to draw 3D objects on the screen. When you complete this tutorial, you'll have a 3D model drawing on your screen. The model will have textures and lighting. Let's get started!

Step 1: Downloading the Art Assets

The first thing that you will need before you start coding are some art assets to play around with. In this case, you need a 3D model, and an associated texture file so that the model has some detail. These assets will be loaded into your game using the XNA Framework Content Pipeline, which is a feature built right into the Solution Explorer feature of supported version of Microsoft Visual Studio tools.

You can find these assets in this sample file ([GoingBeyond1_Tutorial_Sample.zip](#)). Download the sample file now and extract its contents to a directory on your local drive.

Step 2: Creating the New Project

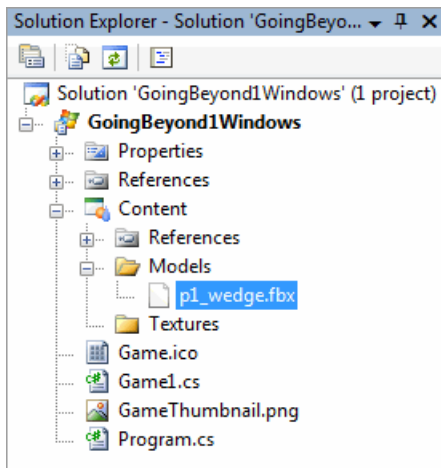

Now that the art assets are available to you, the next step is to create the actual code project that you will be writing.

- Click the **File** menu, and then click **New Project** to create a new project. A dialog box will appear with a tree list on the left pane, marked **Project Types**.
- Select the **XNA Game Studio 3.1** tree node underneath the **Visual C#** node. A set of available projects will appear in the right pane.
- In the right pane of the dialog box, click either **Windows Game (3.1)** or **Xbox 360 Game (3.1)**, depending on whether you are developing on the Xbox 360 or Windows. If you develop for Xbox 360, be sure you have a membership in the XNA Creators Club as described in [Connecting to Your Xbox 360 Console with XNA Game Studio 3.1](#) Otherwise, you will not be able to play your game!
- Type a name for your game into the **Name** field, and a path to where you want the game files stored in the **Location** field.
- Click **OK**.

The code for your new game will be displayed. The project already contains many of the methods that are needed to start and run a game. Right now, however, you need to make sure your art assets are being loaded. Then you can modify the game to display them on the screen. Follow these steps to get some art into your project.

- Make sure you can see the **Solution Explorer** for your project on the right side of the window. If you cannot see it, click the **View** menu, and then click **Solution Explorer**. When it appears, you will see files associated with your project in a tree structure.
- In **Solution Explorer**, look for a node named **Content**. This is where you will store the art and audio for your game. You must add two folders underneath this one.
- Right-click the **Content** node, click **Add**, and then click **New Folder**. This will create a new folder under the **Content** node. Name this folder Models.
- Repeat the last step, creating a new folder under the **Content** node. This time, call the folder Textures.

Your project structure should look similar to this:

You are now ready to add the art from the previously downloaded sample file. The first is a 3D model that will go into this new Content\Models folder, and the second is a texture that will be drawn on the 3D model; this will go in the Content\Textures folder. The files you need are included in the Content sub-project from the GoingBeyond1_Tutorial_Sample.zip file. To add them:

- Right-click the Models folder in the **Solution Explorer**, click **Add**, and then click **Existing Item**. Using the dialog box that appears, browse back to the path you extracted the contents of the sample file to and find the Contents\Models folder. Select **p1_wedge.fbx**. If you cannot see any files, make sure you change the **Files of type** selection box to read **Model Files**. Click **OK**.
- Now, copy the texture associated with the model into the Textures folder. To do this, open a Windows Explorer window and browse to the Content\Textures folder of the extracted sample. Copy wedge_p1_diff_v1.tga, and then browse to your project folder, then into the Content\Textures folder, and paste in the file you just copied.

Note that you do not see the texture you added in **Solution Explorer**. When you add a model, the textures that the model uses do not need to be added to the Content Pipeline. If you need to add textures that you will access manually (such as textures used for 2D sprite drawing), do so via **Solution Explorer**. Otherwise, you can simply copy the texture files to the appropriate folder.

When the files are added to the project, the Content Pipeline automatically identifies them as content files and sets the appropriate processors to run when you build your project. This will happen silently; you will not need to do anything. If you would like to learn more about the Content Pipeline, see [Content Pipeline](#).

Note

Model files contain path information for the textures they use. The ship model you recently added to your project expects to find its texture in a Textures folder that exists alongside the folder the model is in. This will be true for all models used in this tutorial. Models you create or retrieve from other sources may have different path requirements and therefore may require different folder setups. Determine the correct texture paths by examining the model files, or compiling the model as part of your game using XNA Game Studio and noting any Content Pipeline path errors that are returned.

At this point, you are ready to code.

Step 3: Load the Model by Using the Content Pipeline

Take a look at the code for Game1.cs. It should still be on your screen from opening up your project. You will see a lot already done for you. Each of the methods already in the code are waiting for you to drop in your own calls to the XNA Framework. For now, start by modifying the [LoadContent](#) method.

- In the code, find the [LoadContent](#) method.
- Modify the code (including adding the lines shown above the method) to look like this:

C#

```
// Set the 3D model to draw.
Model myModel;

// The aspect ratio determines how to scale 3d to 2d projection.
float aspectRatio;

protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    myModel = Content.Load<Model>("Models\\p1_wedge");
    aspectRatio = graphics.GraphicsDevice.Viewport.AspectRatio;
}
}
```

In that step, you have told the Content Pipeline to load your model into your game when [LoadContent](#) is called at the beginning of your game. Note how you have to pass in the path to the asset relative to your project directory. Also note that there is no extension on the asset anymore. The name of the asset can be anything you want, but by default it is the name of the asset file minus its extension. To see more information on how to change the name of your asset, see [Game Asset Properties](#).

The code now loads the model. Your next step is to get it showing on the screen.

Step 4: Display the Model on the Screen (and Make It Rotate)

You will want to modify two of the methods in your Game1.cs file.

- In the [Draw](#) method, you will draw the model on the screen with texture and lighting.
- In the [Update](#) method, you will make the model change its orientation based on time, so it appears to rotate over time.

Do the harder work first—drawing the model. The first step is to use some XNA Framework methods to set up the model's position and lighting.

- In the code, find the [Draw](#) method.
- Modify the code (including adding the lines shown above the method) to look like this:

C#

```
// Set the position of the model in world space, and set the rotation.
Vector3 modelPosition = Vector3.Zero;
float modelRotation = 0.0f;

// Set the position of the camera in world space, for our view matrix.
Vector3 cameraPosition = new Vector3(0.0f, 50.0f, 5000.0f);

protected override void Draw(GameTime gameTime)
{
    graphics.GraphicsDevice.Clear(Color.CornflowerBlue);

    // Copy any parent transforms.
    Matrix[] transforms = new Matrix[myModel.Bones.Count];
    myModel.CopyAbsoluteBoneTransformsTo(transforms);

    // Draw the model. A model can have multiple meshes, so loop.
    foreach (ModelMesh mesh in myModel.Meshes)
    {

```

```

// This is where the mesh orientation is set, as well
// as our camera and projection.
foreach (BasicEffect effect in mesh.Effects)
{
    effect.EnableDefaultLighting();
    effect.World = transforms[mesh.ParentBone.Index] *
        Matrix.CreateRotationY(modelRotation)
        * Matrix.CreateTranslation(modelPosition);
    effect.View = Matrix.CreateLookAt(cameraPosition,
        Vector3.Zero, Vector3.Up);
    effect.Projection = Matrix.CreatePerspectiveFieldOfView(
        MathHelper.ToRadians(45.0f), aspectRatio,
        1.0f, 10000.0f);
}
// Draw the mesh, using the effects set above.
mesh.Draw();
}
base.Draw(gameTime);
}

```

This code uses helper methods provided by the XNA Framework to set up the necessary 3D math and lighting to display the model on the screen. Use the [World](#) matrix to change the position of the model in the world, the [View](#) matrix to change the position and direction of the camera (your eye), and the [Projection](#) matrix to control how the view of the 3D world is turned into a 2D image (projected) on your screen.

The call to [CopyAbsoluteBoneTransformsTo](#) and associated code inside the setup of the [World](#) matrix are not strictly necessary for this model. However, when using more complicated models, which often use hierarchical structure (where mesh positions, scales, and rotations are controlled by "bones"), this code ensures that any mesh is first transformed by the bone that controls it, if such a bone exists. The mesh is then transformed relative to the bone transformation.

If you compile and run your code now, you will see your model on the screen! It is a spaceship with detail texture. But if you can resist the urge to compile your project and run, you can easily make the model rotate in real-time so you can see all of it:

- In the code, find the [Update](#) method.
- Modify the code (including adding the lines shown above the method) to look like this:

C#

```

protected override void Update(GameTime gameTime)
{
    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back ==
        ButtonState.Pressed)
        this.Exit();

    modelRotation += (float)gameTime.ElapsedGameTime.TotalMilliseconds *
        MathHelper.ToRadians(0.1f);

    base.Update(gameTime);
}

```

And that's it. Compile and run your project by hitting the F5 key or clicking the **Debug** menu, and then clicking **Start Debugging**.

Congratulations!

You did it. There is a lot to making games, but you have taken the first step. A 3D model with lighting and movement in real time. From here, there is no limit to where you could go!

For simplicity's sake, we took some shortcuts that could be optimized for better performance. An obvious improvement would be to precalculate the [View](#) and [Projection](#) matrices instead of calculating them every time [Draw](#) is called, since they do not change. Try out this optimization as a first step. When you are ready to make your game interactive, go to the next tutorial.

Ideas to Expand

Got the urge to tinker with the project a bit? Try these ideas.

- Modify the lighting parameters in the [Draw](#) call. Look at [BasicEffect](#) for an idea of what you can modify.
- Instead of looking at a blue background, try adding an image as your background. See [How To: Make a Scrolling Background](#) for guidance. Hint: Make sure you use a call to [SpriteBatch.Draw](#) that allows you to specify a *layerDepth* parameter, and set that depth to 1.0f.
- Get more ideas and resources at [XNA Creators Club Online](#).

Tutorial 2: Making Your Model Move Using Input

This article details how to use the XNA Framework Input API to take user input from an Xbox 360 Controller and apply it to the model displayed in Tutorial 1.

For more information on using a keyboard to control the model, see [Optional Step: Controlling the Ship With Keyboard Input](#).

Note

This tutorial builds on code you have written during the previous tutorial: [Tutorial 1: Displaying a 3D Model on the Screen](#). Follow the steps in the previous tutorial before starting this tutorial.

The Complete Sample

The code in this tutorial illustrates the technique described in the text. A complete code sample for this tutorial is available for you to download, including full source code and any additional supporting files required by the sample.

[Download GoingBeyond2_Tutorial_Sample.zip](#).

Step 1: Connect Your Xbox 360 Controller

The first step in this tutorial is to make sure you can provide some input to your game. We'll use the Xbox 360 Controller. Designed for use with both a Windows computer and an Xbox 360 console, the controller features many analog and digital inputs, as well as vibration motors to give feedback to the user.

This tutorial uses only the Xbox 360 Controller, but there are more ways to take input: the XNA Framework has support for keyboard and mouse devices. Mouse devices are supported only on Windows, not on Xbox 360. For more information on the different input types, see [Input Overview](#).

For now, connect your Xbox 360 Controller and get ready to code!

Step 2: Create Variables to Turn and Move the Model

We want our ship to move around on the screen. To do that, we'll need to create some variables to track the position and orientation of our model in the world.

Fortunately, from our last tutorial ([Tutorial 1: Displaying a 3D Model on the Screen](#)), we have two variables to do just that: *modelPosition*, which is a three-dimensional vector, and *modelRotation*, which is a floating-point value.

Currently, this system allows three degrees of translation (changing position in the world), but only one degree of rotation (changing orientation). For this demonstration, we will use that limitation to simplify our input. In many 3D games, there are three degrees of translation, and three degrees of rotation, but this is a good start.

What we can do right now to make input a little more interesting is add another vector for velocity. By updating the position with the velocity each frame, our 3D model can accelerate and decelerate smoothly. Let's try it.

- Make sure your project from [Tutorial 1: Displaying a 3D Model on the Screen](#) is open. If it isn't, open it by selecting the **File** menu, clicking **Open Project**, and browsing to your project.
- View the code by double-clicking `Game1.cs` in Solution Explorer.
- In the code, find the `Update` method. Modify it to look like this:

C#

```
// Set the velocity of the model, applied each frame to the model's position.  
Vector3 modelVelocity = Vector3.Zero;
```

```

protected override void Update(GameTime gameTime)
{
    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back == ButtonState.Pressed)
        this.Exit();

    // Get some input.
    UpdateInput();

    // Add velocity to the current position.
    modelPosition += modelVelocity;

    // Bleed off velocity over time.
    modelVelocity *= 0.95f;

    base.Update(gameTime);
}

```

The code you've just added to input runs every frame, and does a few different things. First, it gets rid of the code that automatically rotates the ship. You'll be controlling that by using your controller. Next, it calls a method named **UpdateInput**. That method does not exist yet. You'll have to create it in the next step. Last, it adds the velocity of our model to its position, moving it in the world by its velocity, and decays the velocity so that eventually the model will slow down.

Step 3: Take Input from the User

Now that the model is set up to move with velocity, you now need to provide some logic that will change the velocity based on controller input.

A simple system that we can use is an orientation thrust method: in essence, you can point the front of your model in different directions using your controller's thumbstick, then apply thrust in the direction you are pointing using your controller's trigger. By building up thrust in a direction, the model will begin to move.

We can map our controls to the game this way.

- Pressing left or right on the left thumbstick will increase or decrease the value of the *modelRotation* variable by some amount.
- Pressing on the right trigger will add a vector in the direction of our *modelRotation* variable to our *modelVelocity* vector.
- Pressing the **A** button will reset the position, velocity, and rotation values of the model to "warp" the ship back to the center of the screen.

Note

Both the triggers and the thumbsticks are analog controls, meaning that they can report their movements in varying amounts, rather than just on or off. On the Xbox 360 Controller, the two thumbsticks and two triggers are analog controls, and all other buttons are digital buttons.

Let's code it!

- Find some empty space in your code below the `Update` method.
- Add a new method called **protected void UpdateInput()**.
- Modify the method to look like this:

C#

```

protected void UpdateInput()
{
    // Get the game pad state.
    GamePadState currentState = GamePad.GetState(PlayerIndex.One);
    if (currentState.IsConnected)
    {
        // Rotate the model using the left thumbstick, and scale it down
        modelRotation -= currentState.ThumbSticks.Left.X * 0.10f;
    }
}

```

```

    // Create some velocity if the right trigger is down.
    Vector3 modelVelocityAdd = Vector3.Zero;

    // Find out what direction we should be thrusting,
    // using rotation.
    modelVelocityAdd.X = -(float)Math.Sin(modelRotation);
    modelVelocityAdd.Z = -(float)Math.Cos(modelRotation);

    // Now scale our direction by how hard the trigger is down.
    modelVelocityAdd *= currentState.Triggers.Right;

    // Finally, add this vector to our velocity.
    modelVelocity += modelVelocityAdd;

    GamePad.SetVibration(PlayerIndex.One,
        currentState.Triggers.Right,
        currentState.Triggers.Right);

    // In case you get lost, press A to warp back to the center.
    if (currentState.Buttons.A == ButtonState.Pressed)
    {
        modelPosition = Vector3.Zero;
        modelVelocity = Vector3.Zero;
        modelRotation = 0.0f;
    }
}
}
}

```

That method does a lot. Let's take it piece by piece to investigate exactly what you're doing with input and the model.

```

// Get the game pad state.
GamePadState currentState = GamePad.GetState(PlayerIndex.One);

```

This call to [GetState](#) retrieves a [GamePadState](#) object, which contains the information we need about the controller—in this case, thumbstick and trigger positions.

```

// Rotate the model using the left thumbstick, and scale it down
modelRotation -= currentState.ThumbSticks.Left.X * 0.10f;

```

Retrieving the x-axis value of the left thumbstick (left and right movement) returns a value that is added to the *modelrotation* variable. The value is scaled down so that the rotation isn't too fast.

```

// Create some velocity if the right trigger is down.
Vector3 modelVelocityAdd = Vector3.Zero;

// Find out what direction we should be thrusting,
// using rotation.
modelVelocityAdd.X = -(float)Math.Sin(modelRotation);
modelVelocityAdd.Z = -(float)Math.Cos(modelRotation);

// Now scale our direction by how hard the trigger is down.
modelVelocityAdd *= currentState.Triggers.Right;

```

A little math here helps translate the rotation of the ship into a vector. Taking the sine value of the rotation gives us the proper amount of X (left and right) movement, and the cosine gives us the Z (forward and back) movement. Then, we take the vector and lengthen it by how hard the player is holding down the right trigger.

```

// Finally, add this vector to our velocity.
modelVelocity += modelVelocityAdd;

```

Finally, the created vector is added to the current velocity vector to create the final velocity vector that will be applied to move the model around.

```
GamePad.SetVibration(PlayerIndex.One,
    currentState.Triggers.Right,
    currentState.Triggers.Right);
```

We're using the right trigger values to give some feedback to the player with the Xbox 360 Controller vibration motors, using [SetVibration](#). The Xbox 360 Controller has two motors that run at different speeds, so experiment to find the best combination for the action that's happening in the game.

```
// In case you get lost, press A to warp back to the center.
if (currentState.Buttons.A == ButtonState.Pressed)
{
    modelPosition = Vector3.Zero;
    modelVelocity = Vector3.Zero;
    modelRotation = 0.0f;
}
```

This little extra will move the model back to its original position and orientation in case it leaves the screen.

Optional Step: Controlling the Ship With Keyboard Input

An Xbox controller is not the only means of control available for your ship. You can also use the standard keyboard that is hooked up to your computer. The following instructions assume that you have completed the previous steps in this tutorial.

⚠Caution

Keyboard input is not supported for the Xbox 360 platform. Controlling the ship on an Xbox 360 requires an Xbox 360 Controller.

The keyboard-specific code will be added to the `Game1.Update` and `Game1.UpdateInput` methods that were modified earlier. Let's handle the easy stuff first – modification of the `Game1.Update` method.

Modifying the Update Method

Currently, you can only exit your game with the controller or by clicking the **Close** button. Let's modify the following code:

```
if (GamePad.GetState(PlayerIndex.One).Buttons.Back == ButtonState.Pressed)
```

to match this:

```
if (GamePad.GetState(PlayerIndex.One).Buttons.Back == ButtonState.Pressed ||
    Keyboard.GetState().IsKeyDown(Keys.Escape))
```

The new code now closes the game when you press the Escape key.

Modifying the UpdateInput Method

This step involves more code than the previous step. Once you have modified the code, you can control the ship's rotation with the A (rotate left) and D (rotate Right) keys and accelerate with the Enter key.

In the `Game1.UpdateInput` method, after the existing declaration of the `currentState` variable, add the following line of code:

```
KeyboardState currentKeyState = Keyboard.GetState();
```

This captures the current state of the keyboard, including which keys were being pressed at the time.

Remove the following line (Don't forget the matching curly brace!):

```
if (currentState.IsConnected)
{
```

This allows keyboard input to be received if a controller is not connected.

Search farther down the code and find the line that assigns the X value of the left thumbstick to `modelRotation`. Right before that line, add the following:

```
if (currentKeyState.IsKeyDown(Keys.A))
    modelRotation += 0.10f;
else if (currentKeyState.IsKeyDown(Keys.D))
    modelRotation -= 0.10f;
```

```
else
```

This first examines the keyboard for input (specifically, the A and D keys) and changes the rotation value accordingly. If no keyboard input is detected, the game controller is checked for input.

Search farther down for the following line of code:

```
modelVelocityAdd *= currentState.Triggers.Right;
```

Right before that code, add the following:

```
if (currentKeyState.IsKeyDown(Keys.W))
    modelVelocityAdd *= 1;
else
```

This code checks to see if the W key is pressed and, if so, increases the current velocity. If the W key is not pressed, the game controller is checked for input.

The final modification warps the ship back to its original position if the Enter key is pressed.

Look for the code that checks the state of the A button on the controller (near the end of the method). Modify this line to also check for a key press. After the modification, it should look like this:

```
if (currentState.Buttons.A == ButtonState.Pressed || currentKeyState.IsKeyDown(Keys.Enter))
```

Rebuild and run the game and you can now steer the ship with the A and D keys, accelerate with the W key, and warp back with the Enter key!

Congratulations!

At this point, your ship moves and gives you feedback through your Xbox 360 Controller. The player is in control of the action.

When you're ready, let's add the final element—audio—to get you on your way. Once the player can control the action, and see and hear the results of their actions, you're well on your way to creating a game.

Ideas to Expand

Want to play around some more with input? Try these ideas.

- Change the game to view your model from the top, as in a top-down arcade game. (Hint: Play with the *cameraPosition* vector. Note that you can't set it exactly up and down because the camera vector cannot be the same as the "up" vector.)
- Scale the vibration to occur more powerfully as the ship approaches the viewer. (Hint: Use the distance between *modelPosition* and *cameraPosition*.)
- Try using a keyboard to control the ship. See the [Keyboard](#) class. (Hint: You can plug a USB keyboard into your Xbox 360 console.)
- Get more ideas and resources at [XNA Creators Club Online](#).

The Complete Sample

The code in this tutorial illustrates the technique described in the text. A complete code sample for this tutorial is available for you to download, including full source code and any additional supporting files required by the sample.

[Download GoingBeyond3_Tutorial_Sample.zip](#).

Step 1: Get Some Wave Files

Audio in XNA Game Studio is wave based. There are two methods for using wave files in your game: using XACT to create and play your sound effects or using the [SoundEffect](#) class. We'll use the second method because it lets you quickly get some cool sound effects into your game.

Note

For more information on using XACT, see [Audio Overview](#).

The first thing to do is get some wave files. The files used in this tutorial are included in the (GoingBeyond3_Tutorial_Sample.zip). Download this file now and extract it to its own directory.

- Make sure your project from [Tutorial 2: Making Your Model Move Using Input](#) is open. If it is not, open it by clicking the **File** menu, and then click **Open Project** and browse to your project.
- In Solution Explorer, right-click the **Content** node, click **Add**, and then click **New Folder**. Name this folder `Audio`.
- Right-click the **Audio** folder you just created, click **Add**, and then click **New Folder**. Name this folder `Waves`.
- Open Windows Explorer. Browse to the folder containing the content from your recently extracted sample file and from there to the `Content\Audio\Waves` folder. Inside that folder, you will see two audio files: `engine_2.wav` and `hyperspace_activate.wav`.
- Copy those files to the `Content\Audio\Waves` folder in Windows Explorer.
- Right-click the **Waves** folder, click **Add**, and then click **Existing Item**. Using the dialog box that appears, browse back to the location of the extracted tutorial sample files and find the `Contents\Audio\Waves` folder. Select both wave files, and click **OK**.

Step 2: Loading the Wave Files by Using the Content Pipeline

You probably remember that you have already used the content pipeline to load content into your game. In this step, you will use that same technique to load sound effects into your game. With a few simple lines of code, you can play those sound effects at the appropriate time.

Open your `Game1.cs` file, and take a look at the **LoadContent** method. This is where the ship model is loaded by the content pipeline. You will add new code that declares two [SoundEffect](#) members and one [SoundEffectInstance](#), and loads the recently added sound effect files into those new member variables.

- After the code that declares the **myModel** class member, add the following code:

C#

```
//Set the sound effects to use
SoundEffect soundEngine;
SoundEffectInstance soundEngineInstance;
```

```
SoundEffect soundHyperspaceActivation;
```

- Modify the **LoadContent** code (including adding the lines shown above the method) to look like this:

C#

```
// The aspect ratio determines how to scale 3d to 2d projection.
float aspectRatio;

protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    myModel = Content.Load<Model>("Models\\p1_wedge");
    soundEngine = Content.Load<SoundEffect>("Audio\\Waves\\engine_2");
    soundEngineInstance = soundEngine.CreateInstance();
    soundHyperspaceActivation =
        Content.Load<SoundEffect>("Audio\\Waves\\hyperspace_activate");

    aspectRatio = graphics.GraphicsDevice.Viewport.AspectRatio;
}
```

In these steps, you declared two member variables, and told the content pipeline to load two wave files into your game when **LoadContent** is called at the beginning of your game. You also assigned a **SoundEffectInstance** to one of those files, so you can monitor the playback later.

The code now loads the wave files. Your next step is to play them at the appropriate times.

Step 3: Play Sounds Using the Audio API

You can access the sounds you wish to play in your game through a **SoundEffect** object, or play directly by calling **Play**.

For your looping engine sound, call **SoundEffectInstance.Play** to begin looping the engine sound effect. Use the **SoundEffectInstance** to pause and resume the sound effect as your engines turn on and off when the user holds the trigger. When the player presses the **A** button to warp, play the hyperspace sound by calling **SoundEffect.Play**. Calling **SoundEffect.Play** plays the sound, but it doesn't allow us to pause it (which is okay for the hyperspace sound, but not for the engine sound).

- Find the **UpdateInput** method. Modify it to look like this:

C#

```
protected void UpdateInput()
{
    // Get the game pad state.
    GamePadState currentState = GamePad.GetState(PlayerIndex.One);
    if (currentState.IsConnected)
    {
        // Rotate the model using the left thumbstick, and scale it down
        modelRotation -= currentState.ThumbSticks.Left.X * 0.10f;

        // Create some velocity if the right trigger is down.
        Vector3 modelVelocityAdd = Vector3.Zero;

        // Find out what direction we should be thrusting,
        // using rotation.
        modelVelocityAdd.X = -(float)Math.Sin(modelRotation);
        modelVelocityAdd.Z = -(float)Math.Cos(modelRotation);

        // Now scale our direction by how hard the trigger is down.
        modelVelocityAdd *= currentState.Triggers.Right;

        // Finally, add this vector to our velocity.
    }
}
```

```

        modelVelocity += modelVelocityAdd;

        GamePad.SetVibration(PlayerIndex.One,
            currentState.Triggers.Right,
            currentState.Triggers.Right);

        //Play engine sound only when the engine is on.
        if (currentState.Triggers.Right > 0)
        {

            if (soundEngineInstance.State == SoundState.Stopped)
            {
                soundEngineInstance.Volume = 0.75f;
                soundEngineInstance.IsLooped = true;
                soundEngineInstance.Play();
            }
            else
                soundEngineInstance.Resume();
        }
        else if (currentState.Triggers.Right == 0)
        {
            if (soundEngineInstance.State == SoundState.Playing)
                soundEngineInstance.Pause();
        }

        // In case you get lost, press A to warp back to the center.
        if (currentState.Buttons.A == ButtonState.Pressed)
        {
            modelPosition = Vector3.Zero;
            modelVelocity = Vector3.Zero;
            modelRotation = 0.0f;
            soundHyperspaceActivation.Play();
        }
    }
}

```

Many things are happening here. Here is a breakdown of what you are doing.

```
SoundEffectInstance soundEngineInstance;
```

The [SoundEffectInstance](#) represents an instance of a sound. In this case, **soundEngineInstance** will represent the sound of your engines when you hold the right trigger.

```

//Play engine sound only when the engine is on.
if (currentState.Triggers.Right > 0)
{

    if (soundEngineInstance.State == SoundState.Stopped)
    {
        soundEngineInstance.Volume = 0.75f;
        soundEngineInstance.IsLooped = true;
        soundEngineInstance.Play();
    }
    else
        soundEngineInstance.Resume();
}
else if (currentState.Triggers.Right == 0)
{
    if (soundEngineInstance.State == SoundState.Playing)
        soundEngineInstance.Pause();
}

```

This code manages the engine sound. Since you enter this code once each frame, you have to make sure you do not

continually try to play the same sound. You only want to modify the state of the [SoundEffectInstance](#) if there is a change, such as the trigger being released after being held. If the sound is stopped (which it will be at the start of the game), we call [Play](#) to start it up.

From that point forward, each release of the trigger will call [Pause](#) and halt playback of the [SoundEffectInstance](#). Subsequently, holding the trigger again will call [Resume](#), and playback will continue.

```
// In case you get lost, press A to warp back to the center.
if (currentState.Buttons.A == ButtonState.Pressed)
{
    modelPosition = Vector3.Zero;
    modelVelocity = Vector3.Zero;
    modelRotation = 0.0f;
    soundHyperspaceActivation.Play();
}
```

Finally, pressing the **A** button warps, gets, and plays a sound all at once using [Play](#). Since you do not need to stop or pause this sound, but can just let it play, there is no reason to hold on to the sound in a [SoundEffectInstance](#) object.

Congratulations!

At this point, you have a spaceship floating in 3D space. This spaceship moves around when you use your Xbox 360 Controller, it makes sounds, and it gives you feedback in your controller. You have created the very beginnings of a 3D game using XNA Game Studio, and you are only just getting started. There is so much more to explore!

Introduction

Understanding the basics of game coding is the single most-difficult step for a beginning game programmer. While it is easy to find samples that show completed games, tips and tricks, or tutorials that show you how to do specific techniques, there are very few that help you through the process of game construction. The objective of this tutorial is to help you learn about the process of game construction, while guiding you through writing a relatively complete game. In addition, this tutorial will use only those assets found in the complete sample file ([GoingBeyond4_Tutorial_Sample.zip](#)), eliminating the need to install additional content. Download the sample file now and extract its contents to a directory on your local drive.

The game you implement will be a simple clone of the popular Asteroids® game by Atari®. The place of Asteroids in video game history is well known, and you are encouraged to read the [interesting history of the game on Wikipedia](#). This tutorial assumes you have a general idea of how the Asteroids game works.

A lot of initial work in this tutorial is already done for you. In fact, this tutorial picks up at the end of the [Tutorial 3: Making Sounds with XNA Game Studio](#) tutorial. Once you have completed the first three tutorials in [Going Beyond: XNA Game Studio in 3D](#), you will have a moveable spaceship with sounds and rendering in 3D space. In another 60 to 90 minutes of coding time, you will have a relatively complete Asteroids-style game.

Before You Begin: Getting the Project Ready

Begin this tutorial by completing the first three tutorials in the [Going Beyond: XNA Game Studio in 3D](#) series, or by downloading the completed code for the third tutorial (Video Tutorial 3: Making Sounds with XNA Game Studio and XACT) from the [XNA Creators Club Online Web site](#).

Step 1: Ship Shape

The first three tutorials in the [Going Beyond: XNA Game Studio in 3D](#) series explained the basics of a single interactive object, rendered in 3D. A true game, however, needs more than just one object. The first step toward making this tutorial into a game is to prepare the game to track and render several objects.

Think of the idea of your ship on the screen. It is drawn using a `Model` class, it has a position tracked by a `Vector3`, and still another `Vector3` tracks velocity. A `float` tracks the rotation angle. Each of these data types is modified or checked in different places along the code path, and while the end result looks good to the user, the drawback comes when you try to extend the gameplay to include another object that needs similar data.

If, for instance, you wanted to add a second ship that would also draw on the screen, and had the ability to move and turn, you would have to create a copy of each of the variables you were using for the first ship. You would have to duplicate the code you wrote that checked and modified each variable. Each copied line would be nearly identical to the original line, except that it was acting on a new variable.

For a game that will ultimately have more than a dozen objects all drawing and moving around, this is unworkable. The duplicated code would make your code unreadable and painful to modify. However, there is a better way. If you create a code object that holds the common variables that allow you to draw and move a 3D object, then maintain a list of these objects, you can draw and move them all together using the same code. This process is called encapsulation, and is the beginning of object-oriented programming, which becomes more and more important the larger your game becomes.

Start by right-clicking on your project in Solution Explorer, and select **Add**, then **Class**. Type `Ship.cs` into the **Name** box, then click **Add**.

When you add the new file, it will open up in the code window. This new file represents a class, or code object. This particular class is named `Ship`. You will notice it is very minimal now; modify it so it looks like the following:

```
C#  
  
using System;  
using System.Collections.Generic;  
using System.Text;  
using Microsoft.Xna.Framework;  
using Microsoft.Xna.Framework.Content;  
using Microsoft.Xna.Framework.Graphics;  
using Microsoft.Xna.Framework.Input;  
  
namespace GoingBeyond4  
{  
    class Ship  
    {  
        public Model Model;  
        public Matrix[] Transforms;  
  
        //Position of the model in world space  
        public Vector3 Position = Vector3.Zero;  
  
        //Velocity of the model, applied each frame to the model's position  
        public Vector3 Velocity = Vector3.Zero;  
  
        public Matrix RotationMatrix = Matrix.Identity;  
        private float rotation;  
        public float Rotation  
        {  
            get { return rotation; }  
            set  
            {  
                float newVal = value;  
                while (newVal >= MathHelper.TwoPi)  
                {  
                    newVal -= MathHelper.TwoPi;  
                }  
                while (newVal < 0)  
                {  
                    newVal += MathHelper.TwoPi;  
                }  
  
                if (rotation != newVal)  
                {  
                    rotation = newVal;  
                    RotationMatrix = Matrix.CreateRotationY(rotation);  
                }  
            }  
        }  
    }  
  
    public void Update(GamePadState controllerState)  
    {  
        // Rotate the model using the left thumbstick, and scale it down.
```

```

        Rotation -= controllerState.ThumbSticks.Left.X * 0.10f;

        // Finally, add this vector to our velocity.
        Velocity += RotationMatrix.Forward * 1.0f *
            controllerState.Triggers.Right;
    }
}

```

You can see that the `Ship` class now does a lot—it holds onto the ship's position, velocity, rotation, and 3D model, and has its own `Update` method that will move the ship around.

Now that you have created the `Ship` class, you need to change the code in the `Game1.cs` code file to take advantage of this new, encapsulated data. Double-click on **Game1.cs** in your Solution Explorer.

Start with drawing the ship's model. Your original drawing code was inside the `Draw` method, but that will not scale up to multiple objects very well. You will be drawing `Model` objects on the screen, so create a method that will draw a chosen `Model`. Below the `Draw` method, add a new method called `DrawModel`, like so:

C#

```

public static void DrawModel(Model model, Matrix modelTransform,
    Matrix[] absoluteBoneTransforms)
{
    //Draw the model, a model can have multiple meshes, so loop
    foreach (ModelMesh mesh in model.Meshes)
    {
        //This is where the mesh orientation is set
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.World =
                absoluteBoneTransforms[mesh.ParentBone.Index] *
                modelTransform;
        }
        //Draw the mesh, will use the effects set above.
        mesh.Draw();
    }
}

```

This `DrawModel` method takes your model-drawing algorithm and applies it to any `Model` object passed into it, drawing the `Model` on the screen. Next, modify the `Draw` call so that it calls this new method:

C#

```

protected override void Draw(GameTime gameTime)
{
    graphics.GraphicsDevice.Clear(Color.CornflowerBlue);

    Matrix shipTransformMatrix = ship.RotationMatrix
        * Matrix.CreateTranslation(ship.Position);
    DrawModel(ship.Model, shipTransformMatrix, ship.Transformations);
    base.Draw(gameTime);
}

```

The code from the previous tutorial contained declarations for `modelPosition` and `modelRotation` values above the `Draw` call. Delete those—you will not need them anymore. Also delete the `cameraPosition` variable—you will recreate this later.

Next, modify the `Update` and `UpdateInput` methods to use the values in the new `Ship` class as follows:

C#

```

protected override void Update(GameTime gameTime)
{
    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back ==
        ButtonState.Pressed)
        this.Exit();
}

```

```

// Get some input.
UpdateInput();

// Add velocity to the current position.
ship.Position += ship.Velocity;

// Bleed off velocity over time.
ship.Velocity *= 0.95f;

base.Update(gameTime);
}

protected void UpdateInput()
{
    // Get the game pad state.
    GamePadState currentState = GamePad.GetState(PlayerIndex.One);
    if (currentState.IsConnected)
    {
        ship.Update(currentState);

        //Play engine sound only when the engine is on.
        if (currentState.Triggers.Right > 0)
        {
            if (soundEngineInstance.State == SoundState.Stopped)
            {
                soundEngineInstance.Volume = 0.75f;
                soundEngineInstance.IsLooped = true;
                soundEngineInstance.Play();
            }
            else
                soundEngineInstance.Resume();
        }
        else if (currentState.Triggers.Right == 0)
        {
            if (soundEngineInstance.State == SoundState.Playing)
                soundEngineInstance.Pause();
        }

        // In case you get lost, press A to warp back to the center.
        if (currentState.Buttons.A == ButtonState.Pressed)
        {
            ship.Position = Vector3.Zero;
            ship.Velocity = Vector3.Zero;
            ship.Rotation = 0.0f;
            soundHyperspaceActivation.Play();
        }
    }
}
}

```

Above the `UpdateInput` method, remove the `modelVelocity` variable above `Update`—it is no longer needed.

Finally, you need to make a change to the way your initialization and content loading are handled. Starting from the top of the `Game` class and continuing down to just above the call to `Update`, modify the code as follows:

C#

```

GraphicsDeviceManager graphics;

//Camera/View information
Vector3 cameraPosition = new Vector3(0.0f, 0.0f, -5000.0f);
Matrix projectionMatrix;
Matrix viewMatrix;

//Audio Components
SoundEffect soundEngine;
SoundEffectInstance soundEngineInstance;

```

```

SoundEffect soundHyperspaceActivation;

//Visual components
Ship ship = new Ship();

public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";
}

/// <summary>
/// Allows the game to perform any initialization it needs to before
/// starting to run. This is where it can query for any required
/// services and load any non-graphic related content.
/// Calling base.Initialize will enumerate through any components
/// and initialize them as well.
/// </summary>
protected override void Initialize()
{
    projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
        MathHelper.ToRadians(45.0f),
        GraphicsDevice.DisplayMode.AspectRatio,
        1.0f, 10000.0f);
    viewMatrix = Matrix.CreateLookAt(cameraPosition,
        Vector3.Zero, Vector3.Up);

    base.Initialize();
}

private Matrix[] SetupEffectDefaults(Model myModel)
{
    Matrix[] absoluteTransforms = new Matrix[myModel.Bones.Count];
    myModel.CopyAbsoluteBoneTransformsTo(absoluteTransforms);

    foreach (ModelMesh mesh in myModel.Meshes)
    {
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.EnableDefaultLighting();
            effect.Projection = projectionMatrix;
            effect.View = viewMatrix;
        }
    }
    return absoluteTransforms;
}

protected override void LoadContent()
{
    ship.Model = Content.Load<Model>("Models/p1_wedge");
    ship.Transform = SetupEffectDefaults(ship.Model);
    soundEngine = Content.Load<SoundEffect>("Audio/Waves/engine_2");
    soundEngineInstance = soundEngine.CreateInstance();
    soundHyperspaceActivation =
        Content.Load<SoundEffect>("Audio/Waves/hyperspace_activate");
}

```

While it may seem like a lot of work, the modified code is a good example of encapsulation, and will come in handy as you develop your game.

Step 2: Camera Work

Now that you have a ship object ready, the next step is to get the ship flying around the screen from a top-down point of view. You will accomplish this by simply changing the camera's angle and distance. Finally, you will adjust the rotation mechanics on the user input, so that it matches the behavior you want.

Reverse the camera position along the z-axis by simply altering the value from negative 5000 to positive 25000. The `cameraPosition` member is declared near the start of the `Game1` class. Now your `cameraPosition` declaration will look like this:

C#

```
Vector3 cameraPosition = new Vector3(0.0f, 0.0f, 25000.0f);
```

Unfortunately, if you run the tutorial with only that change, the ship does not show up. This is because the "projection matrix" of the camera is not correct. The formal term that describes the problem is "bounding frustum culling" (also called "viewing frustum culling"). Look in the XNA Game Studio documentation for the [BoundingFrustum](#) class, which includes a key diagram to help you learn more about frustums and how they relate to the camera. A camera's near and far plane is set in a specific way to (usually) address performance concerns. In this case, the camera's original near plane is 1 and the far plane is at 10,000. When the camera was set at 5,000 units, like in Figure 1, the ship was in the camera's view space.

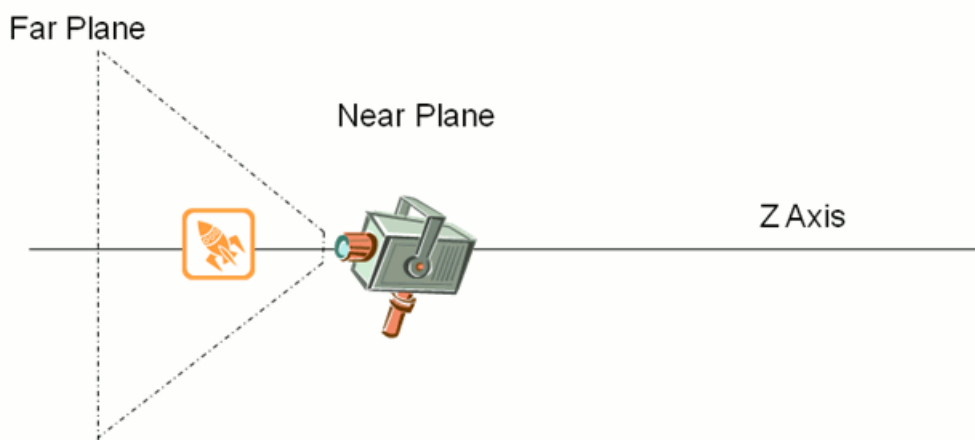

Figure 1. Original camera setting and view space

That's perfectly fine when the spaceship was located 5,000 units away from the camera. But when you moved the camera starting point to 25,000, the camera's view space was in the wrong place, as in Figure 2, leaving the ship too far away to be seen.

Figure 2. New camera position with incorrect view space

Correct the viewing space problem now. Inside the `Initialize` method of the `Game1` class, you will see the method that creates the `projectionMatrix`:

C#

```
projectionMatrix = Matrix.CreatePerspectiveFieldOfView(  
    MathHelper.ToRadians(45.0f),  
    GraphicsDevice.DisplayMode.AspectRatio,  
    1.0f, 10000.0f);
```

You need to change the near and far clipping planes of the frustum so that the ship is back in the viewing space. You determine

the near and far clipping planes by simple math. The camera is 25,000 units away from the ship, so you set the near plane 5,000 units "closer" to the camera, and the far plane 5,000 units "farther away," like this:

C#

```
projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
    MathHelper.ToRadians(45.0f),
    GraphicsDevice.DisplayMode.AspectRatio,
    20000.0f, 30000.0f);
```

This corrects the viewing space so that the ship is inside it, as in Figure 3.

Figure 3. Corrected viewing space

Running the program now will show you the view facing the back end of the ship, rather than facing the nose end. If you fly the ship toward or away from you, you will see the ship disappear as it moves outside the frustum after a few seconds. Now alter the orientation of the ship and how it responds to your input.

In the `Ship` class, you will change the default orientation of the ship so that it starts from a "top-down" perspective. Double-click on **Ship.cs** in Solution Explorer.

If the ship is initially facing away from you, a 90-degree rotation along the x-axis will give you the top-down view. Don't forget, you are looking at the ship down the z-axis, so from your perspective, changes in x are "left/right" and changes in y are "up/down." Thus, rotating the ship on the x-axis flips the ship around as if it were spinning on the wings. In the XNA Framework, angular measurements are given in radians, which means you are rotating the ship $\text{Pi}/2$ radians.

Replace the existing declaration of `RotationMatrix` with the following:

C#

```
public Matrix RotationMatrix =
    Matrix.CreateRotationX(MathHelper.PiOver2);
```

Now, every time you change the ship's rotation (in the ship's `Rotation` property "set" method), you alter the rotation matrix to include this default rotation, plus the rotation amount along the z-axis supplied by the player's controller. You could just as well rotate along any other axis, provided you:

- Position the camera properly.
- Perform your translation and rotation calculations in relation to the correct axis.

Failing to properly calculate translation and rotation movement can yield some surprising, if not frustrating, results. Avoid this by modifying the set method of the `Rotation` property. Change the existing `if` clause to match the following:

C#

```
if (rotation != value)
{
    rotation = value;
    RotationMatrix =
        Matrix.CreateRotationX(MathHelper.PiOver2) *
        Matrix.CreateRotationZ(rotation);
}
```

You should notice that your ship appears to be flying slowly now. That is because your view is much farther away than it used

to be. Just under the declaration of `Velocity`, add a floating-point constant that you can use to adjust the ship's velocity:

C#

```
//amplifies controller speed input
private const float VelocityScale = 5.0f;
```

At the end of the ship's `Update` method, change the current `Velocity` computation to use the `VelocityScale` value to give the ship a little extra speed (more accurately, it increases the number of units per frame in the game):

C#

```
Velocity += RotationMatrix.Forward * VelocityScale *
    controllerState.Triggers.Right;
```

Running with these changes will now give you a top-down view of the ship, which you can fly around on the screen. If you fly off the screen, press the **warp** button. It's a good idea to change the original use of the **A** button to another button, as you will be using the **A** button to fire in a later step.

Step 3: You Need Rocks. Lots of Them.

You have a ship in the game, so now add asteroids to it. For the sake of simplicity, you are only going to track each asteroid's position, direction, and speed. Create a simple class that has only those three members. Right-click on the **GoingBeyond4Windows** project in Solution Explorer, click **Add**, and then click **Class**. Name it `Asteroid.cs`. (Don't forget to add a using statement for `Microsoft.Xna.Framework`). Because this class is "lightweight," you will change it from a class to a structure. (Literally, change the word "class" to "struct" in the file.) There are many nuances about when to use and not use a structure (called a "value type" in C# parlance), which are beyond the scope of this document. Many of the issues relate to performance and garbage collection (GC). In a blog post by the Compact Framework team (<http://blogs.msdn.com/netcfteam/archive/2006/12/22/managed-code-performance-on-xbox-360-for-xna-part-2-gc-and-tools.aspx>) they say this about value types:

"Games typically have lots of small objects that represent game state. The obvious optimization here is to reduce live object count. You can do that by defining those data structures as structs which are value types (to use more general terminology). Value types stay off the GC heap... of course that assumes that your structs don't get boxed in to objects, which can often happen unknowingly in your code."

In this case, you will use a value type for the `Asteroid` (and later for bullets) to reduce garbage collection events, as well as to keep the implementation simple.

Add these three members to the structure:

C#

```
public Vector3 position;
public Vector3 direction;
public float speed;
```

Double-click on your `Game1.cs` file. Inside your `Game1` class, you will create a simple array that contains asteroids. Add some additional members to your `Game1` class to render the asteroids. After the declaration for the ship (`Ship ship = new Ship();`), add the following:

C#

```
Model asteroidModel;
Matrix[] asteroidTransforms;
Asteroid[] asteroidList = new Asteroid[GameConstants.NumAsteroids];
Random random = new Random();
```

There is something new in each of these four lines, so look at each one. The first line is an object that holds on to a lot of information that describes the actual asteroid model loaded by the Content Pipeline processor. You will do that shortly. The second line retains state information related to specific lighting and effect transformations on the asteroid. Because you are not adding any special lighting effects, you will set up a default effect on the model and leave it. The third line is a simple array of asteroids, but you will notice the introduction of the `GameConstants` class, which will generally hold values that you might want to change as you develop and test the game. There will be more about that shortly. The final line creates a random number generator, which you will use for a few purposes in the game.

Look at this new `GameConstants` class briefly. One nice design trick for simple games like this is to gather game parameters, which you might want to customize, into a single location. Create that class now. Click **Add**, and then click **Class**. Name it `GameConstants.cs`. Once the file opens, add these constants to the class (you will use the `PlayfieldSize` constants later):

C#

```
//camera constants
public const float CameraHeight = 25000.0f;
public const float PlayfieldSizeX = 16000f;
public const float PlayfieldSizeY = 12500f;
//asteroid constants
public const int NumAsteroids = 10;
```

As you might guess from the addition of the camera constants, you will want to modify the `CameraPosition` declaration in the `Game1` class to look like this now:

C#

```
Vector3 cameraPosition = new Vector3(0.0f, 0.0f,
    GameConstants.CameraHeight);
```

And the initialization of the `projectionMatrix` (located in the `Initialize` method) to look like this:

C#

```
projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
    MathHelper.ToRadians(45.0f),
    GraphicsDevice.DisplayMode.AspectRatio,
    GameConstants.CameraHeight - 1000.0f,
    GameConstants.CameraHeight + 1000.0f);
```

Turn your attention back to the `Asteroid` structure again. To render the asteroid, you need to add an asteroid model to the Content Pipeline. You already have a `Content/Models` directory in your game, since it is storing your ship model. Add the "asteroid1.x" model to that directory by right-clicking on the directory, clicking **Add**, and then clicking **Existing Item**. Then navigate back to the path to which you extracted the contents of the sample file. (Remember, you had to do this when you did "Tutorial 1: Displaying a 3D Model on the Screen" from the "Going Beyond: XNA Game Studio in 3D" series). Select the **asteroid1.x** file from your `Content/Models` directory (you might need to select files of type "Content Pipeline Files" to see it), and add it to your `Models` directory. In addition to adding this model, you will also need to manually copy the asteroid's texture file, "asteroid1.tga," from the `Content/Textures` directory of the sample to the `Content/Textures` subfolder in your game project folder. Just manually copy it. Do not use the **Add**, and then **Existing Item** approach. Also, be very careful about the copying process. A common beginner's mistake is to copy a Texture file into a Model directory. This is not a good idea.

Now you will visit the `LoadContent` method in the `Game1` class. This is where you will load the mesh model for your asteroid that you just added. Just below the line where you added the `p1_wedge` model, load the asteroid model and transforms:

C#

```
asteroidModel = Content.Load<Model>("Models/asteroid1");
asteroidTransforms = SetupEffectDefaults(asteroidModel);
```

Next, you'll need a method to populate the `asteroidList` with several asteroids. It will be called at the end of the `Initialize` method in the `Game1` class (before the `base.Initialize()` call). When you create an asteroid, you will give it a starting speed and random direction. For now, start the asteroids from the center of the screen.

Create a separate method called `ResetAsteroids`, which will populate the list of asteroids.

```
private void ResetAsteroids()
{
    for (int i = 0; i < GameConstants.NumAsteroids; i++)
    {
        asteroidList[i].position = Vector3.Zero;
        double angle = random.NextDouble() * 2 * Math.PI;
        asteroidList[i].direction.X = -(float)Math.Sin(angle);
        asteroidList[i].direction.Y = (float)Math.Cos(angle);
        asteroidList[i].speed = GameConstants.AsteroidMinSpeed +
```

```
        (float)random.NextDouble() * GameConstants.AsteroidMaxSpeed;
    }
}
```

Note

You will need to add two floating-point constants (code given below), `AsteroidMinSpeed` and `AsteroidMaxSpeed`, to the `GameConstants` class yourself. In this example, 100.0 is the minimum speed, and 300.0 is the maximum.

C#

```
public const float AsteroidMinSpeed = 100.0f;
public const float AsteroidMaxSpeed = 300.0f;
```

Then add a call to `ResetAsteroids()` just before the call to `base.Initialize()` in the `Initialize` method.

The direction values of the asteroids are using a basic trigonometric function to determine the x and y components of the direction, based on the starting angle. Do not modify the z value because the game only plays in two dimensions.

Now that you have created the asteroids, you need to render them. You should recognize that this should go in the `Draw()` method. Indeed, you will simply look through the `asteroidList` and render each asteroid in the same manner as the ship. So, add this code after the completion of the rendering of the ship in the `Draw()` method.

C#

```
for (int i = 0; i < GameConstants.NumAsteroids; i++)
{
    Matrix asteroidTransform =
        Matrix.CreateTranslation(asteroidList[i].position);
    DrawModel(asteroidModel, asteroidTransform, asteroidTransforms);
}
```

If you run this code as-is right now, you will see the ship and single asteroid rendered in the center. There are actually 10 asteroids there, but they are stacked one on top of the other.

The next step is to give the asteroids some motion. This is accomplished in the `Update()` method by simply iterating over the list and updating their position. Do that just after you update the ship's velocity:

C#

```
for (int i = 0; i < GameConstants.NumAsteroids; i++)
{
    asteroidList[i].Update(timeDelta);
}
```

One thing you added is a time delta. This is a small efficiency trick. Calculate the `timeDelta` value once per update, rather than repeatedly calling the property to check for the total seconds passed. This will be the first line of the `Update()` method (in the `Game1` class):

C#

```
float timeDelta = (float)gameTime.ElapsedGameTime.TotalSeconds;
```

Notice that you are calling each asteroid's `Update()` method in this loop, so you will need to add that method to the `Asteroid` structure (inside the structure's braces, not outside it). Thanks to the expressiveness of the XNA Framework Math library, this can be written in a very simple manner:

```
public void Update(float delta)
{
    position += direction * speed * GameConstants.AsteroidSpeedAdjustment * delta;
}
```

Note

You will need to add the floating-point constant, `AsteroidSpeedAdjustment`, to the `GameConstants` class. In this case, use a default value of 5.0.

If everything went well, you will see the asteroids all flying away from the ship in random directions until they all disappear from the screen.

What is wrong with this picture?

Keep the asteroids in the game by wrapping the asteroid around the screen. This is accomplished by allowing the asteroids to drift off the screen, then shifting them to the other side once they have disappeared. The values of playfield size constants were made from some rough approximations based on the actual viewing space. A properly designed game will carefully calculate the field of view area and determine the limits based on asteroid model sizes, and other parameters. In this case, use the `PlayfieldSize` constants in a simple fashion to determine the "wraparound" trigger areas. After you update the asteroid's position in the `Asteroid` class's `Update` method, you then determine if you need to move the asteroid around:

C#

```
if (position.X > GameConstants.PlayfieldSizeX)
    position.X -= 2 * GameConstants.PlayfieldSizeX;
if (position.X < -GameConstants.PlayfieldSizeX)
    position.X += 2 * GameConstants.PlayfieldSizeX;
if (position.Y > GameConstants.PlayfieldSizeY)
    position.Y -= 2 * GameConstants.PlayfieldSizeY;
if (position.Y < -GameConstants.PlayfieldSizeY)
    position.Y += 2 * GameConstants.PlayfieldSizeY;
```

Now you should see your asteroids calmly wrapping around the screen as they drift through space. Perfect! Well, almost. This game will not be very interesting if you start all the asteroids in the center, since that would result in a collision with the ship. You need to add some code to start the asteroids on the left or right edge of the screen.

Choosing where to start the asteroid is a little tricky. For the x value of the asteroid's position, you must first choose to start on the left or right side of the screen. Use the random number generator to pick either a 0 or 1. If it's 0, you will start on the left. If it's 1, you will start on the right. To do this, call `random.Next(2)`, which generates a number between 0 and up to, but not including, the passed value (so it only returns a 0 or 1). For the y value of the asteroid's position, simply choose a random number that is within the playfield's y range. This means you will modify the line that assigns the asteroid position a value of `Vector3.Zero` so that the final method looks like this:

C#

```
private void ResetAsteroids()
{
    float xStart;
    float yStart;
    for (int i = 0; i < GameConstants.NumAsteroids; i++)
    {
        if (random.Next(2) == 0)
        {
            xStart = (float)-GameConstants.PlayfieldSizeX;
        }
        else
        {
            xStart = (float)GameConstants.PlayfieldSizeX;
        }
        yStart =
            (float)random.NextDouble() * GameConstants.PlayfieldSizeY;
        asteroidList[i].position = new Vector3(xStart, yStart, 0.0f);
        double angle = random.NextDouble() * 2 * Math.PI;
        asteroidList[i].direction.X = -(float)Math.Sin(angle);
        asteroidList[i].direction.Y = (float)Math.Cos(angle);
        asteroidList[i].speed = GameConstants.AsteroidMinSpeed +
            (float)random.NextDouble() * GameConstants.AsteroidMaxSpeed;
    }
}
```

Note

Do not forget to declare the two floating-point values, `xStart` and `yStart`, just before the **for** loop.

It might look a little confusing, but run through the math calculations a couple times to get comfortable with what is going on. At this point, you have a ship in the center of the screen, with several asteroids starting on the sides, moving in random directions and speeds.

Step 4: When Ships and Asteroids Collide

Now, add a few more content items to your game, which you will use in Steps 3 and 4. You will add one model and three sounds to the game:

1. Add "pea_proj.x" (the bullet model) to the Models section in your project. To do this, right-click **Models**, click **Add**, and then click **Existing Item**. Do not forget you might need to change the **Files of Type** drop-down to **Content Pipeline Files**.

The model is located in the downloaded samples directory under Content/Models—in the same place the asteroid model was lurking. You will also need to copy the "pea_proj.tga" file from the Content/Texture location to your Content/Textures location. Again, do not use **Add** and then **Existing Item** here.

2. As in Tutorial 3 ("Making Sounds with XNA Game Studio"), navigate to the Content/Audio/Waves directory of the downloaded sample directory and copy weapons/explosion3.wav, explosions/explosion2.wav, and weapons/tx0_fire1.wav into your Content/Audio/Waves directory.

Right after the existing sound effect variables, add three new ones to store the sound effects you just added:

C#

```
SoundEffect soundExplosion2;  
SoundEffect soundExplosion3;  
SoundEffect soundWeaponsFire;
```

Now, modify the `LoadContent` method to load your new sound effects:

C#

```
soundExplosion2 =  
    Content.Load<SoundEffect>("Audio/Waves/explosion2");  
soundExplosion3 =  
    Content.Load<SoundEffect>("Audio/Waves/explosion3");  
soundWeaponsFire =  
    Content.Load<SoundEffect>("Audio/Waves/tx0_fire1");
```

The new explosion and weapons fire effects are now ready to be used when needed during game play.

You have something visually interesting now. You have a ship, with sound effects, that you can move around. You also have asteroids happily flying around on the screen. Unfortunately, you cannot shoot the asteroids. On the other hand, the asteroids also cannot hurt you—yet. Add some collision detection between the ship and the asteroids. In a later step, you will get even by shooting back.

With the XNA Framework, simple collision detection is easy. In this step, you will be using a [BoundingSphere](#), which is an object that creates the smallest-sized sphere (by default) that can enclose the target model. The **BoundingSphere** contains many different intersection tests, including the ability to detect intersections with planes, rays, boxes, and, of course, other spheres (among other things). Hence, you will put an invisible bubble around each object you want to test, and then determine if they intersect each other.

One trick to remember in gameplay is that you should consider different rules for collisions, depending on the context. In this case, you will deliberately create a bounding sphere around the ship that is smaller than the ship. This is a little game programming trick. Most models are uneven in shape, but a **BoundingSphere** only takes into account the point farthest from the model's center when creating the sphere's radius. This results in collisions that often appear like they were nowhere near the player's ship. In addition, creating a slightly smaller sphere gives a little more "forgiveness" in case a player gets too close to an asteroid. So, create two constants in the `GameConstants` class that sets bounding sphere sizes for the asteroids and ship:

C#

```
public const float AsteroidBoundingSphereScale = 0.95f; //95% size  
public const float ShipBoundingSphereScale = 0.5f; //50% size
```

Now, create the actual bounding sphere around the ship, just after you update the asteroid positions in the `Update` method of

the `Game1` class. Then create a loop that visits each asteroid. Inside this loop, you create a temporary bounding sphere around the asteroid and determine whether the ship and asteroid sphere are intersecting. If the two spheres intersect, you play an explosion sound and break out of the loop:

C#

```
//ship-asteroid collision check
BoundingSphere shipSphere = new BoundingSphere(
    ship.Position, ship.Model.Meshes[0].BoundingSphere.Radius *
        GameConstants.ShipBoundingSphereScale);
for (int i = 0; i < asteroidList.Length; i++)
{
    BoundingSphere b = new BoundingSphere(asteroidList[i].position,
        asteroidModel.Meshes[0].BoundingSphere.Radius *
            GameConstants.AsteroidBoundingSphereScale);
    if (b.Intersects(shipSphere))
    {
        //blow up ship
        soundExplosion3.Play();
        break; //exit the loop
    }
}
```

Running this program now gives you some great feedback. First, the collision check seems to work pretty well. Second, you hear a collision sound. Third, the sound does not seem right. This is because as the asteroid and ship move through each other, the collision check is constantly firing every frame, with the XNA Framework trying to play the explosion in every frame, causing garbled sound. You can solve this problem by removing the colliding objects from the updating and rendering. In a real game, this means the ship explodes and you lose a life. In the tutorial, simply remove the ship and the offending asteroid from the display and then update. You'll add this feature in the next step.

Step 5: Boom - You're Dead

The code starts getting a little more complex now, but you will leverage some handy secrets in XNA Game Studio to make it easy. To start, you need to create a Boolean flag that tells you if the ship is alive or dead. This will go in the `Ship` class, right after the declaration of `VelocityScale`:

```
public bool isActive = true;
```

Before you test for a ship and asteroid collision, you need to verify the `isActive` flag is **true**. This is done by wrapping the collision code you already wrote in an **if** statement. This is easy with XNA Game Studio. Highlight the entire block of code that does the collision check (the **BoundingSphere** declaration and the loop right after it), then right-click the selected code and click **Surround With**, then select the **if** statement (not the **#if** statement) from the list. You will see your code is now wrapped in an **if** statement, awaiting a Boolean condition. Now all you have to do is replace **true** with `ship.isActive`. Finally, set `ship.isActive` to **false** after you play the explosion sound.

This fixes the explosion sound, but both the ship and the offending asteroid are still visible in the game. First, remove the ship. Since you have set the flag in the `Update()` method, that still leaves you the responsibility to not draw the ship anymore. So once again wrap a chunk of code in the `Draw()` method with the **if** statement. By now you should be familiar with what portion of the code draws the ship. Select the line of code that draws the ship, right-click, click **Surround With**, and insert an `if (ship.isActive)` test.

Running the code now should let you merrily smash your ship into an asteroid, with an accompanying explosion and the disappearance of your ship.

Finally, you need to remove the colliding asteroid. This requires a flag just like the ship. Each asteroid needs an `isActive` flag that tells whether you should draw or update the asteroid. This is accomplished in five steps, which you should attempt to do on your own:

1. Create an `isActive` flag inside the `Asteroid` class, similar to what you did with the ship.
2. Set the `isActive` flag to **true** when you create each asteroid in the `ResetAsteroids` method in the `Game1` class.
3. In the code where you draw the asteroids, surround the drawing code in an **if** statement. This happens inside the loop where you iterate through each asteroid.
4. Similarly, you now need to do the same thing in the update section, checking to see whether an asteroid is active before you execute a collision test with the ship.

5. If a ship does collide with an asteroid, set that asteroid's active state to **false** just after you play the explosion sound.

If you did all the steps correctly, you should have an almost-functional game! Collisions, sounds, moving ships. It's all starting to come together! This leads to the next question: What to do once you blow up the ship? Easy. Press the **Warp** button. In [Tutorial 2: Making Your Model Move Using Input](#), you wrote some code that reset the ship back to the center. It's still there and still useful (except back then it was the **A** button). Now go ahead and add a `ship.isActive = true` statement in the code block for pressing the **B** button. (Hint: Look in the `UpdateInput` method in the `Game1` class). Also, if you have not changed the Warp button from **A** to **B**, now is the time to do it. Instant life-regeneration!

The next step will add bullets to the game, so you can shoot back. The good news is that all the work you have done up to now will make the bullet work seem easy.

Step 6: Revenge of the Ship

In many ways, a bullet in the game is like an asteroid: it travels in a direction and collides with things. You are going to treat bullets just a little differently though, giving the game a little fine-tuning in the process.

Conveniently, the `Bullet` structure is exactly like the `Asteroid` structure, so all you need to do is copy the `Asteroid` implementation file, rename the new file to `Bullet.cs`, and the structure name to `Bullet`. In addition, you will want to add these new constants to the `GameConstants` class for later use:

C#

```
public const int NumBullets = 30;
public const float BulletSpeedAdjustment = 100.0f;
```

Think ahead a little bit right now, though. How long do you want the bullets to fly around in space? Do you want them to wrap around the screen? Maybe only live for a certain number of seconds or travel a certain distance? Do you want the bullets to be able to collide with both asteroids and the ship? Any of these approaches are legitimate ways to make the game physics behave. In this case, though, the bullets are simply going to disappear once they go off the screen. This means the `Update()` method in the `Bullet` class will flag the bullet as inactive once it drifts off the view.

This is a simple check, similar to what was done with the `Asteroid` structure:

C#

```
public void Update(float delta)
{
    position += direction * speed *
        GameConstants.BulletSpeedAdjustment * delta;
    if (position.X > GameConstants.PlayfieldSizeX ||
        position.X < -GameConstants.PlayfieldSizeX ||
        position.Y > GameConstants.PlayfieldSizeY ||
        position.Y < -GameConstants.PlayfieldSizeY)
        isActive = false;
}
```

As with the `Asteroid` structure, you are now done with the `Bullet` structure. However, you have to do several things to make the bullets actually work in the game. You have done this all before with the asteroids, but review the basic steps:

1. Load the model into the Content Pipeline and set the effect transforms.
2. Create a list to track all bullets in the game.
3. Create a bullet and make a firing sound when a player presses a specific button.
4. Draw the bullet in-flight.
5. Test the asteroids and bullets for collisions. If they collide, make an explosion sound and remove the colliding bullet and asteroid.

Begin by creating the needed instance variables. Underneath the same place that you created the `asteroidList` and `asteroidModel` variables, create a list to hold the bullets and a model to hold the bullet's shape.

C#

```
Model bulletModel;
Matrix[] bulletTransforms;
Bullet[] bulletList = new Bullet[GameConstants.NumBullets];
```

Then in the `LoadContent()` method, assign the `pea_proj` model to `bulletModel`. Remember, you added `pea_proj.x` to the `Content/Models` directory earlier:

C#

```
bulletModel = Content.Load<Model>("Models/pea_proj");
bulletTransforms = SetupEffectDefaults(bulletModel);
```

Unlike the asteroids, you do not create bullets inside `Initialize`. Instead, create a bullet every time a user presses the **A** button on the controller. Add a new condition to the `UpdateInput()` method at the very end:

C#

```
//are we shooting?
if (ship.isActive && currentState.Buttons.A == ButtonState.Pressed)
{
    //add another bullet. Find an inactive bullet slot and use it
    //if all bullets slots are used, ignore the user input
    for (int i = 0; i < GameConstants.NumBullets; i++)
    {
        if (!bulletList[i].isActive)
        {
            bulletList[i].direction = ship.RotationMatrix.Forward;
            bulletList[i].speed = GameConstants.BulletSpeedAdjustment;
            bulletList[i].position = ship.Position + (200 * bulletList[i].direction);
            bulletList[i].isActive = true;
            soundWeaponsFire.Play();
            score -= GameConstants.ShotPenalty;
            break; //exit the loop
        }
    }
}
```

There is an interesting trick in the above code that needs explaining. When it calculate the initial position of the bullet, it appears as if it's firing out the nose of the ship. Thus, the code begins by determining where the bullet is starting from, which is the ship's center. Then it translates the bullet 200 additional units in the direction of the bullet (200 is the rough approximation of the distance from the ship's center to the nose of the ship).

This kind of "motion offset" is very common in game development. One "extra credit" feature you can do is to add the ship's current velocity to the bullet's velocity.

Now it's actually possible to run your game and press the fire (**A**) button, but you will not yet be able to see the bullets (because you have not drawn them). When you press the fire button (the **A** button), you might have observed that the sound behaves just like the original problem you had with the asteroid/ship explosions. You are triggering the sound too many times. In fact, you probably noticed that you can hold the fire button down and it will fire a continuous "stream" of bullets (until all the bullet "slots" are used). There is a simple fix to the `UpdateInput()` method to fire the bullet only once every time the button is pressed.

The problem with `UpdateInput` is that it is failing to track the user's previous input state. Create a variable that does this. Just after the `GraphicsDeviceManager` declaration (near the beginning of the `Game1` class), add this variable:

C#

```
GamePadState lastState = GamePad.GetState(PlayerIndex.One);
```

Then, at the end of the `UpdateInput` method, save the user's game pad state:

C#

```
lastState = currentState;
```

Now all you need to do is change the `if` statement for the "fire" effect to verify that the button was not held down the last time the code updated:

```
if (ship.isActive && currentState.Buttons.A == ButtonState.Pressed &&
```

```
lastState.Buttons.A == ButtonState.Released)
```

When you run the program, you will now hear a firing sound for every time you individually press the **A** button. Now that you see how to do this, add the same check to your **hyperspace** button for consistency reasons. The next step is to draw the bullet as it is flying around the screen. Conveniently, this code is identical to the code that draws the asteroids, except you replace the word "asteroid" with "bullet" (in the `Draw` method):

C#

```
for (int i = 0; i < GameConstants.NumBullets; i++)
{
    if (bulletList[i].isActive)
    {
        Matrix bulletTransform =
            Matrix.CreateTranslation(bulletList[i].position);
        DrawModel(bulletModel, bulletTransform, bulletTransforms);
    }
}
```

Then you will again do exactly the same thing in the `Update` method. Just after the part where you update the asteroid positions (but before you do the asteroid/ship collision test), add the code to update the bullets:

C#

```
for (int i = 0; i < GameConstants.NumBullets; i++)
{
    if (bulletList[i].isActive)
    {
        bulletList[i].Update(timeDelta);
    }
}
```

If you run the code at this point in time, you actually have an "almost working" game! All that is left is testing for collisions between the bullet and the asteroids. This process is really quite easy. All you need to do is loop through each asteroid, checking to see if a bullet is colliding with it. If so, deactivate both the colliding bullet and asteroid and continue through the list of asteroids until you are done. The code is almost literally a copy of the ship/asteroid collision code, except instead of `if (shipAlive)` you have a loop through each asteroid. One thing to note: Do this collision check before checking to see if the ship collides with an asteroid—that way, the player gets credit for a "kill" before getting destroyed!

C#

```
//bullet-asteroid collision check
for (int i = 0; i < asteroidList.Length; i++)
{
    if (asteroidList[i].isActive)
    {
        BoundingBox asteroidSphere =
            new BoundingBox(asteroidList[i].position,
                asteroidModel.Meshes[0].BoundingBox.Radius *
                    GameConstants.AsteroidBoundingBoxScale);
        for (int j = 0; j < bulletList.Length; j++)
        {
            if (bulletList[j].isActive)
            {
                BoundingBox bulletSphere = new BoundingBox(
                    bulletList[j].position,
                    bulletModel.Meshes[0].BoundingBox.Radius);
                if (asteroidSphere.Intersects(bulletSphere))
                {
                    soundExplosion2.Play();
                    asteroidList[i].isActive = false;
                    bulletList[j].isActive = false;
                    break; //no need to check other bullets
                }
            }
        }
    }
}
```

```
}  
}
```

If everything went well, you can now fly a ship around, shoot asteroids, and collide with asteroids. Congratulations, you have written your first XNA Framework game! But wait, the blue background looks, well, nothing at all like a good Asteroids game. You need a space background and, of course, a way to keep score. That is the last step.

Step 7: Space, the Final Frontier

The last step will be to add finishing touches to the game to make it both visually appealing and to give it more of a game feel. You will do this in two parts. The first part is to add a 2D background texture to the game to give it a nice space appearance. The second part will be adding a simple scoring mechanism to the game. When it comes to doing either step, the first thing to remember is that all 2D items are drawn as sprites. A background and score are no different in terms of how they are drawn, but as you will learn, it does matter when they are drawn.

For the first step, you need to create a texture for the starry background. Begin by adding the `stars Texture2D` object in the same place you declared your `Asteroid` and `Bullet` models:

C#

```
Texture2D stars;
```

Just after you create the `bulletModel` and `bulletTransforms` objects, load the texture:

C#

```
stars = Content.Load<Texture2D>("Textures/B1_stars");
```

Lastly, at the beginning of the `Draw()` method, just after you call `Clear` on the graphics device, draw the star background. It's important to draw the background at the beginning instead of the end, otherwise, it will obscure everything already drawn (asteroids, and so on) by laying the background on top of the previously drawn objects.

C#

```
spriteBatch.Begin(SpriteBlendMode.None, SpriteSortMode.Immediate,  
    SaveStateMode.None);  
spriteBatch.Draw(stars, new Rectangle(0, 0, 800, 600), Color.White);  
spriteBatch.End();
```

Now add the `B1_stars.tga` file into the `Content/Textures` area in your project (right-click **Textures**, click **Add**, and then click **Existing Item**). Then browse to the `Content\Textures` folder of the extracted sample and select the `B1_stars.tga` file. When you run your game now, you should see a pretty star field in the background, with all your gameplay in the foreground.

All that is left is keeping score in the game. This is accomplished in a few simple steps:

1. Create a sprite font and add it to the Content Pipeline processing.
2. Load the sprite font with the rest of your content.
3. Set the display string and call the `DrawString` method.

Creating the sprite font is simple. The first thing to do is create a new folder under the `Content` folder called `Fonts`. Then right-click this folder, click **Add**, and then click **New Item**. From the menu, pick `Sprite Font`. The default file name for this file is `SpriteFont1.spritefont`. While you could leave it that way, give it the same name as the font you want to use. Since you will be using the `Kootenay` font, name the file `Kootenay.spritefont`. Feel free to experiment with different fonts later, once you are comfortable with this process. Once you create the file, it will open to allow you to edit the different font parameters. Just accept the settings and close it for now.

Note

Before you go on, it's important to understand that fonts are very technical pieces of art. The people and companies that create them pour an enormous amount of work in them. In many cases, fonts are protected under copyright and licensing terms that widely vary. Just because a font is installed on your computer does not mean you automatically have the right to redistribute the font to anybody else. Keep this in mind if you ever decide to share games that you write. Fortunately, the default font used by the `Sprite Font` item is redistributable. For more information, see [How To: Draw Text](#).

Now that you created the sprite font, add some code in the `Game1` class so that you can display something. Just after you declare the `stars` object, add a few more declarations:

C#

```
SpriteFont kootenay;
int score;
Vector2 scorePosition = new Vector2(100, 50);
```

The first declaration will hold the sprite font. The second is a simple counter for the score. Finally, the `scorePosition` object will let you position the score in screen coordinates. You could just as well move the `scorePosition` into the `GameConstants` class, but due to compilation rules regarding the `Vector2` class, you cannot make it a `const` value.

Loading the sprite font is a one-line addition to the end of the `LoadContent` method:

C#

```
kootenay = Content.Load<SpriteFont>("Fonts/Kootenay");
```

All that is left is to display the score on the screen. This is pretty simple, provided you respect the rules of drawing order. So far, there are four very distinct drawing steps in the `Draw` method. Draw the background and then the game elements (ship, then asteroids, then bullets). As mentioned previously, if you draw the background after the game elements, all you see is the star field, because drawing the star field last covers the entire screen space. This same issue applies for the game score. Draw the game score last so that it appears overlaid on the rest of the game.

Hopefully by now, you will realize that the score will be drawn just before the `base.Draw` call is made in the `Draw` method. The actual code to draw the string is simply a sprite batch `Begin/End` pair, with the call to `DrawString` in between:

C#

```
spriteBatch.Begin(SpriteBlendMode.AlphaBlend,
    SpriteSortMode.Immediate, SaveStateMode.None);
spriteBatch.DrawString(kootenay, "Score: " + score,
    scorePosition, Color.LightGreen);
spriteBatch.End();
```

When you run the game now, you should see a score displayed in the upper-left corner. You will also notice that the game elements appear to render underneath the score, giving the effect you want. Now think about how you want to score the game.

Good gameplay not just about "running and gunning," it's about forcing the player to make decisions and tradeoffs to achieve one or more goals. In this game, you are going to penalize the player for each round the player fires (offensive actions come at a cost) and presses the **Warp** button (defensive actions come at a cost). You will also penalize the player for dying. In most video games, you are given a limited number of lives, and you subtract a "life" when the player's avatar gets destroyed. However, in this game, a multi-life system is not implemented (you should do that as "extra credit"), so simply take away points. Also, reward points for each asteroid destroyed. First, set up some scoring values in the `GameConstants` class:

C#

```
public const int ShotPenalty = 1;
public const int DeathPenalty = 100;
public const int WarpPenalty = 50;
public const int KillBonus = 25;
```

Now, alter the scores in the appropriate places. For instance, the shot penalty would be added to the `UpdateInput` method, just after it registers that the player fired a bullet, most likely just after the `soundWeaponsFire.Play()` line:

```
score -= GameConstants.ShotPenalty;
```

You will need similar approaches in three other areas, which you should accomplish on your own:

- When the ship is determined to have collided with an asteroid (subtract `DeathPenalty` from score).
- When a bullet is determined to have collided with an asteroid (add `KillBonus` to score).
- When the player presses the warp button (subtract `WarpPenalty` from score).

Finally

The initial goal of this tutorial was to show you that the tools, materials, and knowledge to write a game are right at your fingertips, and to guide you through the process of writing your first game. By now, you have learned how to:

- Change camera views to achieve different rendering perspectives.
- Write simple collision-detection routines.
- Create a game environment where many things appear to be happening at once.
- Integrate 2D and 3D rendering.
- Render text in your game.
- Create a feel of "gameplay" where the player has both benefits and penalties with their decisions.

Hopefully, you have also enjoyed the process of making the game. After all, making a game should be just as much fun as playing one! But this is only the beginning. While the game you made is interesting, there are *many* things you can still do to make the game more engaging and enjoyable. Here are several suggestions (but by no means a complete list) on how you can take your game to the next level:

- Wrap the ship around on the screen.
- Vibrate the controller when a ship collides with an asteroid.
- Split the big asteroids into successively smaller ones.
- Add explosion effects when a bullet hits an asteroid.
- Add engine particle effects as the ship flies around.
- Add a smart "UFO" that attacks the player's ship.
- Add a "high score" capability to the game.
- Determine when the playing field is cleared and start a new level, perhaps with more or faster asteroids.

At this point, you've been given many of the basic elements you need to build a game: graphics, input, and sound. Even so, you may be wondering, "How do I build a game?"

Games are an expressive process, with plenty of room for creative problem solving. There is truly no one right way to make a game. With the example you have created, there are still many missing elements. What else does the ship interact with? Does it have a goal? What obstacles prevent the ship from reaching the goal?

Answering these questions will define your game, and make it your own. Play some games that inspire you, check out the [XNA Creators Club Online](#), read up on the [Programming Guide](#), explore the XNA Framework, and have fun building a game of your very own. We hope you enjoy XNA Game Studio!

Tutorial 5: Adding Multiplayer and Networking Support to the Game

This tutorial adds two-player competitive game play to the game completed in Tutorial 4.

Note

In order to test the network functionality of this sample, each instance must be running on a separate computer, each with XNA Game Studio installed.

Step 1: Simplify the Update Method

This tutorial is going to add some details to the **Update** and **Draw** methods of your game, so as a first step we will work on simplifying the code in these methods.

Move the bullet-asteroid collision check into a method to simplify the code.

C#

```
bool CheckForBulletAsteroidCollision(float bulletRadius,  
float asteroidRadius)
```

```

{
    for (int i = 0; i < asteroidList.Length; i++)
    {
        if (asteroidList[i].isActive)
        {
            BoundingSphere asteroidSphere =
                new BoundingSphere(asteroidList[i].position,
                    asteroidRadius *
                    GameConstants.AsteroidBoundingSphereScale);
            for (int j = 0; j < bulletList.Length; j++)
            {
                if (bulletList[j].isActive)
                {
                    BoundingSphere bulletSphere =
                        new BoundingSphere(bulletList[j].position,
                            bulletRadius);
                    if (asteroidSphere.Intersects(bulletSphere))
                    {
                        asteroidList[i].isActive = false;
                        bulletList[j].isActive = false;
                        score += GameConstants.KillBonus;
                        return true; //no need to check other bullets
                    }
                }
            }
        }
    }
    return false;
}

```

Similarly, we will make new methods for the ship-asteroid collision check, and replace the corresponding code in the **Update** method with the call to this new **CheckForShipAsteroidCollision** method.

C#

```

public bool CheckForShipAsteroidCollision(float shipRadius,
    float asteroidRadius)
{
    //ship-asteroid collision check
    if (ship.isActive)
    {
        BoundingSphere shipSphere = new BoundingSphere(ship.Position,
            shipRadius * GameConstants.ShipBoundingSphereScale);
        for (int i = 0; i < asteroidList.Length; i++)
        {
            if (asteroidList[i].isActive)
            {
                BoundingSphere b =
                    new BoundingSphere(asteroidList[i].position,
                        asteroidRadius *
                        GameConstants.AsteroidBoundingSphereScale);
                if (b.Intersects(shipSphere))
                {
                    //blow up ship
                    //soundExplosion3.Play();
                    ship.isActive = false;
                    asteroidList[i].isActive = false;
                    score -= GameConstants.DeathPenalty;
                    return true;
                }
            }
        }
    }
    return false;
}

```

This class uses the ship model. While you perform this, add a **shipModel** to the **Game** class, and initialize it as you did the

other models. When we add a player class to the code, the players will all share the same ship model data.

C#

```
Model asteroidModel;
Model bulletModel;
Model shipModel;
Matrix[] asteroidTransforms;
Matrix[] bulletTransforms;
Matrix[] shipTransforms;
```

Initialize the ship model with the other models in the game class.

C#

```
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    shipModel = Content.Load<Model>("Models/p1_wedge");
    shipTransforms = SetupEffectDefaults(shipModel);
    asteroidModel = Content.Load<Model>("Models/asteroid1");
    asteroidTransforms = SetupEffectDefaults(asteroidModel);
    bulletModel = Content.Load<Model>("Models/pea_proj");
    bulletTransforms = SetupEffectDefaults(bulletModel);
    stars = Content.Load<Texture2D>("Textures/B1_stars");
    soundEngine = Content.Load<SoundEffect>("Audio/Waves/engine_2");
    soundEngineInstance = soundEngine.CreateInstance();
    soundHyperspaceActivation =
        Content.Load<SoundEffect>("Audio/Waves/hyperspace_activate");
    soundExplosion2 =
        Content.Load<SoundEffect>("Audio/Waves/explosion2");
    soundExplosion3 =
        Content.Load<SoundEffect>("Audio/Waves/explosion3");
    soundWeaponsFire =
        Content.Load<SoundEffect>("Audio/Waves/tx0_fire1");
    lucidaConsole = Content.Load<SpriteFont>("Fonts/Lucida Console");
}
```

The **Update** method should now look something like this:

C#

```
protected override void Update(GameTime gameTime)
{
    float timeDelta = (float)gameTime.ElapsedGameTime.TotalSeconds;

    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back ==
        ButtonState.Pressed)
        this.Exit();

    // Get some input.
    UpdateInput();

    // Add velocity to the current position.
    ship.Position += ship.Velocity;

    // Bleed off velocity over time.
    ship.Velocity *= 0.95f;

    for (int i = 0; i < GameConstants.NumAsteroids; i++)
    {
        asteroidList[i].Update(timeDelta);
    }

    for (int i = 0; i < GameConstants.NumBullets; i++)
```

```

    {
        if (bulletList[i].isActive)
        {
            bulletList[i].Update(timeDelta);
        }
    }

    if (CheckForBulletAsteroidCollision(
        bulletModel.Meshes[0].BoundingSphere.Radius,
        asteroidModel.Meshes[0].BoundingSphere.Radius))
    {
        soundExplosion2.Play();
    }

    bool shipDestroyed = CheckForShipAsteroidCollision(
        shipModel.Meshes[0].BoundingSphere.Radius,
        asteroidModel.Meshes[0].BoundingSphere.Radius);
    if (shipDestroyed)
    {
        soundExplosion3.Play();
    }

    base.Update(gameTime);
}

```

Next, we will look for ways to simplify the **UpdateInput** method. The code used to shoot a bullet could be moved into a new method, as well as the code to warp the ship to center and to play the engine sound.

C#

```

public void ShootBullet()
{
    //add another bullet. Find an inactive bullet slot and use it
    //if all bullets slots are used, ignore the user input
    for (int i = 0; i < GameConstants.NumBullets; i++)
    {
        if (!bulletList[i].isActive)
        {
            bulletList[i].direction = ship.RotationMatrix.Forward;
            bulletList[i].speed = GameConstants.BulletSpeedAdjustment;
            bulletList[i].position = ship.Position
                + (200 * bulletList[i].direction);
            bulletList[i].isActive = true;
            score -= GameConstants.ShotPenalty;
            return;
        }
    }
}

```

C#

```

public void WarpToCenter()
{
    ship.Position = Vector3.Zero;
    ship.Velocity = Vector3.Zero;
    ship.Rotation = 0.0f;
    ship.isActive = true;
    score -= GameConstants.WarpPenalty;
}

```

C#

```

void PlayEngineSound(GamePadState currentState)
{
    //Play engine sound only when the engine is on.
    if (currentState.Triggers.Right > 0)

```

```

{
    if (soundEngineInstance.State == SoundState.Stopped)
    {
        soundEngineInstance.Volume = 0.75f;
        soundEngineInstance.IsLooped = true;
        soundEngineInstance.Play();
    }
    else
        soundEngineInstance.Resume();
}
else if (currentState.Triggers.Right == 0)
{
    if (soundEngineInstance.State == SoundState.Playing)
        soundEngineInstance.Pause();
}
}

```

It is also possible to simplify the check for whether a current button is pressed. We will create a new method called **IsButtonPressed** that takes only one parameter, the button to check. This method will check a set of global variables storing the current and last states of the game pad.

C#

```

GamePadState currentState;
GamePadState lastState;

...
bool IsButtonPressed(Buttons button)
{
    switch (button)
    {
        case Buttons.A:
            return (currentState.Buttons.A == ButtonState.Pressed &&
                lastState.Buttons.A == ButtonState.Released);
        case Buttons.B:
            return (currentState.Buttons.B == ButtonState.Pressed &&
                lastState.Buttons.B == ButtonState.Released);
        case Buttons.X:
            return (currentState.Buttons.X == ButtonState.Pressed &&
                lastState.Buttons.X == ButtonState.Released);
        case Buttons.Back:
            return (currentState.Buttons.Back == ButtonState.Pressed &&
                lastState.Buttons.Back == ButtonState.Released);
        case Buttons.DPadDown:
            return (currentState.DPad.Down == ButtonState.Pressed &&
                lastState.DPad.Down == ButtonState.Released);
        case Buttons.DPadUp:
            return (currentState.DPad.Up == ButtonState.Pressed &&
                lastState.DPad.Down == ButtonState.Released);
    }
    return false;
}

```

Using these new methods in **UpdateInput** will result in the following simplified code:

C#

```

protected void UpdateInput()
{
    // Get the game pad state.
    currentState = GamePad.GetState(PlayerIndex.One);
    if (currentState.IsConnected)
    {
        if (ship.isActive)
        {
            ship.Update(currentState);
        }
    }
}

```

```

        PlayEngineSound(currentState);
    }
    // In case you get lost, press B to warp back to the center.
    if (IsButtonPressed(Buttons.B))
    {
        WarpToCenter();
        soundHyperspaceActivation.Play();
    }

    //are we shooting?
    if (ship.isActive && IsButtonPressed(Buttons.A))
    {
        ShootBullet();
        soundWeaponsFire.Play();
        bool isFiring = true;
    }
    lastState = currentState;
}
}

```

Step 2: Encapsulate Player Code

Just as we encapsulated the ship and asteroid data in Tutorial 4, we now need to encapsulate the player data so we can easily create multiple instances of the data needed to save the state of any player in a multiplayer game. In this step, we are going to refactor the code, moving any relevant data and methods from the **Game** class and into a new **Player** class.

The first step is to create a new class to contain the player object code. Right-click on your game project in Solution Explorer, and choose **Add** and then **Class**. In the **Name** field, enter `Player.cs` and click **Add**.

In this class, we are going to use some objects from the **Framework**, **Graphics**, and **Input** namespaces. To do this, add a using statement to the top of the class to include these namespaces.

```

using System;
using System.Collections;
using Microsoft.Xna.Framework;
using Microsoft.Xna.Framework.Graphics;
using Microsoft.Xna.Framework.Input;

namespace GoingBeyond5
{
    public class Player
    {
        public Player()
        {
        }
    }
}

```

Next, look at **Game1.cs** and determine what data should be associated with a player. The player object would keep the information about the game pad state, ship, bullets, asteroids, and score. Move these to `Player.cs`. Upon inspection of the code, you might notice that the random number generator is only used to reset the asteroids for a player, so let's move this to the `Player.cs` file as well. You might also notice that the last gamepad state is something that would be associated with a player.

In addition to this data, we will store a picture for each player as a [Texture2D](#).

C#

```

internal GamePadState lastState;

internal Ship ship = new Ship();
internal Asteroid[] asteroidList =
    new Asteroid[GameConstants.NumAsteroids];
internal Bullet[] bulletList = new Bullet[GameConstants.NumBullets];

internal int score;

Random random = new Random();

```

If you compile your project at this time, you will receive some warnings that these member variables no longer exist in Game1.cs. These warnings can help you determine which methods in Game1.cs deal primarily with the player data.

One of the warnings indicates that the *asteroidList* referenced in the **ResetAsteroids** function does not exist in the current context. Looking at this, you can see that the **ResetAsteroids** function deals with resetting the asteroids for a player. Move the **ResetAsteroids** method into the **Player** class.

The **ResetAsteroids** method was previously called during game initialization, so also move the call to **ResetAsteroids** to the **Player** constructor.

C#

```
using System;
using System.Collections;
using Microsoft.Xna.Framework;
using Microsoft.Xna.Framework.Graphics;
using Microsoft.Xna.Framework.Input;

namespace GoingBeyond5
{
    public class Player
    {
        internal GamePadState lastState;

        internal Ship ship = new Ship();
        internal Asteroid[] asteroidList =
            new Asteroid[GameConstants.NumAsteroids];
        internal Bullet[] bulletList = new Bullet[GameConstants.NumBullets];

        internal int score;

        Random random = new Random();

        public Player()
        {
            ResetAsteroids();
        }

        internal void Update(GameTime gameTime)
        {
            float timeDelta = (float)gameTime.ElapsedGameTime.TotalSeconds;
            // Add velocity to the current position.
            ship.Position += ship.Velocity;

            // Bleed off velocity over time.
            ship.Velocity *= 0.95f;

            for (int i = 0; i < GameConstants.NumAsteroids; i++)
            {
                asteroidList[i].Update(timeDelta);
            }

            for (int i = 0; i < GameConstants.NumBullets; i++)
            {
                if (bulletList[i].isActive)
                {
                    bulletList[i].Update(timeDelta);
                }
            }
        }

        private void ResetAsteroids()
        {
            float xStart;
            float yStart;
            for (int i = 0; i < GameConstants.NumAsteroids; i++)
            {
                if (random.Next(2) == 0)
                {
```

```

        xStart = (float)-GameConstants.PlayfieldSizeX;
    }
    else
    {
        xStart = (float)GameConstants.PlayfieldSizeX;
    }
    yStart =
        (float)random.NextDouble() * GameConstants.PlayfieldSizeY;
    asteroidList[i].position = new Vector3(xStart, yStart, 0.0f);
    double angle = random.NextDouble() * 2 * Math.PI;
    asteroidList[i].direction.X = -(float)Math.Sin(angle);
    asteroidList[i].direction.Y = (float)Math.Cos(angle);
    asteroidList[i].speed = GameConstants.AsteroidMinSpeed +
        (float)random.NextDouble() * GameConstants.AsteroidMaxSpeed;
    asteroidList[i].isActive = true;
    }
}

```

Continue moving methods associated with the player data into the **Player** class. Here, we move the **WarpToCenter**, **ShootBullet**, **CheckForShipAsteroidCollision**, and **CheckForBulletAsteroidCollision** methods into the **Player** class.

There is also some code in the **Update** method that applies specifically to the player. Remove this code from **Game.Update** and create a new method called **Player.Update** with the player specific code. This requires that you add a new instance of the **Player** object to your **Game** class.

C#

```
Player player = new Player();
```

Make these changes to create the new **Update** function in **Player** class.

C#

```

internal void Update(GameTime gameTime)
{
    float timeDelta = (float)gameTime.ElapsedGameTime.TotalSeconds;
    // Add velocity to the current position.
    ship.Position += ship.Velocity;

    // Bleed off velocity over time.
    ship.Velocity *= 0.95f;

    for (int i = 0; i < GameConstants.NumAsteroids; i++)
    {
        asteroidList[i].Update(timeDelta);
    }

    for (int i = 0; i < GameConstants.NumBullets; i++)
    {
        if (bulletList[i].isActive)
        {
            bulletList[i].Update(timeDelta);
        }
    }
}

```

Change the **Update** function in the **Game** to use the new method.

C#

```

protected override void Update(GameTime gameTime)
{
    player.Update(gameTime);

    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back ==
        ButtonState.Pressed)
        this.Exit();
}

```

```

// Get some input.
UpdateInput();

if (player.CheckForBulletAsteroidCollision(
    bulletModel.Meshes[0].BoundingSphere.Radius,
    asteroidModel.Meshes[0].BoundingSphere.Radius))
{
    soundExplosion2.Play();
}

bool shipDestroyed = player.CheckForShipAsteroidCollision(
    shipModel.Meshes[0].BoundingSphere.Radius,
    asteroidModel.Meshes[0].BoundingSphere.Radius);
if (shipDestroyed)
{
    soundExplosion3.Play();
}

base.Update(gameTime);
}

```

When you are finished, your **Player** class will look like this:

C#

```

using System;
using System.Collections;
using Microsoft.Xna.Framework;
using Microsoft.Xna.Framework.Graphics;
using Microsoft.Xna.Framework.Input;

            }
        }
    }
    return false;
}
}
}
}

```

With this step complete, update the **UpdateInput** method of the game to use the new **Player** class.

C#

```

protected void UpdateInput()
{
    // Get the game pad state.
    currentState = GamePad.GetState(PlayerIndex.One);
    lastState = player.lastState;
}

```

```

if (currentState.IsConnected)
{
    if (player.ship.isActive)
    {
        player.ship.Update(currentState);
        PlayEngineSound(currentState);
    }
    // In case you get lost, press B to warp back to the center.
    if (IsButtonPressed(Buttons.B))
    {
        player.WarpToCenter();
        soundHyperspaceActivation.Play();
    }

    //are we shooting?
    if (player.ship.isActive && IsButtonPressed(Buttons.A))
    {
        player.ShootBullet();
        soundWeaponsFire.Play();
        bool isFiring = true;
    }
    player.lastState = currentState;
}
}

```

Finally, change the **Game.Draw** so that it accesses the data from the new **Player** class.

C#

```

protected override void Draw(GameTime gameTime)
{
    graphics.GraphicsDevice.Clear(Color.CornflowerBlue);

    spriteBatch.Begin(SpriteBlendMode.None, SpriteSortMode.Immediate,
        SaveStateMode.None);
    spriteBatch.Draw(stars, new Rectangle(0, 0, 800, 600), Color.White);
    spriteBatch.End();

    Matrix shipTransformMatrix = player.ship.RotationMatrix
        * Matrix.CreateTranslation(player.ship.Position);
    if (player.ship.isActive)
    {
        DrawModel(shipModel, shipTransformMatrix, shipTransforms);
    }
    for (int i = 0; i < GameConstants.NumAsteroids; i++)
    {
        Matrix asteroidTransform =
            Matrix.CreateTranslation(player.asteroidList[i].position);
        if (player.asteroidList[i].isActive)
        {
            DrawModel(asteroidModel, asteroidTransform,
                asteroidTransforms);
        }
    }

    for (int i = 0; i < GameConstants.NumBullets; i++)
    {
        if (player.bulletList[i].isActive)
        {
            Matrix bulletTransform =
                Matrix.CreateTranslation(player.bulletList[i].position);
            DrawModel(bulletModel, bulletTransform, bulletTransforms);
        }
    }
    spriteBatch.Begin(SpriteBlendMode.AlphaBlend,
        SpriteSortMode.Immediate, SaveStateMode.None);
}

```

```

        spriteBatch.DrawString(lucidaConsole, "Score: " + player.score,
                               scorePosition, Color.LightGreen);
        spriteBatch.End();
        base.Draw(gameTime);
    }

```

At this point, you should be able to compile and run your game! We have been making small, iterative changes to make the code more elegant, but when you run the game, it should still look essentially the same. In the next step we will begin making the changes to the game rendering to allow the players to see one another.

Step 3: Split the Screen

Now that we have a way to create multiple players, we need a place to display the second player. In Game1.cs, create three new member variables to store the main viewport, the left viewport, and the right viewport.

C#

```

Viewport mainWindowport;
Viewport leftViewport;
Viewport rightViewport;

```

When we use only half of the screen, the aspect ratio will change. In the constructor for the game, divide the aspect ratio by 2 to account for the split screen. If you compile and run your game after making this change, the game will be distorted due to the fact that the aspect ratio is no longer equivalent to the width and height of the back buffer.

C#

```

public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";

    // this game is split screen, so divide the aspect ratio by 2.
    aspectRatio = (float)GraphicsDeviceManager.DefaultBackBufferWidth /
        (2 * GraphicsDeviceManager.DefaultBackBufferHeight);
}

```

In **LoadContent**, initialize the values for each viewport. We first set the main viewport to equal the graphics device viewport. The left viewport and right viewport will have a width that is half of the main viewport, with the right viewport beginning one pixel past the center of the screen.

C#

```

protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    shipModel = Content.Load<Model>("Models/p1_wedge");
    shipTransforms = SetupEffectDefaults(shipModel);
    asteroidModel = Content.Load<Model>("Models/asteroid1");
    asteroidTransforms = SetupEffectDefaults(asteroidModel);
    bulletModel = Content.Load<Model>("Models/pea_proj");
    bulletTransforms = SetupEffectDefaults(bulletModel);
    stars = Content.Load<Texture2D>("Textures/B1_stars");
    soundEngine = Content.Load<SoundEffect>("Audio/Waves/engine_2");
    soundEngineInstance = soundEngine.CreateInstance();
    soundHyperspaceActivation =
        Content.Load<SoundEffect>("Audio/Waves/hyperspace_activate");
    soundExplosion2 =
        Content.Load<SoundEffect>("Audio/Waves/explosion2");
    soundExplosion3 =
        Content.Load<SoundEffect>("Audio/Waves/explosion3");
    soundWeaponsFire =
        Content.Load<SoundEffect>("Audio/Waves/tx0_fire1");
    lucidaConsole = Content.Load<SpriteFont>("Fonts/Lucida Console");
}

```

```

// Initialize the values for each viewport
mainViewport = GraphicsDevice.Viewport;
leftViewport = mainViewport;
rightViewport = mainViewport;
leftViewport.Width = leftViewport.Width / 2;
rightViewport.Width = rightViewport.Width / 2;
rightViewport.X = leftViewport.Width + 1;
}

```

Notice that the **Draw** method in game contains all the code necessary to draw a player. Rename **Draw** to **DrawPlayer**, and change the method so that it returns nothing and accepts two arguments, the *Player* to draw, and the *Viewport* to draw the player in. At the beginning of **DrawPlayer**, set the graphics device viewport to the viewport argument. Don't forget to remove the call to the **Draw** method of the base class, located at the end of the function.

C#

```

void DrawPlayer(Player player, Viewport viewport)
{
    graphics.GraphicsDevice.Viewport = viewport;

    spriteBatch.Begin(SpriteBlendMode.None, SpriteSortMode.Immediate,
        SaveStateMode.None);
    spriteBatch.Draw(stars, new Rectangle(0, 0, 800, 600), Color.White);
    spriteBatch.End();

    Matrix shipTransformMatrix = player.ship.RotationMatrix
        * Matrix.CreateTranslation(player.ship.Position);
    if (player.ship.isActive)
    {
        DrawModel(shipModel, shipTransformMatrix, shipTransforms);
    }
    for (int i = 0; i < GameConstants.NumAsteroids; i++)
    {
        Matrix asteroidTransform =
            Matrix.CreateTranslation(player.asteroidList[i].position);
        if (player.asteroidList[i].isActive)
        {
            DrawModel(asteroidModel, asteroidTransform,
                asteroidTransforms);
        }
    }
    for (int i = 0; i < GameConstants.NumBullets; i++)
    {
        if (player.bulletList[i].isActive)
        {
            Matrix bulletTransform =
                Matrix.CreateTranslation(player.bulletList[i].position);
            DrawModel(bulletModel, bulletTransform, bulletTransforms);
        }
    }
    spriteBatch.Begin(SpriteBlendMode.AlphaBlend,
        SpriteSortMode.Immediate, SaveStateMode.None);
    spriteBatch.DrawString(lucidaConsole, "Score: " + player.score,
        scorePosition, Color.LightGreen);
    spriteBatch.End();
}

```

Finally, recreate the **Draw** method, calling **DrawPlayer** in this new, shorter method, and move the call to **base.Draw(gameTime)** into this method.

C#

```

protected override void Draw(GameTime gameTime)
{
    DrawPlayer(player, leftViewport);
    base.Draw(gameTime);
}

```

```
}
```

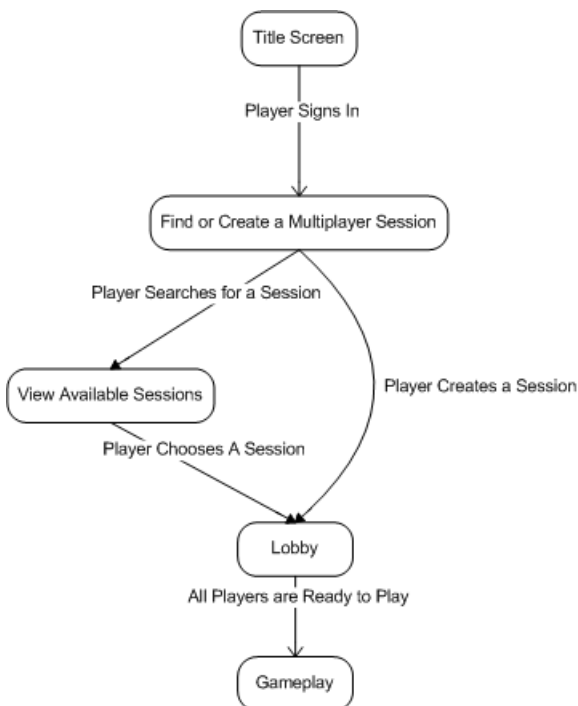

If you run your game now, you will see that the game for the local player is now showing on the left side of the screen:

Step 4: Game State Management

- [The Title Screen](#)
- [The Lobby](#)
- [List Available Network Sessions](#)

In a networked game, you will want the game to display different information depending on the state of the game. For example, if the player has not yet signed in, you will want to display a message with instructions on how to sign in. If the player would like to host or join an multiplayer game on the subnet, you will need to display a list of available games. Once a player selects a game to join you will need to allow the player to wait in the lobby until all players are ready to start the game.

To do this, we will create the main **Update** and **Draw** methods so that they choose the right area to update or draw - the title screen, the list of available sessions, the lobby, or the game. In this step of the tutorial, we will make separate update and draw methods to handle the particular requirements of the title screen, session selection screen, lobby, and game.

Begin by declaring the new global variables we will need in the game to manage the network session. Declare a variable to hold the current network session for the game, a collection of available network sessions, the index of the network session a player has selected to join, and a packet reader and writer to read network data.

C#

```
NetworkSession networkSession;  
AvailableNetworkSessionCollection availableSessions;
```

```
int selectedSessionIndex;
PacketReader packetReader = new PacketReader();
PacketWriter packetWriter = new PacketWriter();
```

While you are looking at the global variables for the game, comment out the **Player** instance that is declared there. We are going to instead associate the player data with a person who has signed into the session.

C#

```
//Player player = new Player();
```

To use network services in a game, we need to add a [GamerServicesComponent](#) to the game. Once this component has been added, we can respond to the event that occurs when a gamer signs in.

In the **Game** constructor, add a new [GamerServicesComponent](#) to the collection of game components. Also in the **Game** constructor, add a new event handler for the [SignedIn](#) event.

C#

```
public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";

    aspectRatio = (float)GraphicsDeviceManager.DefaultBackBufferWidth /
        (2 * GraphicsDeviceManager.DefaultBackBufferHeight);

    // Add Gamer Services
    Components.Add(new GamerServicesComponent(this));

    // Respond to the SignedInGamer event
    SignedInGamer.SignedIn +=
        new EventHandler<SignedInEventArgs>(SignedInGamer_SignedIn);
}
```

One of the arguments that is passed to the [SignedIn](#) event is an instance of [SignedInEventArgs](#). This type contains a property called [Gamer](#). Each [Gamer](#) has a [Tag](#) object which can be used to attach data to the gamer. We are going to use the [Tag](#) property to store the **Player** that is associated with a particular gamer. Because this data does not exist yet when a gamer signs in, we will create a new **Player** when responding to the [SignedIn](#) event.

C#

```
void SignedInGamer_SignedIn(object sender, SignedInEventArgs e)
{
    e.Gamer.Tag = new Player();
}
```

We want to look at the input for the list of signed-in gamers during gameplay. Rename the current **Update** function **HandleGameplayInput** and set the accessibility level to "private." Also remove the call to **base.Update**. Change this method to accept a *Player* argument in addition to the *GameTime*. Also update the network session when this method is called.

C#

```
private void HandleGameplayInput(Player player, GameTime gameTime)
{
    if (IsButtonPressed(Buttons.Back))
        this.Exit();

    // change UpdateInput to take a Player
    UpdateInput(player);

    player.Update(gameTime);
    networkSession.Update();

    //base.Update(gameTime);
}
```

There is a static property called [SignedInGamers](#) that contains the list of all signed-in players. We will use this property in the **Update** method to get the **Player** data from a [SignedInGamer](#). Note that this loop wraps the update code that was already in this method. We also change **UpdateInput** to accept an instance of **Player**. This method also updates the **lastState** and **currentState** member variables, so the update of these variables can be removed from **UpdateInput**

C#

```
protected override void Update(GameTime gameTime)
{
    if (!Guide.IsVisible)
    {
        foreach (SignedInGamer signedInGamer in
            SignedInGamer.SignedInGamers)
        {
            Player player = signedInGamer.Tag as Player;
            lastState = player.lastState;
            currentState = GamePad.GetState(signedInGamer.PlayerIndex);

            if (networkSession != null)
            {
                // Handle the lobby input here...
            }
            else if (availableSessions != null)
            {
                // Handle the available sessions input here..
            }
            else
            {
                // Handle the title screen input here..
            }
            player.lastState = currentState;
        }
    }
    base.Update(gameTime);
}
```

The **UpdateInput** method will stay the same, except that it now gets the player to update from the *Player* argument instead of a global variable. There is also no need for the *currentState* and *lastState* variables to be updated in this method, so you can comment out these lines.

C#

```
protected void UpdateInput(Player player)
{
    //// Get the game pad state.
    //currentState = GamePad.GetState(PlayerIndex.One);
    //lastState = player.lastState;
    ...
    //player.lastState = currentState;
}
}
```

Finally, rename the **Draw** method to **DrawGameplay** and set the accessibility to "private." In this method, we will check to see if a network session has been created or joined before we start drawing the game. For each person in the networked game, we will draw to a different area of the screen.

C#

```
private void DrawGameplay(GameTime gameTime)
{
    GraphicsDevice.Viewport = mainViewport;
    GraphicsDevice.Clear(Color.CornflowerBlue);

    Player player;
    if (networkSession != null)
    {
```

```

        foreach (NetworkGamer networkGamer in networkSession.AllGamers)
        {
            player = networkGamer.Tag as Player;
            if (networkGamer.IsLocal)
            {
                DrawPlayer(player, leftViewport);
            }
            else
            {
                DrawPlayer(player, rightViewport);
            }
        }
    }
}

```

If you compile and run your game at this point, you will see a blank screen. Do not panic! This is because we made the game play state of the game contingent on the user signing in and creating or joining a network session. We will implement these game states next.

The Title Screen

First, create a method to draw the title screen.

C#

```

private void DrawTitleScreen()
{
    GraphicsDevice.Clear(Color.CornflowerBlue);
    string message = "";

    if (SignedInGamer.SignedInGamers.Count == 0)
    {
        message = "No profile signed in! \n" +
            "Press the Home key on the keyboard or \n" +
            "the Xbox Guide Button on the controller to sign in.";
    }
    else
    {
        message += "Press A to create a new session\n" +
            "X to search for sessions\nB to quit\n\n";
    }
    spriteBatch.Begin();
    spriteBatch.DrawString(lucidaConsole, message,
        new Vector2(101, 101), Color.Black);
    spriteBatch.DrawString(lucidaConsole, message,
        new Vector2(100, 100), Color.White);
    spriteBatch.End();
}

```

Next, change the **Draw** method so that it draws our new title screen if there is no network session available and no available sessions to list.

C#

```

protected override void Draw(GameTime gameTime)
{
    if (networkSession != null)
    {
    }
    else if (availableSessions != null)
    {
        // Show the available session...
    }
    else
    {
        DrawTitleScreen();
    }
}

```

```
    base.Draw(gameTime);  
}
```

We also need to handle the title screen input.

C#

```
protected void HandleTitleScreenInput()  
{  
    if (IsButtonPressed(Buttons.A))  
    {  
        CreateSession();  
    }  
    else if (IsButtonPressed(Buttons.X))  
    {  
        availableSessions = NetworkSession.Find(  
            NetworkSessionType.SystemLink, 1, null);  
  
        selectedSessionIndex = 0;  
    }  
    else if (IsButtonPressed(Buttons.B))  
    {  
        Exit();  
    }  
}
```

This method creates a session if the user selects this option.

C#

```
void CreateSession()  
{  
    networkSession = NetworkSession.Create(  
        NetworkSessionType.SystemLink,  
        1, 8, 2,  
        null);  
  
    networkSession.AllowHostMigration = true;  
    networkSession.AllowJoinInProgress = true;  
  
    HookSessionEvents();  
}
```

When creating a session, subscribe to the [GamerJoined](#) event.

C#

```
private void HookSessionEvents()  
{  
    networkSession.GamerJoined +=  
        new EventHandler<GamerJoinedEventArgs>(  
            networkSession_GamerJoined);  
}
```

When responding to the [GamerJoined](#) event, we want to either create a new **Player** if the player is not local, or get the player if the player has already signed in and has a **Player** object associated with it.

C#

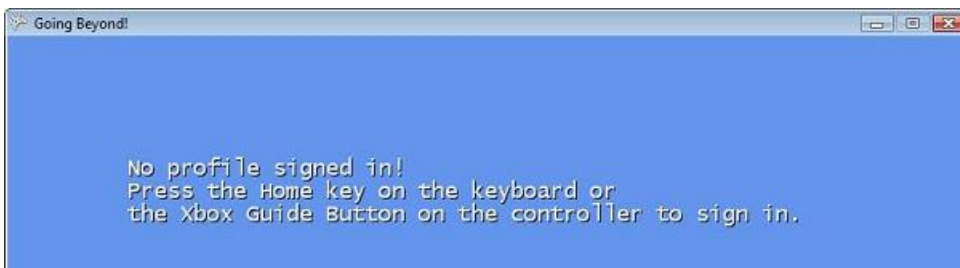

```
void networkSession_GamerJoined(object sender, GamerJoinedEventArgs e)  
{  
    if (!e.Gamer.IsLocal)  
    {  
        e.Gamer.Tag = new Player();  
    }  
    else  
    {  
        e.Gamer.Tag = GetPlayer(e.Gamer.Gamertag);  
    }  
}
```

```
}  
}
```

C#

```
Player GetPlayer(String gamertag)  
{  
    foreach (SignInGamer signInGamer in  
        SignInGamer.SignedInGamers)  
    {  
        if (signInGamer.Gamertag == gamertag)  
        {  
            return signInGamer.Tag as Player;  
        }  
    }  
  
    return new Player();  
}
```

If you run your game, you will see the new title screen with sign-in instructions for the player. Because we have a [GamerServicesComponent](#) added to the game, you can now sign in or view the Guide when you follow the instructions on the screen.

Once a player signs in, the instructions for finding or creating a new network session will also be displayed.

The Lobby

First, we will create a game screen to display the players waiting in the lobby.

C#

```
private void DrawLobby()  
{  
    GraphicsDevice.Clear(Color.CornflowerBlue);  
    spriteBatch.Begin();  
    float y = 100;  
  
    spriteBatch.DrawString(lucidaConsole, "Lobby (A=ready, B=leave)",  
        new Vector2(101, y + 1), Color.Black);  
    spriteBatch.DrawString(lucidaConsole, "Lobby (A=ready, B=leave)",  
        new Vector2(101, y), Color.White);  
  
    y += lucidaConsole.LineSpacing * 2;  
  
    foreach (NetworkGamer gamer in networkSession.AllGamers)  
    {  
        string text = gamer.Gamertag;  
  
        Player player = gamer.Tag as Player;  
  
        if (player.picture == null)  
        {
```

```

        GamerProfile gamerProfile = gamer.GetProfile();
        player.picture = gamerProfile.GamerPicture;
    }

    if (gamer.IsReady)
        text += " - ready!";

    spriteBatch.Draw(player.picture, new Vector2(100, y),
        Color.White);
    spriteBatch.DrawString(lucidaConsole, text, new Vector2(170, y),
        Color.White);

    y += lucidaConsole.LineSpacing + 64;
}
spriteBatch.End();
}

```

Next, we will need a method to handle any input from the user while the user is in the lobby.

C#

```

protected void HandleLobbyInput()
{
    // Signal I'm ready to play!
    if (IsButtonPressed(Buttons.A))
    {
        foreach (LocalNetworkGamer gamer in networkSession.LocalGamers)
            gamer.IsReady = true;
    }

    if (IsButtonPressed(Buttons.B))
    {
        networkSession = null;
        availableSessions = null;
    }

    // The host checks if everyone is ready, and moves
    // to game play if true.
    if (networkSession.IsHost)
    {
        if (networkSession.IsEveryoneReady)
            networkSession.StartGame();
    }

    // Pump the underlying session object.
    networkSession.Update();
}

```

Add code to the **Draw** method so that it will call the **DrawLobby** function if the user should be in the lobby.

C#

```

protected override void Draw(GameTime gameTime)
{
    if (networkSession != null)
    {
        //If the session is not null, we're either
        //in the lobby or playing the game...
        // Draw the Lobby
        if (networkSession.SessionState == NetworkSessionState.Lobby)
            DrawLobby();
    }
    else if (availableSessions != null)
    {
        // Show the available session...
    }
}

```

```

else
{
    DrawTitleScreen();
}

base.Draw(gameTime);
}

```

Finally, change the **Update** method of the game so it will call the method that handles the lobby input.

C#

```

protected override void Update(GameTime gameTime)
{
    if (!Guide.IsVisible)
    {
        foreach (SignedInGamer signedInGamer in
            SignedInGamer.SignedInGamers)
        {
            Player player = signedInGamer.Tag as Player;
            lastState = player.lastState;
            currentState = GamePad.GetState(signedInGamer.PlayerIndex);

            if (networkSession != null)
            {
                if (networkSession.SessionState ==
                    NetworkSessionState.Lobby)
                    HandleLobbyInput();
            }
            else if (availableSessions != null)
            {
                // Handle the available sessions input here...
            }
            else
            {
                HandleTitleScreenInput();
            }
            player.lastState = currentState;
        }
    }
    base.Update(gameTime);
}

```

Compile and run the game. Sign in and create a session to see the lobby.

List Available Network Sessions

Just as we created a method to draw an update the other game states, we will also create methods to draw and update the list of available network sessions.

C#

```

private void DrawAvailableSessions()
{
    GraphicsDevice.Clear(Color.CornflowerBlue);
    spriteBatch.Begin();
    float y = 100;

    spriteBatch.DrawString(lucidaConsole,

```

```

        "Available sessions (A=join, B=back)",
        new Vector2(101, y + 1), Color.Black);
spriteBatch.DrawString(lucidaConsole,
    "Available sessions (A=join, B=back)",
    new Vector2(100, y), Color.White);

y += lucidaConsole.LineSpacing * 2;

int selectedIndex = 0;

for (
    int sessionIndex = 0;
    sessionIndex < availableSessions.Count;
    sessionIndex++)
{
    Color color = Color.Black;

    if (sessionIndex == selectedIndex)
        color = Color.Yellow;

    spriteBatch.DrawString(lucidaConsole,
        availableSessions[sessionIndex].HostGamertag,
        new Vector2(100, y), color);

    y += lucidaConsole.LineSpacing;
}
spriteBatch.End();
}

```

C#

```

protected void HandleAvailableSessionsInput()
{
    if (IsButtonPressed(Buttons.A))
    {
        // Join the selected session.
        if (availableSessions.Count > 0)
        {
            networkSession = NetworkSession.Join(
                availableSessions[selectedIndex]);
            HookSessionEvents();

            availableSessions.Dispose();
            availableSessions = null;
        }
    }
    else if (IsButtonPressed(Buttons.DPadUp))
    {
        // Select the previous session from the list.
        if (selectedIndex > 0)
            selectedIndex--;
    }
    else if (IsButtonPressed(Buttons.DPadDown))
    {
        // Select the next session from the list.
        if (selectedIndex < availableSessions.Count - 1)
            selectedIndex++;
    }
    else if (IsButtonPressed(Buttons.B))
    {
        // Go back to the title screen.
        availableSessions.Dispose();
        availableSessions = null;
    }
}
}

```

Change the **Draw** and **Update** methods to call these methods when the game should show the list of available sessions.

C#

```
protected override void Draw(GameTime gameTime)
{
    if (networkSession != null)
    {
        //If the session is not null, we're either
        //in the lobby or playing the game...
        // Draw the Lobby
        if (networkSession.SessionState == NetworkSessionState.Lobby)
            DrawLobby();
    }
    else if (availableSessions != null)
    {
        DrawAvailableSessions();
    }
    else
    {
        DrawTitleScreen();
    }

    base.Draw(gameTime);
}
```

C#

```
protected override void Update(GameTime gameTime)
{
    if (!Guide.IsVisible)
    {
        foreach (SignedInGamer signedInGamer in
            SignedInGamer.SignedInGamers)
        {
            Player player = signedInGamer.Tag as Player;
            lastState = player.lastState;
            currentState = GamePad.GetState(signedInGamer.PlayerIndex);

            if (networkSession != null)
            {
                if (networkSession.SessionState ==
                    NetworkSessionState.Lobby)
                    HandleLobbyInput();
            }
            else if (availableSessions != null)
            {
                HandleAvailableSessionsInput();
            }
            else
            {
                HandleTitleScreenInput();
            }
            player.lastState = currentState;
        }
    }
    base.Update(gameTime);
}
```

When a player joins an available session, the other players waiting in the lobby can now be seen.

Step 5: Receive Network Data

We can now create a network session with multiple players in the session, but we need a way for players to send and receive data from other players in the game.

First, create a method to receive the data from a network gamer.

C#

```
void ReceiveNetworkData(LocalNetworkGamer gamer, GameTime gameTime)
{
    while (gamer.IsDataAvailable)
    {
        NetworkGamer sender;
        gamer.ReceiveData(packetReader, out sender);

        if (!sender.IsLocal)
        {
            Player player = sender.Tag as Player;
            player.ship.isActive = packetReader.ReadBoolean();
            player.ship.Position = packetReader.ReadVector3();
            player.ship.Rotation = packetReader.ReadSingle();
            player.score = packetReader.ReadInt32();
            if (packetReader.ReadBoolean())
            {
                player.ShootBullet();
            }
            if (packetReader.ReadBoolean())
            {
                player.ship.isActive = false;
            }
            for (int i = 0; i < GameConstants.NumAsteroids; i++)
            {
                player.asteroidList[i].isActive =
                    packetReader.ReadBoolean();
                player.asteroidList[i].position =
                    packetReader.ReadVector3();
            }
            player.Update(gameTime);
        }
    }
}
```

Next, change the **UpdateInput** method to call **ReceiveNetworkData** for every signed-in player on the local system that might receive data. Note that the **ReceiveNetworkData** needs an instance of **GameTime** to pass to the **Player.Update** method, so we will update **UpdateInput** to take the *GameTime* as a parameter. At the end of the **UpdateInput** Method, send the data from the local gamer to any network gamers in the game.

C#

```
private void HandleGameplayInput(Player player, GameTime gameTime)
{
    ...
    UpdateInput(player, gameTime);
    ...
}
```

```
}
```

C#

```
private void UpdateInput(Player player, GameTime gameTime)
{
    bool isFiring = false;
    bool shipDestroyed = false;

    foreach (LocalNetworkGamer gamer in networkSession.LocalGamers)
    {
        ReceiveNetworkData(gamer, gameTime);

        // this code is the same code we have been
        // using to update the player input
        if (currentState.IsConnected)
        {
            if (player.ship.isActive)
            {
                player.ship.Update(currentState);
                PlayEngineSound(currentState);
            }
            // In case you get lost, press B to warp back to the center.
            if (IsButtonPressed(Buttons.B))
            {
                player.WarpToCenter();
                // Make a sound when we warp.
                soundHyperspaceActivation.Play();
            }

            //are we shooting?
            if (player.ship.isActive && IsButtonPressed(Buttons.A))
            {
                player.ShootBullet();
                soundWeaponsFire.Play();
                isFiring = true;
            }

            if (player.CheckForBulletAsteroidCollision(
                bulletModel.Meshes[0].BoundingSphere.Radius,
                asteroidModel.Meshes[0].BoundingSphere.Radius))
            {
                soundExplosion2.Play();
            }

            shipDestroyed = player.CheckForShipAsteroidCollision(
                shipModel.Meshes[0].BoundingSphere.Radius,
                asteroidModel.Meshes[0].BoundingSphere.Radius);

            if (shipDestroyed)
            {
                soundExplosion3.Play();
            }
        }
        packetWriter.Write(player.ship.isActive);
        packetWriter.Write(player.ship.Position);
        packetWriter.Write(player.ship.Rotation);
        packetWriter.Write(player.score);
        packetWriter.Write(isFiring);
        packetWriter.Write(shipDestroyed);
        for (int i = 0; i < GameConstants.NumAsteroids; i++)
        {
            packetWriter.Write(player.asteroidList[i].isActive);
            packetWriter.Write(player.asteroidList[i].position);
        }

        gamer.SendData(packetWriter, SendDataOptions.None);
    }
}
```

```
}  
}
```

Finally, change **Draw** and **Update** so that each method calls the **DrawGameplay** and **HandleGameplayInput** method at the appropriate time.

C#

```
protected override void Draw(GameTime gameTime)  
{  
    if (networkSession != null)  
    {  
        // Draw the Lobby  
        if (networkSession.SessionState == NetworkSessionState.Lobby)  
            DrawLobby();  
        else  
            DrawGameplay(gameTime);  
    }  
    else if (availableSessions != null)  
    {  
        DrawAvailableSessions();  
    }  
    else  
    {  
        DrawTitleScreen();  
    }  
  
    base.Draw(gameTime);  
}
```

C#

```
protected override void Update(GameTime gameTime)  
{  
    if (!Guide.IsVisible)  
    {  
        foreach (SignedInGamer signedInGamer in  
            SignedInGamer.SignedInGamers)  
        {  
            Player player = signedInGamer.Tag as Player;  
            lastState = player.lastState;  
            currentState = GamePad.GetState(signedInGamer.PlayerIndex);  
  
            if (networkSession != null)  
            {  
                if (networkSession.SessionState ==  
                    NetworkSessionState.Lobby)  
                    HandleLobbyInput();  
                else  
                    HandleGameplayInput(player, gameTime);  
            }  
            else if (availableSessions != null)  
            {  
                HandleAvailableSessionsInput();  
            }  
            else  
            {  
                HandleTitleScreenInput();  
            }  
            player.lastState = currentState;  
        }  
    }  
    base.Update(gameTime);  
}
```

With this final change, your game can now be played by two players over the network.

Where do you go from here? Using the **Player** class, you could extend the game to allow for two players on the same local machine. You could also change the game to display more than two players by splitting the screen again, or get rid of the split-screen and implement code to allow the players to shoot at one another.

More advanced screen management techniques are available from the [XNA Creators Club Online Web site](#), along with numerous other game programming techniques that can be used to add functionality to this game.

Upgrading XNA Game Studio Projects

Guides for upgrading XNA Game Studio Projects are provided in the following sections:

Describes how to upgrade your XNA Game Studio 2.0 game to target XNA Framework 3.0 in Microsoft Visual Studio 2008.

[Troubleshooting Upgrades](#)

Describes common issues with upgrading XNA Game Studio projects.

Choosing an XNA Framework Version

XNA Framework 3.0 and 3.1

XNA Game Studio 3.1 supports both XNA Game Studio 3.1 and XNA Game Studio 3.0 project formats. To target XNA Framework 3.1, use an XNA Game Studio 3.1 project. XNA Game Studio 3.0 projects will target XNA Framework 3.0.

Important

You should not mix projects that target different versions of the XNA Framework in the same solution.

Unless you have a special need to maintain an XNA Game Studio 3.0 project, you should upgrade your projects to XNA Game Studio 3.1 to take advantage of the new features in this release. For more information, see [What's New in XNA Game Studio 3.1](#).

XNA Game Studio 3.1 projects must use the Microsoft Cross Platform Audio Creation Tool version 3 (XACT3), which is new to XNA Game Studio 3.1. The version of XACT provided with XNA Game Studio 3.0, XACT2, writes project files (.xap) that are incompatible with XNA Game Studio 3.1 projects. XNA Game Studio 3.0 projects must continue to use XACT2. Both versions of XACT are available in the **Start** menu, under **All Programs | Microsoft XNA Game Studio 3.1 | Tools**.

XNA Framework 2.0

XNA Game Studio 2.0 projects, targeting XNA Framework 2.0, are not supported in this release. All XNA Game Studio 2.0 projects must be upgraded to target either XNA Framework 3.1 or XNA Framework 3.0.

For more information about upgrading XNA Game Studio 2.0 projects, see [Upgrade Guide: XNA Game Studio 2.0 to XNA Game Studio 3.0](#).

Upgrade Guide: XNA Game Studio 3.0 to XNA Game Studio 3.1

To take advantage of the latest XNA Game Studio features, projects should be upgraded to XNA Game Studio 3.1. However, unlike converting a project from XNA Game Studio 2.0 to XNA Game Studio 3.0, this operation is not enforced automatically.

For a quick understanding of the new features introduced in XNA Game Studio 3.1, see [What's New in XNA Game Studio 3.1](#).

Upgrading Your Projects

To upgrade projects from XNA Game Studio 3.0 to XNA Game Studio 3.1

1. Right-click your solution in Visual Studio's **Solution Explorer**.

This opens a context sensitive menu with the option: **Upgrade Solution...**

2. Click **Upgrade Solution...** to open the **Upgrade Solution** dialog box.

This lists all the projects in the current solution that will be upgraded.

3. If you are sure you want to upgrade now, click **Upgrade**.

This upgrades all the listed projects to XNA Game Studio 3.1. You will be presented with a dialog box that prompts you to save your existing projects.

Click **Yes** to save your projects and continue with the upgrade. If you click **No** or **Cancel**, your project will not be upgraded. You *must* save the files before you upgrade them.

Important

This step will only save your project files and continue with the upgrade. It does not back up your projects. Be sure to back up your project files *before* continuing with the upgrade. You cannot Undo the upgrade once it begins.

Note

If you have any Microsoft Cross-Platform Audio Creation Tool (XACT) project files (.xap) that were created with XNA Game Studio 3.0, they must be loaded and saved with XACT3 or they will not work with XNA Game Studio 3.1. XACT3 can be launched from the **Start** menu, by clicking **All Programs, Microsoft XNA Game Studio 3.1, Tools, and Microsoft Cross-Platform Audio Creation Tool 3 (XACT3)**. For more information about XACT, see [Audio Overview](#).

The chief tasks that the Project Upgrade Wizard performs are:

- Updates XNA Framework references and properties from XNA Game Studio 3.0 to XNA Game Studio 3.1.
- Updates the import targets file references in the game project for what is required for XNA Game Studio 3.1.
- Updates the import targets file references in the content project for what is required for XNA Game Studio 3.1.

Upgrade Guide: XNA Game Studio 2.0 to XNA Game Studio 3.1

Describes how to upgrade your XNA Game Studio 2.0 game to XNA Game Studio 3.1 in Microsoft Visual Studio 2008.

XNA Game Studio 2.0 game projects require upgrade to the new format for development in Visual Studio 2008 and XNA Game Studio 3.1. This upgrade is necessary in every case, regardless of the complexity or simplicity of the project.

For a quick understanding of the new features introduced in XNA Game Studio 3.1, see [What's New in XNA Game Studio 3.1](#).

Upgrading Your Projects

Projects that were created in XNA Game Studio 2.0 must be upgraded to work with Microsoft Visual Studio 2008 and *at least* XNA Game Studio 3.0. There is no direct way to upgrade a project from XNA Game Studio 2.0 to XNA Game Studio 3.1. However, to upgrade a project to XNA Game Studio 3.1, it must first be upgraded to XNA Game Studio 3.0.

To upgrade a project from XNA Game Studio 2.0 to XNA Game Studio 3.1

1. Upgrade the project from XNA Game Studio 2.0 to XNA Game Studio 3.0, using the procedure in [Upgrade Guide: XNA Game Studio 2.0 to XNA Game Studio 3.0](#).
2. Upgrade the project from XNA Game Studio 3.0 to XNA Game Studio 3.1, using the procedure in [Upgrade Guide: XNA Game Studio 3.0 to XNA Game Studio 3.1](#).

Upgrade Guide: XNA Game Studio 2.0 to XNA Game Studio 3.0

Describes how to upgrade your XNA Game Studio 2.0 game to target XNA Framework 3.0 in Microsoft Visual Studio 2008.

XNA Game Studio 2.0 game projects must be upgraded to target either XNA Framework 3.1 or XNA Framework 3.0 for development in Visual Studio 2008 and XNA Game Studio 3.1. This upgrade is necessary in every case, regardless of the complexity or simplicity of the project.

Note

To take advantage of the latest features in XNA Game Studio, you should upgrade your projects to XNA Game Studio 3.1. To do so, first follow the procedure in this guide to upgrade the project to XNA Game Studio 3.0. When that is complete, see [Upgrade Guide: XNA Game Studio 3.0 to XNA Game Studio 3.1](#). XNA Framework 3.0 games are still supported in XNA Game Studio 3.1, however.

For a quick understanding of the features introduced in XNA Game Studio 3.0, see [XNA Game Studio 3.0: What's New in This Release](#).

Upgrading Your Projects

Projects created in XNA Game Studio 2.0 must be upgraded to work with Microsoft Visual Studio 2008 and XNA Game Studio 3.0.

The Project Upgrade Wizard for XNA Game Studio 3.0 executes automatically whenever you open a project or solution in Visual Studio 2008 that was created for XNA Game Studio 2.0. The instructions provided by the Project Upgrade Wizard will lead you through the upgrade process.

The chief tasks that the Project Upgrade Wizard performs are:

- Updates XNA Framework references and properties from XNA Framework 2.0 to XNA Framework 3.0.
- Updates the import targets file references in the game project for what is required for XNA Framework 3.0.
- Updates the import targets file references in the content project for what is required for XNA Framework 3.0.
- Establishes content compression properties (introduced in XNA Game Studio 3.0) to the default settings.

Troubleshooting Upgrades

Projects don't build because a reference to assembly version X is missing, but I am not targeting X.

Be sure to check the dependencies of all assemblies included with your projects. Also, make sure that any assemblies you're using in your projects target the same version of the XNA Framework that your project is targeting. Projects (or libraries) that target different versions of the XNA Framework cannot interact and should not be located in the same solution.

Projects don't build because a type can't be converted from type Foo (assembly version X) to type Foo (assembly version Y).

Check to see that all classes in your project use the classes, methods, properties, and events that exist in the XNA Framework version you are targeting. In some cases, methods may have been deprecated or some parameters may have changed.

My importer or processor is missing from the list of importers or processors available in the content pipeline.

The importer or processor used by your project may not support the version of XNA Framework that you are targeting. Be sure that you have updated versions of all components used by your title.

My content won't build because the importer or processor can't be found, but I have a reference to it.

The importer or processor used by your project may not support the version of XNA Framework that you are targeting. Be sure that you have updated versions of all components used by your title.

My audio project files are not loaded in my converted solution.

Audio project files (.xap) that were created with XACT2 in XNA Game Studio 3.0 must be loaded and saved with XACT3 before they will work with XNA Game Studio 3.1. For more information, see [Upgrade Guide: XNA Game Studio 3.0 to XNA Game Studio 3.1](#).

Using XNA Framework Starter Kits

An XNA Framework Starter Kit is a complete or near-complete, self-contained game that includes both game code and game assets. A starter kit is ready for you to load and build. Each kit comes with its own documentation, including descriptions of programming techniques, and suggestions for how it may be customized. A starter kit provides a great way to see a working XNA Framework game in action and to see what is possible using XNA Game Studio for game development.

To Load and Build an XNA Framework Starter Kit

1. From the **File** menu, click **New**, and then click **New Project**.

The **New Project** dialog box appears.

2. In **Project types**, under the **Visual C#** node, select **XNA Game Studio 3.1**.

The **New Project** dialog box displays the XNA Framework–specific project types.

Next, you need to select an XNA Framework Starter Kit project type.

3. Select an available starter kit and then click **OK**.

The selected starter kit loads into your version of Visual Studio.

4. To build and launch the starter kit project, press F5.

Starter Kit: Platformer

The Platformer Starter Kit is a near-complete, self-contained game solution that includes both game code and game assets. The game is a standard 2D platformer with levels, enemies, and collectable gems.

This starter kit is intentionally incomplete. Several nonessential features and systems are not finished. This makes it easier and quicker to understand the structure of the game, and how the pieces fit together to provide a rich gaming experience. The Platformer Starter Kit includes the following features:

- Cross-platform support for Windows, Zune, and Xbox 360.
- Control of the player character using either the keyboard or gamepad.
- Simple physics modeling (falling and jumping) and dynamic collision checking.
- Production-level sprite sheets, sound effects, and other game assets.
- High and low resolution assets, and an additional content project containing audio assets.
- New features from XNA Game Studio, such as the simple sound API and multiple content projects whose usage depends on the target platform.

Figure 1. Gameplay Screen for the Platformer Starter Kit

Player Controls

The player character is controlled using either the keyboard or gamepad.

Action	Keyboard	Gamepad	Zune
Run left, Run right	A, D	Left thumbstick or analog D-pad	Device control pad (version 1) or Zune pad (version 2)
Jump	Space	A	Click the center of either the device control pad (version 1) or the Zune pad (version 2)

Platformer Code Architecture

The following is a list of classes shipped with the Platformer starter kit. The file containing the implementation for each class shares the name of the class. For example, Gem.cs contains the Gem class implementation.

Name	Description
Gem	Implements a floating gem in the game. Gems are collectable by the player, and are worth a set amount of points. Gems are used to load, draw, and update a gem. For more information, see Basic Platformer Features .
Circle (structure)	Implements a bounding circle for checking collision against gem objects. For more information, see Basic Platformer Features .

Tile (structure)	Stores basic information about a game tile. For more information, see Basic Platformer Features .
TileCollision (enumeration)	Stores the different collision types a tile can have: Passable, Impassable, Platform. For more information, see Basic Platformer Features .
AnimationPlayer (structure)	Implements playback of the animation stored by <code>Animation</code> . For more information, see Intermediate Platformer Features .
Animation	Stores an animated texture. Used to animate the player character and enemy sprite sheets. For more information, see Intermediate Platformer Features .
Enemy	Implements an enemy in the game. Used to load, draw, and update an enemy. For more information, see Intermediate Platformer Features .
FaceDirection (enumeration)	Stores the different directions an enemy can face. For more information, see Intermediate Platformer Features .
PlatformerGame	Implements major game components such as content and level loading, HUD management and display, and game object updating. For more information, see Advanced Platformer Features .
Level	Implements a level in the game. A <code>Level</code> object contains a multi-dimensional array of tiles, a player character, a start and end location, point total, remaining level time, a list of gems, and a list of enemies. For more information, see Advanced Platformer Features .
Player	Implements the player character. Used to load, draw, and update the character. For more information, see Advanced Platformer Features .
RectangleExtensions	Implements an extension to the standard XNA Framework structure Rectangle . For more information, see Advanced Platformer Features .

Execution Flow

Think of the execution flow of Platformer as follows:

1. The next level is loaded. Important methods are `PlatformerGame.LoadContent` and `PlatformerGame.LoadNextLevel`.
2. The game is updated using `PlatformerGame.Update` and `Level.Update`. If the player is dead or if time has expired, input is ignored and the game is in a pause state. If the player has reached the exit, the remaining time is converted to points. If there is still time and the player hasn't reached the exit location, the time remaining is decremented and all level objects are updated (player character, enemies, gems, and so on) using their `Update` methods. At this time, checks are also made for the player reaching the exit and falling off the edge of the screen.
3. The gameplay screen is drawn using `PlatformerGame.Draw`. This method, in turn, calls `Level.Draw` and `PlatformerGame.DrawHud`.

`Level.Draw` is responsible for drawing the tiles, player character, gems and enemies using calls to the `Draw` method of each previously-mentioned game object.

Platformer Game Design

The design of Platformer should be familiar to all gamers. You must avoid the enemies and reach the level exit before time expires (collecting gems along the way). If you complete the level with time remaining, that time is converted to a point bonus, and it is added to your current score. You lose a life if you run into an enemy, fall off a ledge, or run out of time before collecting all gems and reaching the exit.

Figure 1. Gameplay Screen for the Platformer Starter Kit

Game World

The game world is composed of individual levels where each level is automatically constructed, using several square tile types, from an existing text file. This text file uses a set of symbols to map out the level, locating the start and exit points, enemy starting positions, gem locations and tile locations (including their type). For a complete listing of the level file format, see [Advanced Platformer Features](#).

Three tile types are implemented by Platformer and represent the ledges and impassable areas of a level.

N Properties	
a m e	
I m p a s s a b l e	Players and enemies cannot pass through the tile from any direction.
P a s s a b l e	Players and enemies can pass through the tile freely. The main purpose of this tile type is to provide decoration to the level – decoration such as jungle foliage, rocks, and other scenery.

Platformer	Platform tiles behave like passable tiles except that players and enemies can stand on (or in the case of the player character, fall onto) the top edge of the tile without falling.
	This is implemented by checking for collision between the character's bounding rectangle and the top edge of the platform tile. If collision occurs, the affected character's Y velocity (that is, the character's speed when falling) is forced to 0. If the character stood, or fell onto, a passable tile, no collision checking is performed. This causes the character to continue falling until the character reaches an impassable tile or passes the bottom edge of the screen. For more information on collision checking and game world physics, see Advanced Platformer Features .

In addition to tiles, there are several special objects that represent special locations or objects in the game world.

Name	Properties
Level Start	The player character begins the level at this location, facing to the right.
Gem	An object that players collect for points and level completion. The player must collect <i>all</i> gems and reach the exit before time expires to complete the level.
Level Exit	The location the player must reach to complete the level before time expires. Failure to reach the exit (and collect all gems) forces the player to lose a life and begin at the Level Start location.

Player Character

The player character can run and jump. The player is affected by a simple gravity implementation, and can run off platforms without jumping. When falling, the character is halted by any collision with a platform-type tile. If the player character is moving and not under direct control of the player, simple pseudo-drag is implemented. This gradually stops the player character instead of causing an instant stop.

Enemies

Initially, Platformer implements a single enemy type. This enemy slowly walks back and forth along a platform, automatically turning around at the platform's edge. The player character cannot kill the enemy and is immediately killed by the enemy upon contact.

Starter Kit Assets

Assets in the various content projects are platform-dependent. For Windows and Xbox 360 projects, the HighResolutionContent content project is used. It contains fonts, level backgrounds, higher-resolution tile textures (64x48) and single-animation sprite sheets. Each sprite list is a strip of single frames (96x96) that provide animation when displayed sequentially. For instance, the Celebrate.png asset is a series of frames of a celebration by the player character. The entire set of animation lists for a specific character (either enemy or player) are kept in a separate directory.

Zune projects use a lower resolution set of these level backgrounds, tile textures, fonts, and single-frame sprite lists. For example, tile texture resolutions are 32x32 and sprite lists contain frames that are half the size of their higher-resolution counterpart, 48x48.

In addition to the HighResolutionContent and LowResolutionContent content projects, all projects use an additional content project, SharedContent. This content project contains the sound effects for the game. It includes sound effects used when the player character collects a gem, reaches the level exit, or dies by falling or enemy contact. Unlike texture files, sound files are shared between all three platforms. Having a separate set of lower fidelity sound effects for the Zune would not be worth the effort and loss in quality when compared to the size saved when Platformer is installed.

Shared projects (such as SharedContent) are the default in XNA Game Studio, but it is also possible to set up platform-specific game content projects. It's easier to implement if you do a little planning before adding new projects to your solution. For more information on sharing game assets between projects, see [Platform-Specific Content Projects](#).

Exploring the Basic Classes

The Platformer starter kit can be pretty overwhelming the first time you see it. However, it can be broken down into more manageable pieces, based on the complexity of the game object and its usage by the Platformer game. In this section, we'll explore Platformer's basic classes and structures. We'll talk about their purpose and design and point out features that can be modified or expanded on. For information on more complex classes, see [Intermediate Platformer Features](#) and [Advanced Platformer Features](#).

Gem Class and Circle Structure

The `Gem` class implementation is located in `Gem.cs`. Important methods include:

LoadContent

Loads a grayscale gem-shaped texture.

Update

Updates the gem height at regular intervals during gameplay. This method is used to cause all gems in the level to oscillate up and down in relation to each other. The motion is implemented with a sine curve over time. In addition, the X-coordinate of the gem is used to produce a nice syncopated pattern.

Draw

Draws the gem using the specified color shade. The default color is yellow.

OnCollected

Plays a sound indicating retrieval by the player. This is an great place to modify the default behavior of gem collection!

Properties include the parent `Level`, its position in world space, and a bounding circle.

The bounding circle (implemented by the `Circle` structure, located in `Circle.cs`) is used to determine if the player is colliding with the gem. If the player collides with the gem, it is removed from the gem collection of the parent `Level` and points are added to the player's score. The most important method of `Circle` is `Intersects`. This method checks for intersection with a rectangle (used to represent the bounding area of other game objects). This method is called by `Level.UpdateGems` and if it returns **true**, the gem is removed and the `OnGemCollected` method is called. For more information on `OnX` methods, see [Changing the Behavior of Existing Game Events](#).

Gems are the only objects that use a bounding circle. All other objects use a bounding rectangle.

Gem Animation

The default animation of gems is based on a sine wave. They slowly rise and fall as a group during gameplay. The `Gem.Update` method controls this animation.

Tip

You can easily modify this behavior by changing the default height and speed of the animation.

Tile Structure and TileCollision Enumeration

The `Tile` structure implementation is located in `Tile.cs`. It has a constructor, but its main purpose is storing the properties of a level tile.

Properties include the tile dimensions (width and height), the collision behavior of the tile object, and the texture used when drawing the tile object.

The collision behavior (stored in the `Collision` property) is the most important property of the `Tile` structure. This property determines what kind of collision detection is done, if any. For more information on supported tile types, see [Game World](#).

The `TileCollision` enumeration lists all possible collision behaviors for a tile and is located in `Tile.cs`.

Basic Modifications to the Platformer Starter Kit

Changing the Behavior of Existing Game Events

Tip

Modifying default behaviors in the game is as easy as modifying the related `OnXEvent` method.

Platformer handles important events in the game using methods that follow an `OnX` naming convention, where X is an important event name. For instance, when the player character collects a gem, `OnCollected` is ultimately called. The complete list of methods called before `Gem.OnCollected` is as follows:

1. `Level.Update`
2. `Level.UpdateGems`
3. `Level.OnCollected`
4. `Gem.OnCollected`

When a gem is collected, the default behavior is to play a "gem collected" sound (`GemCollected.wma`). If you wanted to change this behavior, there are two places you should focus on: the `Level.OnCollected` and `Gem.OnCollected` methods. Add (or remove existing) code to do different things. For instance, to create a "cursed" gem (subtracts points from the player's total when collected), modify the `Level.OnCollected` method to subtract `Gem.PointValue` from the total instead of adding to it.

Intermediate Platformer Features

Discusses intermediate classes of the Platformer Starter Kit, and offers recommendations for modifying or extending Platformer features.

In this section, we'll explore Platformer's intermediate features and the classes that implement them, such as sprite animation. We'll talk about their purpose and design, and point out features that can be modified or expanded on. For information on basic classes, see [Exploring the Basic Classes](#). For advanced classes, see [Advanced Platformer Features](#).

Figure 1. Jumping Animation for Player Character

Exploring the Intermediate Classes

The following classes are more complex than the basic Platformer classes, and they implement some intermediate features of Platformer.

AnimationPlayer Structure and Animation Class

The `AnimationPlayer` structure is used to animate the player character and the enemies of the current level. It stores a single animation sprite sheet in the `Animation` property, of type `Animation`. Animation begins with a call to the `PlayAnimation` method, but if the animation is already playing, the method immediately returns. This prevents the animation from being interrupted for any reason.

The animation infrastructure is intentionally simple and customized for the base version of Platformer. It is not designed to scale up or be used independently of Platformer. The only requirement is that the animation frame is square in shape.

Platformer provides five animations for the player character and three animations for each of the different enemies. However, not all are initially used in the game.

Note
For enemies, the Die animation is not used.

The `AnimationPlayer` structure implementation is located in `AnimationPlayer.cs`. Important methods include:

- `Draw`
Advances the current time of the animation and, based on the time, draws a single frame from the related sprite sheet.
- `PlayAnimation`
Begins playing a specified animation, using a single-animation sprite sheet. If the specified animation is already running, it is not interrupted.

Properties include the sprite sheet used for animation, the current frame index, and the origin of the current frame.

The `Animation` class implementation is located in `Animation.cs`. It stores important attributes of an animation, such as frame count, texture used for animation, frame width, and so on.

Enemy Class and FaceDirection Enumeration

The `Enemy` class implementation is located in `Enemy.cs`. Important methods include:

LoadContent

Loads a specific enemy sprite strip. The enemy type is determined by the level structure file. Platformer implements four different enemy types. These types differ only in appearance. They are stored in separate directories in the appropriate content project, under the Sprites directory. Each enemy type has two animations: Run and Idle. The third animation, Die, is not used, but it is included for future development.

Update

Updates the enemy location. The default enemy behavior is to pace back and forth across a platform, pausing at the platform's edge.

If an enemy detects that it will move into an impassable tile (such as a wall) or walk off the edge of a platform tile, the value of the `FaceDirection` property is reversed, causing the enemy to begin walking in the opposite direction.

Draw

Draws the enemy character using the specified animation frame.

Before drawing the current animation, `Draw` checks the current orientation of the enemy. If the enemy is facing to the right, the current frame is flipped by specifying `SpriteEffects.FlipHorizontally` in the call to `SpriteBatch.Draw`.

Properties are similar to the `Gem` class: the parent `Level`, its position in world space, and a bounding rectangle. This differs from the gem object implementation, which used a circle. A rectangular bounding rectangle makes more sense for enemy characters (and the player character) because of their interaction with the rectangular tiles that make up the level – especially the platform tiles.

The `Enemy` class is a simpler version of the `Player` class because it cannot jump and has only a single behavior: relentless pacing upon its current platform.

Expanding Platformer

A logical expansion for Platformer is the use of power-ups in the game. In this topic, an Invincibility power-up is implemented in the default version of the Platformer starter kit. This power-up gives the player character temporary invincibility against enemies is indicated by a red gem. For complete details on this expansion, see [Platformer: Adding a Power-Up](#).

Platformer: Adding a Power-Up

Extends the base Platformer starter kit code by adding a power-up gem and player character effect.

Tip

It is *highly* recommended that you are already familiar with the structure and features of the Platformer starter kit. This extension involves modifications to several files in the Platformer starter kit. For more information on the Platformer starter kit, see [Starter Kit: Platformer](#).

This extension modifies five areas of the Platformer starter kit. It is recommended that you use the base Platformer starter kit solution as the starting point for your modifications.

Adding a power-up gem involves the following major steps:

- Modifying Gem.cs to support a power-up attribute and draw the power-up gem in a special way.
- Modifying AnimationPlayer.cs to draw a special effect on the player when invincible.
- Modifying Player.cs to support and monitor a power-up state, drawing a special effect when the character is powered-up.
- Modifying Enemy.cs to support being killed by a powered-up player character and to draw a Die animation.
- Modifying Level.cs to recognize and load a power-up gem from a level structure file. The level code must also notify other game objects that a power-up gem has been collected.

Figure 1. Power-Up Gem Extension

Modifying the Gem Class

Modification of the `Gem` class begins by changing some existing properties and adding a `IsPowerUp` property. Modify the existing code for the `PointValue` and `Color` properties to match the following:

C#

```
public readonly int PointValue;
public bool IsPowerUp { get; private set; }
public readonly Color Color;
```

This modification also adds the new property, `IsPowerUp`. Modify the existing `Gem` constructor to accept a new `isPowerUp` parameter. After the modification, it should match the following:

C#

```
public Gem(Level level, Vector2 position, bool isPowerUp)
{
```

```
    ...  
}
```

In the existing constructor, after the code setting the level and position of the gem object, add the following:

C#

```
    IsPowerUp = isPowerUp;  
    if (IsPowerUp)  
    {  
        PointValue = 100;  
        Color = Color.Red;  
    }  
    else  
    {  
        PointValue = 30;  
        Color = Color.Yellow;  
    }
```

This code sets the `IsPowerUp` property of the gem, and then raises the point value if it is a power-up.

The last modification to the `Gem` class is to call the `PowerUp` method (a method added later) of the proper player character. Add the following code after any existing code in the `OnCollected` method:

C#

```
    if (IsPowerUp)  
        collectedBy.PowerUp();
```

This completes the modification of `Gem.cs`. Let's move on to `AnimationPlayer.cs`, and add support for drawing the power-up effect.

Modifying the AnimationPlayer Class

Your modifications in this class are small. You'll add code using the new color being passed in to tint the player character sprite, and you'll add a new `Draw` method.

Modify the existing `Draw` method declaration to accept an additional parameter called `color`. This indicates the current color to use as a tint when drawing the invincible player character. After the modification, it should look like the following:

C#

```
    public void Draw(GameTime gameTime, SpriteBatch spriteBatch, Vector2 position, SpriteEffects spriteEffects, Color color)  
    {  
        ...  
    }
```

Now that we have a tint color being passed in, let's use it in our `Draw` call. Staying within this method, modify the final call to `Draw` to match the following:

C#

```
        spriteBatch.Draw(Animation.Texture, position, source, color, 0.0f, Origin, 1.0f, spriteEffects, 0.0f);
```

Now add a new `Draw` method, after the previous one, to be called when the power-up effect is not needed:

C#

```

public void Draw(GameTime gameTime, SpriteBatch spriteBatch, Vector2 position, SpriteEffects spriteEffects)
{
    Draw(gameTime, spriteBatch, position, spriteEffects, Color.White);
}

```

That was the last of the code for the strobing tint effect. Let's move on to the `Player` class, found in the `Player.cs` file, and add that `PowerUp` method, among other modifications.

Modifying the Player Class

Modification of the `Player` class begins by adding support for a power-up state. After the `IsAlive` property, add the following code:

C#

```

// Powerup state
private const float MaxPowerUpTime = 6.0f;
private float powerUpTime;
public bool IsPoweredUp
{
    get { return powerUpTime > 0.0f; }
}
private readonly Color[] poweredUpColors = {
    Color.Red,
    Color.Blue,
    Color.Orange,
    Color.Yellow,
};

private SoundEffect powerUpSound;

```

This code adds some properties to monitor the power-up time, an `IsPoweredUp` method, a `Color` array that stores the colors used to produce the special tinting of the player character, and a sound effect that plays while the character is powered up.

While you're here, add the `PowerUp` sound effect to the **SharedContent** content project.

1. Right-click the **Sounds** directory of the **SharedContent** content project, and select **Add**, then **Existing Item...**
2. Select the `PowerUp.wma` file, and then click **OK**.
3. Select the new sound effect, and change the **Content Processor** to **SoundEffect** (using the **Properties** window).

Load the new sound effect by adding the following line to the `LoadContent` method:

C#

```
powerUpSound = Level.Content.Load<SoundEffect>("Sounds/PowerUp");
```

Modify the `Reset` method to set the `powerUpTime` property to 0.

C#

```
powerUpTime = 0.0f;
```

In the `Update` method, you'll need to check to see if the player character is powered up and, if so, update the time remaining. Add the following code after the `ApplyPhysics` call:

C#

```
    if (IsPoweredUp)
        powerUpTime = Math.Max(0.0f, powerUpTime - (float)gameTime.ElapsedGameTime.TotalSeconds);
```

We'll use the `Draw` method to indicate that the player is temporarily invincible. A strobing tint is applied while the player is invincible. Add the following code after the code that flips the player character sprite:

C#

```
    // Calculate a tint color based on power up state.
    Color color;
    if (IsPoweredUp)
    {
        float t = ((float)gameTime.TotalGameTime.TotalSeconds + powerUpTime / MaxPowerUpTime)
* 20.0f;
        int colorIndex = (int)t % poweredUpColors.Length;
        color = poweredUpColors[colorIndex];
    }
    else
    {
        color = Color.White;
    }
```

If the player is invincible, a color is selected from the array you added earlier and used to tint the character sprite when it is later drawn. The final modification to this function is to add the tint color to the call to `AnimationPlayer.Draw`. Modify the call to match the following:

C#

```
sprite.Draw(gameTime, spriteBatch, Position, flip, color);
```

The final bit of code is the new `PowerUp` method. Add this new code after the `Draw` method:

C#

```
public void PowerUp()
{
    powerUpTime = MaxPowerUpTime;
    powerUpSound.Play();
}
```

This is a simple bit of code that sets the powerup time to a predefined value, which is 3 seconds in this case.

You're done with `Player.cs`. It's now time to modify his fiendish enemies.

Modifying the Enemy Class

Modification of the `Enemy` class begins by adding and loading the death animation. You'll need to add the `Die` animation (`Die.png`) to both the `HighResolutionContent` and `LowResolutionContent` content projects for each monster type.

1. From **Solution Explorer**, expand the **HighResolutionContent** icon, and navigate down to the `\Sprites\MonsterA` directory.
2. Right-click the **MonsterA** icon, and use the **Add Existing Item** dialog box to add the `Die.png` game asset.
3. Do the same for the `MonsterA` directory located in the **LowResolutionContent** content project.
4. Repeat Steps 1-3 for each remaining monster type.

Add a declaration for a new `Enemy` property of type `Animation` to the existing animation list, called `dieAnimation`.

C#

```
private Animation dieAnimation;
```

You'll want a sound effect to play when an enemy dies, so go ahead and add the existing `MonsterKilled.wma` game asset to the `Sounds` directory of the **SharedContent** content project using the **Add Existing Item** dialog box. Now you need a new variable for storing that sound effect. Add the following code after the animation variables:

C#

```
// Sounds  
private SoundEffect killedSound;
```

Add another property after the existing `BoundingBox` variable:

C#

```
public bool IsAlive { get; private set; }
```

Now that an enemy can be killed by the player character, you need to track whether enemies are alive or dead. In the `Enemy` constructor (right below the last modification), initialize `IsAlive` to **true**.

C#

```
this.IsAlive = true;
```

In the `LoadContent` method, load the death animation:

C#

```
dieAnimation = new Animation(Level.Content.Load<Texture2D>(spriteSet + "Die"), 0.07f, false);
```

And then the sound effect:

C#

```
// Load sounds.  
killedSound = Level.Content.Load<SoundEffect>("Sounds/MonsterKilled");
```

Since this is the first sound effect for enemies, you'll need to add a reference to `Microsoft.Xna.Framework.Audio` to this file. Add the following code after any existing **using** code:

C#

```
using Microsoft.Xna.Framework.Audio;
```

Now that enemies can be dead, optimize the update code a bit, and only update living enemies. In the `Update` method, add the following code after calculating the elapsed time:

C#

```
if (!IsAlive)
```

```
return;
```

Let's modify the `Draw` method to play the proper animation, depending on the state of the enemy. Replace the following code:

C#

```
if (!Level.Player.IsAlive ||
    Level.ReachedExit ||
    Level.TimeRemaining == TimeSpan.Zero ||
    waitTime > 0)
{
    sprite.PlayAnimation(idleAnimation);
}
else
{
    sprite.PlayAnimation(runAnimation);
}
```

with this code:

C#

```
if (!IsAlive)
{
    sprite.PlayAnimation(dieAnimation);
}
else if (!Level.Player.IsAlive ||
    Level.ReachedExit ||
    Level.TimeRemaining == TimeSpan.Zero ||
    waitTime > 0)
{
    sprite.PlayAnimation(idleAnimation);
}
else
{
    sprite.PlayAnimation(runAnimation);
}
```

Finally, add the `OnKilled` method:

C#

```
public void OnKilled(Player killedBy)
{
    IsAlive = false;
    killedSound.Play();
}
```

That completes the modification of `Enemy.cs`.

All right, we are coming up on the home stretch now. There is one final file to modify before you can compile and check out the power-up gem in action.

Modifying the Level Class

The modifications for the `Level` class are pretty extensive. You'll need to add support for a new gem type, and also support for killing an enemy if the invincible character collides with it.

First, let's add support for the new gem type. In the `Tile LoadTile(char tileType, int x, int y)` method, modify the code for the 'G' case to match the following:

C#

```
// Gem
case 'G':
    return LoadGemTile(x, y, false);

// Power-up gem
case 'P':
    return LoadGemTile(x, y, true);
```

This updates the code for a normal gem, passing **false**, and adds the ability to read in power-up gems. Now, you'll need to update the `LoadGemTile` method to accept a new parameter. Modify `LoadGemTile` to accept an additional parameter (of type **bool**) called `isPowerUp`. Make sure that the new parameter is last in the method declaration. It should match the following declaration:

C#

```
private Tile LoadGemTile(int x, int y, bool isPowerUp)
```

In this same function, modify the call to `gem.Add` to match the following:

C#

```
gems.Add(new Gem(this, new Vector2(position.X, position.Y), isPowerUp));
```

This modification now calls the recently modified `Gem` constructor.

If you remember, you earlier changed the implementation of the point value for a gem. Now is a good time to update the `OnGemCollected` method to use the new `PointValue` field. In this method, modify the `score` assignment to match the following:

C#

```
score += gem.PointValue;
```

Now that you can recognize and load the power-up gem, let's add support for its effect when the player character collects it.

Modify the `UpdateEnemies` method to first check that the current enemy is alive and, if so, upon collision check for a powered up player. If the player is powered up, you need to "kill" the enemy.

Change this code:

C#

```
if (enemy.BoundingBox.Intersects(Player.BoundingBox))
{
    OnPlayerKilled(enemy);
}
```

to match the following:

C#

```
if (enemy.IsAlive && enemy.BoundingBox.Intersects(Player.BoundingBox))
{
    if (Player.IsPoweredUp)
    {
        OnEnemyKilled(enemy, Player);
    }
}
```

```
    }  
    else  
    {  
        OnPlayerKilled(enemy);  
    }  
}
```

Next, add the implementation of the `OnEnemyKilled` method, after the `UpdateEnemies` method:

C#

```
private void OnEnemyKilled(Enemy enemy, Player killedBy)  
{  
    enemy.OnKilled(killedBy);  
}
```

This follows the practice of Platformer. It implements an `OnX` method to announce an important event has occurred.

Testing the Power-Up Extension

Before you can see the power-up gem in action, you'll need to add one to the second level structure file. Open this file now (1.txt) and replace any G with a P. Recompile and check out the Invincibility power-up!

Figure 1. Gameplay Screen for the Platformer Starter Kit

Exploring the Advanced Classes

The following classes are more complex than the basic and intermediate classes, and they implement the critical features of Platformer such as the game level, the player character, and the Platformer game structure.

PlatformerGame Class

The `PlatformerGame` class implementation is located in `PlatformerGame.cs`. Important methods include:

LoadContent

Loads the game fonts and the next level of Platformer by calling `LoadNextLevel`, which is another very important method.

For more information on level loading, see [Exploring Platformer's Physics](#).

Update

Handles basic game input (for both keyboard and gamepad) and calls `Level.Update`, ... you guessed it, another very important method. For more information on level updating, see the `Level` class description.

Draw

Draws the major components of Platformer: the gameplay screen and the HUD. The gameplay screen is drawn by calling `Level.Draw`, which in turn draws some things and calls the `Draw` method of any level object smart enough to draw itself (for example, the player character).

The structure of the game is easy to follow because the majority of Platformer objects are responsible for loading, updating, and drawing themselves. The `PlatformerGame` class is like a conductor; it tells each object what to do and when. As discussed in the [overview](#), the program flow can be broken up into three common steps: initializing (loading of the level, etc.), updating, and drawing. Each of these stages is discussed in detail in the appropriate class sections.

The `LoadNextLevel` method is an important step in the process of loading a level. This method locates and reads a physical file describing the current level. Level files are numbered sequentially, starting with 0, and stored in the `..\Content\Levels` directory (in the appropriate platform/build directory). For instance, the Level 0 file for the debug Windows version of Platformer is located in the `..\Platformer\Platformer\bin\x86\Debug\Content\Levels\0` directory.

⚠ Caution

Platformer ships with some ready-to-use levels. If you add new levels, ensure that the **Copy to Output Directory** property, for the related game asset, is set to **true**. In addition, follow the naming convention and directory structure for new levels. For instance, a new level would be in the 2 directory, underneath Levels, in the appropriate game content directory. For more information on the level structure file, see [Loading the Tiles](#).

`PlatformerGame` tracks the current level using the `levelIndex` variable. When `LoadNextLevel` is called, `levelIndex` is pre-incremented and an absolute path is built to the file. Once the directory is found, the file is passed to the `Level` constructor and the level is created and populated. If the level needs to be reloaded (due to running out of time), `ReloadCurrentLevel` is called.

Level Class

The `Level` class implementation is located in `Level.cs`. Important methods include:

Draw

Draws the current state of the level and its contained elements. Level tiles are drawn by calling `DrawTiles`. The player character, gems, and enemies are drawn by calling their respective `Draw` methods.

Each level has three layers of background. These backgrounds are loaded in the `Level` constructor. They are drawn in order, from back to front. After all layers have been drawn, the level tiles, player character, gems, and enemies are drawn. The base implementation of Platformer uses only the leftmost segment of the background texture assets.

Tip

For a tutorial on adding parallax scrolling to Platformer, see [Platformer: Adding a Scrolling Background](#).

Update

Updates the level state, including all objects contained by the level. In addition, collision checking between objects (such as the player character and platform tiles) and the time limit for the level (includes remaining time animation) are also handled here.

While the game is paused (either through a player death or reaching the exit), all input is ignored and the Idle animation for the enemies is played.

LoadTiles

Called during level construction, this method loads the level layout using a structure file previously located by `PlatformerGame.LoadNextLevel`. For more information on this level structure file, see [Loading the Tiles](#).

OnExitReached, OnPlayerKilled, and OnGemCollected

Called from `Update` when important events occur in a level. These events include the player character reaching the exit, dying, or collecting a gem. Modify these to change the default behavior of these events.

Player Class

The `Player` class implementation is located in `Player.cs`. Important methods include:

ApplyPhysics

Called during `Player.Update`, it updates the player's velocity and position based on input, gravity, and drag factors. Once position is determined, the player character is checked for collision with surrounding tiles. This is the most math-intensive method of the class, and it depends heavily on the game world physics model.

Draw

Orients player correctly, and then calls `AnimationPlayer.Draw` to draw the current frame of the character. As mentioned elsewhere, animation frames are intentionally square. This simplifies the animation code, making it easier to understand.

Update

Gets input from either the keyboard or a game controller, and updates the `movement` and `isJumping` fields. The player's position and velocity are then updated by calling `ApplyPhysics`.

LoadContent

Loads the various sprite sheets and sounds used by the player character.

HandleCollisions

Implements collision detection between the player character and neighboring tiles.

Important properties include:

BoundingBox

Used for checking collisions between the player character and neighboring tiles and objects, like a gem or exit location. The `RectangleExtensions` class is an important part of the collision checking code. For more information, see [RectangleExtensions](#) class.

Tip

Consider using per-pixel collision detection to improve the interaction between the player character and the level elements. This is an advanced extension, but it is worth the effort. For more information, download the 2D Per-Pixel Collision sample found on the [XNA Creators Club Web site](#). It's part of Collision Series 2.

Velocity

The velocity of the player character. This is affected by the game world physics, and it represents acceleration from running, jumping, or falling. For more information, see [Platformer Physics](#).

RectangleExtensions Class

This class is an extension to the XNA Framework [Rectangle](#) structure. `RectangleExtensions` implements two methods – `GetIntersectionDepth` and `GetBottomCenter`. These methods support the conceptualization of a rectangle as a "squared circle" with two radii.

Here is what I mean. It is given that a circle has one radius; the length from the center to its perimeter. This makes intersection checking with another circle easy. If the distance between the centers is shorter than the sum of the radii, the circles intersect.

Now apply this concept to a rectangle. Imagine that a rectangle has two radii: one from the center to the height of the rectangle (the "height" radius) and another from the center to the width of the rectangle (the "width" radius). Once you know the centers of the rectangles, you can use a similar approach to check for rectangle intersection as you did earlier with the two circles. If the X-value of the distance between the centers is greater than the sum of the width radii and the Y-value of the distance between the centers is greater than the sum of the height radii, the rectangles do not intersect.

Loading the Level

When starting a new game, the procedure for loading a level (from a program execution viewpoint) is as follows:

1. `PlatformerGame.LoadContent`
2. `PlatformerGame.LoadNextLevel`
3. `Level.Level`
4. `Level.LoadTiles`

A level can also be loaded in the following cases:

- When the player character reaches the exit of the current level. The next level is then loaded from `PlatformerGame.HandleInput` when the player continues the game.
- When reloading the level. This is called if time runs out. These events cause a restart of the level.

Before `PlatformerGame` can load the level, it must first find a physical file that contains the level structure. The `LoadNextLevel` method looks in the `..\Content\Levels` directory (underneath the appropriate platform/build directory) for these level structure files. Once found, a new level is constructed with a call to `Level.Level`.

In the level constructor, the level time is initialized, the tiles are loaded (using the level structure file) and then the background textures and "exit reached" sound are loaded. The `LoadTiles` method is the important part here.

Loading the Tiles

This is the workhorse of the level loading process. This method first reads in the character-based level file and verifies that all lines are the proper length. It then iterates over each line, reading the level structure from top to bottom until complete. A 2D array (composed of `Tile` objects) is then allocated to store each tile in the level.

At this point, the text-based lines, read from the level structure file, can be converted into actual tile layers for the current level. The `LoadTile` method reads a character from the current line and, based on a dictionary of characters, loads the appropriate type and game assets for the tile. The dictionary for the level structure file is as follows:

Text Character	Description
'.'	Blank tile. This tile is <code>TileCollision.Passable</code> , and has no related texture.
'X'	Exit tile. This tile is <code>TileCollision.Passable</code> , and uses the <code>Exit.png</code> texture. The location is stored, and then the tile assets are loaded with a call to <code>Level.LoadTile</code> .
'G'	Gem tile. This tile is <code>TileCollision.Passable</code> , uses the <code>Gem.png</code> texture, and loads the tile by calling <code>LoadGemTile</code> . The base implementation of <code>Platformer</code> adds a gem to the list of gems maintained by the level, and places the gem in an blank tile.

'-'	Floating platform. This tile is <code>TileCollision.Platform</code> , and uses the <code>Platform.png</code> texture.
'A', 'B', 'C', and 'D'	Starting tile for the various Platformer enemies. This tile is <code>TileCollision.Passable</code> , and contains one of the four enemies used by Platformer. They differ only in appearance; an obvious place for extending the base implementation of Platformer! The base implementation of Platformer instantiates an <code>Enemy</code> object (adding the enemy to the level's <code>enemies</code> list), and places it in the level.
'~'	Platform block. This tile is <code>TileCollision.Platform</code> , and uses a randomly-chosen texture from the set of textures whose name begins with "BlockB." This tile is loaded by calling <code>LoadVarietyTile</code> , which is a method that randomly loads a tile texture from a subset of tile textures.
':'	Passable block. This tile is <code>TileCollision.Passable</code> , and uses a randomly-chosen texture from the set of textures whose name begins with "BlockB."
'1'	Starting position for Player 1. This tile is <code>TileCollision.Passable</code> , and contains the player character. The base implementation of Platformer instantiates a <code>Player</code> object, and places him, facing the player, in the level. The location in the level is stored and used, in the event of player death, as a resurrection point.
'#'	Impassable block. This tile is <code>TileCollision.Impassable</code> , and uses a randomly-chosen texture from the set of textures whose name begins with "BlockA."

Exploring Platformer's Physics

Platformer implements a basic game physics model. It is used to perform the various actions of the player character: jumping, running, and falling. The main implementation is provided by `ApplyPhysics` and `GetJumpVelocity`. Both are implemented in the `Player.cs` source file.

ApplyPhysics

This method contains the bulk of the physics modeling, and is only called from `Level.Update`. It is responsible for computing the base velocity of the player character using horizontal movement and downward acceleration (gravity). In addition, pseudo drag is applied, gradually slowing the character down if he is running along a flat surface without input from the player. The player character also has a top running speed. Once the base velocity is computed, `GetJumpVelocity` is called.

GetJumpVelocity

This method is called from `ApplyPhysics` and computes the Y velocity (either jumping up or falling down) of the player character.

During jump ascension, the Y velocity is overridden by a power curve, as seen below.

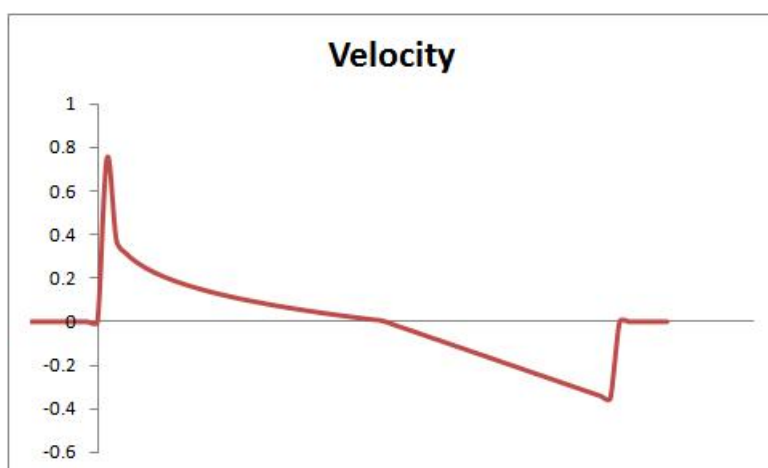

Figure 2. Velocity Curve (over Time)

During descent, gravity controls the Y velocity and clamps at a terminal velocity. The acceleration curve is graphed below.

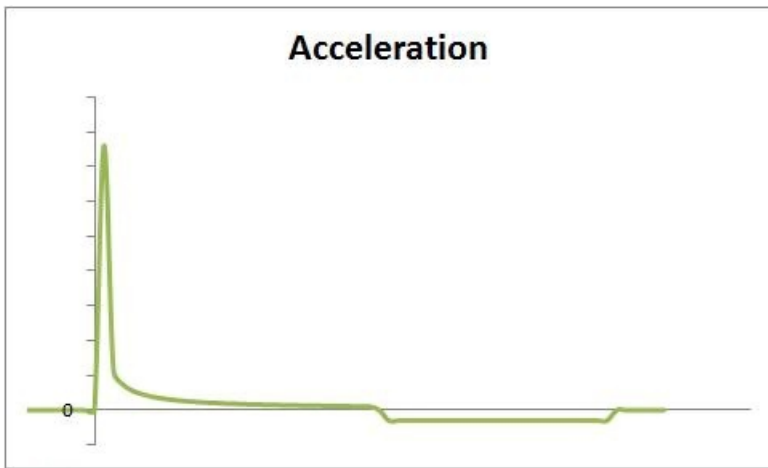

Figure 3. Acceleration Curve (over Time)

Expanding Platformer

A common feature of Platformer-type games is a scrolling level. In [Platformer: Adding a Scrolling Level](#), you'll add a scrolling level with multiple scrolling backgrounds to the default version of the Platformer starter kit.

Platformer: Adding a Scrolling Level

Extends the base Platformer starter kit code by adding a scrolling level. Specifically, it provides parallax scrolling.

One of the more impressive features of platformer games in the 80s was the scrolling level. This topic details the process for adding this feature to the Platformer game. You'll implement multiple scrolling backgrounds, with the back layer scrolling the slowest, and the front layer scrolling the fastest. This is called parallax scrolling. It provides an illusion of depth in the game.

Figure 1. Parallax Scrolling Extension

Tip

It is *highly* recommended that you are already familiar with the structure and features of the Platformer starter kit. This extension involves modifications to several files in the Platformer starter kit. For more information on the Platformer starter kit, see [Starter Kit: Platformer](#).

This extension modifies two areas of the Platformer starter kit, and it adds a new class. It is recommended that you use the base Platformer starter kit solution as the starting point for your modifications.

Adding parallax scrolling involves the following major steps:

- Modifying `PlatformerGame.cs` to call `SpriteBatch.Begin` and `SpriteBatch.End` at a different time.
- Modifying `Level.cs` to use a new object type for the background textures instead of `Texture2D`. In addition, a camera is implemented and used to draw a portion of the background instead of the entire background.
- Adding a new class called `Layer` that replaces the usage of `Texture2D` for background textures.

Modifying the PlatformerGame Class

The only modification for this class involves modifying the `Draw` method. You'll move the `SpriteBatch.Begin` and `SpriteBatch.End` calls to the `DrawHud` method. This allows the `Level.Draw` method to set up its own batch for drawing the scrolling backgrounds.

In `PlatformerGame.Draw`, remove the `spriteBatch.Begin()`; and `spriteBatch.Begin()`; lines of code.

In the `PlatformerGame.DrawHud` method, add the following line before any existing code:

C#

```
spriteBatch.Begin();
```

At the end of the same method, add:

C#

```
spriteBatch.End();
```

The `DrawHud` method now implements a single batch.

That completes the modifications for `PlatformerGame.cs`. The next step adds support for a new class, called `Layer` to the `Level` class.

Modifying the Level Class

The main point of these modifications is to support the usage of a new kind of texture class (`Layer`) that enables parallax scrolling. Each of the three background textures will use the new class; therefore, the surrounding code also needs to accommodate the new class.

First, change the type used by the `layers` array from `Texture2D[]` to `Layer[]`. This is the new background texture class, added later.

C#

```
private Layer[] layers;
```

Now, look for a variable block, commented as "Level game state," and add a new variable called `cameraPosition`.

C#

```
private float cameraPosition;
```

This represents the leftmost world coordinate that can be seen by the player. Typically, a 3D camera sits at some position in world space and has a field of view. In the case of `Platformer`, the camera is represented by the left-most coordinate in the field of view and the field of view is inferred from the width of the viewport.

In the `Level` constructor, you'll need to change the initialization code for the `layers` array. Replace this code:

C#

```
layers = new Texture2D[3];
for (int i = 0; i < layers.Length; ++i)
{
    // Choose a random segment if each background layer for level variety.
    int segmentIndex = random.Next(3);
    layers[i] = Content.Load<Texture2D>("Backgrounds/Layer" + i + "_" + segmentIndex);
}
```

with the following:

C#

```
layers = new Layer[3];
layers[0] = new Layer(Content, "Backgrounds/Layer0", 0.2f);
layers[1] = new Layer(Content, "Backgrounds/Layer1", 0.5f);
layers[2] = new Layer(Content, "Backgrounds/Layer2", 0.8f);
```

The new code initializes the array with three new `Layer` objects. Each of these objects loads a different texture, and has a different scrolling speed (the third parameter of the `Layer` constructor).

Note

`Platformer` assumes that scrolling speed values have a range between 0 and 1. A value of 0 means no scrolling and 1 means scrolling at the same pace as the level tiles.

It's now time to modify the drawing code for the level. Locate the `Level.Draw` method, and replace it with the following method declaration:

C#

```
public void Draw(GameTime gameTime, SpriteBatch spriteBatch)
{
    spriteBatch.Begin();
    for (int i = 0; i <= EntityLayer; ++i)
        layers[i].Draw(spriteBatch, cameraPosition);
    spriteBatch.End();

    ScrollCamera(spriteBatch.GraphicsDevice.Viewport);
    Matrix cameraTransform = Matrix.CreateTranslation(-cameraPosition, 0.0f, 0.0f);
    spriteBatch.Begin(SpriteBlendMode.AlphaBlend, SpriteSortMode.Immediate, SaveStateMode
        .None, cameraTransform);

    DrawTiles(spriteBatch);

    foreach (Gem gem in gems)
        gem.Draw(gameTime, spriteBatch);

    Player.Draw(gameTime, spriteBatch);

    foreach (Enemy enemy in enemies)
        enemy.Draw(gameTime, spriteBatch);

    spriteBatch.End();

    spriteBatch.Begin();
    for (int i = EntityLayer + 1; i < layers.Length; ++i)
        layers[i].Draw(spriteBatch, cameraPosition);
    spriteBatch.End();
}
```

Now, let's go over what just changed. Initially, the first sprite batch draws all three background layers. Then, instead of moving a camera throughout the world, you'll move the world backwards such that the camera is always at the origin. This greatly simplifies the drawing logic because you can now call a specialized `SpriteBatch.Begin` overload that uses a transform matrix (calculated earlier in the method).

You'll recognize the next chunk of code because it is unchanged from the original implementation. It draws the level elements: tiles, gems, enemies, and the player character. The last batch does nothing in the base implementation of `Platformer`. It is left in for drawing foreground textures. For example, if a foreground texture (such as trees or bushes) was drawn, it would obscure the player character when he "walked" behind the texture.

Because the scrolling extension draws tiles off-screen, you should be aware that this could impact the frame rate. To avoid any slowdown you'll need to implement a simple culling feature that limits the amount of tiles drawn to only those on the screen at the time. This reduces the drawing load, speeding up the game. At the beginning of the `DrawTiles` method, add the following code:

C#

```
// Calculate the visible range of tiles.
int left = (int)Math.Floor(cameraPosition / Tile.Width);
int right = left + spriteBatch.GraphicsDevice.Viewport.Width / Tile.Width;
right = Math.Min(right, Width - 1);
```

Below this modification, modify the first line of the inner loop (the one that loops from 0 to `Width`) to match the following:

C#

```
for (int x = left; x <= right; ++x)
```

Now, only visible tiles are drawn but note that other items, such as gems and enemies, are still drawn even when off screen. The culling of non-tiles is another excellent place for extending Platformer!

The last modification in this file adds the new `ScrollCamera` method. This method calculates how much background is scrolled when the player reaches the screen's edge. When the begin scrolling is platform-dependent. Because the Zune screen is the narrowest of the three, it looks the farthest ahead. The other two don't look ahead as much. This factor is used to calculate the edges of the screen and how far to scroll when the player reaches that edge. Scrolling continues until either end of the level is reached. At that point, the camera position is clamped.

Add the following code, after the `Draw` method:

```
C#  
  
    private void ScrollCamera(Viewport viewport)  
    {  
#if ZUNE  
const float ViewMargin = 0.45f;  
#else  
const float ViewMargin = 0.35f;  
#endif  
  
    // Calculate the edges of the screen.  
float marginWidth = viewport.Width * ViewMargin;  
float marginLeft = cameraPosition + marginWidth;  
float marginRight = cameraPosition + viewport.Width - marginWidth;  
  
    // Calculate how far to scroll when the player is near the edges of the screen.  
float cameraMovement = 0.0f;  
if (Player.Position.X < marginLeft)  
    cameraMovement = Player.Position.X - marginLeft;  
else if (Player.Position.X > marginRight)  
    cameraMovement = Player.Position.X - marginRight;  
  
    // Update the camera position, but prevent scrolling off the ends of the level.  
float maxCameraPosition = Tile.Width * Width - viewport.Width;  
cameraPosition = MathHelper.Clamp(cameraPosition + cameraMovement, 0.0f, maxCameraPos  
ition);  
    }  
}
```

The final step adds the new `Layer` class.

Implementing the Layer Class

Because the backgrounds will be scrolling during gameplay, you'll need something more specialized than a `Texture2D` class to draw these textures. The background textures provided are divided into three segments that tile seamlessly into one scrolling background.

Using the **Add Class** dialog, add a new C# class, called `Layer`, to the PlatformerWindows solution. At the top of the file, add some useful XNA Framework references:

```
C#  
  
using Microsoft.Xna.Framework;  
using Microsoft.Xna.Framework.Graphics;  
using Microsoft.Xna.Framework.Content;
```

In this new class, add the following properties:

```
C#  
  
public Texture2D[] Textures { get; private set; }
```

```
public float ScrollRate { get; private set; }
```

These properties store the background texture of the layer and its scroll speed.

Now add the constructor:

C#

```
public Layer(ContentManager content, string basePath, float scrollRate)
{
    // Assumes each layer only has 3 segments.
    Textures = new Texture2D[3];
    for (int i = 0; i < 3; ++i)
        Textures[i] = content.Load<Texture2D>(basePath + "_" + i);

    ScrollRate = scrollRate;
}
```

This constructor accepts a content manager, a base path to the background asset, and the scroll speed of the background layer. Note that each layer has only three segments.

It loads each segment of the background in the `Textures` array, and then sets the scroll speed.

The final method to add is the `Draw` method. Add this code after the constructor method:

C#

```
public void Draw(SpriteBatch spriteBatch, float cameraPosition)
{
    // Assume each segment is the same width.
    int segmentWidth = Textures[0].Width;

    // Calculate which segments to draw and how much to offset them.
    float x = cameraPosition * ScrollRate;
    int leftSegment = (int)Math.Floor(x / segmentWidth);
    int rightSegment = leftSegment + 1;
    x = (x / segmentWidth - leftSegment) * -segmentWidth;

    spriteBatch.Draw(Textures[leftSegment % Textures.Length], new Vector2(x, 0.0f), Color.White);
    spriteBatch.Draw(Textures[rightSegment % Textures.Length], new Vector2(x + segmentWidth, 0.0f), Color.White);
}
```

This method first calculates which of the background segments to draw, and then draws them offset by the previously calculated amount. It is assumed that two segments are enough to cover any screen.

Modifying the Level Structure File

At this point, the parallax scrolling extension is completely coded. However, if you recompile and run the game, you will see no difference. Like the Power-Up Gem [extension](#), you'll need to modify an existing map to enable the scrolling. However, it won't be as easy as modifying an extra character or two. You would need to come up with a lot of new content, past the default edge of the level, to fully illustrate the scrolling. However, since the format of the level structure file is text-based, you can just use the following text block as a demonstration case.

C#

```
.....
.....
.....G.....X...
.....###.....#####
.....G.....
```

```

.....###.....G.GDG.....G.G.G.....
.....G.....#####.....#####.....
.....###.....
.....G.....G.G.....G.G.....
.....###.....#####.....#####.....
.....G.....
.....###.....GDG.G.....G.G.G.G.G.G.G.G.G.
.....#####.....##.G.G.G.G.G.G.G.G..
.1.....GCG.G.G.GCG.G.G.GCG.
#####.....#####

```

Copy this text and then open the 0.txt file (located in the HighResolutionContent content project). Select all text in the level structure file, and then paste the new text in. Save the file and do the same for the equivalent low-resolution level structure file. Once you have made changes to both maps, recompile and run the game. You can now run far to the right in the first level, and the three background layers scroll at different speeds. Pretty cool effect, eh?!

Platformer: Adding Touch Support

Extends the base Platformer starter kit code by adding touch screen and accelerometer support for input.

This extension modifies five areas of the Platformer starter kit. The following steps assume that you have generated a new Platformer starter kit project and it is loaded into XNA Game Studio.

Tip

To prevent build warnings and errors, it is recommended that you remove both the Windows and Xbox 360 versions of the project from the newly-generated Platformer solution. It is also recommended that you set the solution platform to Zune.

With these changes in place, you can now build and debug the starter kit without misleading errors and warnings.

Adding touch screen and accelerometer support involves the following major steps:

- Modifying PlatformerGame.cs to center the gameplay screen and accept touch screen input.
- Modifying Level.cs to support input from the accelerometer and touch panel.
- Modifying Player.cs to control the player character using input from the accelerometer and touch screen.
- Modifying Enemy.cs to offset the enemy location. This accounts for the overall offsetting of the gameplay screen required by the higher resolution of a Zune HD device.
- Modifying Gem.cs to offset the gem location. This accounts for the overall offsetting of the gameplay screen required by the higher resolution of a Zune HD device.

For more information on touch screen and accelerometer support, see [Zune HD Input Overview](#).

Modifying PlatformerGame.cs

The original Platformer starter kit was designed for Zune devices with a resolution of 240 x 320. However, the Zune HD device supports a higher resolution: 272 x 480. If you were to install an unmodified version of Platformer on the new Zune, two things would be obvious immediately:

- The gameplay screen does not fill the entire screen. The right edge of the level is not flush with the screen edge, and a large portion of the default cornflower blue screen is visible on the bottom.
- There is no way to control the player character. Unlike the earlier Zune device, the Zune pad is gone and there is no dedicated Back button.

The first set of modifications you'll make addresses the higher resolution issue. First, the preferred back buffer dimensions will be increased, and then an offset will be used to shift the gameplay screen over and down. This offset centers gameplay much like letterboxing centers a 4:3 image on a widescreen television. After the modification, you will see thin black bars (on the sides) and thick black bars (on the top and bottom).

Open the PlatformerGame.cs file and, near the top of the file, modify the width and height of the back buffer to match the following:

C#

```
private const int BackBufferWidth = 272;
private const int BackBufferHeight = 480;
```

The next modification changes the default cornflower blue screen color to black. This supports the illusion of letter boxing. In the Draw method, modify the [Clear](#) method call to match the following:

C#

```
graphics.GraphicsDevice.Clear(Color.Black);
```

The final modification uses a 2D vector to offset the text drawn on the gameplay screen. In the same file, locate the `DrawHud` method and declare a new [Vector2](#) object with a horizontal and vertical offset at the top of the method:

C#

```
Vector2 screenOffset = new Vector2(16, 80);
```

This vector is added to the current position of any shadowed text, causing the text to be drawn farther to the right (half the difference between the old and new screen width) and farther down (half the difference between the old and new screen height). Let's modify those placements now. In the same method, find the two calls to `DrawShadowedString`. Modify the third parameter (`hudLocation`) by adding the new offset vector to the current value. The code below is the result of modifying the second call:

C#

```
DrawShadowedString(hudFont, "SCORE: " + level.Score.ToString(),
    hudLocation + screenOffset
    + new Vector2(0.0f, timeHeight * 1.2f), Color.Yellow);
```

That completes the modifications needed to center the gameplay screen on the Zune device. The next modifications focus on adding touch screen support for responding to game status messages.

First, let's add support for the state of the device's touch screen and accelerometer. After adding the back buffer constants, insert the following code:

C#

```
AccelerometerState accelState;
TouchCollection touchState;
```

These states are used mainly by the `PlatformerGame` and `Player` objects. Due to the nature of the touch screen and accelerometer states, you should only retrieve these device states once per frame. Then you pass the current state value (either `accelState` or `touchState`) to other objects that need input from those devices. It is not recommended that you call either of the `GetState` methods more than once per frame as different values will result.

In the same file, locate the `Update` method, and modify the call to `Level.Update` to pass the states of the accelerometer and touch screen to the `Level` object:

C#

```
level.Update(gameTime, accelState, touchState);
```

Now that the device states have been passed on, you'll add new code to the `HandleInput` method that responds to user touches on the screen when a status overlay message is displayed (game win or loss). The first step is to retrieve the states of the touch screen and accelerometer with calls to the `GetState` method. Add the following code after the existing `GetState` calls:

C#

```
accelState = Accelerometer.GetState();
touchState = TouchPanel.GetState();
bool buttonTouched = false;
```

The next modification looks at the collection of touch locations and checks each location for a `TouchLocation.Pressed` state. If one is found, the `buttonTouched` variable is updated to `true`. The code used for this check is fairly common when querying the state of the current touch locations. For demonstration purposes, the three major states are checked, but the code only reacts to screen presses. For more information on using states, see [Zune HD Input Overview](#). Add the following code after the check for the exit condition:

C#

```
//interpret touch screen presses
foreach (TouchLocation location in touchState)
{
    switch (location.State)
    {
        case TouchLocationState.Pressed:
            buttonTouched = true;
            break;
        case TouchLocationState.Moved:
            break;
        case TouchLocationState.Released:
            break;
    }
}
```

Now that the `buttonTouched` variable holds the correct value, modify the `continuePressed` assignment to also use this value:

C#

```
bool continuePressed =
    keyboardState.IsKeyDown(Keys.Space) ||
    gamepadState.IsButtonDown(ContinueButton) || buttonTouched;
```

At this point, some of the gameplay screen elements are offset properly, and the game responds to touches when a status overlay message is displayed. It's now time to move on to the modification of the `Level.cs` file.

Modifying Level.cs

Modifications in this file consist mainly of applying position offsets to some elements. In addition, you'll update the `Level.Update` definition and pass those state values onto the `Player` object. That's the object that will mainly use these values.

First, add the `Microsoft.Xna.Framework.Input` namespace to the list of namespaces at the top of the file. This provides quick access to the new input-related types:

C#

```
using Microsoft.Xna.Framework.Input;
```

Locate the `Level.Update` method definition and modify it to match the following:

C#

```
public void Update(GameTime gameTime, AccelerometerState accelState, TouchCollection touchState)
```

Further down in that method, find the call to `Player.Update` and modify it to match the following:

C#

```
Player.Update(gameTime, accelState, touchState);
```

That completes the state-related modifications. The remaining changes offset more screen elements to further improve the letterbox appearance of the gameplay screen.

Locate the `Draw` method and add a screen offset vector declaration to the beginning of the function:

C#

```
Vector2 screenOffset = new Vector2(0, 80);
```

You can now use this offset to move the backgrounds to the center of the screen. Modify both `SpriteBatch.Draw` calls by adding the `screenOffset` vector value to the second parameter:

C#

```
spriteBatch.Draw(layers[i], Vector2.Zero + screenOffset,
    Color.White);
```

The next set of modifications are to the `DrawTiles` method, located after the `Draw` method. There is a slight difference between the screen offset vector used earlier. The vector used in the `DrawTiles` method also shifts the tiles to the right, centering them in the screen. This is necessary because the maps are slightly thinner than the width of the display.

Tip

The background textures, used by the Zune version of Platformer, have always been wider than the actual screen of the Zune device. Therefore, only the first portion of each background texture was seen even though the entire texture was loaded by the application. To achieve a solid edge to the gameplay screen (both tiles and background centered on the screen) you could modify the background layers of the `LowResolutionContent` project by specifying a width of 320 for each background layer. This is the original width, which matches the layout of the level tiles. However, if you do this, you will also have to change the value of the `screenOffset` vector used in the `Level.Update` method as follows: `new Vector2(16, 80);`.

Add a screen offset vector declaration to the beginning of the function:

C#

```
Vector2 screenOffset = new Vector2(16, 80);
```

Modify the existing `SpriteBatch.Draw` call by adding the `screenOffset` vector value to the second parameter:

C#

```
spriteBatch.Draw(texture, position + screenOffset,  
                Color.White);
```

At this point, the project doesn't compile (due to the `Player.Update` change), but the next step fixes that.

Modifying Player.cs

This is the main modification for the project. In this step, you'll modify the input code of the player character so that it responds to accelerometer and touch screen inputs. There are many ways to modify the original control schema. This extension takes the simple approach and uses a combination of both accelerometer and touch screen inputs. The player character is controlled by tilting the device. Tilt it to the left and the player character runs to the left edge of the screen; tilt it to the right and he runs to the right edge. Due to the sensitivity of the accelerometer there is a built-in dead zone that makes it easier to prevent the player character from constantly running back and forth. This can be modified to suit your individual preference. You could even expose this to the player as a customization feature. Finally, tapping the screen causes him to jump. The jump is determined by his velocity and current direction.

Open the `Player.cs` file and locate the `Update` method. You'll need to modify the declaration to match the call made in the `Level.cs` file. It should match the following:

C#

```
public void Update(GameTime gameTime, AccelerometerState accelState,  
                  TouchCollection touchState)
```

In the same method, modify the first line of code to match the following:

C#

```
GetInput(accelState, touchState);
```

This passes the current states of the accelerometer and touch screen so that the player character position and jumping state are properly updated. The next modification updates the `GetInput` method signature to match this new call, and it adds new code that controls the player character through touch and the tilt of the device.

Modify the first line of the `GetInput` method to match the following:

C#

```
private void GetInput(AccelerometerState accelState,  
                     TouchCollection touchState)
```

In the method body, find the location of the following comment: `// Check if the player wants to jump..` Just before this comment, insert the following code:

C#

```
if (Math.Abs(accelState.Acceleration.X) > 0.10f)  
{  
    if (accelState.Acceleration.X > 0.0f)  
        movement = 1.0f;  
    else  
        movement = -1.0f;  
}  
  
//override digital if touch input is found  
// Process touch locations.  
bool touchJump = false;
```

```

foreach (TouchLocation location in touchState)
{
    switch (location.State)
    {
        case TouchLocationState.Pressed:
            touchJump = true;
            break;
        case TouchLocationState.Moved:
            break;
        case TouchLocationState.Released:
            break;
    }
}

```

This code does two things: checks for accelerometer changes and for presses on the touch screen.

Player movement is controlled by the side-to-side tilt of the device. Tilting the device to the left turns and runs the character in that direction. Tilting to the right turns and moves the character to the right. Due to the sensitivity of the accelerometer it is necessary to code in a "dead zone" for the accelerometer input. The tilt value, along the x-axis, must be greater than 0.1 for the character to begin running. This allows small movement of the device along the x-axis without moving the character. If the acceleration value exceeds the threshold, the `movement` variable is updated with the proper value (positive for left movement, negative for right).

After the movement is determined, the touch screen is checked for any presses that occurred during the current frame. If any are found, the `touchJump` variable is set to **true**.

The final modification to this method is to add the `touchJump` value to the calculation of the `isJumping` variable. Modify the existing assignment to match the following:

C#

```

// Check if the player wants to jump.
isJumping =
    gamePadState.IsButtonDown(JumpButton) ||
    keyboardState.IsKeyDown(Keys.Space) ||
    keyboardState.IsKeyDown(Keys.Up) ||
    keyboardState.IsKeyDown(Keys.W) ||
    touchJump;

```

There is one more area to modify before you're done with this file: rendering of the player character. You can do this by modifying the existing `Player.Draw` method.

As with earlier modifications to the placement of game play elements, the player character also is offset using vector addition. The modifications are similar to those done in the past. Locate the `Draw` method, and add the following code to the beginning of the method:

C#

```

Vector2 screenOffset = new Vector2(16, 80);

```

Modify the existing `sprite.Draw` call to match the following:

C#

```

sprite.Draw(gameTime, spriteBatch, Position + screenOffset, flip);

```

This completes the `Player.cs` modifications. The remaining modifications finish the letterbox effect of the gameplay screen by shifting the enemies and gems in the current level.

Modifying Enemy.cs

In this file, the only code you need to modify is the `Enemy.Draw` method. Open the `Enemy.cs` file, and locate the `Draw` method. At the beginning of the method, add the following code:

C#

```

Vector2 screenOffset = new Vector2(16, 80);

```

Modify the last line of code in the method (the `Draw` method call) to match the following:

C#

```
sprite.Draw(gameTime, spriteBatch, Position + screenOffset, flip);
```

After modification, the enemy sprites are properly shifted on the gameplay screen to match the other game elements.

Modifying Gem.cs

As with the `Enemy.cs` file, the only modification being made is to the `Gem.Draw` method. Open the `Gem.cs` file and locate the `Draw` method. At the beginning of the method, add the following code:

C#

```
Vector2 screenOffset = new Vector2(16, 80);
```

Modify the `Draw` method call to match the following:

C#

```
spriteBatch.Draw(texture, Position + screenOffset, null, Color,
    0.0f, origin, 1.0f, SpriteEffects.None, 0.0f);
```

After modification, the gem sprites are properly shifted on the gameplay screen to match the other game elements.

Using XNA Game Studio

Describes how to use XNA Game Studio. XNA Game Studio is seamlessly integrated with supported versions of Microsoft Visual Studio tools, exposing an array of new and updated features for developing 2D and 3D games.

These features include:

- A game component model.
- A framework library for Microsoft Windows, Xbox 360, and Zune game development.
- Integration with the XNA Framework Content Pipeline.

XNA Game Studio brings these features together to provide an easier and quicker path for developing games for Windows, Xbox 360, and Zune.

This section discusses what you will need in order to develop managed game titles using the features of the XNA Framework.

Creating a Windows Game or Library Project

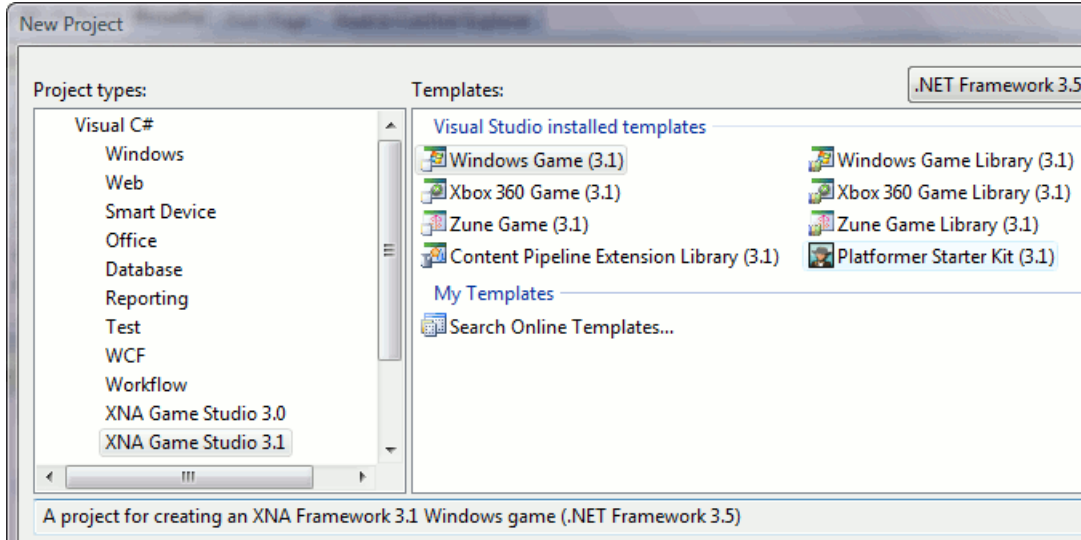

Describes how XNA Game Studio includes a set of project templates that will help you to develop Windows-based projects using the XNA Framework.

Starting a New Project

To start a new project

- To begin a new Windows-based project, click **File**, and then click **New Project**.

You'll be presented with a dialog box that lists a number of project templates.

XNA Game Studio provides template types for XNA Framework game development in the **XNA Game Studio 3.1** section of the **Visual C#** project types. The templates offered for developing XNA Framework games for Windows are:

- Windows Game (3.1)—A project for creating an XNA Framework 3.1 game application for Windows.
- Windows Game Library (3.1)—A project for creating an XNA Framework 3.1 game library for Windows.
- Content Pipeline Extension Library (3.1)—A project for creating an XNA Framework 3.1 Content Pipeline Extension Library.

For information about XNA Game Studio project templates for the Xbox 360 or Zune, see [Creating an Xbox 360 Game or Library Project](#) and [Creating a Zune Game or Library Project](#).

Note

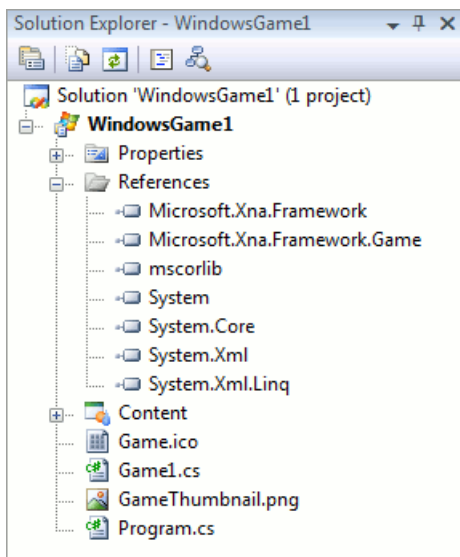

XNA Game Studio 3.1 continues to support creation and use of XNA Game Studio 3.0 projects. If you'd like to create a new XNA Game Studio 3.0 project, click the **XNA Game Studio 3.0** category in the **Project Types** box to gain access to the 3.0 project types. For more information, see [Upgrading XNA Game Studio Projects](#).

Windows Game (3.1)

XNA Game Studio provides a Windows Game (3.1) template that creates and loads a set of starter files. This new project contains basic code that implements a simple, framed window with a colored background.

Results

The new starter project contains the following important features.

Project Properties

These properties control many aspects of your current project. Some examples include general application settings, debug settings, and additional project resources. You can use the Project Designer to modify the values for these properties.

In addition to these properties, assembly information (such as the game title) is stored in the AssemblyInfo.cs file. You can use the [Assembly Information](#) dialog box to modify this information, or you can manually edit the .cs file.

References

References to the following assemblies are added automatically to a new Windows Game project:

- Microsoft.Xna.Framework
- Microsoft.Xna.Framework.Game
- mscorlib
- System
- System.Core
- System.Xml
- System.Xml.Linq

In addition to these standard assemblies, you can add other assemblies as needed for your project.

Content

The nested content project stores and builds content for the game. For more information, see [Game Content Project](#).

Game.ico File

A 32 × 32 default icon, representing your game.

Game1.cs File

This file is a good starting point for adding simple game logic and basic features. It implements a single class (derived from **Game** and called `Game1`), and it overrides five methods: **LoadContent**, **UnloadContent**, **Initialize**, **Draw**, and **Update**. In addition, the `Game1` constructor is defined. Use these methods to initialize your game components, load and render your game content, and handle any input from the user or changes to the game environment.

GameThumbnail.png

The icon appears when this game is packed for distribution as a .ccgame, which is described in [Sharing Your Game Package](#).

Program.cs File

This file also implements a single class (called `Program`) that provides an entry point to game execution. Usually, little code is added to this file unless the game is fairly advanced.

To create a Windows Game (3.1) project

1. On the **File** menu, click **New Project**.
2. Select the **Windows Game (3.1)** project type.
3. Type the name for the game project in the **Name** text box.

You can also modify the default values for the **Location** and **Solution Name** controls.

4. Click **OK** to create and load the new project.

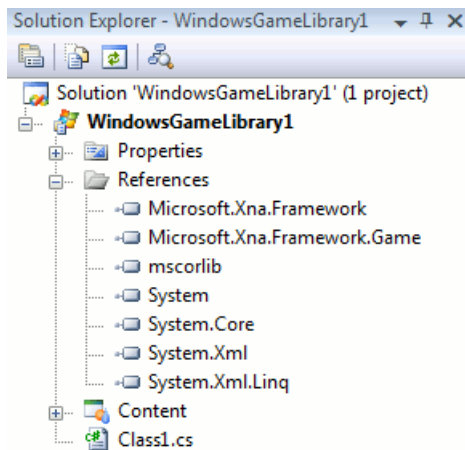

Windows Game Library (3.1)

XNA Game Studio provides a Windows Game Library (3.1) template that creates and loads a set of starter files. Typically, projects of this type contain managed classes that implement basic or advanced features used by a game engine or 3D renderer. Once completed, these class libraries can be referenced by other Windows projects. They provide common functionality without having that code reside within the game project.

The new project contains basic code that implements an empty library, usable by other Windows Game projects or Windows Game libraries.

Results

The new starter project contains the following important features.

Project Properties

These properties control many aspects of your current project. Some examples include general application settings, debug settings, and additional project resources. You can modify the values for these properties using the Project Designer.

In addition to these properties, assembly information (such as the library title) is stored in the AssemblyInfo.cs file. This information can be modified using the [Assembly Information](#) dialog box or by manually editing the .cs file.

References

References to the following assemblies are added automatically to a new Windows Game Library project:

- Microsoft.Xna.Framework
- Microsoft.Xna.Framework.Game
- mscorlib
- System
- System.Core
- System.Xml
- System.Xml.Linq

In addition to these standard assemblies, you can add other assemblies as needed for your project.

Content

The nested Content project stores and builds content that is to be included in the game library. This is useful for including reusable content assets that support the classes and methods in the game library. For more information, see [Game Content Project](#).

Class1.cs File

This file implements an empty C# class within a namespace. This provides a starting point for the class library.

To create a Windows Game Library (3.1) project

1. On the **File** menu, click **New Project**.
2. Select the **Windows Game Library (3.1)** project type.

3. Type the name for the library project in the **Name** text box.

You can also modify the default values for the **Location** and **Solution Name** controls.

4. Click **OK** to create and load the new project.

Content Pipeline Extension Library (3.1)

XNA Game Studio provides a Content Pipeline Extension Library (3.1) template that creates and loads a set of starter files. The template provides a starting point for developers wishing to create their own custom importers and processors for their game content. For more information on the XNA Framework Content Pipeline, and content processors in general, see [Content Pipeline](#).

Note

Content Pipeline Extension Library projects require .NET Framework 3.5. This version of the .NET Framework must be selected in the combo box in the upper-right corner of the **New Project** dialog box. Otherwise, the Content Pipeline Extension Library (3.1) template will not be presented. The .NET Framework 3.5 is the default selection.

The new project contains basic code that implements an empty processor, usable by the XNA Framework Content Pipeline. Solution configurations for all available platforms are created automatically. This means that the Content Pipeline extension project builds processors and importers for any available platform without any change to the project.

Note

A solution configuration determines which project configurations are active, as well as which projects are built and/or deployed when you invoke the **Build** and **Run** commands. By default, if a project does not have a configuration that matches the active solution configuration, the solution build will skip that project.

In addition to the project template, there are additional code templates related to projects of this type. You can use the **Add New Item** dialog box to add these items to your project. Here are some basic descriptions:

Content Processor item

An item template comprised of a single code file (called **ContentProcessorN.cs**). The numerical suffix (*N*) guarantees uniqueness within the project. This file is similar to the **ContentProcessor1.cs** file created for the Content Pipeline Extension Library (3.1) template. The file declares a class derived from [ContentProcessor](#) with an override of the abstract [Process](#) method.

Content Importer item

An item template comprised of a single code file called **ContentImporterN.cs**. The numerical suffix (*N*) guarantees uniqueness within the project. The file declares a class derived from [ContentImporter](#) with an override of the abstract [Import](#) method.

Content Type Writer item

An item template comprised of a single code file called **ContentTypeWriterN.cs**. The numerical suffix (*N*) guarantees uniqueness within the project. The file declares a class derived from [ContentTypeWriter](#) with overrides of the abstract [Write](#) and [GetRuntimeReader](#) methods.

Content Type Reader item

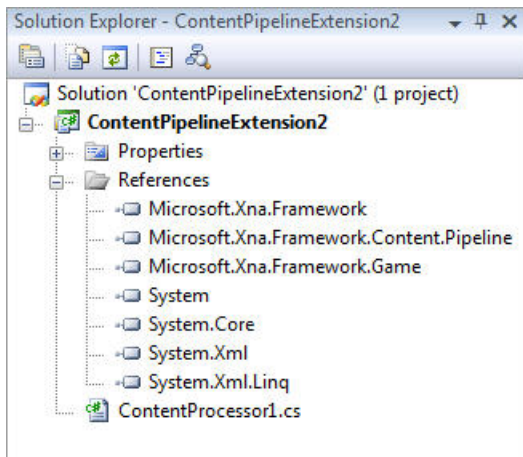

An item template comprised of a single code file called **ContentTypeReaderN.cs**. The numerical suffix (*N*) guarantees uniqueness within the project. The file declares a class derived from [ContentTypeReader](#) with an override of the abstract [Read](#) method.

Unlike the **Content Type Writer** item, this item is not available when adding a new item to a Content Pipeline Extensions Library project. It is only available for game or game library projects.

Whenever items of this type are added to a project, references to any dependent assemblies are added automatically. These references include assemblies that are likely to be required when customizing the newly-added class.

Results

The new starter project contains the following important features.

Project Properties

These properties control many aspects of your current project. Some examples include general application settings, debug settings, and additional project resources. You can modify the values for these properties using the Project Designer.

In addition to these properties, assembly information (such as the library title) is stored in the AssemblyInfo.cs file. This information can be modified using the [Assembly Information](#) dialog box or manually editing the .cs file.

References

References to the following assemblies are added automatically to a new Content Pipeline Extension Library project:

- Microsoft.Xna.Framework
- Microsoft.Xna.Framework.Content.Pipeline
- Microsoft.Xna.Framework.Game
- System
- System.Core
- System.Xml
- System.Xml.Linq

In addition to these standard assemblies, you can add other assemblies as needed for your project.

ContentProcessor1.cs File

This file implements an empty C# processor within a namespace, providing a starting point for the custom content processor.

To create a Content Pipeline Extension Library (3.1) project

1. On the **File** menu, click **New Project**.
2. Select the **Content Pipeline Extension Library (3.1)** project type.
3. Type the name for the library project in the **Name** text box.
You can also modify the default values for the **Location** and **Solution Name** controls.
4. Click **OK** to create and load the new project.

Deploying an Xbox 360 Game

Describes how XNA Game Studio can copy executable and media files to the Xbox 360 retail console once you are ready to deploy them. As you develop your Xbox 360 game, it is convenient to deploy your game executable to your console for testing purposes.

However, before deploying, you need to use the **XNA Game Studio Device Center** dialog box to establish a connection between the console and your computer. For a detailed explanation of this process, see [Connecting to Your Xbox 360 Console with XNA Game Studio 3.1](#).

Note

For more information about troubleshooting deployment to your console, see [Troubleshooting Xbox 360 Game Deployment](#).

Deploying Your Game

This procedure shows you how to deploy your Xbox 360 game from XNA Game Studio to a console. This assumes you established a connection between that console and your computer.

Note

An XNA Framework game deployed to the Xbox 360 console cannot exceed 2 GB. Also, this means that any single file you deploy must be smaller than 2 GB.

To deploy your Xbox 360 game

1. Load an Xbox 360 Game project into XNA Game Studio.

Make sure the **Output** window is visible so you can follow the progress of your deployment in detail, and so you can tell where a problem occurred, if one does.

2. To display the Output window, from the **View** menu, click **Output**, or press CTRL+W, and then press the letter O key.
3. From the Xbox 360 dashboard, go to the **My Xbox** menu, select **Game Library**, and press the **A** controller button.

Note

Also, you have the option of using the Xbox 360 Guide: From the **Games** page, select **Game Library**, and press the **A** controller button.

4. From the **Game Library** page, select **Community Games** on the **Collections** tab, and press the **A** controller button.
5. Select **XNA Game Studio Connect**, and press the **A** controller button.
6. Select **Launch**, and press the **A** controller button.

The **Waiting for computer connection** page appears.

7. In XNA Game Studio, deploy the game by either right-clicking the solution name and then selecting **Deploy Solution**, or, from the **Build** menu, selecting **Deploy Solution**.

During this process, both the Output window of XNA Game Studio and the **Connect to Computer** screen show the deployment progress. You can view a list of the deployed files and some additional information.

8. Press **B** to return to the **Game Library**.

Your deployed game appears in the list of **Recent Games**.

9. Select the game you just deployed from this menu, and press the **A** controller button.
10. Choose **Play Game**, and press the **A** controller button again to start the game.

Incremental Deployment

Incremental deployment is enabled automatically for XNA Game Studio projects. This means that the IDE tracks which files have been deployed already to your Xbox 360 console. Subsequently, it only deploys updated files. Also, if a file that was part of the previous deployment is no longer in the game, that file is deleted from the console during deployment. (This only applies to previously-deployed files, not to files that were generated on the console.) The output window reflects exactly what actions were taken during deployment.

A full deployment, which deletes any previous game files and copies the entire game to the console, is triggered by the following conditions:

- This is the first time the project has been deployed.
- A different configuration is used than in the last deployment to this device.
- The game was deleted from the Xbox 360 console since the last deployment.
- The solution has been cleaned since the last deployment. (For more information about cleaning the solution, see the "Cleaning the Solution Before You Build" section that follows.)
- The last deployment to the device was from a different source than the currently loaded solution, such as a copy on another Windows-based computer or a .ccgame package.

If you cancel during a deployment, some files may not have transferred. This leaves the game in an indeterminate state. The next incremental deployment will behave as if the last deployment never occurred. It will update the correct files on the Xbox 360 console.

Cleaning the Solution Before You Build

Cleaning your game solution before you build removes all intermediate and output files generated by the build. This forces the next build to regenerate everything.

If you select **Rebuild** on the **Build** menu, the build automatically regenerates everything, but you may also want to clean your solution before you do a build. This is particularly true if you are experiencing unexpected build errors.

In Microsoft Visual C# Express Edition, the **Clean Solution** option is not included in the **Build** menu by default. However, it is easy to add it if you want to make cleaning your solution convenient.

To add the Clean Solution option

1. In XNA Game Studio, right-click the menu or toolbar at the top of the window, and click **Customize**.
2. In the **Customize** dialog box, click the **Build** menu (or any other menu where you want to add the command).
This opens the menu, and leaves it open.
3. From the **Customize** dialog box, click the **Commands** tab, and select **Build** from the **Categories** pane on the left.
4. From the **Commands** pane on the right, drag the **Clean Solution** command into the open **Build** menu, and then drop it where you want it.
5. Close the dialog box.

Now, whenever you want to clean the solution, you can click **Clean Solution** from the menu where you added it.

Managing Several Xbox 360 Consoles with XNA Game Studio Device Center

Using the **XNA Game Studio Device Center** dialog box, XNA Game Studio supports deployment and debugging on multiple Xbox 360s.

The **XNA Game Studio Device Center** does the following:

- Creates connections between your Windows-based computer and each of your Xbox 360 console devices. If you have more than one Xbox 360, you can use **XNA Game Studio Device Center** to create connections between your Windows-based computer and each of your Xbox 360 console devices. Each connection allows you to deploy and debug XNA Framework 3.1 games to a specific Xbox 360 console device.
- Manages the list of available Xbox 360 console devices. This allows you to add and delete devices from the list of devices available for deployment.
- Allows you to set the default Xbox 360 console device to use for deployment. Similar to the default printer in Microsoft Windows, the default Xbox 360 console device is the device to which XNA Game Studio will deploy, unless you specifically select a different Xbox 360 console device for deployment. If there is only one Xbox 360 console device, it is set as the default device.
- Stores the list of Xbox 360 console devices on a per-user basis. Each user has a different list of Xbox 360 console devices to which he or she can deploy, and a different default device to use for deployment.

XNA Game Studio installs the **XNA Game Studio Device Management Toolbar** into Visual Studio. The **XNA Game Studio Device Management Toolbar** does the following:

- When you click the **Launch XNA Game Studio Device Center** button, provides easy access to the **XNA Game Studio Device Center** dialog box.
- Allows you to choose a specific Xbox 360 console device for deployment. Use the **XNA Game Studio Deployment Device** drop-down list. Also, do this if you want to deploy to a different Xbox 360 console device than your default device.

The **XNA Game Studio Device Management Toolbar** automatically appears within Visual Studio when an Xbox 360 Game project or Xbox 360 Library project is loaded in supported versions of Visual Studio tools.

Note

If your startup project is not an Xbox 360 or Zune project, most of the toolbar buttons will be unavailable. To make these buttons available, change your startup project to an Xbox 360 Game or Library project.

For more information about how to add Xbox 360 console devices to the **XNA Game Studio Device Center** dialog box, see [Connecting to Your Xbox 360 Console with XNA Game Studio 3.1](#). For more information about using the features of **XNA Game Studio Device Center**, see [Using XNA Game Studio Device Center](#).

Managing Multiple Xbox 360 Deployments

As noted previously, **XNA Game Studio Device Center** gives you the option to choose a specific Xbox 360 console device for deployment. This enables you to deploy your game to multiple Xbox 360s. Also, this supports testing and debug of networked games.

If you want to execute the same game instance on all Xbox 360 consoles, you can deploy the same build to all consoles.

However, if you want to debug and modify one instance of the game while the game continues to execute on all other consoles, you can do this by using a unique configuration to build and deploy the instance you want to modify. This is an advanced scenario, but one that is common for debugging networked games.

Deployment Troubleshooting

If you are unable to deploy your Xbox 360 game successfully, see [Troubleshooting Xbox 360 Game Deployment](#).

Debugging an Xbox 360 Game

Discusses issues that apply to debugging Xbox 360 games on your retail console.

Note

These issues also apply when debugging a Zune application.

Debugging an Xbox 360 game is similar to the process for [deploying](#) your game, with one exception. Instead of clicking **Deploy Solution**, click **Start Debugging** on the **Debug** menu. To run the game without actually debugging it, click **Start Without Debugging** on the **Debug** menu.

The following features are not available when debugging an Xbox 360 game with XNA Game Studio:

Feature	Description
Interop Debugging	Debugging both managed and native code simultaneously.
Assembly Debugging	Debugging only your assemblies and not system assemblies.
Edit and Continue	Editing the binary content of your game without interrupting your debugging session.
Exception Interrupting	Stopping unhandled exceptions before they unwind, so the user can make changes and retry the operation.
Debugger Visualizers	Displaying a more informative view of a specific data type, such as XML data.
Exception Assistant Support	The additional features provided by Exception Assistant are not available when debugging Xbox 360 games. Information on exceptions is provided by the standard Exceptions dialog box within XNA Game Studio.
Debugging a Running Process	Attaching the debugger to a process that is currently executing.

Troubleshooting Xbox 360 Game Deployment

Provides some helpful troubleshooting tips for Xbox 360 deployment if you are unable to establish a successful connection between your computer and your Xbox 360 console.

Be Sure Your Console is Correctly Configured

- You must have an XNA Creators Club membership, which you can purchase from Xbox LIVE Marketplace.
- XNA Game Studio Connect must be installed on the console.
- You must be signed in to Xbox LIVE with an Xbox 360 gamer profile associated with your XNA Creators Club membership.
- XNA Game Studio Connect must be running on the console. This means the connection to Xbox LIVE must remain active. Otherwise, XNA Game Studio Connect closes.

Use a Freshly Generated Key

The key generated by the console in the **XNA Game Studio Connect** page is good only for connecting one computer to one console under one user profile.

A key is valid until a computer connects to the Xbox 360 using that key, or until a new key is generated by the console. For example, if you delete a console from the list of consoles available for deployment, you cannot add it back again using the same key. Instead, you must generate a new key on the console, and use that new key to connect the computer to the console.

Your Connection Keys Might Have Been Modified

If a connection worked once and is now failing, the connection key for the console may have been changed accidentally. If this is the problem, you can fix it simply by adding a new connection, using a new key.

If You Wish to Reset All Connections

You can reset all connections by pushing **Reset All Connections**. This invalidates all connections to the Xbox 360 console device, and generates a new key for a new connection.

Note

If you reset all connections, any Windows-based computer with a connection to this Xbox 360 console device will not be able to connect until it reestablishes a new connection to the Xbox 360 console device.

The Computer and the Xbox Console Must Be on the same Subnet

If the computer and Xbox 360 console are on different subnets, they won't establish a proper connection. Typically, you should connect both machines to the same hub or router. It is best not to use a wireless connection—a weak or noisy signal can cause a failure in the connection and deployment.

To determine whether your computer and console are on the same subnet:

1. On your computer, open a command window (click **Start**, and then click **All Programs**, click **Accessories**, and finally click **Command Prompt**).
2. At the command prompt, type `ipconfig`, and press ENTER.

Make note of both the IP address and of the subnet mask in the configuration listing that appears.

3. On your Xbox 360 dashboard, go to the **My Xbox** menu, and select **System Settings**.

Note

You can use the Xbox 360 Guide to do the same thing: go to the **Settings** blade and select **System Settings**.

4. From **System Settings**, select **Network Settings**, and then click **Configure Network**.

Make note of the IP address and subnet mask.

5. Compare the settings to make sure that the computer and console are on the same subnet.

Check for Firewall Interference

In some cases, your firewall could be blocking communication between your computer and the Xbox 360 console. Verify that the following conditions have been met.

- The xnatrans.exe executable is not blocked on the computer.
- Incoming communication for UDP ports 3825 and 3835 is not blocked.
- Outgoing communication for UDP port 1000 is not blocked.
- Outgoing communication for TCP port 1001 is not blocked.

See [Third-Party Firewall Settings](#) for more details.

Creating a Zune Game or Library Project

Describes how XNA Game Studio includes a set of project templates that will help you to develop game projects for Zune using the XNA Framework.

Starting a New Project

To start a new project

- To begin a new Zune project, click **File**, and then click **New Project**.

You'll be presented with a dialog that lists a number of project templates.

Project Types

XNA Game Studio provides template types for XNA Framework game development in the **XNA Game Studio 3.1** section of the **Visual C#** project types. The templates offered for developing XNA Framework games for Zune are:

- Zune Game (3.1)—A project for creating an XNA Framework 3.1 game application for Zune.
- Zune Game Library (3.1)—A project for creating an XNA Framework 3.1 game library for Zune.
- Content Pipeline Extension Library (3.1)—A project for creating an XNA Framework 3.1 Content Pipeline Extension Library. For more information, see [Creating a Windows Game or Library Project](#).

For information about XNA Game Studio project templates for Windows or Xbox 360, see [Creating a Windows Game or Library Project](#) and [Creating an Xbox 360 Game or Library Project](#).

Note

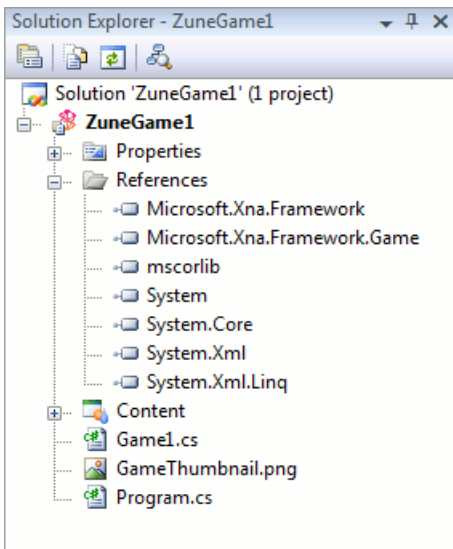

XNA Game Studio 3.1 continues to support creation and use of XNA Game Studio 3.0 projects. If you'd like to create a new XNA Game Studio 3.0 project, click the **XNA Game Studio 3.0** category in the **Project Types** box to gain access to the 3.0 project types. For more information, see [Upgrading XNA Game Studio Projects](#).

Zune Game (3.1)

XNA Game Studio provides an Zune Game template that creates and loads a set of starter files. This new project contains basic code that renders a colored background.

Results

The new starter project contains the following important features.

Project Properties

These properties control many aspects of your current project. Some examples include general application settings, debug settings, and additional project resources. You can use the Project Designer to modify the values for these properties.

In addition to these properties, assembly information (such as the game title) is stored in the AssemblyInfo.cs file. You can use the [Assembly Information](#) dialog box to modify this information, or you can manually edit the .cs file.

References

References to the following assemblies are added automatically to a new Zune Game project:

- Microsoft.Xna.Framework
- Microsoft.Xna.Framework.Game
- mscorlib
- System
- System.Core
- System.Xml
- System.Xml.Linq

In addition to these standard assemblies, you can add other assemblies as needed for your project.

Content

The nested content project stores and builds content for the game. For more information, see [Game Content Project](#).

Game1.cs File

This file is a good starting point for adding simple game logic and basic features. It implements a single class (derived from **Game** and called **Game1**), and it overrides five methods: **LoadContent**, **UnloadContent**, **Initialize**, **Draw**, and **Update**. In addition, the **Game1** constructor is defined by this file. Use these methods to initialize your game components, load and render your game content, and handle any input from the user or changes to the game environment.

GameThumbnail.png

The icon appears in the Games Library, and when this game is packed for distribution as a .ccgame. For more information about distribution, see [Sharing Your Game Package](#).

Program.cs File

This file also implements a single class (called **Program**) that provides an entry point to game execution. Usually, little code is added to this file unless the game is fairly advanced.

To create an Zune Game (3.1) project

1. From the **File** menu, click **New Project**.
2. Select the **Zune Game (3.1)** project type.
3. Type the name for the game project in the **Name** text box.

You can also modify the default values for the **Location** and **Solution Name** controls.

4. Click **OK** to create and load the new project.

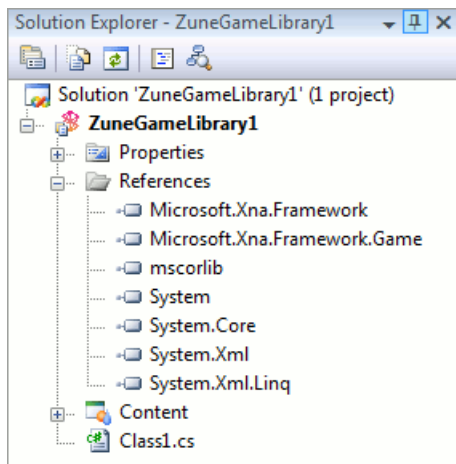

Zune Game Library (3.1)

XNA Game Studio provides an Zune Game Library (3.1) template that creates and loads a set of starter files. Typically, projects of this type contain managed classes that implement basic or advanced features used by a game engine. Once completed, these class libraries can be referenced by other Zune projects. Also, they provide common functionality without having that code reside within the game project.

The new project contains basic code that implements an empty library, usable by other Zune Game projects or Zune Game libraries.

Results

The new starter project contains the following important features.

Project Properties

These properties control many aspects of your current project. Some examples include general application settings, debug settings, and additional project resources. You can use the Project Designer to modify the values for these properties.

In addition to these properties, assembly information (such as the library title) is stored in the AssemblyInfo.cs file. You can use the [Assembly Information](#) dialog box to modify this information, or you can manually edit the .cs file.

References

References to the following assemblies are added automatically to a new Zune Game Library project:

- Microsoft.Xna.Framework
- Microsoft.Xna.Framework.Game
- mscorlib
- System
- System.Core
- System.Xml
- System.Xml.Linq

In addition to these standard assemblies, you can add other assemblies as needed for your project.

Content

The nested Content project stores and builds content that is to be included in the game library. This is useful for including reusable content assets that support the classes and methods in the game library. For more information, see [Game Content Project](#).

Class1.cs File

This file implements an empty C# class within a namespace. It provides a starting point for the class library.

To create an Zune Game Library (3.1) project

1. From the **File** menu, click **New Project**.
2. Select the **Zune Game Library (3.1)** project type.
3. Type the name for the library project in the **Name** text box.

You can also modify the default values for the **Location** and **Solution Name** controls.

4. Click **OK** to create and load the new project.

Deploying a Zune Game

Describes how XNA Game Studio can copy executable and media files to a Zune device once you are ready to deploy them. As you develop your Zune game, it is convenient to be able to deploy your game executable to your device for testing purposes.

However, before deploying, you need to use the **XNA Game Studio Device Center** dialog box to establish a connection between the device and your computer.

Note

For more information about troubleshooting deployment to your Zune device, see [Troubleshooting Zune Game Deployment](#).

Deploying Your Game

This procedure shows you how to deploy your Zune game from XNA Game Studio to a Zune device. This assumes you already have a connection between that device and your computer.

To Deploy Your Zune Game

1. Load a Zune Game project into XNA Game Studio.
2. In XNA Game Studio, deploy the game by either right-clicking the solution name and then selecting **Deploy Solution**, or, from the **Build** menu, selecting **Deploy Solution**.

During this process, both the Output window of XNA Game Studio and the **Connect to Computer** screen show the deployment progress by displaying a list of the deployed files and other information. Also, you can see the names of the files on the device screen as they are deployed.

3. Select the top level **Games** menu on the device to start the game.

Incremental Deployment

Incremental deployment is enabled automatically for XNA Game Studio projects. This means that the IDE tracks which files have already been deployed to your device. Subsequently, it only deploys updated files. Also, if a file that was part of the previous deployment is no longer in the game, that file is deleted from the console during deployment. (This applies only to previously-deployed files, not to files generated on the device.) The output window reflects exactly what actions were taken during deployment.

A full deployment, which deletes any previous game files and copies the entire game to the device, is triggered by the following conditions:

- This is the first time the project has been deployed.
- A different configuration is used than in the last deployment to this device.
- The last deployment to the device was from a different source than the currently loaded solution—a source such as a copy on another Windows-based computer or a .ccgame package.
- The game was deleted from the device since the last deployment.
- The solution has been cleaned since the last deployment. (For more information about cleaning the solution, see the "Cleaning the Solution Before You Build" section that follows.)

Cleaning the Solution Before You Build

Cleaning your game solution before you build removes all intermediate and output files generated by the build. This forces the next build to regenerate everything.

If you select **Rebuild** on the **Build** menu, the build automatically regenerates everything. However, you may also want to clean your solution before doing a build. This is particularly true if you are experiencing unexpected build errors.

In Microsoft Visual C# Express Edition, the **Clean Solution** option is not included in the **Build** menu by default. However, it is easy to add if you want to make cleaning your solution convenient.

To add the Clean Solution option

1. In XNA Game Studio, right-click the menu or toolbar at the top of the window, and then click **Customize**.
2. In the **Customize** dialog box, click on the **Build** menu (or on any other menu where you want to add the command).

This opens the menu, and leaves it open.

3. From the **Customize** dialog box, click the **Commands** tab, and select **Build** from the **Categories** pane on the left.
4. From the **Commands** pane on the right, drag the **Clean Solution** command into the open **Build** menu, and drop it where you want it.
5. Close the dialog box.

Now, whenever you want to clean the solution, you can click **Clean Solution** from the menu where you added it.

Managing Several Zunes with XNA Game Studio Device Center

Using the **XNA Game Studio Device Center** dialog box, XNA Game Studio supports deployment and debugging on multiple Zune devices.

The **XNA Game Studio Device Center** does the following:

- Creates connections between your Windows-based computer and each of your Zune devices. Each connection allows you to deploy and debug XNA Framework 3.1 games to a specific Zune device.
- Manages the list of available Zune devices, allowing you to add and delete devices from the available deployment list.
- Allows you to set the default Zune device to use for deployment. Similar to the default printer in Microsoft Windows, the default Zune is the device to which XNA Game Studio will deploy unless you specifically select a different Zune device for deployment. If there is only one Zune device, it is set as the default device.
- Stores the list of Zune devices on a per-user basis. Each user has a list of different Zune devices to which he or she can select for deployment, and a different default device to use for deployment.

XNA Game Studio installs the **XNA Game Studio Device Management Toolbar** into Visual Studio. The **XNA Game Studio Device Management Toolbar** does the following:

- Gives you easy access to the **XNA Game Studio Device Center** dialog box from within Visual Studio by clicking the **Launch XNA Game Studio Device Center** button.
- Allows you to choose a specific Zune device to deploy by using the **XNA Game Studio Deployment Device** drop-down list. Use this if you want to deploy to a Zune device other than your default device.

The **XNA Game Studio Device Management Toolbar** automatically appears within Visual Studio when an Xbox 360 (or Zune) Game project or Xbox 360 (or Zune) Library project is loaded in supported versions of Visual Studio tools.

Note

If your startup project is not an Xbox 360 or Zune project, most of the toolbar buttons will be unavailable. To make these buttons available, change your startup project to a Zune Game or Library project.

For more information about using the features of **XNA Game Studio Device Center**, see [Using XNA Game Studio Device Center](#).

Troubleshooting Zune Game Deployment

Provides some helpful troubleshooting tips for Zune deployment if you are unable to establish a successful connection between your computer and your Zune device.

When XNA Game Studio Device Center fails to find and add your Zune device, or when XNA Game Studio fails during deployment of a game to your Zune device, you will get the following error message:

```
Could not connect to [Zune name]. Make sure the device is connected, a game is not already running, the screen is not locked, and the Zune software is not running on your computer.
```

One of the following conditions may have caused this failure:

- The Zune device to which you are deploying is not connected to your computer. Make sure the Zune device is securely connected to your computer with the Zune Sync Cable.
- The Zune software currently is running on your computer. You must close the Zune software before deploying to your Zune device.
- A game currently is running on the Zune. Close the game and wait for the Zune device to reboot before you try to deploy again.
- The Zune screen is locked. To deploy to the Zune device, unlock the screen by entering the lock code.

After you correct the condition, wait at least 30 seconds before retrying. If you try to deploy sooner, XNA Game Studio probably won't recognize the change.

Managing Game Assets

Describes game assets, which are the collection of data files used to support gameplay such as bitmaps, models, textures, or sounds. Game assets are governed by the XNA Framework Content Pipeline.

This section discusses how you can manage the game assets held by a game project.

In This Section

Game Content Project

Describes a project type (nested within a standard XNA Game Studio project) designed to store all content for a game application.

Overview

A game content project uses the XNA Framework Content Pipeline to build game content (models, textures, sounds, and so forth). You add content items to this project as project items. Item properties define how each content item is imported and processed as part of the build operation. Game content projects are built automatically whenever their parent projects are built. In addition, their configurations and platforms are the same as their parent projects.

Game content projects have a **References** node that lists the assemblies and projects containing the importers and processors currently used in a Content Pipeline build. Individual content items are listed and their properties are accessible using the **Properties** window. You can use either the standard **Add New Item** dialog box or the **Add Existing Item** dialog box to add items to a game content project.

⚠ Caution

The **Build Action** property of any project item moved into the nested content project is set automatically to **Compile**. This value persists even if the same item later is moved out of the nested content project.

Content in Game Libraries

Classes and methods in game libraries may rely on specific content, such as textures and shaders, to perform their game-related functions. For this purpose, game libraries provide their own content subfolders that can contain those assets to ensure they will be available.

When a game project includes reference to a game library, a copy of the output of the game library is included in the output directory of the game project. In this way, both the game library's referenced assembly and its associated content are available at run time.

All content in the game content subproject of a successfully built game library will be compiled through the content pipeline, just as the code of a game library is stored in its compiled form. This permits game projects that reference these reusable elements of the game library to build more quickly.

Content within a game library may be referenced directly by the game project. There is no requirement that the classes or methods of the game library must reference the content in a game library.

Project Designer Properties

These properties are not available to game content projects. All changeable properties are in the Content Pipeline Properties, described below.

Content Pipeline Properties

The content project has additional properties (other than those available in the Project Designer tabs) that specify operating parameters for the XNA Framework Content Pipeline. To access these properties, select the **Content** node in Solution Explorer, then from the **View** menu, select **Properties Window** (or type the function key F4).

Content Root Directory

Specifies the name of the subdirectory that will hold the final output files of pipeline content generated from this project folder. This may be useful if your game project has multiple content projects and you wish to keep the output of each in different subdirectories.

Code-Only Builds

By manually editing a .csproj file, you can build your game project without also building the nested content project. If you are using XNA Game Studio, open the related .csproj file, and add the following property:

```
<SkipNestedContentBuild>true</SkipNestedContentBuild>
```

If you are building from the command-line, use the following command to skip the nested content project:

```
Msbuild /p:SkipNestedContentBuild=true WindowsGame1.csproj
```

For more information on using MSBuild with project files, see [How To: Edit Project Files](#) and [Visual Studio Integration \(MSBuild\)](#).

In addition, you can build only the nested content project from the command line by invoking MSBuild directly on the .contentproj file of your nested content project.

Adding Game Content Projects

Describes how XNA Game Studio supports the use of multiple content project folders within a game project.

When initially created, an XNA Game Studio game project contains a single subordinate content project to contain game assets to be managed through the content pipeline. It may be convenient to create and maintain additional content projects, perhaps to manage differing types or collections of content.

To add a new content project

1. Open an XNA Framework game or library project in XNA Game Studio.
2. In Solution Explorer, right-click the game project node.
3. Click **Add**, and then click **New Content Project...**
4. In the **Add New Content Project** dialog box, enter the name for the new content project.

The same procedure can also be performed by selecting **Add New Content Project...** from the **Project** menu.

To add an existing content project

1. Open an XNA Framework game or library project in XNA Game Studio.
2. In Solution Explorer, right-click the game project node.
3. Click **Add**, and then click **Existing Content Project...**
4. In the file selection dialog box, navigate to the existing content project file, and then select it.

The same procedure can also be performed by selecting **Add Existing Content Project...** from the **Project** menu.

Note

It is acceptable to add the same content project to projects for different platforms (as in a cross-platform solution). However, if your solution contains multiple projects for the same platform, do not add the same content project to these projects. This will result in unpredictable behavior.

To remove a content project

1. Open an XNA Framework game or library project in XNA Game Studio.
2. In Solution Explorer, expand the game project node and right click the game content project.
3. Click **Remove**.

Adding Game Assets to Your Game

Demonstrates how to add a texture asset to your game. The same procedure can also be applied to model and sound assets. It is assumed that an existing Windows, Xbox 360, or Zune game project is loaded in XNA Game Studio.

There are two ways to add a texture asset to your game, either by adding the asset file or by adding a link to the asset.

Tip

Adding an existing asset to your project is quite different from adding an existing item as a link to your project. The first method creates a copy of the asset file and adds the copy to your project. Adding an asset as a link stores only the path to the asset file.

Adding the Texture Asset to the Game Project

When you add a game asset (not as a link), XNA Game Studio makes a copy of the asset file and adds the copy to the content project. For this reason, adding a game asset in this manner may be most appropriate when the asset is used by only one developer in one project and is not expected to be changed.

To add the texture asset to the game project

1. From the Solution Explorer window, right-click the **Content** node, click **Add**, and then click **Existing Item**.
2. Navigate to the location of the texture, and select it.
For this example, the asset is called B1_nebula01.tga.
3. Click the **Add** button.
This creates a copy of the selected asset in your project.
4. Save the solution.

Adding the Texture Asset as a Link to the Game Project

Adding an asset as a link is useful if the referenced asset depends on additional external assets. It ensures that the solution always uses the latest version. For this reason, adding a game asset as a link may be most appropriate when the asset is shared with other people or other game projects, or is likely to be changed.

To add the texture asset as a link to the game project

1. From the Solution Explorer window, right-click the **Content** node, click **Add**, and then click **Existing Item**.
2. Navigate to the location of the texture, and select it.
For this example, the asset is called B1_nebula01.tga.
3. Click the small arrow to the right of the **Add** button, and then click **Add as Link**.
This creates a reference to the selected asset (and not a copy) in your project.
4. Save the solution.

Verifying the Content Importer

You should use this procedure each time you add a game asset. This ensures that the asset will be correctly recognized and processed by the Content Pipeline.

To verify the game asset will use the correct content importer

1. After you add the asset to the solution, open the **Properties** window to verify that you specified the correct importer and processor.
2. To verify, right-click on the file in Solution Explorer, and then, from the context menu, click **Properties**.
For this example, the **Content Importer** is Texture - XNA Framework and the **Content Processor** is Texture - XNA Framework.

For more information on the **Properties** window of a game asset, see [Game Asset Properties](#).

3. Save the solution.

[Content Pipeline](#)

Game Asset Properties

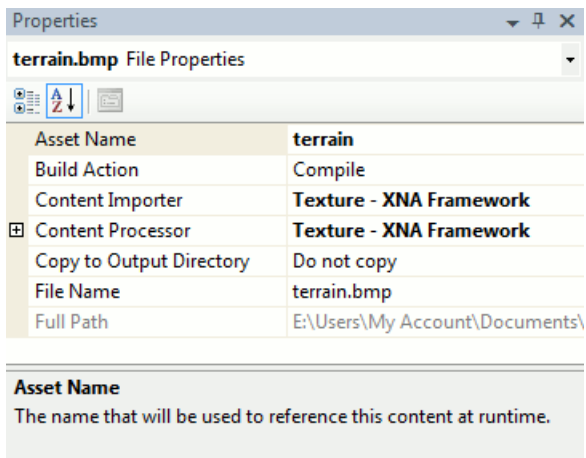

Describes property settings indicating which actions the project system should perform on a game asset file of a supported type.

For example, you can set file properties to indicate the importer and processor to be used for the game asset file.

Note

When adding a game asset of a type not recognized by XNA Game Studio, you need to modify the **Content Processor** and **Content Importer** properties (by specifying a custom processor and custom importer that build assets of this type) before the asset is built by the Content Pipeline.

To examine the properties of a game asset, right-click on the file in Solution Explorer and choose **Properties** on the context menu. The Properties window then appears.

In addition to the [standard properties](#), XNA Game Studio content files have additional custom properties: **Asset Name**, **Content Importer**, and **Content Processor**.

Asset Name

The name of the managed object, generated by the Content Pipeline from the game asset. This name is used at run time to load the managed asset, using the [ContentManager.Load](#) method. The default name is the original file name without the file extension.

Content Importer

The name of the importer for the related game asset. The list contains both custom importers referenced by the content project and standard importers provided by XNA Game Studio.

Content Processor

The name of the processor for the related game asset. The list contains both custom processors referenced by the content project and standard processors provided by XNA Game Studio. Processors that have modifiable parameters are indicated with a small plus sign next to the Content Processor row. Clicking this expands the Content Processor row to display any supported parameters. Modify these parameter values as you would other properties in this pane. For more information on parameterized processors, see [Parameterized Processors](#).

Creating Cross-Platform Games

Describes how Game Studio facilitates developing a game that will run on multiple platforms.

The XNA Framework makes developing a game with rich play on any Microsoft platform easy. Even better, once your game works on one platform, it can run on any other platform supported by the XNA Framework, using the same base source code with minimal changes.

For example, the same XNA Framework game could be built three ways: the first to be played on a desktop computer running Windows, the second to be downloaded to an Xbox 360, and a third to load onto a Zune device.

XNA Game Studio provides several features that facilitate development and management of games designed to run on multiple platforms.

The Structure of a Cross-Platform Game in Game Studio

When you develop a game to run on multiple platforms, there must be a separate project for each platform. Each project may reference the same source code files and game asset files, but building each project will create an executable that can run on its designated platform.

Method 1: A Solution File for Each Platform.

One approach to maintaining separate projects for each platform might be to create a solution file for each supported platform, each with its own single project. If the projects in each solution reference the same source and game asset files, changes to those files will be reflected in each solution.

The drawback to this method is that each solution will have to be maintained separately. When you make changes to a project, such as adding new source and game asset files, renaming or removing items, the changes you make in one solution will not be reflected automatically in other solutions.

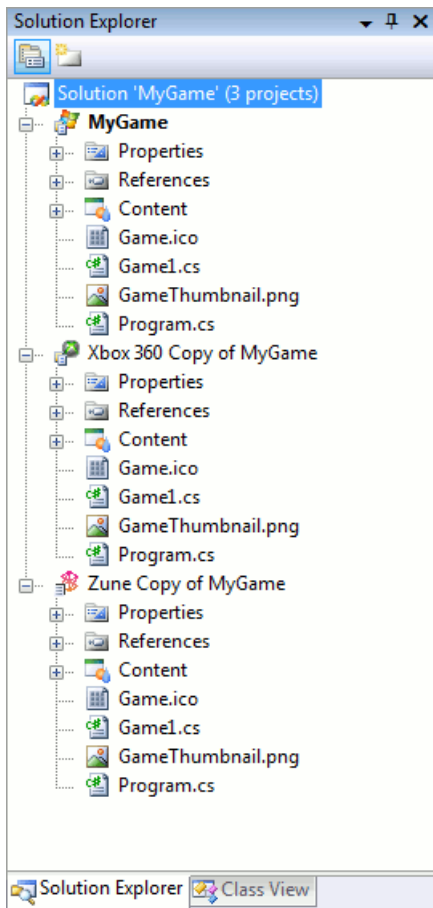

Method 2: A Solution File with Multiple Projects

A cross-platform game is best maintained as multiple projects within a single solution, so that Game Studio can more easily synchronize changes across all platforms.

For example, the Game Studio solution for MyGame might house a project folder for the following:

1. Windows version of MyGame.
2. Xbox 360 version of MyGame.
3. Zune version of MyGame.

Each of these projects will reference the same C# code files and game asset file, but each will build a version that can execute on the intended platform.

When you use the [Cross-Platform Conversion Wizards](#) to create these parallel projects, the project created is [linked to the original project](#).

Managing Platform-Specific Content

Source code and game asset files should be shared for all platforms as much as possible. However, some files may need to have unique versions for different platforms.

This requirement occurs most frequently for game assets in the content pipeline. For example, to produce the highest quality images, graphic files for a game designed to run on the Xbox 360 platform may be very high resolution bitmaps. The Zune platform, however, has a much smaller screen and supports much lower-resolution graphics. For this reason, your game projects are likely to reference differing game assets that are appropriate to each platform – large, high-resolution graphics for the Xbox 360 and small, low-resolution graphics for the Zune.

At the same time, your game may still have content assets, such as menus, that are shared across all platforms. For these assets, it will still be useful for each project to maintain a content project folder that is synchronized across all platform projects.

To accommodate this, Game Studio enables a project to contain multiple content projects. The first project, synchronized to the content folders of all other projects, can contain the shared assets. Subsequent content project folders may contain game assets specific to that platform, and can be made to be exclusive to that parent project (not synchronized to other projects).

Unsynchronized content projects are created by adding a content project, then removing its synchronized versions in other game projects. You can use the [Add Game Content Project](#) procedure to add new platform-specific content projects to code projects.

The topic [How To: Create a Cross-Platform Game Solution](#) demonstrates how this can be used to manage platform-specific content across multiple platforms.

You can create several content project folders within a game project. You are not restricted to the two described in our example. If you find it convenient to maintain more, Game Studio will permit it.

Cross-Platform Game Project Converter

Describes how XNA Game Studio facilitates the process of converting a game for Windows, Xbox 360, or Zune to any of the other two game platforms.

The conversion process creates a new game project of the appropriate type. The new game project will be created in the same folder as the source project, and will share content and settings from the original game project.

- [Cross-Platform Game Conversion](#)
- [Changes Made to a Project During Conversion](#)
- [Linked Projects After Conversion](#)
- [References the Conversion Utility Cannot Replace](#)
- [Changes that May Be Necessary after Conversion](#)

Limitations of Game Conversion

The conversion utility is not meant to be an end-to-end conversion, but it greatly simplifies the process of converting a game to the corresponding platform. Specific code changes will still be required. For example, if a Windows game is controlled by the keyboard and mouse, the converted game will not be changed to respond to an Xbox 360 game controller. You can use the [cross-platform conditional compilation symbols](#) to create sections of code that will execute only on the appropriate platform.

Cross-Platform Game Conversion

To convert a game for another platform

1. Load the game into a supported version of Visual Studio tools.
2. From the **Project** menu, choose the **Create Copy of [project name]** item, where the [project name] will be the name of the game project.

The presented items in the **Project** menu will vary according to the designated platform of the currently selected project:

Windows	Xbox 360	Zune
Create Copy of [Project Name] for Xbox 360	Create Copy of [Project Name] for Windows	Create Copy of [Project Name] for Windows
Create Copy of [Project Name] for Zune	Create Copy of [Project Name] for Zune	Create Copy of [Project Name] for Xbox 360

When complete, a new version of the game project will be added to your solution. It will be named for the platform (for example, "Xbox 360 Copy of [Project Name]" or "Windows Copy of [Project Name]"). The new game project will be selected.

3. Press F2 if you want to rename the project from the name given by the conversion utility.

Note

The solution may only contain one copy of a project for each platform. Solutions that do not conform to this will be unable to correctly synchronize projects and produce an error message during conversion.

Changes Made to a Project During Conversion

- All references to XNA Framework assemblies will be replaced by their equivalents for the other platform.
- All original configurations will be replaced by default configurations for the new platform.
- The XnaPlatform project property will change to that of the new platform.
- The [Content Build Compression](#) properties are set to the default values for the new platform.
- The ProjectGuid property will be replaced. This is not the same as the GUID assembly attribute (usually found in AssemblyInfo.cs), which will not be changed.
- The default Platform property and project output type settings will be replaced with values for the appropriate target platform.

Linked Projects After Conversion

The new project created by the conversion wizard shares code, content, and settings from the original game project by being linked.

Projects copied through the conversion wizard are linked so that:

- An item or folder added to any project is also added to the other projects.
- An item or folder renamed in any project is also renamed in the other projects.
- An item or folder deleted from any project is also deleted from the other projects.

All other actions not specifically cited above are not synchronized between projects. Of particular note, this includes the following actions:

- Excluding an item from a project has no effect on other projects. This is useful for items that are inappropriate for one or more platforms, yet needed for another platform (or platforms). For an example, see [How To: Create a Cross-Platform Game Solution](#).
- Changing properties in a project or folder has no effect on other projects.

The exception to this behavior is items in and properties of linked content project folders (for example, the **Content** project or content projects that you [create](#)) that exist within game projects. Excluding an item from a content project always excludes the item from all of its linked content projects. (As examining the properties of the linked content project folders will show, each is referencing the same project file. So, adding or removing an item to one will affect all.) This behavior is unique to content projects.

Note

Folders that are empty (as when they are first created) are not synchronized between projects. Once items are placed into a folder (so that it is no longer empty), the folder is synchronized across all other projects.

References the Conversion Utility Cannot Replace

- HintPath metadata (added using browse-to-file) and strong name references will be changed into simple-named references.
- Project references to non-XNA Framework projects will be deleted.

Note

Unlike references to non-XNA Framework projects, all referenced XNA Framework game or game library projects are recursively converted. This means that if an XNA Framework project references another in the solution (with a project-to-project reference), conversion of the referencing project automatically converts the referenced project. The result is the converted copy of the first project referencing the converted copy of the second project.

For example, if you are converting a Windows game to the Xbox 360 that references a Windows game library in the same solution, conversion also occurs for the Windows game library. After a completed conversion, the result is an Xbox 360 game (a converted copy of the Windows game) that references an Xbox 360 game library (a converted copy of the Windows game library).

- COM references will be deleted. The conversion wizard will provide a warning to the output window when this occurs.
- COM file references will be deleted. The conversion wizard will provide a warning to the output window when this occurs.
- Web references are removed, possibly resulting in compile time errors for the converted project. For example, any code that instantiates a Web reference-related class or invokes its methods will cause compile-time errors. The conversion wizard will provide a warning to the output window when this occurs.

Caution

If you need to remove a file from only one project, use the **Exclude from Project** command rather than the **Delete** command. The **Delete** command removes the file from disk, making it inaccessible to the other project.

Changes that May Be Necessary after Conversion

- In some cases, a converted reference (for example, a strong name reference) may fail to resolve. If this happens, either delete the reference or replace it with a reference to an assembly version for the correct platform.

For example, if a reference to System.Data (often added automatically to Windows projects) was converted for the Xbox 360, you must remove it because System.Data are not supported on Xbox 360. However, if the converted reference was to something like a third-party game engine, you might be able to change the reference to an Xbox 360 version of the engine instead.

If a converted reference is deleted, ensure that any platform-specific code does not depend on that reference.

- Any code specific to one target platform, for example, mouse-based user input in a Windows game, will not be converted for the other platform. You must manually change this code to use an Xbox 360-compatible input device.

Other common examples include any .settings files (due to missing types), code generated from any Windows Forms in the project, and certain types of resources. For example, string or binary resources are fine but bitmap resources will fail.

Platform-Specific Content Projects

Describes how XNA Game Studio supports maintaining platform-specific game assets through the use of multiple content projects within a game project.

A cross-platform solution in XNA Game Studio is composed of multiple game projects, with one project for each platform. The projects are synchronized with each other such that adding or renaming a file in one project is reflected automatically in the other projects.

Content projects that are [added to a game project](#) follow the same synchronization rules. This means that adding a content project to one game project will automatically add the same content project to all other game projects in the XNA Game Studio solution. For each of the other projects, all references to XNA Framework assemblies will be appropriate for the project's platform.

It may be useful to maintain a content project that is exclusive to a game project, such as for game assets that are specifically meant for use on that project's platform. For example, you may want to use high-resolution bitmaps for a project that will run on the Windows platform, but use low-resolution versions for the Zune project.

To create content projects that are not synchronized with other game projects, you must first add a content project to the needed game project, and then remove the synchronized projects in the game projects where they are not needed.

To create an exclusive content project for a Windows game

This example procedure assumes that the XNA Game Studio solution contains three game projects: for Windows, Xbox 360, and Zune.

1. In Solution Explorer, right-click the Windows game project node (for example, MyGame).
2. Click **Add**, and then click **New Content Project...**
3. In the **Add New Content Project** dialog box, enter the name for the new content project (for example, MyWindowsContent).
4. In Solution Explorer, expand the Xbox 360 game project node (for example, Xbox 360 Copy of MyGame).
5. Within the Xbox 360 game project, right-click the new content project (MyWindowsContent), and select **Remove**.
6. In Solution Explorer, expand the Zune game project node (for example, Zune Copy of MyGame).
7. Within the Zune game project, right-click the new content project (MyWindowsContent) and select **Remove**.

Managing Cross-Platform Builds and Deployment

Describes how to build and deploy individual projects within a cross-platform solution.

When you are developing a cross-platform game in XNA Game Studio, your solution will be composed of a project for each possible platform. You need to understand how to use the features within Visual Studio that control the particular projects that are built and deployed following the **Start** (F5) key and **Build** commands.

For example, if you are developing a cross-platform project for both Windows and Xbox 360, you will want to limit game build and deployment solely to the Xbox 360 project when you are trying to develop and debug the Xbox 360 version of the game.

You will need to know how to do the following:

1. Set the deployment options to limit builds and deployment to the startup project.
2. Set one of the projects in your cross-platform solution as the startup project.

You can also use the Solution Configuration to control the characteristics of the build.

Setting Deployment Options

You can use the **Build and Run** settings to limit **Start** and **Build** commands to the startup project.

To set Build and Run options

1. From the **Tools** menu, click **Options...**
2. If you are using Visual C# Express, make sure the check box in the **Options** dialog box at the bottom left-hand corner labeled **Show all settings** is checked.
3. In the **Options** dialog box, expand the **Projects and Solutions** node, and select the **Build and Run** options set.
4. Check the box labeled **Only build startup projects and dependencies on Run** (it is unchecked by default).

This setting will limit build and deployment to the startup project.

In addition, you may want to set the option that automatically sets the currently selected project as the startup project.

To automatically set the startup project

- Check the box labeled **For new solutions use the currently selected project as the startup project** (it is unchecked by default).

This setting will establish that the currently selected project is the startup project. This option will only take effect for new solutions.

Setting the Startup Project Manually

The startup project is the project (or projects) that will be run by Visual Studio when you start the debugger. If you set the **Build and Run** settings as described previously, the **Start** command (also initiated by the **F5** key) will be limited solely to the startup project (or projects).

Further, if the startup project is set automatically to the currently selected project, it is not necessary to manually set the startup project.

The startup project name always appears in boldface in Solution Explorer.

To set the startup project manually

1. In Solution Explorer, right-click the project you want to set as the startup project.
2. In the context menu, click **Set as StartUp Project**.

Also, you can use Solution Explorer to select the project or, from the **Project** menu, select the project by clicking **Set as StartUp Project**.

Using Solution Configurations

Solution configurations store solution level properties that direct which style of object and executable output are produced by the **Start** (F5) key and **Build** commands. In a cross-platform solution in XNA Game Studio, the solution configuration platform setting is a composite of the platform settings for each project in the solution.

The **Solution Configuration** control in the Visual Studio toolbar establishes the "Active" (or default) configuration for all projects in the solution. For example, the active configuration may be set to the "Debug" configuration, which includes all symbol information and minimal compiler optimization; or it may be set to the "Release" configuration. Changing this setting will affect the build of all projects set to the active configuration.

The **Solution Platforms** control in the Visual Studio toolbar establishes which platform version of the projects in a solution will be built and deployed. In a cross-platform solution, the options may be "Mixed Platforms" (that is, all that are specified in the solution configuration), "x86" (for Windows), "Xbox 360," or "Zune."

For example, if you set the solution platform to "Zune," only the Zune projects in the solution will be built and deployed. Xbox 360 or Windows projects are not affected.

Note that this differs from the startup project, which determines which project is run, but not which project is built and deployed. If the Windows project is set as the startup project, but the solution platform is set to "Mixed Platforms," all projects will be built when you press the F5 key, but only the Windows project will execute. Using the previous example, if you change the solution platform setting to "Zune," only the Zune project will be built, but it won't run. The Windows project will not be built, and Visual Studio will run the last built (and perhaps out of date) Windows executable.

To limit Visual Studio to both building and running only the platform version you are currently working on, the solution platform setting should match the platform of the startup project.

You can also limit action to a specific project by right-clicking the project in **Solution Explorer**, and selecting the desired action (such as **Build**, **Deploy** or **Debug**) that appears in the context menu.

Each project may have its own configuration settings, which may override the active configuration. The project's configurations also will specify the target platform (for example, Windows, Xbox 360, or Zune). The platform settings are set automatically for a project when you use the **Create Copy...** command to create the synchronized project for a new platform.

To change the project configuration settings

- In Solution Explorer, right-click the solution, and click **Configuration Manager** on the context menu.

Note

You can also start the Configuration Manager by selecting it in the drop-down **Solution Configurations** menu on the toolbar.

Cross-Platform Conditional Compilation Symbols

Describes the conditional compilation variables available for maintaining common source code in XNA Game Studio cross-platform projects.

XNA Game Studio projects define symbols for each compatible platform for use with conditional compilation directives such as **#if**. You can use this to maintain source code that acts differently on Windows, Xbox 360 or Zune when that source is shared between projects.

The conditional compilation symbols for each compatible platform are:

Windows Platform	Xbox 360 Platform	Zune Platform
WINDOWS	XBOX or XBOX360	ZUNE

Usage

Where source code needs to support different actions when executing on different platforms, it should use the XNA Game Studio conditional compilation symbols with the **#if**, **#else** and **#elif** directives.

For example, a game that needs to execute on Windows, Xbox 360, and Zune, but calls different services (such as for input devices) for each platform might use the directives in a style similar to this:

```
#if WINDOWS

// Execute code that is specific to Windows

#elif XBOX

// Execute code that is specific to Xbox 360

#elif ZUNE

// Execute code that is specific to Zune

#else

// Print a compile-time error message
#error The platform is not specified or is unsupported by this game.

#endif
```

[How To: Draw a Sprite](#) shows an example of conditional compilation where the available screen space is calculated differently for Xbox 360 and Windows.

Definition

The **Conditional compilation symbols** are defined in the **Build** tab of the Project Designer properties for each project. These symbols are properly established when the XNA Game Studio project is first created or converted for another platform through the [conversion wizard](#).

How To: Create a Cross-Platform Game Solution

Demonstrates how to create a cross-platform solution and manage game assets between platform projects.

This tutorial shows how create a solution with multiple synchronized projects where each project holds the same base source code, but the object generated from each is targeted to execute on a different XNA Game Studio-compatible platform. It also shows how to create game content projects within each platform project that hold non-synchronized or partially synchronized content specific to each platform.

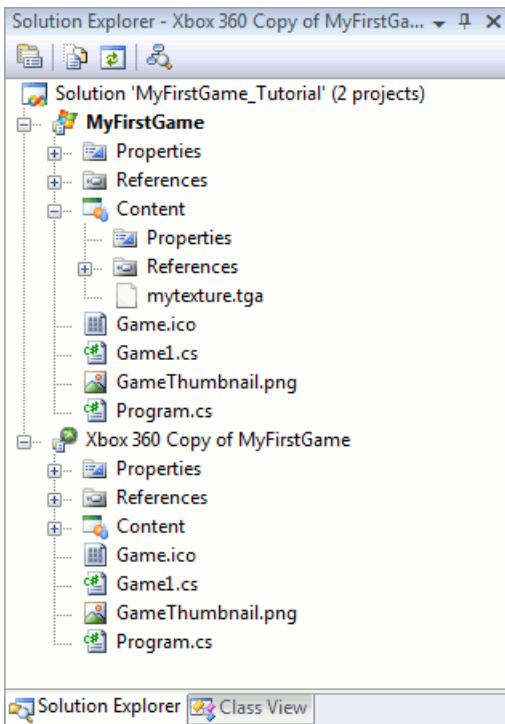

The scope of the tutorial is limited to demonstrating how to use the synchronized project features of Visual Studio to manage a cross-platform solution. It does not demonstrate changes to the source code that would likely be needed in order to execute effectively on different platforms.

Creating a Cross-Platform Solution

To create a game solution with multiple projects for Windows, Xbox 360 and Zune

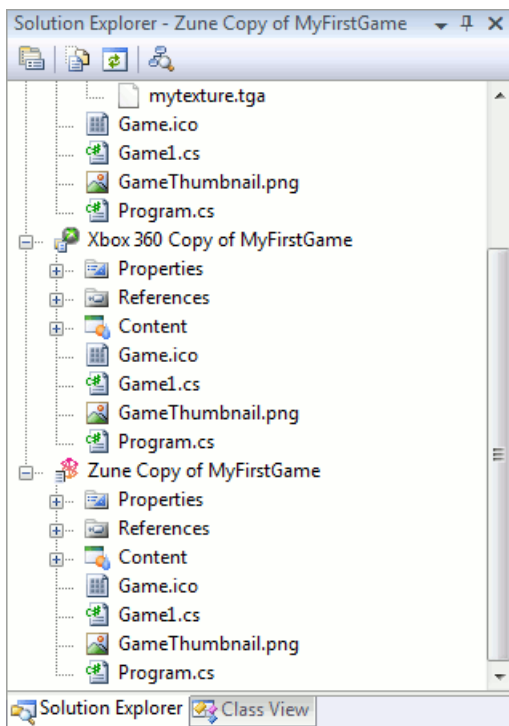

1. Follow the steps of [Your First Game: Microsoft XNA Game Studio in 2D](#) to create a Windows game for XNA Game Studio.
2. In Solution Explorer, select the **MyFirstGame** project.
3. From the **Project** menu, click **Create Copy of MyFirstGame for Xbox 360**.

When complete, a new version of the game project named "Xbox 360 Copy of MyFirstGame" will be added to your solution.

4. In Solution Explorer, select the **MyFirstGame** project once again.
5. From the **Project** menu, click **Create Copy of MyFirstGame for Zune**.

When complete, a new version of the game project named "Zune Copy of MyFirstGame" will be added to your solution.

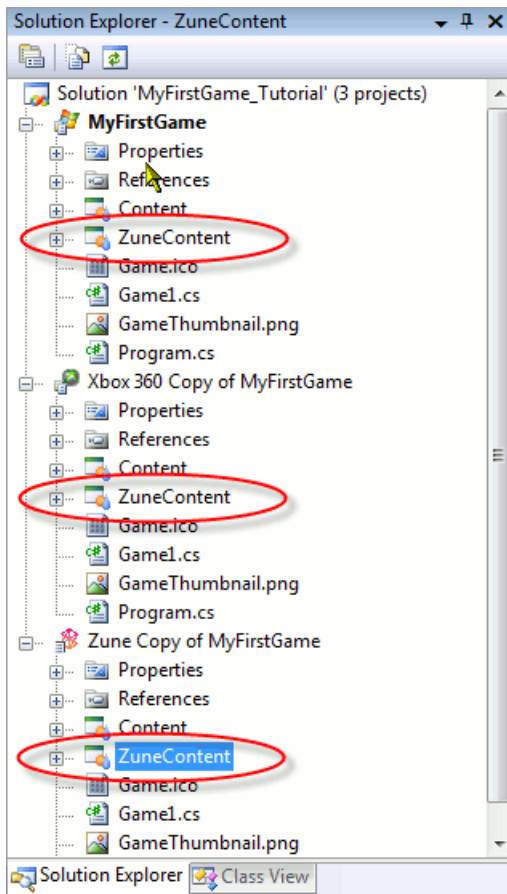

Creating Platform-Specific Content

Because different devices have different characteristics, you may need to maintain different content that is specific to each platform. In the example below, we create a content project for the Zune project that will contain low-resolution textures compatible with that device. We will also create content projects that are synchronized between the Windows project and the Xbox 360 project. These projects hold high-resolution textures that are compatible with both platforms, but are not part of the Zune project.

To create content projects exclusive to each platform project

1. In Solution Explorer, right-click the **Zune Copy of MyFirstGame** project, select **Add**, and then click **New Content Project...**
2. In the **Add New Content Project** dialog box, enter "ZuneContent" as the name for the new content project, and then click **Add**.

A new "ZuneContent" project has been added to all three projects.

3. Right-click the **ZuneContent** project in **MyFirstGame**, and then click **Remove**.

4. Right-click the **ZuneContent** project in **Xbox 360 Copy of MyFirstGame**, and then click **Remove**.

At this point, a "ZuneContent" project exists only in "Zune Copy of MyFirstGame." Any items added to this content project will be used exclusively by the Zune version of the game.

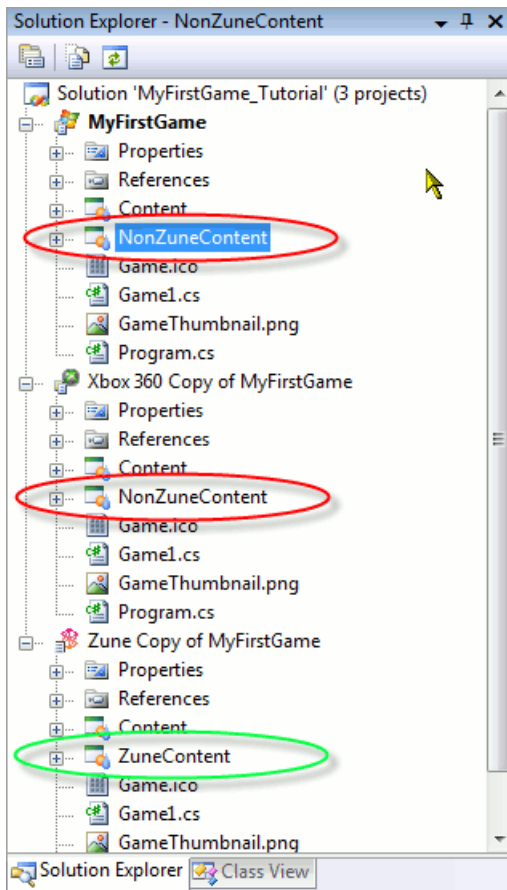

5. In Solution Explorer, right-click the **MyFirstGame** project, select **Add**, and then click **New Content Project...**

6. In the **Add New Content Project** dialog box, enter "NonZuneContent" as the name for the new content project, and then click **Add**.

A new "NonZuneContent" project has been added to all three projects.

7. Right-click the **NonZuneContent** project in **Zune Copy of MyFirstGame**, and click **Remove**.

The solution now has "NonZuneContent" projects in the Windows and Xbox 360 projects, and a "ZuneContent" project in the Zune project.

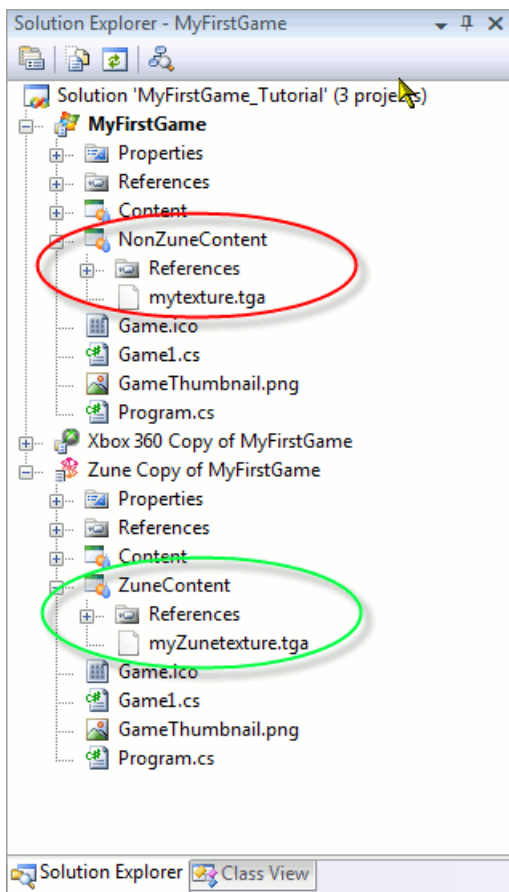

To populate the platform-specific content projects

1. In Solution Explorer, in the **MyFirstGame** project, click and drag the bitmap asset (for example, mytexture.tga) from the **Content** project to the **NonZuneContent** project.
2. In the **Content** project, right-click the bitmap asset (mytexture.tga), and select **Exclude From Project**.

The bitmap asset should now be in the "NonZuneContent" projects of both "MyFirstGame" and "Xbox 360 Copy of My First Game," and no longer in any of the projects' "Content" projects.

3. In Solution Explorer, in the **Zune Copy of MyFirstGame** project, right-click the **ZuneContent** project, select **Add**, and then click **Existing Item**.
4. In the **Add Existing Item** dialog box, select a bitmap file to add (for example, myZunetexture.tga).

This bitmap should be of appropriate resolution for the Zune device. You should now have the bitmap asset common to the Windows and Xbox 360 projects (mytexture.tga) in "NonZuneContent" and the bitmap asset for Zune (myZunetexture.tga) in "ZuneContent".

5. Right-click the newly-added file (myZunetexture.tga), and click **Properties**.
6. In the Properties pane, change the **AssetName** property to match the same name as the **AssetName** property of the version in the "NonZuneContent" project (for example, mytexture).

Setting this property to the same value will help the common source code to load the correct asset for the project's platform.

Using XNA Game Studio Device Center

Describes how to use the XNA Game Studio Device Center. The XNA Game Studio Device Center enables you make one or more game devices available for deployment of your games. These can be either Xbox 360 consoles or Zune devices. XNA Game Studio Device Center also lets you set the default device for deployment.

Accessing the XNA Game Studio Device Center

To access the XNA Game Studio Device Center, you can click the **Launch XNA Game Studio Device Center** on the **XNA Game Studio Device Management toolbar** from within Visual Studio.

Another way to access the XNA Game Studio Device Center is to use the **Start** menu.

- From the **Start** menu, choose **Programs**, choose **XNA Game Studio 3.1**, and then click **XNA Game Studio Device Center**.

When XNA Game Studio Device Center appears, it shows a list of game devices available for deploying and debugging XNA Game Studio games.

Adding a Game Device to the List of Devices Available for Deployment

You can use the **XNA Game Studio Device Center** to add a game device (either an Xbox 360 console or a Zune).

To add a game device

- Perform one of the following steps:
 - On the left-hand side of the screen, click **Add Device**.
 - or-
 - From the Visual Studio **XNA Game Studio Device Management** toolbar, click **Add a New Device**.

Either action brings up the **XNA Game Studio Devices** dialog box. This enables you to create a connection between your Windows-based computer and your game device.

You can find detailed step-by-step instructions on how to create a connection and add a game device to the list of devices in the following documents:

- [Connecting to Your Xbox 360 Console with XNA Game Studio 3.1](#)
- [Connecting to your Zune Device with XNA Game Studio](#)

Setting the Default Xbox 360 Console for Deployment

The default Xbox 360 is the console automatically selected for deployment and debugging when developing Xbox 360 console games with XNA Game Studio. The current default device is shared by all instances of XNA Game Studio that are running.

To set an Xbox 360 console as the default Xbox 360 device, right-click the icon for the device, and then click **Set as Default Xbox 360**.

If you have only one Xbox 360 console, that console automatically is selected as the default device.

Setting the Default Zune for Deployment

The default Zune is the Zune device automatically selected for deployment and debugging when developing Zune games with XNA Game Studio. The current default device is shared by all instances of XNA Game Studio that are running.

To set a Zune device as the default, right-click the icon for the device, and then click **Set as Default Zune**.

If you have only one Zune, that device automatically is selected as the default device.

Taking a Screen Capture from an Xbox 360 Console or Zune

The XNA Game Studio device center provides the ability to take a screen capture of an executing game on an Xbox 360 console or Zune. To take a screen capture, the following conditions must be met:

- The Xbox 360 console or Zune must be properly connected to the PC.
- The Xbox 360 console or Zune must be executing a game that was launched from Visual Studio.
- The game executing must have been built using the Debug configuration.

To take a screen capture through the Device Center

Once your game is deployed and executing on the game device according to the above conditions:

1. Right-click the icon for the device.
2. From the context menu, select **Take a Screen Capture**.

The captured screen will be displayed, and you can save it as a graphics file.

Removing a Game Device from the List of Devices

To remove a game device from the list of devices, either right-click the icon for the device and click **Remove**, or press the Delete key.

Using the List of Devices

The list of devices in XNA Game Studio Device Center is unique to each user. Each user can have a different list of game devices, and a different default device.

Visual Studio Unsupported Features

Describes the features of Visual Studio that are not supported for XNA Game Studio.

The following Microsoft Visual Studio items are not supported for XNA Game Studio projects:

- Creating or running Visual Studio Team System 2008 Test Edition unit tests for an Xbox 360 or Zune Game project. For this reason, the **Create Unit Tests...** command is hidden in the **Code Editor** context menu.
- Adding Windows Form, User Control, or Component classes to an Xbox 360 or Zune Game project. For this reason, these options are not available from the **Project** context menu.
- Adding service references to an XNA Game Studio project. For this reason, the **Add Service Reference** command is not available from the **References** context menu or the **Project** context menu.
- Adding Web references to an XNA Game Studio project. For this reason, the **Add Web Reference** command is not available from the **References** context menu or the **Project** context menu.
- Adding data sources. Data sources are not supported on the Xbox 360 or Zune platforms. For this reason, the **Data** menu is hidden when an Xbox 360 or Zune Game project is active.
- Publishing the project using the Visual Studio **Publish** command. This command is available from the **Build** menu for Windows projects only, as described in the topic [Distributing Your Finished Windows Game](#). This command is not available for projects on the Xbox 360 or Zune platforms. You should use the **Deploy** command instead. For more information on deployment, see [Deploying an Xbox 360 Game](#) or [Deploying a Zune Game](#).

Assembly Information Dialog Box

You can open the **Assembly Information** dialog box from the **Application** page in the Project Designer.

To open the Project Designer

1. Perform one of the following steps:
 - Under the project node in Solution Explorer, double-click the **Properties** folder.
-or-
 - From the **Project** menu, select **[project name] Properties**.
2. On the **Application page**, click **Assembly Information**.

Use this dialog box to change the assembly information for the current project. This information includes the game title, company name, copyright, and trademark, plus a brief description. When the game is installed on the target device (such as an Xbox 360 console or Zune), some of this information will be displayed in the game selection interface for that device.

The assembly information specified here only affects the values seen in the Xbox 360 Dashboard's **Game Library** if the project is a game project. Assembly information of library projects is not used when deploying or displaying information about a game.

Title

This field specifies a title for the assembly manifest, and is required to deploy a game to a game device. On most game devices, only the first 25 characters of this field are visible.

On the Xbox 360 console, the title appears in the **Game Library**.

On Zune, the title appears in the **Games** list.

Description

This field specifies an optional description for the assembly manifest. Only the first 300 characters of this field are visible.

On the Xbox 360 console, the description appears in the **Game Library**.

On Zune, the description appears after you select the game from the **Games** list.

Company

Specifies a company name for the assembly manifest.

Product

Specifies a product name for the assembly manifest.

Copyright

Specifies a copyright notice for the assembly manifest.

Trademark

Specifies a trademark for the assembly manifest.

Assembly Version

Specifies the version of the assembly.

File Version

Specifies a version number that instructs the compiler to use a specific version for the Win32 file version resource (Windows projects only).

GUID

Specifies a unique GUID that identifies the assembly. When you create a project, Visual Studio generates a GUID for the

assembly.

Neutral Language

Specifies which culture the assembly supports.

Make Assembly COM-Visible

Specifies whether types within the assembly will be accessible to COM (Windows projects only).

Platform Differences Summary

These are the differences in operation of the **Assembly Information** dialog box for specific platforms:

Platforms	Differences
Xbox 360, Zune	<ol style="list-style-type: none">1. The File Version field is not available.2. The Make Assembly COM-Visible check box is not available.

XNA Game Studio Device Management Toolbar

You can use the XNA Game Studio Device Management toolbar to maintain a list of one or more external game devices (such as Xbox 360 consoles or Zunes) available for deployment. It is available when you load a game project or game library project in supported versions of Visual Studio tools.

Platform Differences Summary

These are the differences in operation of the **Assembly Information** dialog box for specific platforms:

Platforms	Differences
Xbox 360, Zune	The XNA Game Studio Device Management toolbar is available.

Add Reference Dialog Box

Use the **Add Reference** dialog box to add component references required by your project. Because the Xbox 360 and Zune platforms do not have the same feature set as the Windows platform, the **COM** tab is hidden and the **.NET** tab contains only Xbox 360 or Zune-specific assemblies. These assemblies include:

- **Microsoft.Xna.Framework**
- **Microsoft.Xna.Framework.Game**
- **mscorlib**
- **system**
- **system.core**
- **system.xml**
- **system.xml.linq**

These assemblies are added automatically to an Xbox 360 or Zune project.

To open the **Add References** dialog box, right-click the **References** item in Solution Explorer, and then click **Add Reference**.

⚠Caution	
The Projects tab lists all projects in the solution, regardless of platform. The assemblies in the Browse and Recent tabs may also include references to assemblies that are not for the project's platform. Projects must only reference assemblies that are intended for their platform. For example, Xbox 360 projects do not support references to assemblies that target platforms other than Xbox 360, nor do Zune projects support assemblies that do not target Zune.	

Platform Differences Summary

These are the differences in operation of the **Assembly Information** dialog box for specific platforms:

Platforms	Differences
Xbox 360, Zune	<ol style="list-style-type: none">1. The COM tab is not available.2. The .NET tab contains only Xbox 360 or Zune-specific assemblies.

Add New Item Dialog Box

You can open the **Add New Item** dialog box by right-clicking the solution in Solution Explorer, or by selecting it from the **Project** menu. Use this dialog box to add new Xbox 360 or Zune-supported items. This list contains the following items.

- C# Class
- C# Interface
- C# Code File
- XML File
- XML Schema

Note

This option is available only in Microsoft Visual Studio.

- Text File
- Assembly Information File
- Resources File

Caution

The string resource type is the only built-in resource type supported by Xbox 360 or Zune projects. Adding other resource types such as bitmaps or icons to a resource file may result in compilation errors.

- Class Diagram

Note

This option is available only in Microsoft Visual Studio.

- Game Component
- Content Type Reader

The Assembly Information File template for Xbox 360 or Zune projects excludes the **AssemblyFileVersion** attribute. Neither the Xbox 360 platform nor the Zune platform support this attribute.

Project Properties

Project properties are grouped into pages in the Project Designer. You can access the Project Designer in the **Project** menu by clicking **Properties**, or by double-clicking the **Properties** item in Solution Explorer. The Project Designer property pages are located in the same middle pane used by the code editor.

- On the **Application** page, the **Target Framework** drop-down list box is disabled for Xbox 360 and Zune projects.
- On the **Build** page:
 1. The **Platform target** drop-down menu has been disabled in supported versions of Microsoft Visual Studio tools.
 2. The **Allow unsafe code** property is disabled for Zune.
- On the **Content Build** page, the **Compress content pipeline output files** check box is disabled for Zune projects.
- The **Debug** page has been modified for Xbox 360 and Zune game projects. The **Start Action** and **Enable Debuggers** options have been disabled. The **Working Directory**, **Use Remote Machine**, and **Enable the Visual Studio hosting process** controls have also been disabled.
- The **Settings** project property page allows you to add a settings file to your Xbox 360 or Zune project. However, note that the settings file is not supported for Xbox 360 or Zune projects.
- The **Security** and **Publishing** pages are hidden.

Application Properties Page

Enables the user to change application information for the current XNA Game Studio project.

You open the **Application Properties** page from Project Designer. Open Project Designer by double-clicking the **Properties** item in Solution Explorer or by clicking **[project name] Properties** on the **Project** menu. Then click the **Application** tab.

For information about using most of the fields on this page, see [Application Page, Project Designer \(C#\)](#).

There is also a field specific to XNA Game Studio that lets you specify a thumbnail image for a game project, as explained below.

Setting a Game Thumbnail

The **Game Thumbnail** box enables you set the thumbnail image that appears beside your game on the game device (such as Xbox 360 or Zune) when people are selecting games to play, and on Windows when people are selecting a game to unpack. This image is distinct from the Windows icon.

There are several things to keep in mind when specifying a thumbnail for your game.

File Requirements

- The image must be saved as a .png file.
- If the largest dimension of the image you provide is not exactly 64 pixels, the image will be scaled so that its aspect ratio remains the same and its largest dimension becomes exactly 64 pixels. Such scaling can produce results you might not expect. If you provide an image whose largest dimension is already exactly 64 pixels, you can avoid scaling.
- If you do specify an image that needs to be scaled, it must be smaller than 2048 pixels by 2048 pixels in size, and the .png file that contains it must be smaller than 16 KB in size.

File Location

- The thumbnail file must be specified in the game project. Files specified in the game content subproject will not be recognized as thumbnails.
- The **Game thumbnail** drop-down menu lists all files with a .png extension that have been added to your project, regardless of each file's size or resolution.
- You can also browse for any other .png files accessible from your machine by clicking the ... button beside the **Game thumbnail** drop-down menu. When you select a file from the browse dialog box, that file is added to your project and is set as the game thumbnail.

Content Build Compression

The following options enable you to configure settings for the build process of data in the content pipeline.

Compress content pipeline output files

Produce compressed output when processing content project data to reduce content size.

The defaults for this option vary according to the platform type and build configuration:

	Windows	Xbox 360	Zune
Debug	Off	On	Unsupported
Release	On	On	Unsupported

Game Component Development

Describes how to use XNA Game Studio to develop custom game components for your game projects. You derive the new component either from the [GameComponent](#) class, or, if the component loads and draws graphics content, from the [DrawableGameComponent](#) class. For more information about existing game component support in the XNA Framework, see the Game Components section of [Application Model Overview](#).

Developing Custom Components

XNA Game Studio supports the development of custom game components for use in your game code. You can use the **Add New Item** dialog box to insert basic code for implementing a new component.

To insert a new custom game component

1. Open an XNA Framework game or library project in XNA Game Studio.
2. In Solution Explorer, right-click the game project node.
3. Click **Add**, and then click **New Item**.
4. In the **Add New Item** dialog box, in the **Categories** pane, select **XNA Game Studio 3.1**
5. In the **Templates** pane, select the **Game Component** icon.
6. Enter a name for the source file, and then click **Add**.

The new code is composed of three main methods.

Method Name	Purpose
GameComponent1	The constructor for the game component. The name matches the name you specified when you inserted the new component. Add code that initializes the component here.
Initialize	Called by the framework when the component starts. Add the component-specific starting code here.
Update	Called by the framework when the component needs to be updated. Add the component-specific update code here.

After creating the new component, add your custom code to provide the necessary functionality.

Accessing Custom Item Templates

Describes how to access custom item templates. Visual Studio item templates represent items that a user can add to a project using the **Add New Item** dialog box. With a few modifications to the item template, you can make custom items represented by item templates available to XNA Game Studio projects.

Note

You can find detailed documentation of Visual Studio item templates in the Visual Studio 2008 documentation set [Creating Item Templates](#).

Item templates contain a .vstemplate file that provides an XML description of the template. For Xbox 360 and Zune projects, XNA Game Studio filters the item template list based on the contents of this file. To make an item template properly compatible with XNA Game Studio projects, add the **TemplateGroupID** element to the .vstemplate file.

Values for the **TemplateGroupID** depend on the targeted XNA Framework:

- For XNA Framework 3.0: **TemplateGroupID** can be "XnaFramework-v2," "XnaFramework-v2-Xbox360," "XnaFramework-v2-Zune," "XnaFramework-v2-Devices," and "XnaFramework-v2-Windows."
- For XNA Framework 3.1: **TemplateGroupID** can be "XnaFramework-v3.1," "XnaFramework-v3.1-Xbox360," "XnaFramework-v3.1-Zune," "XnaFramework-v3.1-Devices," and "XnaFramework-v3.1-Windows."

Note

For Windows projects, the **ShowByDefault** element will have a value of "false."

Example

The following XML example defines the **TemplateGroupID** element in the .vstemplate file of an Xbox 360 game-specific item template.

```
... <TemplateData>
  <Name>MyX360Class</Name>
  <Description>My custom Xbox 360 C# class.</Description>
  <ProjectType>CSharp</ProjectType>
  <TemplateGroupID>XnaFramework-v3.1-Xbox360</TemplateGroupID>
  <ShowByDefault>>false</ShowByDefault> ... </TemplateData> ...
```

Game Studio Automation Extenders

Describes DTE extenders to support automation in XNA Game Studio.

This section describes the special extenders that are provided by XNA Game Studio to aid automation within the structure of an XNA game project. These extenders provide mechanisms to retrieve project objects for content projects that are subordinate to code projects, and to retrieve the code project that is parent to a content project.

Retrieving Content Projects from a Code Project

The EnvDTE.Project objects for all content projects subordinate to a code project are retrieved through the EnvDTE.Project.Extender property for that code project. The object returned implements IEnumerable, so that it can be enumerated in a For Each clause. The enumerable items implement EnvDTE.Project.

The extender objects for subordinate content projects are referenced by the string:

```
"Microsoft.Xna.GameStudio.CodeProject.NestedContentProjectsExtender"
```

The following example outputs the name of all content projects within the current code project:

Visual Basic
<pre>Sub ShowNestedContentProjects() Dim proj As Project proj = DTE.Solution.Projects.Item(1) MsgBox(proj.Name & " has extenders " & Strings.Join(proj.ExtenderNames, ", ")) For Each nestedProj As Project In proj.Extender("Microsoft.Xna.GameStudio.CodeProject.NestedContentProjectsExtender") MsgBox(proj.Name & " has nested project " & nestedProj.Name) ShowParentCodeProjects(nestedProj) Next End Sub</pre>

Retrieving Code Projects from a Content Project

The EnvDTE.Project object that is parent to any content project is retrieved through the EnvDTE.Project.Extender property for the content project. The object returned implements IEnumerable, so that it can be enumerated in a For Each clause. The enumerable items implement EnvDTE.Project.

The extender objects for parent code projects are referenced by the string:

```
"Microsoft.Xna.GameStudio.ContentProject.ParentProjectsExtender"
```

The following example outputs the name of all of a content project's parent code projects:

Visual Basic
<pre>Sub ShowParentCodeProjects(ByVal contentProj As Project) Dim parents = New System.Collections.Generic.List(Of String) For Each parentProj As Project In contentProj.Extender("Microsoft.Xna.GameStudio.ContentProject.ParentProjectsExtender") parents.Add(parentProj.Name) Next MsgBox(contentProj.Name & " has parent projects " & Strings.Join(parents.ToArray(), ", ")) End Sub</pre>

A content project may have multiple parent code projects (as in a cross-platform solutions, where content is common to all platforms).

How To: Export an XNA Game Studio Project to a Template

Demonstrates how to manually modify a project template that has been exported from an existing XNA Game Studio project. It is assumed that an existing Windows or Xbox 360 game project is loaded in XNA Game Studio.

Creating an XNA Game Studio Project Template

This procedure enables you to create a template using the **Export Template** wizard, and to modify it to incorporate Game Content into the resulting template.

Note

The **Export Template** wizard of Visual Studio will create a template from an XNA Game Studio project, but it does not recognize the Content subfolder. To create a complete project template, it must be modified using the following manual process.

To create a template, you need to perform these procedures:

1. Export a game project template
2. Export a content project template
3. Merge the two templates manually into a custom template
4. Integrate the result into Visual Studio

You can perform the procedures shown here in either Visual Studio or Visual C# Express.

To create a game project template with the Export Template wizard

1. On the **File** menu, click **Export Template**.

The **Export Template** wizard opens.

2. Click **Project Template**.
3. Select the type of template that you want to create, and click **Next**.
4. Select an icon for your template.

This icon will appear in the **New Project** dialog box.

5. Enter a template name and description.
6. Uncheck the box labeled **Automatically import the template into Visual Studio**.
7. Click **Finish**.

Your project is exported into a .zip file and placed in the specified output location.

At this point in the procedure, you have created the base game project template that will be manually modified.

To create a content project template with the Export Template wizard

1. From the **File** menu, click **Close Solution**.

This closes the current solution.

2. From the **File** menu, click **Open**, and then click **Project/Solution**.
3. Type *.* in the File name field, and press **Enter**.
4. Browse to the Content subfolder of the game project that you just exported.
5. Open the Content.contentproj file to open the content project in its own solution.
6. On the **File** menu, click **Export Template**.
7. If prompted to save the solution, save it to a temporary location.

You can delete it later.

8. Using the wizard in the same manner as the previous sequence, complete the export process, and then click **Finish**.

If you did not uncheck the option to "Display an explorer window on the output files folder," an explorer window presents the folder containing the two ZIP (.zip) files created by the export process.

Next, you need to combine the two exported templates.

To extract the ZIP template

The templates created by the previous procedures are in the form of compressed ZIP files in the "My Exported Templates" folder. This procedure requires extracting the files contained in the ZIP templates, modifying the XML file that describe the project, and compressing the results to a new ZIP template.

1. From the Explorer window, extract the ZIP template for the game project to a temporary location:

Right click the .zip file, click **Extract All**, and then specify **C:\CustomTemplate** as the folder to which files will be extracted.

2. From the Explorer window, extract the ZIP template for the content project to a Content subfolder directly beneath the temporary location used in the previous step:

Right-click the .zip file, click **Extract All**, and then specify **C:\CustomTemplate\Content** as the folder to which files will be extracted.

To merge the two templates manually into a custom template

1. In Visual Studio, from the **File** menu, click **Open** to open the template (.vstemplate) file for the game project.

Specify the file **C:\CustomTemplate\MyTemplate.vstemplate**.

2. In the newly opened XML file, add the following element as a child of the <TemplateData> element:

Game Project XML File
<pre><PromptForSaveOnCreation>true</PromptForSaveOnCreation></pre>

Specifying this element will ensure that the user is prompted to name a new project when the template is used. If not specified, Visual Studio will default to creating a zero-impact project, which is not supported in XNA Game Studio.

3. Add the following XML after the <TemplateContent> element (still inside the <VSTemplate> element):

Game Project XML File
<pre><WizardExtension> <Assembly>Microsoft.Xna.GameStudio, Version=2.0.0.0, Culture=neutral, PublicKeyToken=6d5c3888ef60e27d</Assembly> <FullClassName>Microsoft.Xna.GameStudio.Wizards.NestedProjectWizard</FullClassName> </WizardExtension> <WizardData> <Folder Name="Content" TargetFolderName="Content"> <ProjectItem ReplaceParameters="true" TargetFileName="Content.contentproj">Content.contentproj</ProjectItem> <!-- Content goes here! --> </Folder> </WizardData></pre>

4. In Visual Studio, from the **File** menu, click **Open** to open the template (.vstemplate) file for the content project.

Specify the file **C:\CustomTemplate\Content\MyTemplate.vstemplate**.

5. In the newly opened XML file, locate the <Project> element.

Its child elements will consist of zero or more <ProjectItem> elements, one for each item that was in your exported Content project.

Content Project XML File
<pre><TemplateContent> <Project TargetFileName="Content.contentproj" File="Content.contentproj" ReplaceParameters="true" /> <ProjectItem ReplaceParameters="false" TargetFileName="Miramonte.spritefont">Miramonte.spritefont</ProjectItem> </Project> </TemplateContent></pre>

- Select the <ProjectItem> elements from the content project file, and click **Copy**.
- Paste the <ProjectItem> elements into the game project file—replacing the comment <!-- Content goes here! -->— and then click **Save**.

Game Project XML File

```
<WizardExtension>
  <Assembly>Microsoft.Xna.GameStudio, Version=2.0.0.0, Culture=neutral, PublicKeyToken=6d5c3888ef60e27d</Assembly>
  <FullClassName>Microsoft.Xna.GameStudio.Wizards.NestedProjectWizard</FullClassName>
</WizardExtension>
<WizardData>
  <Folder Name="Content" TargetFolderName="Content">
    <ProjectItem ReplaceParameters="true" TargetFileName="Content.contentproj">Content.contentproj
  </ProjectItem>
    <ProjectItem ReplaceParameters="false" TargetFileName="Miramonte.spritefont">Miramonte.spritefont
  </ProjectItem>
  </Folder>
</WizardData>
```

- In Explorer, browse to the folder where you extracted the game template (for example, C:\CustomTemplate).
- Press **CTRL+A** to select all files and folders in the directory.

Note

Do not select the CustomTemplate directory itself.

- Right-click the selection, and then click **Send To** and **Compressed (zipped) folder** to create a .zip file. It should be created in the same directory. The resulting file is your new, custom project template.

To integrate the custom template into Visual Studio

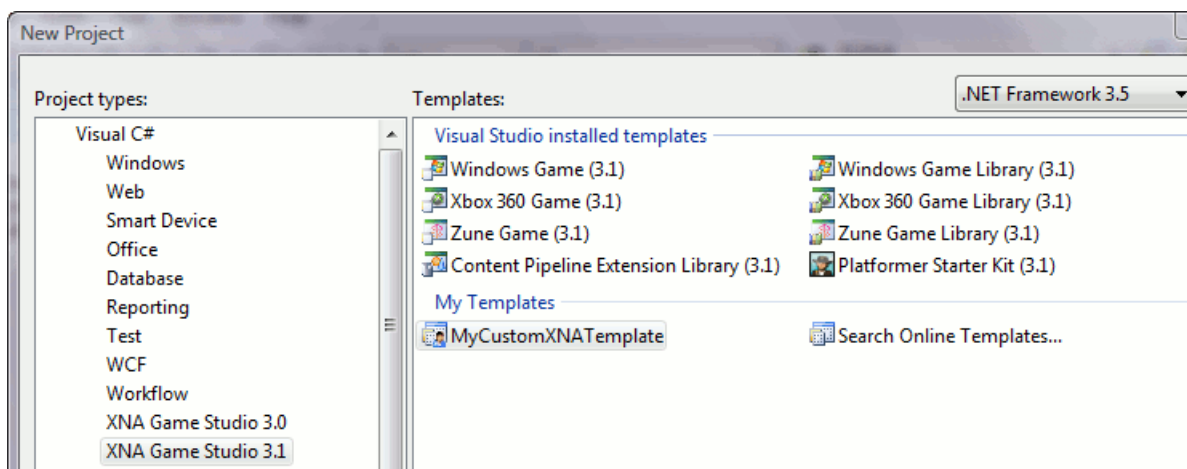

First, you need to find the path for your user templates folder.

- From the **Tools** menu, click **Options**.
- In the resulting dialog box, click the **Projects and Solutions** node.

The path is identified in the **Visual Studio user project templates location** setting. The default setting is a subfolder named ProjectTemplates.

- Copy the .zip file into a subdirectory called Visual C#\XNA Game Studio 3.1\.

When you complete this lengthy procedure correctly, your custom template will appear below the standard XNA Game Studio projects in the **New Project** dialog box. You can use it now.

Sharing and Distributing Your Game

When you've created something incredible and want to show it off to others, XNA Game Studio makes it easy.

The XNA Creators Club offers the best way to share your game with a wide community of gamers, to get feedback and build enthusiasm for your game.

There are a variety of ways to share and distribute your game.

- For all platforms, you can use the XNA Game Studio Package utility (xnapack.exe) to create a special package that other XNA Game Studio users can unpack and play. Using this utility allows you to share your game without exposing your source code or assets to other XNA Game Studio users.

You can share games packaged in this format with [XNA Creators Club](#) members through the [XNA Creators Club Web site](#) for peer review, and possible listing on Xbox LIVE Marketplace.

- For all platforms, you can choose to share your source code and assets with other XNA Game Studio users. This is useful if you would like someone to review or modify your code or assets.
- For Windows games only, you can make your game available to any Windows user by distributing your completed game executables, along with a set of prerequisite software (called "redistributables"). All Windows users can play your game, even if they do not have XNA Game Studio installed on their computer.

The following are the available sharing options for Windows, Xbox 360 and Zune.

	Sharing Your Game Package	Sharing Your Source Code and Assets	Distributing Your Finished Windows Game
Windows	...with XNA Game Studio users	...with XNA Game Studio users	...with any Windows user
Xbox 360	...with XNA Creators Club members ...through Xbox LIVE Marketplace (after a approval)	...with XNA Creators Club members	
Zune	...with XNA Game Studio users	...with XNA Game Studio users	

See the sections below for more information on each sharing and distribution type, including how to prepare your game to be shared or distributed, and how to play a game someone has shared with you.

In This Section

[Sharing Your Game Package](#)

Sharing Your Game Package

Describes how to distribute your game to other XNA Game Studio users in a package that protects your source code and assets.

Quick Information

Platform	Source Code Visible	Format	Windows User Requirements	Xbox 360 User Requirements	Zune User Requirements
Windows, Xbox 360 and Zune	No	.ccgame XNA Creators Club Game Package	<ul style="list-style-type: none"> Must have XNA Game Studio installed. 	<ul style="list-style-type: none"> Must have XNA Game Studio installed. Must have an active membership in the XNA Creators Club. 	<ul style="list-style-type: none"> Must have XNA Game Studio installed.

If you would like to share your XNA Game Studio game with other XNA Game Studio users, but do not want to share your source code and assets, you can use the XNA Game Studio package utility (xnpack.exe). You can use the package utility from within supported versions of Microsoft Visual Studio tools, or from the command line.

You can share games packaged in this format with [XNA Creators Club](#) members through the [XNA Creators Club Web site](#) for peer review and possible listing on the Xbox LIVE Marketplace.

Note
Currently, only Xbox 360 games can be shared through XNA Creators Club.

There are two fundamental ways that a game package can be used:

- [Sharing a Game with Another User](#)
- [Sharing a Game from Another User](#)

Sharing with Another User

The XNA Game Studio package utility compresses your game's built executable and assets into a special compressed format that other XNA Game Studio users can open and play. You may package only XNA Game Studio game projects. The package utility does not support XNA Game Studio library projects.

To package your game using the XNA Game Studio package utility from the Visual Studio development environment

1. In XNA Game Studio, open the project you want to package.
2. On the **Build** menu, click **Package [projname] as XNA Creators Club Game**, where [projname] is the name of the current project.

The output window indicates the status of the packing operation. If the packing operation is successful, the package file will be created with a .ccgame extension, and placed in the appropriate output folder of the project. For example, the package file for the release version of your Windows game would be located in the bin\x86\Release folder. This example assumes that the default project settings have not been modified.

You may share this .ccgame file with other XNA Game Studio users. It is a compressed version of your project that contains no source code or source assets. Other users can play it, but they will not be able to view or modify your source files.

To package your game using the XNA Game Studio package utility from the command line

1. To open an XNA Game Studio command line, open the **Start** menu, click **XNA Game Studio 3.1**, click **Tools**, and then click **XNA Game Studio Command Prompt**.
2. From the command line, use the **cd** command to change the active folder to the appropriate output folder of the project you want to package.
3. Enter a packing command using the following syntax:

```
xnpack assembly [platform] [/nologo] [/output:file] [/quiet] [/thumbnailfile]
```

The command-line parameters are:

Parameter	Usage
<i>assembly</i>	The startup assembly of your project. This is the .exe built by your XNA Game Studio project.
[<i>platform</i>]	Deprecated and optional. Specifies the platform for which the project is built. This value can be "Windows," "Xbox360," or "Zune," and must match your game's project type.
[/nologo]	Suppresses logo/copyright messages.
[/output:file]	Specifies the path and file name of the output file. By default, your game is created in the same folder as the startup assembly with the same name. (Short form: /o:)
[/quiet]	Suppresses all non-error messages.
[/thumbnail:file]	Specifies the path to an optional thumbnail that is displayed with your game. (Short form: /th:) For a Windows game, this thumbnail appears in the graphical unpacking utility. For an Xbox 360 game, the thumbnail also appears in the Game Library . For a Zune game, the thumbnail appears in the Games list.

The following example packs a Windows game called `MyWinGame` and suppresses the logo/copyright messages.

```
xnapack MyWinGame.exe /nologo
```

The Command-line window indicates the current status of the packing operation. If the packing operation is successful, you created the package file, and it is in the same folder as the startup assembly, with a `.ccgame` extension.

After you packed a game, you may share the `.ccgame` file with other XNA Game Studio users. It is a compressed version of your project that contains no source code or source assets. Other users can play it, but they will not be able to view or modify your source files.

Sharing from Another User

When you receive a `.ccgame` file from another XNA Game Studio user, you can use either the graphical unpacking utility or the command-line utility to unpack it.

Consider the following before unpacking.

- You must have XNA Game Studio installed.
- Unpacking a `.ccgame` file automatically deploys the assets and game assembly to the target platform.
 - For a Windows project, you must have the same version of the XNA Framework installed with which the `.ccgame` file was built.
 - For an Xbox 360 project, you must have at least one Xbox 360 console specified already in **XNA Game Studio Device Center**, you must have a valid XNA Creators Club membership, and you must have XNA Game Studio Connect running on the Xbox 360 console to which you are deploying the assets and game assembly.
 - For a Zune project, you must have at least one Zune digital media device specified in **XNA Game Studio Device Center**.

To unpack a packaged game from Windows Explorer

1. From Windows Explorer, double-click the `.ccgame` file you want to unpack.

A dialog box appears.

2. Click **Unpack** to begin the unpacking process.
3. When the unpacking process is complete, the next step depends on the platform.
 - For a Windows project, when the unpacking is complete, a folder containing the game executable opens in Windows Explorer. Run the game by double-clicking the executable.
 - For an Xbox 360 project, when the unpacking is complete, you can run the game from the **Game Library**.
 - For a Zune project, when the unpacking is complete, you can run the game from the **Games** list.

 **Caution**

If the intended destination of an unpacked game already exists, the XNA Game Studio package utility deletes the existing destination and its contents. It then creates a new container or folder containing the contents of the new game package. This applies to games targeting Xbox 360, Zune, and Windows platforms.

To unpack a packaged game from the command line

1. To open an XNA Game Studio command prompt, open the **Start** menu, click **XNA Game Studio 3.1**, click **Tools**, and then click **XNA Game Studio Command Prompt**.
2. From the command line, use the **cd** command to change the active folder to the folder containing the appropriate package.
3. Enter an unpacking command using the following syntax.

```
xnapack unpack package [/listplatforms] [/listtargets] [/nologo] [/platform:name] [/quiet] [/run] [/showui]
[/target:name]
```

The command-line parameters are:

Parameter	Usage
<i>package</i>	An XNA Framework game package, previously created with the XNA Game Studio package utility. If the game is intended for the Xbox 360 console, see Connecting to Your Xbox 360 Console with XNA Game Studio 3.1 for information about adding registered consoles to your computer. If the game is intended for the Zune digital media device, see Connecting to your Zune Device with XNA Game Studio for information about adding registered devices to your computer.
/listplatforms]	Lists the platforms that support the XNA Creators Club game package.
/listtargets]	Lists the platform instances for a given platform. Must be used with /platform option.
/nologo]	Suppresses logo/copyright messages.
/platform:<i>name</i>]	Specifies the platform to which the game package is being deployed. Required if the package supports more than one platform and the target cannot be resolved.
/quiet]	Suppresses all non-error messages.
/run]	Runs the game once installation is complete. Applies only to Xbox 360 and Zune games.
/showui]	Displays the user interface for confirming and copying files.
/target:<i>name</i>]	Specifies the named platform instance to which the game package is being deployed. If no platform instance is specified, the default target is used. For a list of available targets, use the /listtargets option.  Note This option replaces the obsolete option /console .

The following example unpacks an XNA Creators Club game package containing a Windows game called `MyWinGame`, and suppresses all non-error messages.

```
xnapack unpack MyWinGame-Windows.cgame /quiet
```

4. When the unpacking process is complete, the next step depends on the platform.
 - For a Windows project, when the unpacking is complete, a folder containing the game executable opens in Windows Explorer. Run the game by double-clicking the executable.
 - For an Xbox 360 project, when the unpacking is complete, you can run the game from the **Game Library** on your Xbox 360 console.
 - For a Zune project, when the unpacking is complete, you can run the game from the **Games** list on your Zune device.

Caution

If the intended destination of an unpacked game already exists, the XNA Game Studio package utility deletes the existing destination and its contents. It then creates a new container or folder containing the contents of the new game package. This applies to games targeting Xbox 360, Zune, and Windows platforms.

Sharing Your Source Code and Assets

Presents information about sharing your game's source code and assets with other XNA Game Studio users.

Quick Information

Platform	Source Code Visible	Format	Windows User Requirements	Xbox 360 User Requirements	Zune User Requirements
Windows, Xbox 360 and Zune	Yes	.zip or other compressed format	<ul style="list-style-type: none"> Must have XNA Game Studio installed. 	<ul style="list-style-type: none"> Must have XNA Game Studio installed. Must have an active membership in the XNA Creators Club. 	<ul style="list-style-type: none"> Must have XNA Game Studio installed.

Sharing your entire project, including source code and content, is useful when you want other users to review your code or content, or make modifications. However, in some cases you may not want others to see your source code or assets. If you want feedback on gameplay or existing game art, and don't explicitly need your code to be reviewed, consider the method described in [Sharing Your Game Package](#).

Sharing to Another User

To share your project, including source code, with an XNA Game Studio user

- In XNA Game Studio, open the project you want to share.
- On the **Build** menu, click **Clean Solution**.
This removes any built and intermediate files, leaving only the source code and assets. If you do not have this menu item, see "Cleaning the Solution Before You Build" in [Deploying an Xbox 360 Game](#).
- Open Windows Explorer, and browse to the folder that contains the project you want to share.
- Right-click on the project folder in Windows Explorer, click **Send To**, and then click **Compressed (zipped) Folder**.

The compressed file is ready to share.

Sharing from Another User

To open a project with source code as an XNA Game Studio user

- Upon receiving a compressed file with source code and assets, extract the contents into a folder.

Tip

If it is a .zip file, you can right-click the file in Windows Explorer, click **Open With**, and then click **Compressed (zipped) Folders** to begin the extraction process.

- After the files are extracted, start XNA Game Studio.
- In XNA Game Studio, click the **File** menu, and then click **Open Project**.
- Use the dialog box to browse to the project folder you specified in Step 1, and select the .csproj file.
- Click **Open**.

The project is loaded into XNA Game Studio and ready for viewing or modification.

Distributing Your Finished Windows Game

Presents information about how to share your game with any Windows user, even if the user does not have XNA Game Studio installed.

Quick Information

Platform	Source Code Visible	Format	Windows User Requirements
Windows	No	Setup.exe and manifest, or .zip or other compressed format	<ul style="list-style-type: none"> • Must be running at least Windows XP Service Pack 2. • Must have a video card that supports at least Shader Model 1.1.

Important

Games for Windows - LIVE is not available to finished games. This functionality is not included in the redistributable version of the XNA Framework. A game that attempts to use these components without XNA Game Studio installed will result in a [GameServicesNotAvailableException](#).

Also, the XNA Framework Redistributable file does not contain the [Content Pipeline Build Runtime](#). Building content at run time is supported only when XNA Game Studio has been installed on the Windows-based development computer.

If you would like to share your XNA Game Studio game with other Windows users, but do not want to share your source code and assets, you can create an installable package that contains your game binaries and the necessary redistributable files.

The ClickOnce publishing feature of Visual Studio provides a convenient way to produce a portable installation package for distribution on a CD, Web site, or other media.

Sharing With Another Windows User

You may package XNA Game Studio game projects for use without XNA Game Studio installed only for the Windows platform.

You can use one of the following methods to create a portable install package:

Using ClickOnce Deployment

You can use the [ClickOnce](#) feature of Visual Studio to build and create an installation package for your XNA Game Studio game. This method automatically ensures that all required supporting files are included in your installation package.

Using Another Installation Package Tool

You can use an installation package tool of your choice. With this method, you must take more care to include all of the required supporting files for an XNA Game Studio game.

Using ClickOnce Deployment

ClickOnce is a deployment technology that allows you to create self-updating Windows-based applications that can be installed and run with minimal user interaction.

To build a ClickOnce installation package

1. In **Solution Explorer**, select the game project for the Windows platform to which you want to deploy.
2. From the **Build** menu, click **Publish**.
The Publish Wizard appears.
3. In the **Where do you want to publish the application?** page, enter the file path or FTP location where the application will be deployed.
The default location is a folder named "publish" beneath the project's folder.
4. Click **Next** to continue.
5. In the **How will users install the application?** page, select the **From a CD-ROM or DVD-ROM** option if that is your choice (the default), and then click **Next** to continue.
6. In the **Where will the application check for updates?** page, choose an update option:
 - If the application checks for updates, click **The application will check for updates from the following**

Location, and enter the location where updates will be posted. This can be a file location, Web site, or FTP Server.

- If the application will not check for updates, click **The application will not check for updates**.
- Click **Next** to continue.

7. Click **Finish** to deploy the application.

Visual Studio builds your XNA Game Studio game project and, if successful, deploys your application to the location specified in step 3. A Windows Explorer window then opens to show the Setup.exe file produced and the manifest.

The ClickOnce feature for XNA Game Studio automatically includes all of the required software packages as part of the installation package.

An alternate method of initiating ClickOnce is through the **Publish** properties of the Project Designer. These can be accessed by double-clicking the **Properties** item in Solution Explorer or by clicking **[project name] Properties** on the **Project** menu. Then click the **Publish** tab. This tab provides the facility to set several more options, including the version number of the deployed application.

If you wish to distribute your game on a CD, use a CD-Rewriter or DVD-Rewriter to copy the files from the specified location to the CD-ROM or DVD-ROM media.

Special Considerations for Game Data Files

Your game may require the use of a data file to read and store information. For example, the starter kit provided with XNA Game Studio uses an XML file to read and store game settings. Other games may use a text file or other format.

The default behavior of the ClickOnce publishing wizard assigns any XML, text or other data files in a project to "Data File" as its Publish Status. However, this status is for files containing data used by the installer package, not for files accessible to your game when it executes. Files assigned to this type will be placed in the path denoted in the .NET Framework's ApplicationDeployment.DataDirectory property.

This is likely to be inconvenient, as the file will not be accessible to your game through conventional storage APIs. The recommended actions to correct this are as follows:

1. Ensure that the **Build Action** property of the data file is set to "Content." This specifies that the data file is to be included in the install package.
2. Reassign the Publish Status to "Include."

The **Build Type** setting may be changed through the file's property window.

The Publish Status is changed through the **Application Files** dialog box of the **Publish** properties section of Project Designer.

To change the Publish Status

- Double-click the **Properties** item of your project in Solution Explorer.
- Navigate to the **Publish** tab in Project Designer.
- Click the **Application Files** button.
- Select the drop-down box in the **Publish Status** column of the dialog box to change the setting.
- Click **OK**.

Using Another Installation Package Tool

To use an installation package tool other than ClickOnce, you will need to build your game binaries and include the required software packages.

To compile your game binaries for distribution with another installation package tool

1. In XNA Game Studio, open the project you want to package.
2. From the **Build** menu, click **Build Solution**.

This creates the necessary files needed to run your game on other computers.

3. Using an installation package tool of your choice, package all files located in the appropriate output directory of your project.

Required Software Packages

In addition to the requirements listed in the previous table, there are additional software prerequisites that must be installed on a player's machine if the computer does not have XNA Game Studio installed.

The following software packages must be installed on the player's computer in order for your game to run.

- The [.NET Framework 3.5 Redistributable](#).
- The [XNA Framework Redistributable 3.1](#).

Tip

You can verify that your game was built with the XNA Framework 3.1 by loading your project in XNA Game Studio, and clicking the project node in Solution Explorer. The **XNA Framework Version** property is visible in the property pane.

To determine whether the player already has the redistributable installed, use the Windows Installer function [MsiQueryProductState](#) with the product code for the version of the redistributable that you want to verify. The following table lists the product code for the XNA Framework Redistributable 3.1.

Redistributable Version Corresponding To...	Product Code
XNA Game Studio 3.1 (English)	19BFDA5D-1FE2-4F25-97F9-1A79DD04EE20
XNA Game Studio 3.1 (Japanese)	F037A396-7FA3-4FB4-ACB8-3C6FE57B02BD

An alternative to checking the product code for the version of the XNA Framework Redistributable for XNA Game Studio 3.1 is to check the registry for the following value:

```
[HKEY_LOCAL_MACHINE\Software\Microsoft\XNA\Framework\v3.1]
Installed=1
```

- The following files from the [DirectX 9.0c Redistributable](#).
 - OCT2006_d3dx9_31_x86.cab
 - APR2007_d3dx9_33_x86.cab
 - APR2007_xinput_x86.cab
 - Mar2009_xact_x86.cab
 - Mar2009_XAudio_x86.cab
 - Mar2009_X3DAudio_x86.cab
 - DSETUP.dll
 - dsetup32.dll
 - DXSETUP.exe
 - dxupdate.cab

These files are installed automatically as part of the XNA Framework Redistributable install package for XNA Game Studio 3.1. You don't need to follow a separate install step when you create games with this version of XNA Game Studio.

Content Pipeline

Provides an overview of the Content Pipeline. The XNA Game Studio Content Pipeline builds art assets that you have included in your project into a form your game can load at run time on either Windows or the Xbox 360 game machines by calling [ContentManager.Load](#).

This build process for art assets is controlled by Content Pipeline importers and content processors. When you press F5 to build a game created with XNA Game Studio, the appropriate Content Pipeline importer and processor for each asset is invoked, and that asset is automatically built into your game.

The flexibility of this process enables you create and update art assets using a wide variety of digital content creation (DCC) tools. XNA Game Studio supplies importers for several popular export formats supported by DCC tools, and also lets you develop custom importers for other formats.

Overview of the Content Pipeline

Describes how the XNA Game Studio Content Pipeline lets you build art assets into your game automatically from the file formats in which they are maintained.

Most games use art in the form of models, meshes, sprites, textures, effects, terrains, animations, and so on. Such art assets can be created in many different ways and stored in many different file formats. They tend to change frequently in the course of game development.

The Content Pipeline is designed to help you include such art assets in your game easily and automatically. For example, an artist working on a car model can add the resulting file to the XNA Game Studio game project, assign the model a name, and choose an importer and content processor for it. Then a developer who wants to make the car drive can load it, by name, using a call to [ContentManager.Load](#). This simple flow enables the artist to focus on creating assets and the developer to focus on using them, without either having to spend time worrying about content transformation.

Purpose of the Content Pipeline

The XNA Framework Content Pipeline is designed to:

- Enable game artists to use the digital content creation (DCC) tools of their choice.
- Provide a mechanism to decouple digital content's dependency on a particular game engine.
- Provide a simple, expandable content build system that meets the needs of both artists and developers.

Basics of the Content Pipeline

Recognizing that DCC tools save content in many different file formats, the XNA Game Studio Content Pipeline enables you build art assets into your game automatically from the file formats in which they are maintained. Here's a high-level view of how it works.

- XNA Game Studio supplies standard importers and processors for a number of popular DCC file formats (see [Standard Importers and Processors](#)).
- Third parties also create custom importers and processors for XNA Game Studio to support additional formats.
- If you have enough information about a DCC file format, you can write your own custom importer and processor for it using classes provided by the Content Pipeline class library (see [How To: Write a Custom Importer and Processor](#)).
- When you include an art asset file in your XNA Game Studio game project, you use its Properties sheet to specify the appropriate importer and processor. Thereafter, when you press F5 to build your game, the proper importer and processor for each asset is invoked automatically. The asset is built into your game in a form that can be loaded at run time on Windows or the Xbox 360 by using [ContentManager.Load](#).

Importers vs. Content Processors

- An *importer* takes art assets saved in a particular DCC file format and converts them into objects in the XNA Game Studio Content DOM (document object model) that standard content processors can consume, or into some other custom form that a particular custom processor can consume.
- A *processor* takes one specific type of imported art asset, such as a set of meshes, and compiles it into a managed code object that can be loaded and used by XNA Game Studio games on Windows and the Xbox 360.

Automatic Serialization of .XNB Files

Custom content types are processed by the Content Pipeline with a custom importer and run-time processor, which are supplied by you or by an external developer. Part of the process is handled by the Content Pipeline's XNB Serializer. It is responsible for writing to and reading from the intermediate format (.XNB) used by XNA GS. Before XNA GS 3.1, a custom writer (implemented by a user-defined class based on [ContentTypeWriter](#)) was needed to write the custom content data to the .XNB file. In addition, a custom reader (implemented by a user-defined class based on [ContentTypeReader](#)) was needed to read the custom content data from the .XNB file and initialize the proper type with that data.

Starting with XNA Game Studio 3.1, the serialization of custom data to the .XNB format is done automatically for simple types that do not have an existing content type writer. This means that it is no longer necessary to implement a separate writer and reader class for each custom data type.

 **Note**

If your run-time class matches the layout of the design-time class, the Content Pipeline XNB Serializer automatically recognizes the relationship of the two types, and the run-time object is properly loaded with the serialized data. However, if the two differ in a significant way, the [ContentSerializerRuntimeType](#) attribute must be applied to the design time type. This specifies the correct class to initialize with the serialized data.

For instance, the previous version of the SpriteSheet sample implemented a custom writer (called `SpriteSheetWriter`) and a custom reader type (`SpriteSheetReader`). These classes serialized the output data from the processor into XNB format (`SpriteSheetWriter`), and deserialized that same data at run time (`SpriteSheetReader`) into a `SpriteSheet` object.

As mentioned previously, if the output type from the Content Pipeline differs from the run-time type, you will need to use the [ContentSerializerRuntimeType](#) attribute. This is demonstrated in the updated SpriteSheet sample, available on the Creator's Club [Web site](#). The `SpriteSheetContent` class declaration has the following line of code:

```
[ContentSerializerRuntimeType("SpriteSheetRuntime.SpriteSheet, SpriteSheetRuntime")]
```

This tells the serializer into which type the content should be loaded when `ContentManager.Load` is called. This is required because the texture field differs in type between the two classes: `Texture2D` versus `Texture2DContent`.

Note

If you move the run-time `SpriteSheet` class into a different namespace or assembly, you must also update the type's location, which is specified in the [ContentSerializerRuntimeType](#) attribute.

In addition to the [ContentSerializerRuntimeType](#) attribute, you can also version-type your custom content types by applying the [ContentSerializerTypeVersion](#) attribute.

Model Processing with the XNA Framework Content Pipeline

Describes the model conversion process implemented by XNA Framework Content Pipeline.

The conversion of a game asset in your project is a complex and detailed process comprised of many steps. The detailed description of the general process can be found [here](#). However, it can also be helpful to follow the process from the perspective of a single game asset type—specifically, a model. This discussion focuses on one section (a horizontal cross-section, starting with the top asset group) of the Content DOM graphic, shown [here](#).

Output from the Content Importer

The content pipeline content DOM represents an exported scene (from a modeling package) as a hierarchy of [NodeContent](#) objects. This means that a content importer designed to import a 3D scene or model must convert a 3D file into a [NodeContent](#) hierarchy containing a parent, a transform, and a collection of children. Some of these nodes will be of type [MeshContent](#), derived from [NodeContent](#). They represent the 3D objects in the scene with a mesh of triangles.

A [MeshContent](#) object is composed of a collection of [GeometryContent](#) objects. All triangles within a [GeometryContent](#) object have the same material applied to them. Their vertices contain the same type of per-vertex data, such as normals and texture coordinates. Since each [GeometryContent](#) collection is contained by a single [MeshContent](#) object, they share the same world transform.

Each [GeometryContent](#) object contains a [VertexContent](#) object (storing the values of all per-vertex data channels, and also indices into the shared [Positions](#) collection in the parent [MeshContent](#)) and an [IndexCollection Class](#), containing indices into the [VertexContent](#) object.

The content pipeline content DOM represents a model material by the [MaterialContent](#) class. [MaterialContent](#) has two derived classes often used by the content pipeline: [BasicMaterialContent](#) and [EffectContent](#). Think of [BasicMaterialContent](#) as the content pipeline equivalent of [BasicEffect](#). In the same vein, [EffectContent](#) is the content pipeline equivalent of [Effect](#).

Output from the Model Processor

The scene hierarchy (previously created by the content importer) is the input of the model processor (implemented by [ModelProcessor](#)) and is converted into a format usable by your game at run time. Optimization, such as reordering mesh triangles to maximize cache coherency, is also performed at this time. The conversion of content importer output to a run-time type or types, is the main goal of the model processor.

The types output by [ModelProcessor](#) are close to the final XNA Framework run-time types. For example, the [ModelProcessor](#) output type [ModelContent](#) corresponds to the XNA Framework run-time type [Model Class](#). This class is similar to the run-time type but stores the model data as simple managed objects, rather than GPU data types. This approach avoids the instantiation of actual GPU objects during the XNA Game Studio Content Pipeline build process. This is essential when building graphics for the Xbox 360 platform because instantiation of these types on the Windows GPU during the build process would not be feasible.

Conversion of the scene hierarchy is broken down as follows:

The entire scene hierarchy, represented by a root [NodeContent](#) and its children, is converted to a [ModelContent](#) object.

Note

Children of type [NodeContent](#) are turned into [ModelBoneContent Class](#) objects, and children of type [MeshContent](#) are turned into [ModelMeshContent](#) objects.

All [GeometryContent](#) objects, containing the actual triangles, are converted to [ModelMeshPart](#) objects. As mentioned previously, a [GeometryContent](#) object contains a [VertexContent](#), [IndexCollection](#), and [MaterialContent](#) object. Although the [ModelProcessor](#) modifies the data in the [IndexCollections](#), it does not change the type. The [VertexContent](#) object, received as input, has two corresponding output types: a [VertexBufferContent Class](#), containing the optimized triangle data, and an array of [VertexElement Structure](#) objects, specifying the data contained in the [VertexBufferContent Class](#).

The last step hands off any [MaterialContent](#) objects in the scene by chaining to the [MaterialProcessor](#).

See Also [Content Pipeline](#)
[Content Pipeline Architecture](#)

Content Pipeline Architecture

Describes the architecture of the XNA Game Studio Content Pipeline build process. The process is designed to be extensible, so that it can easily support new input file formats and new types of conversion.

While most users of the Content Pipeline can ignore its inner workings, if you are a game developer who wants to create a new importer and processor to support a new file format or game-engine capability, it is useful to understand the stages that the Content Pipeline passes through as an asset is transformed from a digital-content creation (DCC) output file to part of the game binary.

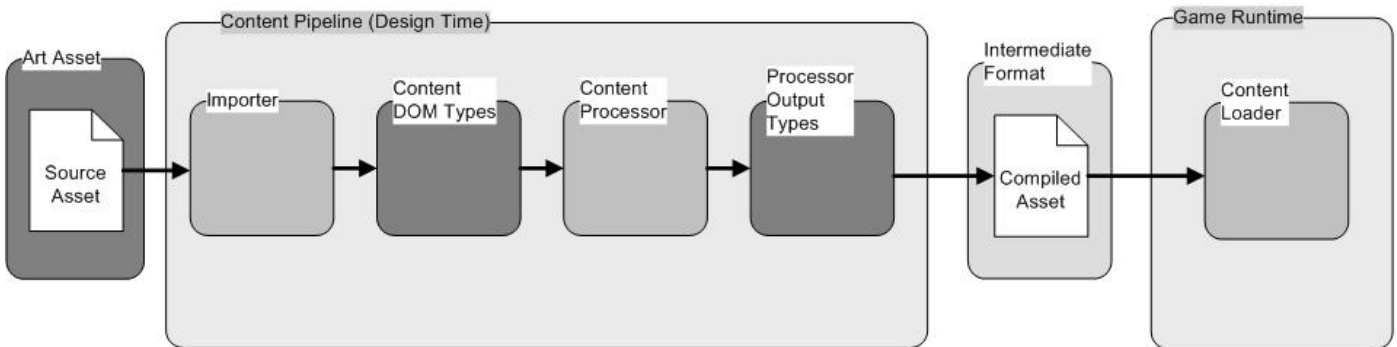

Build-Management Functionality

Once an art asset (such as a car model) is added to an XNA Game Studio project, the Content Pipeline integrates it into the Visual Studio build just as it would any other source file, providing error handling, status information, and other standard build features. For information on how to set Content Pipeline build options, see [Game Asset Properties](#).

In the course of a build, the Content Pipeline invokes four principal components to perform different parts of the transformation from a DCC output file into a binary part of an XNA Game Studio game.

1. [Importer](#)
2. [Content Processor](#)
3. [Content Compiler](#)
4. [Content Loader](#)

The following figure shows the flow of this build process.

Importer and Content DOM Types

XNA Game Studio provides a number of standard importers, which are listed in [Standard Importers and Processors](#). This includes an importer for the Autodesk .fbx format, and one for the DirectX .x format. These importers simplify the importing of art assets, since many DCC tools can export content to one of these formats as well as to their own native formats.

For art assets that are available only in formats not supported by XNA Game Studio standard importers, custom importers may be available as well. Such custom importers can be developed by DCC vendors, game-engine developers, or interested game hobbyists. For more information about how to do this, see [How To: Write a Custom Importer and Processor](#). Once you install a custom importer on your computer, you can associate those art files with the importer in order to invoke the importer whenever you build the art files (see [Using a Custom Importer or Content Processor](#)).

In many cases, Content Pipeline importers convert any content they can into managed objects based on the Content Document Object Model (DOM), which includes strong typing for assets such as meshes, vertices, and materials.

The Content Pipeline can use XML cache files in subsequent passes to speed up game content builds as well as to debug. When a content processor requests that a specified file be imported (typically using the [BuildAndLoadAsset](#) method in its [Process](#) function) and there is an up-to-date cache file already, the Content Pipeline deserializes the cache file instead of invoking the importer. These XML cache files are not used externally, however, because their format may well change in future releases.

Instead of producing standard Content DOM objects, a custom importer may produce custom objects for a particular custom content processor to consume.

Content Processor

A content processor accepts as input the output generated by an importer. Each content processor is tied to specific object types. For instance, the [Effect Processor](#) accepts only [EffectContent](#) objects, representing a DirectX Effect asset. As discussed previously, in many cases, this output consists of standard Content DOM objects, but may also consist of custom objects.

A content processor then produces managed objects that can be used in a game at run time. In the case of standard Content DOM objects, this transformation can be performed by classes in the Content Pipeline class library. However, if a content processor generates custom managed objects, you must provide full functionality for them, including saving and loading to and from a binary file. For more information, see [How To: Write a Custom Importer and Processor](#).

Content Compiler

After you add the various game assets to the project and the content processors generate managed code, the managed code is serialized into a compact binary format (also referred to as an intermediate format) by the Content Pipeline content compiler. This format is tightly coupled to the XNA Framework. It is not designed for use by other run-time libraries. At this point, the asset has been processed by the Content Pipeline and is in a format that can be used by your game at runtime. See the diagram above for details.

Content Loader

When you need the compiled asset in a game, call the [ContentManager.Load](#) method to invoke the content loader. The content loader then locates and loads the asset into the memory space of the game where you can access it.

See Also [Content Pipeline Overview of the Content Pipeline](#)

Content Compression

XNA Game Studio offers data compression - an easy way to decrease the size of certain built game assets (e.g. textures, shaders, and meshes). This reduces the size required for media storage and downloads, and it reduces the deploy time required when debugging a game.

Transparent Compression

Compression and decompression of game assets is a transparent operation to games. You don't need to modify your game to make use of compressed data.

- Compression occurs as part of the content pipeline portion of the build process. It is performed automatically when you select the property in the [Content Build](#) page of the Project Designer.
- Decompression occurs automatically when you access the assets through [ContentManager.Load](#).

Note

Compression of game assets is not available for Zune projects. Microsoft has concluded that the small benefit gained by compressing data for Zune is exceeded by the performance requirements of the Zune processor for decompression.

Compression Algorithm

The compression used by XNA Game Studio uses a variant of the LZ family of compression algorithms, which is an efficient, lossless method.

The ratio of compressed data to source data can vary significantly depending on the character of the source data. However, the average compression ratio for most game asset types is around 60 percent.

The automatic compression algorithms will not compress source data that is very small (a file size less than one disk sector), as the performance benefits of compression are typically lost or even made worse by the execution overhead to decompress the data. These assets will be saved in uncompressed format.

Disabling Compression

Some content types, such as [Song Class](#) and [SoundEffect Class](#) data, may not benefit from a general lossless compression algorithm. This is especially true if the data is already compressed in a specialized format.

When implementing a custom content importer, compression can be disabled by overriding the method [ContentTypeWriter.ShouldCompressContent](#), which must return **false**.

If compression is to be permitted, no action is required. The base class definition of [ContentTypeWriter.ShouldCompressContent](#) returns **true**.

Standard Importers and Processors

Describes the standard Content Pipeline importers and content processors of XNA Game Studio that support various common art-asset file formats.

Importers and content processors are implemented as assemblies. In addition to the standard ones provided by XNA Game Studio and listed below, you can also use custom importers and processors that you or other third parties develop. Use the Properties window to assign an appropriate importer and processor for each game asset you add to your game project (see [Game Asset Properties](#) for more information).

Standard Importers

The table below describes the standard importers shipped with XNA Game Studio and the type of game asset each supports.

All standard importers are declared as part of the Microsoft.Xna.Framework.Content.Pipeline namespace.

Name	Type Name	Output Type	Description
Autodesk FBX - XNA Framework	FbxImporter	NodeContent	Imports game assets specified with the Autodesk FBX format (.fbx). This importer is designed to work with assets exported with the 2006.11 version of the FBX exporter.
Effect - XNA Framework	EffectImporter	EffectContent	Imports a game asset specified with the DirectX Effect file format (.fx).
Sprite Font Description - XNA Framework	FontDescriptionImporter	FontContent	Imports a font description specified in a .spritefont file.
Texture - XNA Framework	TextureImporter	TextureContent	Imports a texture. The following types are supported: .bmp, .dds, .dib, .hdr, .jpg, .pfm, .png, .ppm, and .tga.
X File - XNA Framework	XImporter	NodeContent	Imports game assets specified with the DirectX X file format (.x). This importer expects the coordinate system to be left-handed.

XACT Project - XNA Framework	N/A	N/A	<p>Imports game audio specified in the Microsoft Cross-Platform Audio Creation Tool (XACT) format (.xap).</p> <p> Tip Associating an .xap file with XACT allows you to automatically open XACT when editing any .xap file. Associate the file in XNA Game Studio by right-clicking the .xap file in Solution Explorer, and clicking Open With. Once the dialog box is open, select the XACT-specific string, and then click Set As Default. If the XACT-specific option is not available, you must run XACT before this option appears. The application is available from the Microsoft XNA Game Studio group. From the Start Menu, click Tools, and then click Microsoft Cross-Platform Audio Creation Tool (XACT).</p>
XML Content - XNA Framework	Xml Importer	object	<p>Imports XML content used for editing the values of a custom object at runtime. For instance, you could pass XML code to this importer that looks for the specified property of a custom type and changes it to the specified value. You could then process the custom object with a processor or pass it to your game untouched using the No Processing Required processor.</p> <p>This importer is designed for scenarios like importing an XML file that describes game data at runtime (similar to the Sprite Font Description importer) or importing terrain data in an XML file that is then passed to a processor that generates a random terrain grid using that data.</p>

Standard Content Processors

XNA Game Studio ships with a variety of processors that support several common game asset types. Many of the standard processors, such as the [TextureProcessor](#), support parameters for modifying the default behavior of the processor. For more information, see [Parameterized Processors](#).

The following table describes the standard processors and the type of game asset each supports.

Name	Type Name	Input Type	Output Type	Description
Effect - XNA Framework	EffectProcessor	EffectContent	CompiledEffect	Compiles the string in EffectContent to the appropriate platform.
Model - XNA Framework	ModelProcessor	NodeContentClass	ModelContentClass	<p>A parameterized processor that outputs models as a ModelContent Class object.</p> <p>Available parameters:</p> <ul style="list-style-type: none"> • Color Key Color - Any valid Color. Magenta is the default value. • Color Key Enabled - A Boolean value indicating if color keying is enabled. The default value is true. • Generate Mipmaps - A Boolean value indicating if mipmaps are generated. The default value is false. • Generate Tangent Frames - A Boolean value indicating if tangent frames are generated. The default value is false. • Resize Textures to Power of Two - A Boolean value indicating if a texture is resized to the next largest power of 2. The default value is false. • Scale - Any valid float value. The default value is 1.0. • Swap Winding Order - A Boolean value indicating if the winding order is swapped. This is useful for models that appear to be drawn inside out. The default value is false. • Texture Format - Any valid SurfaceFormat value. Textures are either unchanged, converted to the Color format, or DXT Compressed. For more information, see TextureProcessorOutputFormat. • X Axis Rotation - Amount, in degrees of rotation. The default value is 0. • Y Axis Rotation - Amount, in degrees of rotation. The default value is 0. • Z Axis Rotation - Amount, in degrees of rotation. The default value is 0.

No Processing Required	PassThroughProcessor	Object	Object	<p>Performs no processing on the file.</p> <p>Select this processor if your content is already in a game-ready format (for example, an externally prepared DDS file) or a specialized XML format (.xml) designed for use with XNA Game Studio.</p>
Sprite Font Description - XNA Framework	FontDescriptionProcessor	FontDescription	SpriteFontContent	Converts a .spritefont file specifying a font description into a font.
Sprite Font Texture - XNA Framework	FontTextureProcessor	TextureContent	SpriteFontContent	<p>A parameterized processor that outputs a sprite font texture as a SpriteFontContent object.</p> <p>Available parameters:</p> <ul style="list-style-type: none"> • First Character - Any valid character. The space character is the default value.
Sprite Font Texture - XNA Framework	FontTextureProcessor	Texture2DContent	SpriteFontContent	Converts a specially marked 2D bitmap file (.bmp) into a font. Pixels of Color.Magenta are converted to Color.TransparentBlack .
Texture - XNA Framework	TextureProcessor	TextureContentClass	TextureContentClass	<p>A parameterized processor that outputs textures as a TextureContentClass object.</p> <p>Available parameters:</p> <ul style="list-style-type: none"> • Color Key Color - Any valid Color. [Using a Custom Importer or Content Processor](#)

Parameterized Processors

Describes how parameterized processors work in XNA Game Studio. Many of the standard Content Pipeline content processors shipped with XNA Game Studio support parameter usage. Parameterization makes any standard or custom processor more flexible and better able to meet the needs of your XNA Framework application. In addition to specifying values for standard parameters, you can easily implement parameter support for a new or existing custom processor. For more information, see [Developing with Parameterized Processors](#).

When you select a game asset, the Properties window displays the parameters for the related asset processor. Use the Properties window at any time to modify these parameter values.

Note

If you change the processor for a game asset to a different processor, all parameter values are reset to their default values. This means that if you modify the **Generate Mipmaps** parameter value for the [TextureProcessor](#), then switch to a different processor (for example, [FontTextureProcessor Class](#)), the parameters would be switched to the default values for that processor. If you then switch back again, the modified values are reset to the default values of the original processor. *The values do not revert to the modified values you set originally.*

Standard Parameterized Processors

The following table describes only standard processors that accept parameters, the parameter types, and their default value. For more information on all standard processors, see [Standard Importers and Processors](#).

Texture Processing with XNA Game Studio

In versions before XNA Game Studio 2.0, the following standard processors were used for texture processing.

- TextureProcessor
- ModelTextureProcessor
- SpriteTextureProcessor

In XNA Game Studio, the Texture - XNA Framework processor replaces the functionality of this entire group. For new XNA Game Studio projects and projects converted by the Project Upgrade Wizard for XNA Game Studio 2.0, the correct processor is selected automatically. However, for existing custom processors that make calls to any processor from the list above, the code must be modified to use the new [TextureProcessor](#) with the proper parameters. The following table describes the parameter values required for emulating each previous texture processor.

Processor Type Name	Required Parameters and Values
TextureProcessor	<p>Call the Texture—XNA Framework processor (TextureProcessor) with the following parameter values:</p> <ul style="list-style-type: none"> • GenerateMipmaps: false • Destination format: NoChange • Colorkey Enabled: false • Colorkey Value: Magenta • Resize: false
ModelTextureProcessor	<p>Call the Texture—XNA Framework processor (TextureProcessor) with the following parameter values:</p> <ul style="list-style-type: none"> • GenerateMipmaps: true • Destination format: DXTCompressed • Colorkey Enabled: true • Colorkey Value: Magenta • Resize: false
SpriteTextureProcessor	<p>Call the Texture—XNA Framework processor (TextureProcessor) with the following parameter values:</p> <ul style="list-style-type: none"> • GenerateMipmaps: false • Destination format: Color • Colorkey Enabled: true • Colorkey Value: Magenta

For more information on modifying and declaring parameter values programmatically, see [Developing with Parameterized Processors](#).

See Also [Content Pipeline](#)

Developing with Parameterized Processors

Describes how developing with parameterized processors, both standard and custom, requires additional thought and care. This topic discusses a method for programmatically modifying existing parameter values, and adding new parameters to your own processors.

Programmatically Setting Parameter Values

When you need to pass parameter values from one processor to another (also referred to as chaining), use the [BuildAsset](#) and [BuildAndLoadAsset](#) methods. Pass the parameter and its value using the *ProcessorParameters* argument of the respective function. For example, a custom model processor would invoke a second processor for model textures with a call to [BuildAsset](#) and pass any parameter values in the *ProcessorParameters* argument.

The following code example demonstrates this technique. First, add several parameters to a data dictionary:

```
//create a dictionary to hold the processor parameter
OpaqueDataDictionary parameters = new OpaqueDataDictionary();

//add several parameters to the dictionary
parameters.Add( "ColorKeyColor", Color.Magenta );
parameters.Add( "ColorKeyEnabled", true );
parameters.Add( "ResizeToPowerOfTwo", true );
```

After adding the necessary parameters, pass the dictionary to the chained processor:

```
context.BuildAsset<TextureContent, TextureContent="">(
    texture, typeof( TextureProcessor ).Name,
    parameters,
    null,
    null );
```

This call passes all parameters (stored in *parameters*) to a texture processor.

As stated earlier, any parameters not recognized by the receiving processor are ignored. Therefore, if the parameter *ColorKeyCode* was entered into the dictionary as *ColourKeyCode*, it would be ignored by the receiving processor.

Declaring Process Parameters

Adding one or more parameters to your custom processor requires additional code in your processor's definition. Parameters support the following types:

- bool
- byte
- sbyte
- char
- decimal
- double
- float
- int
- uint
- long
- ulong
- short
- ushort
- string
- enum
- [Vector2](#), [Vector3](#), and [Vector4](#)
- [Color](#)

Parameters of other types are ignored by the processor.

Tip

Apply the `Browsable` attribute (with a value of **false**) to an individual parameter to prevent that parameter from being displayed in the Properties window.

The following code example defines a simple custom processor that switches the coordinate system of a model using a single parameter (called `switchCoordinateSystem`):

```
public class SwitchCoordSystemProcessor : ModelProcessor
{
    #region Processor Parameters
    private bool switchCoordinateSystem = false;

    [DisplayName("Switch Coordinate System")]
    [DefaultValue(false)]
    [Description("Switches the coordinate system of a model.")]
    public bool SwitchCoordinateSystem
    {
        get { return switchCoordinateSystem; }
        set { switchCoordinateSystem = value; }
    }
}
//additional class code follows...
```

In this code, the `SwitchCoordSystemProcessor` class is derived from `ModelProcessor`. This indicates that the processor accepts a model as input. The next few lines declare a single property called `SwitchCoordinateSystem` of type **bool**. Please note that every parameter must have a **set** method. The property also has several attributes applied to it:

Attribute Name	Usage
DisplayName	Name of the property when it appears in the Properties window of XNA Game Studio. If not specified, the internal property name, declared in the source code, is used. For this example, "Switch Coordinate System" would be displayed.
DefaultValue	A UI hint specifying the default value the property could have. This value is used only as a UI hint. It will not be set on the property or override the default value declared in the code.
Description	Descriptive text displayed when you select the property in the Properties window of XNA Game Studio.

This completes the definition of the `SwitchCoordinateSystem` property.

In the next code example, the class definition is continued with an override of the `Process` method:

```
//additional class code precedes...

public override ModelContent Process(NodeContent input, ContentProcessorContext context)
{
    if (switchCoordinateSystem)
    {
        Matrix switchMatrix = Matrix.Identity;
        switchMatrix.Forward = Vector3.Backward;
        MeshHelper.TransformScene(input, switchMatrix);
    }

    return base.Process(input, context);
}
```

This code passes the `SwitchCoordinateSystem` property (declared earlier) value to `TransformScene`, which is a helper method that applies a transform to a scene hierarchy.

Using a Custom Importer or Content Processor

Describes how to use a custom processor or importer in an existing game solution. XNA Game Studio provides standard importers and processors for a number of common file formats used to store basic game assets such as models, materials, effects, sprites, textures, and so on.

Note

For a list of the file formats that these standard importers and processors support, see [Standard Importers and Processors](#).

If you have game assets saved in a format that the standard importers and processors do not support, you may be able to find a custom third-party importer or a processor for XNA Game Studio that supports that file format. If you have enough information about the file format, you can even build your own custom importer or processor, as described in [How To: Write a Custom Importer and Processor](#).

Security Note

Before you open an existing project or component, determine the trustworthiness of the code outside of the Visual Studio designer. Opening projects or components in the Visual Studio designer automatically executes that code on your local machine in the trusted process of VCSEXPRESS.exe or DevEnv.exe.

The following procedure shows how to add such a custom importer and processor to an existing game project. These steps assume that you have copied the new importer or processor to a local subfolder of the game project in question.

To Add a Custom Importer or Processor to a Game Project

1. Open XNA Game Studio.
2. Load the solution associated with your game.
3. From Solution Explorer, right-click the nested content project node, and click **Add Reference**.
4. Navigate to the directory containing the assembly with the custom importer or processor, and then add it to the solution.
5. Save the solution.

The new importer or processor now appears as one of the available choices for importing or processing a newly added game asset.

[Standard Importers and Processors](#)

Extending an XNA Framework Standard Processor

Describes how XNA Game Studio lets you modify or extend the behavior of any of the standard Content Pipeline processors that ship with the product. See [Standard Importers and Processors](#) for a description of the standard processors.

Because there are so many asset variants supported by different digital content creation (DCC) tools, it is often useful to be able to modify how one of the standard processors operates. The following examples illustrate some of the kinds of things you might want to do.

Note

The following code samples are for demonstration purpose only. Most of the functionality described is already available by using parameters on a standard processor.

Adding a Scaling Operation to a Processor

There are many reasons why you might want to modify the existing functionality of a standard processor. Here is one example. If your source assets and your game are at different scales, you might want the processor to scale each model automatically at build time. You can implement such automatic scaling by overriding the [Process](#) method of the [ModelProcessor](#) class, which generates a [Model](#). In the override, you would first scale the entire scene and then invoke the base class functionality to process as usual.

The following code illustrates this technique:

```
[ContentProcessor]
class ScalingModelProcessor : ModelProcessor
{
    public override ModelContent Process(
        NodeContent input, ContentProcessorContext context )
    {
        MeshHelper.TransformScene( input, Matrix.CreateScale( 10.0f ) );
        return base.Process( input, context );
    }
}
```

Generating Additional Data

In some cases, you might want to add information to a game asset that a standard processor would not. For example, if a custom effect you want to apply requires tangent or binormal data, you can extend the standard model processor to build this additional data into the asset. To do this, you would override the [Process](#) method of the [ModelProcessor](#) class. In the override, navigate the [NodeContent](#) hierarchy of the game asset, and call [CalculateTangentFrames](#) for each [MeshContent](#) object you find.

The following code shows how you would do this:

```
[ContentProcessor]
class ModelProcessorWithTangents : ModelProcessor
{
    public override ModelContent Process( NodeContent input, ContentProcessorContext context )
    {
        GenerateTangentFramesRecursive( input );
        return base.Process( input, context );
    }

    private void GenerateTangentFramesRecursive( NodeContent node )
    {
        MeshContent mesh = node as MeshContent;
        if (mesh != null)
        {
            MeshHelper.CalculateTangentFrames( mesh, VertexChannelNames.TextureCoordinate( 0 ),
                VertexChannelNames.Tangent( 0 ), VertexChannelNames.Binormal( 0 ) );
        }

        foreach (NodeContent child in node.Children)
        {

```

```

        GenerateTangentFramesRecursive( child );
    }
}
}

```

Changing the Processors Called for Child Objects

Another technique that can be useful is to override a standard processor and change the way child objects are processed by changing the processors that are used for them.

Consider, for example, the hierarchy of calls through which textures in a model are processed:

- The standard `ModelProcessor.Process` method is called to process a `NodeContent` object that represents the root of a scene.
- `ModelProcessor.Process` in turn calls the `ModelProcessor.ConvertMaterial` method once for every `MaterialContent` object used in the scene.
- `ModelProcessor.ConvertMaterial` in turn invokes the `MaterialProcessor.Process` method on the `MaterialContent` object passed to it.
- `MaterialProcessor.Process` in turn calls the `MaterialProcessor.BuildTexture` method once for each texture in the `MaterialContent.Textures` collection in the `MaterialContent` object passed to it.
- `MaterialProcessor.BuildTexture` in turn invokes the `ModelTextureProcessor.Process` method on the `TextureContent` object passed to it.

One reason that you might want to change how this works is that the `ModelTextureProcessor.Process` method applies DXT1 or DXT5 compression to all textures it processes. If textures in your game assets are compressed already, you might well wish to avoid a second compression.

Here is how to prevent compression from being applied to model textures during processing:

1. Create an override of the standard `MaterialProcessor.BuildTexture` method, and invoke the `TextureProcessor.Process` method, which does no compression, instead of `ModelTextureProcessor.Process`.
2. Create an override of `ModelProcessor.ConvertMaterial` that invokes your override of `MaterialProcessor.BuildTexture` instead of the standard one.

The first of these overrides could be coded as follows:

```

[ContentProcessor]
class NoCompressionMaterialProcessor : MaterialProcessor
{
    protected override ExternalReference<TextureContent> BuildTexture(
        string textureName, ExternalReference<TextureContent> texture, ContentProcessor
Context context )
    {
        return context.BuildAsset<TextureContent, TextureContent>( texture, "TexturePro
cessor" );
    }
}

```

There are several things to note about this code:

- An `ExternalReference` is an asset object that is shared between multiple classes, such as a diffuse texture used by more than one material. When such an asset is specified, the Content Manager loads only one copy of the `ExternalReference` at run time and builds it only once, no matter how many references there are to it.
- The `ContentProcessorContext.BuildAsset` method lets you invoke a processor by name to build the content in an object.
- Although `textureName`, the first argument to `BuildTexture`, is ignored in the override above, you could use it if you wanted to process textures differently depending on normal maps or other criteria.

Given the processor created by your first override above, you could code the second override as follows:

```

[ContentProcessor]
class NoCompressionModelProcessor : ModelProcessor
{
    protected override MaterialContent ConvertMaterial(
        MaterialContent material, ContentProcessorContext context )
    {
        return context.Convert<MaterialContent, MaterialContent>(

```

```
        material, "NoCompressionMaterialProcessor" );  
    }  
}
```

Because this override is processing `MaterialContent` objects in memory rather than `ExternalReference` objects, it uses the `ContentProcessorContext.Convert` function instead of `BuildAsset` to invoke the processor created by your first override.

After building and installing your new `NoCompressionModelProcessor` (see [Using a Custom Importer or Content Processor](#)), you can assign it to any models whose textures are already compressed and no further compression will be applied to them.

Sprite Font XML Schema Reference

Describes the valid tags and values for Sprite-Font (.spritefont) XML files used by the Content Pipeline to create [SpriteFont](#) textures.

Tag Name	Content Type	Content Description
<FontName>	string	The name of the font to be imported. This is not the name of a font file, but rather the friendly name that identifies the font once it is installed on your computer. You can use the Fonts folder in Control Panel to see the names of fonts installed on your system, and to install new ones as well. The Content Pipeline supports the same fonts as the System.Drawing.Font class, including TrueType fonts but not bitmap (.fon) fonts.
<Size>	float	The point size of the font to be imported.
<Spacing>	float	The number of pixels to add between each character when the string is rendered.
<UseKerning>	Boolean	Specifies whether to use kerning information when rendering the font. Default value is true .
<Style>	"Regular," "Bold," "Italic," or "Bold, Italic"	The style of the font to be imported.
<DefaultCharacter>	char	The Unicode character to substitute any time an attempt is made to render characters that are not in the font. Specifying this element is optional.
<CharacterRegions>	One or more <CharacterRegion> tags	One or more numerical ranges indicating which subset of Unicode characters to import.
<CharacterRegion>	One <Start> and one <End> tag	The beginning and end of a region of Unicode characters.
<Start>	char	The first Unicode character to include in a <CharacterRegion>.
<End>	char	The last Unicode character to include in a <CharacterRegion>.

Example

Here is a sample .spritefont file:

```

How To: Write a Custom Importer and Processor

Describes how a content importer adds support for a new art asset file format.

You will need to write a new content importer to add support. Also, you may need to write a custom processor, writer, and reader for the new art asset type after it has been imported.

The Complete Sample

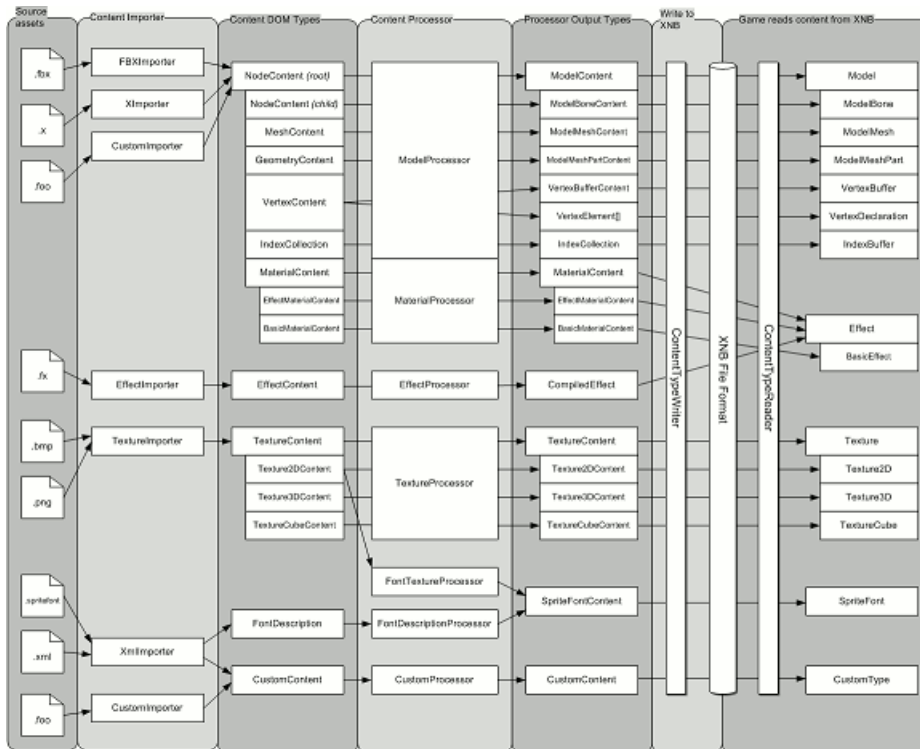

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download CPExtPixelShader_Sample.zip.](#)

Overview

XNA Game Studio already provides standard content pipeline importers and processors to support common art-asset file formats, as described in [Standard Importers and Processors](#). Third parties also provide custom importers and processors to support additional formats. Currently, the XNA Game Studio Content Document Object Model (DOM) provides support for meshes, materials, textures, sprite-fonts, and animations. Outside of these, a custom importer can return a [ContentItem](#) with custom information in its opaque data, or a custom type you have developed.

The following diagram lists the complete Content DOM.

However, if you want to support a new type in the content pipeline, writing your own importer and processor can be fairly straightforward.

For example, suppose you want to compile HLSL source files into pixel shaders. You want the result to be somewhat like the [EffectImporter](#) and [EffectProcessor](#) classes built into XNA Game Studio, but you want to process individual pixel shaders rather than complete effects. This topic provides a simple example to show you the steps you take to write an importer and processor, and also the writer and reader you need to save and load the results. The sections below describe each of the steps.

- [Creating a Content Pipeline Extension Library](#)
- [Implementing a Simple Importer](#)
- [Implementing a Processor to Compile the Shader](#)
- [Implementing a Writer for the Compiled Shader](#)
- [Implementing a Reader for the Pixel Shaders](#)
- [Using the Output of the New Processor in Your Game](#)

Creating a Content Pipeline Extension Library

The first step in writing an importer and processor is to create a new project for them. You need to do this because your importer and processor are used by the content pipeline when your game is being built. They are not part of the game itself. As a result, you need to provide them as a separate library assembly that the content pipeline can link to when it needs to build the new file format you are supporting.

To create a content pipeline extension library

1. In XNA Game Studio, load a game solution you are developing (the sample uses "CPExtPixelShader").
2. From Solution Explorer, right-click the **Solution** node, click **Add**, and then click **New Project**.
3. From the **Add New Project** dialog box, under the **Visual C#** node, from the Project types: pane, select the **XNA Game Studio 3.1** node.
4. Select the **Content Pipeline Extension Library (3.1)** template, assign a name to the new project at the bottom of the dialog box (name this project `PSProcessorLib`), and click **OK**.
5. From Solution Explorer, right-click the **ContentProcessor1.cs** item, and click **Delete**.

The remaining steps create a reference to the `PSProcessorLib` content extension project.

6. From Solution Explorer, right-click the **Content** node of the `CPExtPixelShader` project, and then click **Add Reference**.
7. From the **Projects** tab, select your content extension project, and click **OK**.

The new project is now ready for your custom importer and processor implementation.

Implementing a Simple Importer

Follow these steps to add a content importer to your processor.

To implement a simple importer

1. Create a class to hold the input data you are importing.

In this case, it takes the form of a string of HLSL source code.

2. Add a new C# class named **PSSourceCode** to the processor project.

The first thing to do in the file containing your new class definition is add the following **using** statement at the beginning of the file:

C#

```
using Microsoft.Xna.Framework.Content.Pipeline;
```

3. Now define the class as follows:

C#

```
class PSSourceCode
{
    public PSSourceCode(string sourceCode)
    {
        this.sourceCode = sourceCode;
    }

    private string sourceCode;
    public string SourceCode { get { return sourceCode; } }
}
```

4. Write an importer class to import the HLSL source code.

This class must be derived from `ContentImporter` and implement the `Import` method. All it does is read a text file containing HLSL source code into your **PSSourceCode** class.

5. Using the **New Item** dialog box, add a new **Content Importer** item (called **PSImporter**) to the processor project.

6. Now define the class as follows:

C#

```
[ContentImporter(".psh", DefaultProcessor = "PSProcessor",
    DisplayName = "Pixel Shader Importer")]
class PSImporter : ContentImporter<PSSourceCode>
{
    public override PSSourceCode Import(string filename,
        ContentImporterContext context)
    {
        string sourceCode = System.IO.File.ReadAllText(filename);
        return new PSSourceCode(sourceCode);
    }
}
```

The [ContentImporter](#) attribute applied to the **PSImporter** class provides some context for the user interface of XNA Game Studio. Since this importer supports files with a .psh extension, XNA Game Studio automatically selects the **PSImporter** importer when a .psh file is added to the project. In addition, the *DefaultProcessor* argument specifies which processor XNA Game Studio selects when a .psh file is added.

Note

To specify multiple file types, separate with a comma the file extensions listed in the [ContentImporterAttribute](#). For example, `[ContentImporter (".bmp", ".dds", ".tga")]` declares an importer that accepts .bmp, .dds, and .tga file types. Normally, an importer that accepts multiple file formats is specialized to generate one particular kind of output type, such as textures. However, aside from difficulties of maintenance, there is nothing to prevent a single importer from being written to handle many different content types.

When the game is built, the [ContentImporter.Import](#) function is called once for each XNA content item in the current project.

When invoked against an input file in the appropriate format, a custom importer is expected to parse the file and produce as output one or more content objects of appropriate types. Since an importer's output is passed directly to a content pipeline processor, each type that an importer generates must have at least one processor available that can accept it as input.

Tip

An importer that generates DOM objects may also automatically generate an intermediate XML cache file that serializes these objects. For this to happen, the importer must be implemented with the [CacheImportedData](#) attribute flag set to **true**. This flag is **false** by default. To set the attribute flag to **true**, begin the implementation of your Importer class like this:

```
[ContentImporter( ".MyExt", CacheImportedData = true )]
class PSImporter : ContentImporter<PSSourceCode>
{
    ...
}
```

Implementing a Processor to Compile the Shader

After the new importer has read in the pixel shader source code from a text file, your content processor takes over and compiles the shader into binary form.

To write the processor

1. Create a class to store the compiled output, which in this case takes the form of an array of bytes.
2. Add a C# class called **CompiledPS** to the processor project, and define the new class as follows:

C#

```
class CompiledPS
{
    public CompiledPS(byte[] compiledShader)
    {
        this.compiledShader = compiledShader;
    }
}
```

```

    }

    private byte[] compiledShader;
    public byte[] CompiledShader {
        get { return (byte[])compiledShader.Clone(); }
    }
}

```

Now you are ready to write the processor class, which converts a **PSSourceCode** object into a **CompiledPS** object.

- Using the **New Item** dialog box, add a new **Content Processor** item (called **PSProcessor**) to the processor project.
- Now define the class as follows:

C#

```

[ContentProcessor(DisplayName = "Pixel Shader Processor")]
class PSProcessor : ContentProcessor<PSSourceCode, CompiledPS>
{
    public override CompiledPS Process(PSSourceCode input,
        ContentProcessorContext context)
    {
        CompiledShader shader =
            ShaderCompiler.CompileFromSource(input.SourceCode, null, null,
            CompilerOptions.None, "main",
            ShaderProfile.PS_2_0, context.TargetPlatform);
        if (!shader.Success)
        {
            throw new InvalidContentException(shader.ErrorsAndWarnings);
        }
        return new CompiledPS(shader.GetShaderCode());
    }
}

```

The [Framework.Graphics.ShaderCompiler](#) class compiles the shader to binary code that runs on the platform targeted by your game. The [context.TargetPlatform](#) argument targets the platform. If an error occurs during compilation, **PSProcessor** throws an [InvalidContentException](#). The error appears in the **Error List** window of XNA Game Studio.

Implementing a Writer for the Compiled Shader

The final design-time class to implement is a writer that saves the compiled pixel shader produced by your processor as a binary .xnb file.

To implement the writer for the compiled shader

- Using the **New Item** dialog box, add a new **Content Type Writer** item (called **PSWriter**) to the processor project.
- Define the new class as follows:

C#

```

[ContentTypeWriter]
class PSWriter : ContentTypeWriter<CompiledPS>
{
    protected override void Write(ContentWriter output, CompiledPS value)
    {
        output.Write(value.CompiledShader.Length);
        output.Write(value.CompiledShader);
    }
    public override string GetRuntimeType(TargetPlatform targetPlatform)
    {
        return typeof(PixelShader).AssemblyQualifiedName;
    }
}

```

```

public override string GetRuntimeReader(TargetPlatform targetPlatform)
{
    return "CPEXPixelShader.PSReader, CPEXPixelShader," +
        " Version=1.0.0.0, Culture=neutral";
}
}

```

The `GetRuntimeType` method identifies the type of object your game should load from the .xnb file written by the writer object. In this instance, the .xnb file contains the binary array from your custom **CompiledPS** type, and this method identifies how that array will be mapped to a standard `Framework.Graphics.PixelShader` object type at load time.

The `GetRuntimeReader` method specifies what reader should be invoked to load the .xnb file in your game. It returns the namespace and name of the reader class, followed by the name of the assembly in which that class is physically located.

3. In your code, change the assembly name to match the actual name of your game and its assembly, since that is where you will be loading the shaders.

At this point, the code for your **PSProcessorLib** library is complete.

Implementing a Reader for the Pixel Shaders

Now move from the **PSProcessorLib** library project back to your game project and write the class that your game uses to load the .xnb files that your processor creates. This is the class that your writer specified previously as its reader.

To implement a reader for the pixel shaders

1. In your game project, add a C# class called **PSReader** to your game project.
2. Add the **using** statements you will need at the top of the file:

C#

```

using Microsoft.Xna.Framework.Content;
using Microsoft.Xna.Framework.Graphics;

```

3. Deriving from the `ContentTypeReader` generic class for the `PixelShader` type, override the **Read** method, and define your class as follows:

C#

```

class PSReader : ContentTypeReader<PixelShader>
{
    /// <summary>
    /// Loads an imported shader.
    /// </summary>
    protected override PixelShader Read(ContentReader input,
        PixelShader existingInstance)
    {
        int codeSize = input.ReadInt32();
        byte[] shaderCode = input.ReadBytes(codeSize);

        IGraphicsDeviceService graphicsDeviceService =
            (IGraphicsDeviceService)input.ContentManager.ServiceProvider.
                GetService(typeof(IGraphicsDeviceService));
        return new PixelShader(graphicsDeviceService.GraphicsDevice,
            shaderCode);
    }
}

```

4. At this point, build the processor project.

Once it has completed, you are ready to use the new importer and processor to build pixel shaders into your game.

Using the Output of the New Processor in Your Game

Try adding a test HLSL source file with a .psh extension to your game project and see how it works.

To test your output

1. Copy into a folder in your game project a simple HLSL source file that you know is free of bugs, and rename the file "Ripple.psh."
2. Right-click on your game project in Solution Explorer, click **Add**, click **Existing Item**, and then click **Ripple.psh**.
3. Once you add the file, right-click it in Solution Explorer, and click **Properties**.

You should now see entries in its **Properties** dialog box assigning **PSImporter** as its content importer and **PSPProcessor** as its content processor. Next time you build your game, Ripple.psh will be built into TestShader.xnb in a form appropriate for your target platform.

4. To use the resulting pixel shader in your game, load it using [ContentManager.Load](#) as follows:

```
PixelShader shader = content.Load<PixelShader>( "TestShader" );
```

Tips for Developing Custom Importers

The following information should help you when you develop content pipeline extensions.

Importing Basic Graphics Objects

The following information should help you import basic graphics objects.

- Make your coordinate system right-handed.

From the standpoint of the observer, the positive x-axis points to the right, the positive y-axis points up, and the positive z-axis points toward you (out from the screen).

- Create triangles that have a clockwise winding order.

The default culling mode removes triangles that have a counterclockwise winding order.

- Call [SwapWindingOrder](#) to change the winding order of a triangle.
- Set the scale for graphical objects to 1 unit = 1 meter.
- Call [TransformScene](#) to change the scale of an object.

Taking Advantage of Content Pipeline Mesh Classes

There are several properties and classes that are particularly useful when using [NodeContent](#) objects to represent a 3D scene or mesh.

- The [NodeContent.Children](#) property represents hierarchical information.
- The [NodeContent.Transform](#) property contains the local transform of the 3d object.
- The [Pipeline.Graphics.MeshContent](#) class (a subclass of [Pipeline.Graphics.NodeContent](#)) is used to represent meshes.

The content pipeline provides two classes that make it easier to create and work with [Pipeline.Graphics.MeshContent](#) objects.

- The [Pipeline.Graphics.MeshBuilder](#) class creates new [Pipeline.Graphics.MeshContent](#) objects, when necessary.
- The [Pipeline.Graphics.MeshHelper](#) class implements useful operations on existing [Pipeline.Graphics.MeshContent](#) objects.

Debugging Custom Importers and Processors

In a way that is similar to projects that create a DLL, content pipeline extension projects cannot be directly run or debugged. However, after completing a few simple steps, you can debug any custom importers and processors used by your game. The following procedure details these steps.

Note

The Start External program: control (located on the Debug page of a project's property pages) is not available in the Microsoft Visual C# Express Edition development environment.

To Debug a Custom Importer or Processor

1. Load an existing XNA Game Studio content pipeline extension project (later referred to as ProjCP) containing the custom importers and/or processors to be debugged.
2. Create a separate test game project (later referred to as "ProjG").
3. In the **References** node of ProjG's nested content project, add a project-to-project reference to ProjCP.
4. Add one or two appropriate items of test content to ProjG, and ensure they are set to use the importer or processor (in ProjCP) you wish to debug.
5. Open the property pages for ProjCP.
6. Click the **Debug** tab, and select **Start external program:**.
7. Enter the path to the local version of MSBuild.exe.
For example, C:\WINDOWS\Microsoft.NET\Framework\v3.5\msbuild.exe.
8. For the **Command line arguments** control, enter the path to ProjG's nested content project.
If this path contains spaces, quote the entire path.
9. Set any required breakpoints in the importer or processor code in ProjCP.
10. Build and debug ProjCP.

Debugging ProjCP causes MSBuild to compile your test content while running under the debugger. This enables you to hit your breakpoints in ProjCP and step through your code.

How To: Extend the Font Description Processor to Support Additional Characters

Describes the process of developing a custom content processor needed to add additional characters to a [FontDescription](#) object based on the text that is required by the game.

In a font description (.spritefont) file, the `<CharacterRegions>` area can be used to add additional characters to a font description. This enables you to use a [SpriteFont](#) to render an additional range of characters.

For some languages, this approach is not ideal. For example, Chinese and Japanese both have many thousands of characters. Adding the full range of characters to `<CharacterRegions>` dramatically increases the size of the font asset and the time required to build the font asset. A better solution adds individual characters whenever the specific characters are needed. You can create a custom content processor to implement this solution.

In this example, a file called *messages.txt* contains all the text rendered by the game. The custom processor adds all the characters contained in the text in this file to a [FontDescription](#). Then it processes the object in the standard way using the base [FontDescriptionProcessor](#) functionality. All the characters in *messages.txt* will then be available to the [SpriteFont](#) object at run time.

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download CPFontProcessor_Sample.zip.](#)

Using the Font Description Processor

To specify the character regions and messages to process

1. To add a new Sprite Font called DefaultFont to a game project, go to Solution Explorer, right-click the nested Content node, click **Add**, and then click **New Item**.
2. To add the new sprite font to the game, select the **Sprite Font** template, and then click **Add**.
3. Modify this file to use an existing font and any additional characteristics you prefer.

For more information, see [Sprite Font XML Schema Reference](#).

4. Add a file named *messages.txt* to the game project.
5. Right-click on the game project node in Solution Explorer, click **Add**, and then click **New Item**.
6. Select the **Text File** template, enter **messages.txt** for the file name, and then click **Add** to add the text file to the game.
7. In the new text file, enter any messages that will be printed by the font described in the Sprite Font file.

⚠Caution

We will use the method [File.ReadAllText](#) to read the text in this file. This method requires a carriage return ("`\r`") or line feed ("`\n`") after the last string, so be sure to follow the last line of text in the file with a carriage return or line feed.

To create the new content processor project

The Content Pipeline is part of the build process, and it is separate from your game code. Therefore, you need to create a new assembly that contains the code developed in this topic. Creating this new assembly project is the first step in developing a new processor.

📌Note

It is assumed that you have an existing game project that you will modify. For the purposes of this example, the game project is called "FontGame."

1. To add the new processor project to the game solution, go to Solution Explorer, right-click the **Solution** node, click **Add**, and then click **New Project**.
2. In the dialog box, select the Content Pipeline Extension Library (3.1) template, enter **FontProcessor** in the **Name** field, and then click **OK**. The new project automatically contains references to the XNA Framework run-time and design-time

Content Pipeline assemblies.

To extend the font processor

1. Add the following lines of code, after the last `using` statement:

C#

```
using System.IO;
using System.ComponentModel;
```

2. In `ContentProcessor1.cs`, remove the code near the top of the file, and replace it with the processor and input types.
3. Using attributes, add a processor parameter to the beginning of the class declaration.

This parameter stores the name of the text file that stores the messages displayed by the game.

C#

```
[DefaultValue("messages.txt")]
[DisplayName("Message File")]
[Description("The characters in this file will be automatically added to the font.")]
public string MessageFile
{
    get { return messageFile; }
    set { messageFile = value; }
}
private string messageFile = "..\\messages.txt";
```

4. Change the derivation of `ContentProcessor1` from `ContentProcessor` to `FontDescriptionProcessor`.
5. Modify the `Process` method override to match the following code:

C#

```
public override SpriteFontContent Process(FontDescription input, ContentProcessorContext context)
```

This modification replaces the template parameter and return types with the proper types needed for the extended font processor.

6. Register a Content Pipeline dependency on `messages.txt`.

This dependency tells the Content Pipeline that if `messages.txt` changes, the font must be rebuilt.

C#

```
string fullPath = Path.GetFullPath(MessageFile);

context.AddDependency(fullPath);
```

7. Read the contents of the file, and add each letter to the input font one by one. Note that the `Characters` collection keeps track of duplicates automatically. It is not necessary for the user to make sure that each letter is added only once. The **Characters** collection will contain only one instance of each character, no matter how many times **Add** has been called.

C#

```
string letters = File.ReadAllText(fullPath, System.Text.Encoding.UTF8);

foreach (char c in letters)
{
    input.Characters.Add(c);
}
```

In this example, messages.txt has been saved with Unicode UTF-8 encoding, which is why this encoding format is specified in the call to [File.ReadAllText](#). The default file encoding format for text files that have been added to a Visual Studio project is Western European (Windows) encoding, corresponding to code page 1252. If your text file uses the default encoding, specify the character encoding as follows:

```
string letters = File.ReadAllText( fullPath, System.Text.Encoding.GetEncoding( 1252 ) );
```

8. Call the existing **Process** method of the base [FontDescriptionProcessor](#) to build the font with the newly requested characters.

C#

```
return base.Process(input, context);
```

To associate the custom font processor with the sprite font

1. Compile the solution to build **MyFontProcessor**.

Now you need to add your custom font processor as an available content processor for the game.

2. From **Solution Explorer**, right-click the **Content** node, and then click **Add Reference**.
3. From the **Projects** tab, select your content extension project (**FontProcessor**) node, and click **OK**.

To ensure that the processor project is always up to date when the main game is built, you need to create a project dependency.

4. In Solution Explorer, right-click the game project (**FontGame**) node, and then click **Project Dependencies**.
5. Select the check box next to **FontProcessor**, and then click **OK** to add a new dependency so that **FontGame** depends on **FontProcessor**.
6. Change the content processor for the .spritefont file from **Sprite Font Description - XNA Framework** to the newly created processor.
7. Select the .spritefont file, and then in the **Properties** window, choose your custom processor from the drop-down list associated with the **ContentProcessor** field.

When you build the solution, the new processor adds the characters in the messages.txt file to the list of characters available to the [SpriteFont](#).

Tip

To debug a Content Pipeline importer or processor, add the following line to the processor code to launch the debugger.

```
System.Diagnostics.Debugger.Launch();
```

Application Model Overview

The XNA Framework [Game](#) class provides a framework for processing game simulation based on a fixed or variable time interval.

This overview covers the following topics.

- [Making a New Game](#)
- [Game Loop Timing](#)
- [Starting the Game](#)
- [Game Components](#)
- [Game Services](#)
- [Game Components Consuming Game Services](#)
- [Tasks](#)

Making a New Game

The first step in creating a new game is to make a class that derives from [Game](#). The new class needs to override [Update](#), [Draw](#), and [Initialize](#). The [Update](#) method is responsible for handling game logic, and the [Draw](#) method is responsible for drawing each frame. The [Initialize](#) method is responsible for game setup before the first frame of the game.

Game Loop Timing

A [Game](#) is either fixed step or variable step, defaulting to fixed step. The type of step determines how often [Update](#) will be called and affects how you need to represent time-based procedures such as movement and animation.

Fixed-Step Game Loops

A fixed-step [Game](#) tries to call its [Update](#) method on the fixed interval specified in [TargetElapsedTime](#). Setting [Game.IsFixedTimeStep](#) to **true** causes a [Game](#) to use a fixed-step game loop. A new XNA project uses a fixed-step game loop with a default [TargetElapsedTime](#) of 1/60th of a second.

In a fixed-step game loop, [Game](#) calls [Update](#) once the [TargetElapsedTime](#) has elapsed. After [Update](#) is called, if it is not time to call [Update](#) again, [Game](#) calls [Draw](#). After [Draw](#) is called, if it is not time to call [Update](#) again, [Game](#) idles until it is time to call [Update](#).

If [Update](#) takes too long to process, [Game](#) sets [IsRunningSlowly](#) to **true** and calls [Update](#) again, without calling [Draw](#) in between. When an update runs longer than the [TargetElapsedTime](#), [Game](#) responds by calling [Update](#) extra times and dropping the frames associated with those updates to catch up. This ensures that [Update](#) will have been called the expected number of times when the game loop catches up from a slowdown. You can check the value of [IsRunningSlowly](#) in your [Update](#) if you want to detect dropped frames and shorten your [Update](#) processing to compensate. You can reset the elapsed times by calling [ResetElapsedTime](#).

When your game pauses in the debugger, [Game](#) will not make extra calls to [Update](#) when the game resumes.

Variable-Step Game Loops

A variable-step game calls its [Update](#) and [Draw](#) methods in a continuous loop without regard to the [TargetElapsedTime](#). Setting [Game.IsFixedTimeStep](#) to **false** causes a [Game](#) to use a variable-step game loop.

Animation and Timing

For operations that require precise timing, such as animation, the type of game loop your game uses (fixed-step or variable-step) is important.

Using a fixed step allows game logic to use the [TargetElapsedTime](#) as its basic unit of time and assume that [Update](#) will be called at that interval. Using a variable step requires the game logic and animation code to be based on [ElapsedGameTime](#) to ensure smooth gameplay. Because the [Update](#) method is called immediately after the previous frame is drawn, the time between calls to [Update](#) can vary. Without taking the time between calls into account, the game would seem to speed up and slow down. The time elapsed between calls to the [Update](#) method is available in the [Update](#) method's *gameTime* parameter. You can reset the elapsed times by calling [ResetElapsedTime](#).

When using a variable-step game loop, you should express rates—such as the distance a sprite moves—in game units per millisecond (ms). The amount a sprite moves in any given update can then be calculated as the rate of the sprite times the elapsed time. Using this approach to calculate the distance the sprite moved ensures that the sprite will move consistently if the speed of the game or computer varies.

Starting the Game

Calling the `Game.Run` method starts a game. This method starts a loop that will call `Update` and `Draw` multiple times a second until `Exit` is called.

Game Components

Game components provide a modular way of adding functionality to a game. You create a game component by deriving the new component either from the `GameComponent` class, or, if the component loads and draws graphics content, from the `DrawableGameComponent` class. You then add game logic and rendering code to the game component by overriding `GameComponent.Update`, `DrawableGameComponent.Draw` and `GameComponent.Initialize`. A game component is registered with a game by passing the component to `Game.Components.Add`. A registered component will have its draw, update, and initialize methods called from the `Game.Initialize`, `Game.Update`, and `Game.Draw` methods.

Game Services

Game services are a mechanism for maintaining loose coupling between objects that need to interact with each other. Services work through a mediator—in this case, `Game.Services`. Service providers register with `Game.Services`, and service consumers request services from `Game.Services`. This arrangement allows an object that requires a service to request the service without knowing the name of the service provider.

Game services are defined by an interface. A class specifies the services it provides by implementing interfaces and registering the services with `Game.Services`. A service is registered by calling `Game.Services.AddService` specifying the type of service being implemented and a reference to the object providing the service. For example, to register an object that provides a service represented by the interface `IMyService`, you would use the following code.

```
Services.AddService( typeof( IMyService ), myobject );
```

Once a service is registered, the object providing the service can be retrieved by `Game.Services.GetService` and specifying the desired service. For example, to retrieve `IGraphicsDeviceService`, you would use the following code.

```
IGraphicsDeviceService graphicservice = (IGraphicsDeviceService)Services.GetService( typeof(IGraphicsDeviceService) );
```

Game Components Consuming Game Services

The `GameComponent` class provides the `Game` property so a `GameComponent` can determine what `Game` it is attached to. With the `Game` property, a `GameComponent` can call `Game.Services.GetService` to find a provider of a particular service. For example, a `GameComponent` would find the `IGraphicsDeviceService` provider by using the following code.

```
IGraphicsDeviceService graphicservice = (IGraphicsDeviceService)Game.Services.GetService( typeof( IGraphicsDeviceService ) );
```

Loading Content

To load content and ensure it will be reloaded when necessary

1. Derive a class from [Game](#).
2. Override the [LoadContent](#) method of [Game](#).
3. In the [LoadContent](#) method, load your content, including resources loaded by the [ContentManager](#).

C#

```
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    // TODO: Load your game content here
    Box = Content.Load<Model>("box");
}
```

4. Override the [UnloadContent](#) method of [Game](#).
5. In the [UnloadContent](#) method, unload resources that are not managed by the [ContentManager](#).

C#

```
protected override void UnloadContent()
{
    // TODO: Unload any non ContentManager content here
}
```

Loading Content from a Game Library

XNA Game Studio allows code and content to be run from Game Library projects that are added as references to Game projects. If you use a Game Library, you can embed binary resources directly in the Game Library and load them from within. This allows you to distribute code that displays textures, models, or fonts (such as a [DrawableGameComponent](#)) in a .DLL without distributing the .xnb files separately. Note that embedded resources are loaded into memory with the .DLL, and cannot be unloaded from main memory.

To add content to a Game Library

1. Build an existing project containing the content you wish to add.
2. In a library project, choose **Add, New Item** and select "Resources File."
3. If the **Resource Designer** is not opened automatically, double-click the .resx file in the **Solution Explorer**.
4. From the **Resource Designer**, choose **Add Resource, Add Existing File**.

5. Navigate to the "bin\x86\Debug\Content" directory of the project that built the content you wish to add.

This assumes it was built as an x86 Debug project.

6. Select the .xnb file for the content you wish to add to the library.

Make sure the dialog box is displaying "All Files."

Once content has been added to the **Resource Designer**, any code running from within the Library can load the content with a special [ContentManager](#).

To load content from a Game Library

1. Define a new [ContentManager](#).
2. Create a new instance of the [ResourceContentManager](#) class and assign it to your [ContentManager](#).

The second parameter to the [ResourceContentManager](#) constructor identifies the resource project that contains your embedded resources.

C#

```
ContentManager content;
public GameComponent1(Game game)
    : base(game)
{
    content = new ResourceContentManager(game.Services,
        Resource1.ResourceManager);
}
```

3. In the [LoadContent](#) method, load your content normally using your [ContentManager](#).

C#

```
Model box;
protected override void LoadContent()
{
    box = content.Load<Model>("box2");
    base.LoadContent();
}
```

Adding Pause Functionality to a Game

Typically, there are two circumstances when you want to pause your game—at the request of the user, and when the [Guide](#) appears on the screen (obscuring the playfield). A user request could take several different forms. For example, the user might launch a menu, or the user might execute a specific keystroke. You have to decide for yourself how users can pause your game.

Checking for the presence of the [Guide](#) is more straightforward. You can just query the [Guide.IsVisible](#) property.

When the user requests a pause, you don't want to unpaused until the user tells you to do so. When you pause for the [Guide](#), you should unpaused as soon as the [Guide](#) is dismissed.

Pausing your game often means more than just halting your simulation. It could also require pausing or muting any sounds that might be playing, halting controller vibrations, sending a network message, and so on. To handle those tasks, you need to declare a **BeginPause** and **EndPause** method. **EndPause** resumes anything that was halted by **BeginPause**.

To add pause functionality to a game

1. Add a variable to track the pause state.
2. Add a variable to track the state of the pause key.
3. Add a variable to track if the pause is due to the [Guide](#) or to user action.

C#

```
private bool paused = false;
private bool pauseKeyDown = false;
private bool pausedForGuide = false;
```

4. Add a **BeginPause** method to initiate a pause, setting the variables appropriately:

C#

```
private void BeginPause(bool UserInitiated)
{
    paused = true;
    pausedForGuide = !UserInitiated;
    //TODO: Pause audio playback
    //TODO: Pause controller vibration
}
```

5. Add an **EndPause** method to resume from a paused state, resetting variables appropriately:

C#

```
private void EndPause()
{
    //TODO: Resume audio
    //TODO: Resume controller vibration
    pausedForGuide = false;
    paused = false;
}
```

6. Add a function to poll the state of the pause key with `Keyboard.GetState` and `KeyboardState.IsKeyDown`.

If the key has changed from down to up, toggle the pause state using **BeginPause** or **EndPause**.

C#

```
private void checkPauseKey(KeyboardState keyboardState,
    GamePadState gamePadState)
{
    bool pauseKeyDownThisFrame = (keyboardState.IsKeyDown(Keys.P) ||
        (gamePadState.Buttons.Y == ButtonState.Pressed));
    // If key was not down before, but is down now, we toggle the
    // pause setting
    if (!pauseKeyDown && pauseKeyDownThisFrame)
    {
        if (!paused)
            BeginPause(true);
        else
            EndPause();
    }
    pauseKeyDown = pauseKeyDownThisFrame;
}
```

7. Add a function to poll the state of the `Guide`.

If the `Guide` is newly visible, call **BeginPause**.

If the `Guide` is not visible, but the game was paused for the guide, call **EndPause**.

C#

```
private void checkPauseGuide()
{
    // Pause if the Guide is up
    if (!paused && Guide.IsVisible)
        BeginPause(false);
    // If we paused for the guide, unpaue if the guide
    // went away
    else if (paused && pausedForGuide && !Guide.IsVisible)
        EndPause();
}
```

8. During `Update`, check to see if the user paused, or if the `Guide` is active.

Add a conditional around any update code so it will be called only if the game is not paused. Be sure to call **base.Update** even if the simulation is paused.

C#

```
// Check to see if the user has paused or unpaused
checkPauseKey(keyboardState, gamePadState);

checkPauseGuide();

// If the user hasn't paused, Update normally
if (!paused)
{
    Simulate(gameTime);
}
base.Update(gameTime);
```

Remarks

★Best Practice

You might choose to implement a menu of options to display when a game is paused. This might include options to resume, purchase, save, or quit the game. In multiplayer games, pausing will usually disable local input without pausing the game for remote players.

Some situations in which you may want to pause the simulation update or input are when:

- `Guide.IsVisible` is **true**, as the guide will block user inputs from reaching the game.
- `Game.IsActive` is **false**, indicating that trial mode may have ended for the game.
- `GamePadState.IsConnected` is **false**, indicating that the game controller is disconnected.

Exiting a Game Without Finishing the Current Update

To exit the game loop without running any remaining code in the update handler

1. Derive a class from [Game](#).

You need to create a method that checks [KeyboardState.IsKeyDown](#) for the state of the ESC key.

2. If the ESC key has been pressed, call [Game.Exit](#) and return **true**.

C#

```
bool checkExitKey(KeyboardState keyboardState,
    GamePadState gamePadState)
{
    // Check to see whether ESC was pressed on the keyboard
    // or BACK was pressed on the controller.
    if (keyboardState.IsKeyDown(Keys.Escape) ||
        gamePadState.Buttons.Back == ButtonState.Pressed)
    {
        Exit();
        return true;
    }
    return false;
}
```

3. Call the method in [Game.Update](#), and return from [Update](#) if the method returned **true**.

C#

```
// Check to see if the user has exited
if (checkExitKey(keyboardState, gamePadState))
{
    base.Update(gameTime);
    return;
}
```

4. Create a method to handle the [Game.Exiting](#) event.

The [Exiting](#) event will be issued at the end of the tick in which [Game.Exit](#) is called.

C#

```
public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";
    ...
    this.Exiting += new EventHandler(Game1_Exiting);
    ...
}

void Game1_Exiting(object sender, EventArgs e)
```

```
{  
    // Add any code that must execute before the game ends.  
}
```

2. After creating the [GraphicsDeviceManager](#), set its [PreferredBackBufferWidth](#) and [PreferredBackBufferHeight](#) to the desired screen width and height.
3. Set [IsFullScreen](#) to **true**.

C#

```

Restricting Graphics Devices

To restrict graphics devices to widescreen aspect ratios in full-screen mode

1. Create a class that derives from [GraphicsDeviceManager](#).

C#

```
public class CustomGraphicsDeviceManager : GraphicsDeviceManager
{
    public CustomGraphicsDeviceManager( Game game )
        : base( game )
    {
    }
    ...
}
```

2. Add a **WideScreenOnly** property to the class.

The property will be used to turn the widescreen-only behavior on and off.

C#

```
private bool isWideScreenOnly;
public bool IsWideScreenOnly
{
    get { return isWideScreenOnly; }
    set { isWideScreenOnly = value; }
}
```

3. Determine the minimum desired aspect ratio.

C#

```
static float WideScreenRatio = 1.6f; //1.77777779f;
```

4. Override the [RankDevices](#) method of [GraphicsDeviceManager](#).

Note the call to [base.RankDevices](#). This call ensures that the new version of [RankDevices](#) has an already-ranked list of available devices with which to work.

C#

```
protected override void RankDevices(
    List<GraphicsDeviceInformation> foundDevices )
{
    base.RankDevices( foundDevices );
    ...
}
```

5. Add a check to see if the **WideScreenOnly** property is **true**.

C#

```
if (IsWideScreenOnly)
{
    ...
}
```

6. In the **if** block, loop through all of the found devices, and check whether the [PresentationParameters](#) indicate the device is full-screen.
7. If the device is full-screen, determine the aspect ratio of the device by dividing the [BackBufferWidth](#) by the [BackBufferHeight](#).
8. If the aspect ratio is less than the desired aspect ratio, remove the device from the list of found devices.

C#

```
for (int i = 0; i < foundDevices.Count; )
{
    PresentationParameters pp =
        foundDevices[i].PresentationParameters;
    if (pp.IsFullScreen == true)
    {
        float aspectRatio = (float)(pp.BackBufferWidth) /
            (float)(pp.BackBufferHeight);

        // If the device does not have a widescreen aspect
        // ratio, remove it.
        if (aspectRatio < WideScreenRatio)
        {
            foundDevices.RemoveAt( i );
        }
        else { i++; }
    }
    else i++;
}
```

9. Replace the default [GraphicsDeviceManager](#) with the derived [GraphicsDeviceManager](#).
10. To test the new component, set the **WideScreenOnly** and [IsFullScreen](#) properties to **true**.

C#

```
public Game1()
{
    graphics = new CustomGraphicsDeviceManager(this);
    Content.RootDirectory = "Content";

    this.graphics.PreferMultiSampling = false;
    this.graphics.PreferredBackBufferWidth = 1280;
    this.graphics.PreferredBackBufferHeight = 720;

    this.graphics.IsFullScreen = true;
    this.graphics.IsWideScreenOnly = true;
    graphics.ApplyChanges();
}
```

Adding Time-Out Functionality to a Game

To make a game time out

1. Create a class that derives from [Game](#).
2. Determine the desired time-out limit in milliseconds.

C#

```
// Time out limit in ms.
static private int TimeoutLimit = 80000;
```

3. Add a variable for tracking the elapsed time since the most recent user activity.

C#

```
// Amount of time that has passed.
private double timeoutCount = 0;
```

4. When user input is checked, set a flag indicating whether any user activity has taken place.

C#

```
GamePadState blankGamePadState = new GamePadState(
    new GamePadThumbSticks(), new GamePadTriggers(),
    new GamePadButtons(), new GamePadDPad());
bool checkActivity(KeyboardState keyboardState,
    GamePadState gamePadState)
{
    // Check to see if the input states are different from last frame
    GamePadState nonpacketGamePadState = new GamePadState(
        gamePadState.ThumbSticks, gamePadState.Triggers,
        gamePadState.Buttons, gamePadState.DPad);

    bool keyidle = keyboardState.GetPressedKeys().Length == 0;
    bool gameidle = blankGamePadState == nonpacketGamePadState;
    if ( keyidle && gameidle)
    {
        // no activity;
        return false;
    }
    return true;
}
```

5. In [Update](#), if there has not been any user activity, increment the tracking variable by the elapsed time since the last call to [Update](#).
6. If there has been some user activity, set the tracking variable to zero.

C#

```
// Check to see if there has been any activity
```

```
if (checkActivity(keyboardState, gamePadState) == false)
{
    timeoutCount += gameTime.ElapsedGameTime.Milliseconds;
}
else
    timeoutCount = 0;
```

7. Check whether the value of the tracking variable is greater than the time-out limit.
8. If the variable is greater than the limit, perform some time-out logic such as playing an idle animation or, in this case, exit the game.

C#

```
// Timeout if idle long enough
if (timeoutCount > TimeOutLimit)
{
    Exit();
    base.Update(gameTime);
    return;
}
```

Making a Game Use a Variable Time Step

To make a game use a variable time step

1. Create a class that derives from [Game](#).
2. Set `IsFixedTimeStep` to **false**.

This causes `Update` to be called as often as possible instead of being called on a fixed interval.

C#

```
this.IsFixedTimeStep = false;
```

3. Since the amount of time between calls to `Update` will vary, specify any rates used in the game as units per millisecond (ms).

C#

```
// Speed in world units per ms.  
private double speed = 0.02f;
```

4. In `Update`, get the value of `gameTime.ElapsedGameTime.TotalMilliseconds`.

This indicates the amount of time that has passed since the last call to `Update`.

C#

```
// Time elapsed since the last call to update.  
double elapsedTime = gameTime.ElapsedGameTime.TotalMilliseconds;
```

5. Determine the change that occurred since the last update by multiplying any rates being used by the elapsed time.

C#

```
// Multiply speed by elapsed time to get the distance moved.  
double distance = (speed * elapsedTime);
```

The XNA Rendering Pipeline

Provides a high-level view of the graphics rendering pipeline for XNA games.

The XNA Framework renders graphics by calling into the DirectX 9 rendering pipeline. The following figure shows the subset of the DirectX 9 rendering pipeline used by the XNA Framework:

Vertex Data	Vertex memory buffers provide storage for the untransformed model vertices. Typically, you can use a VertexDeclaration to describe what information (position, color, texture coordinates, normals, and so on) is defined for each vertex. Vertex buffers may contain either indexed or non-indexed vertex data.	VertexBuffer , VertexDeclaration
Primitive Data	Geometric primitives, including points, lines, triangles, and polygons, are referenced in the vertex data with index buffers. If a vertex buffer is not indexed, all of the vertices are placed in the vertex buffer in the order they are to be rendered. Because 3D-line lists or triangle lists often reference the same vertices multiple times, this can result in a large amount of redundant data. Index buffers allow you to list each vertex only once in the vertex buffer. An index buffer is a list of indices in the vertex buffer, given in the order that you want the vertices to render. Displays, Client Bounds, Viewports, and Back Buffers

Describes the relationships between the display, client, viewport, and back buffer size properties.

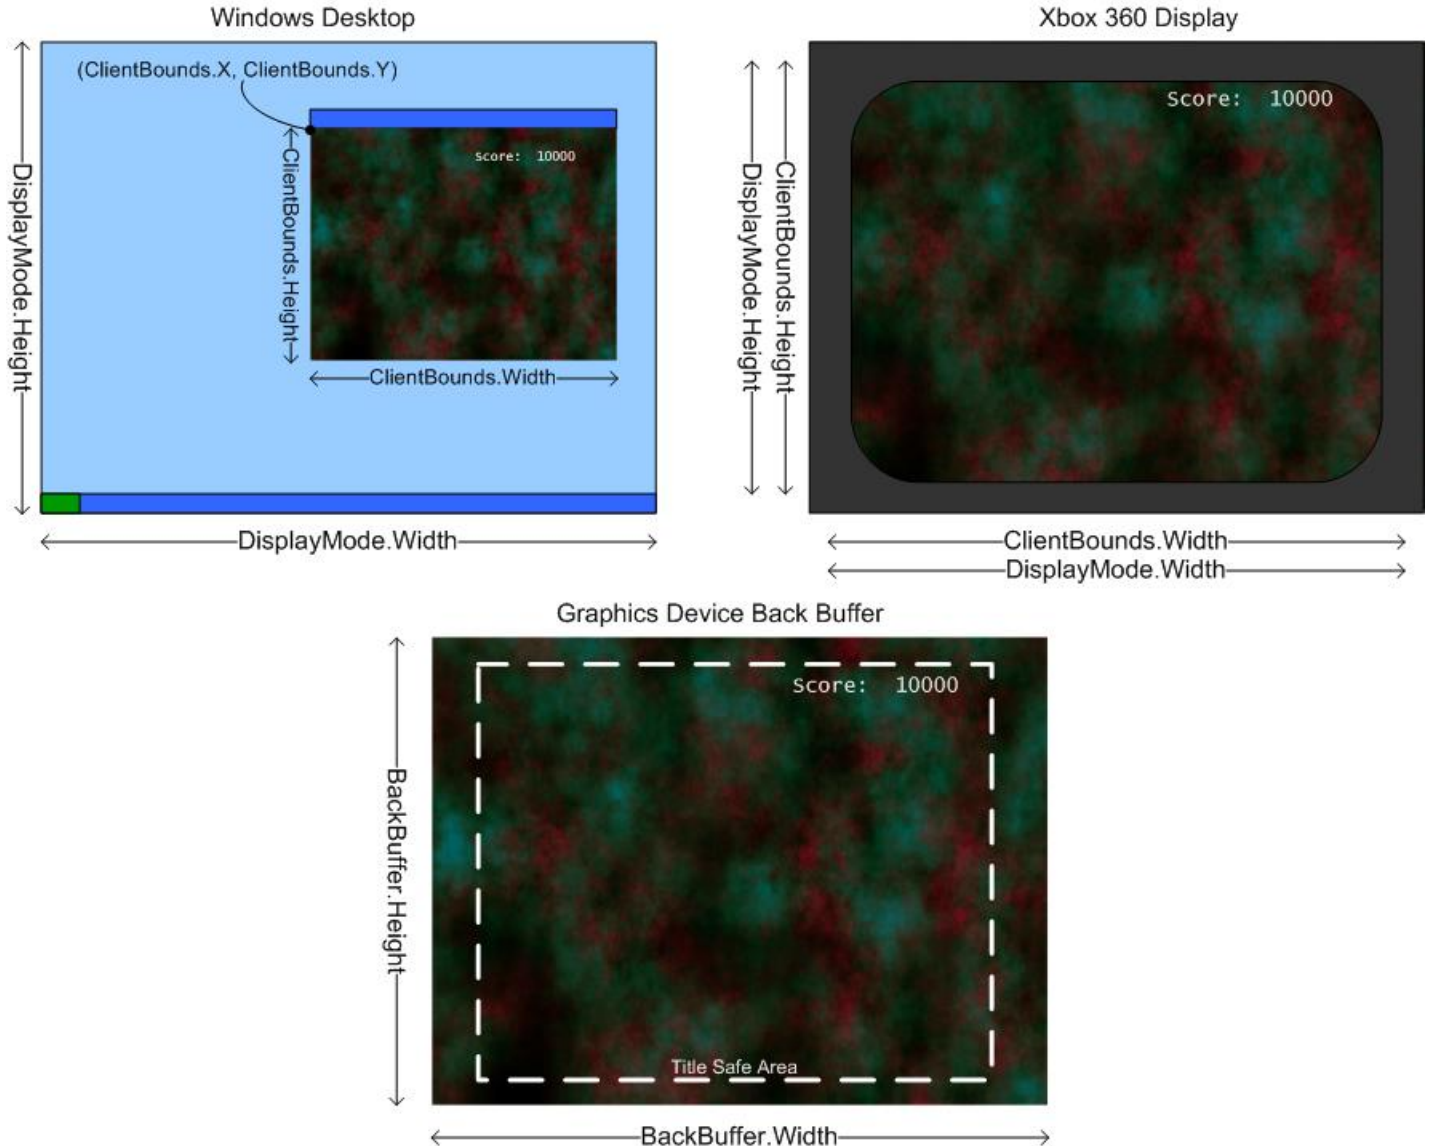

Figure 1. In this diagram, the Windows display is shown with a game that is not in full-screen mode to show the difference between the `DisplayMode` and `ClientBounds` dimensions. Note also that the same back buffer may render differently on an Xbox 360 console compared to a Windows display because the outer 10 to 20 percent of the Xbox 360 back buffer is not "title safe" and may not be visible.

DisplayMode Width and Height

The `DisplayMode Width` and `Height` properties correspond to the *bounds of the display*. The display bounds are different from the bounds of the game window, which can be obtained from the `ClientBounds` dimensions.

When going into full-screen mode on Windows, it is useful to know the display mode width and height so the back buffer dimensions can be set to match the resolution of the display. If the back buffer dimensions are not changed to match the display mode dimensions, the resolution would change when going into full screen mode.

Xbox 360 games should display all text and menu items critical to game play within the inner 80 percent of the x and y resolution for all display modes. This is known as the *title safe region*.

ClientBounds Width and Height

The `ClientBounds Width` and `Height` properties correspond to the *bounds of the game window*, which may be less than the bounds of the display if the game is not full screen. `ClientBounds.X` and `ClientBounds.Y` correspond to the upper-left coordinate of the game window relative to the display mode width and height. On Xbox 360, the `ClientBounds Width` and `Height` properties are always equal to the `DisplayMode Width` and `Height`, and `ClientBounds.X` and `ClientBounds.Y` are always (0, 0).

Viewport Width and Height

The **Viewport Width** and **Height** properties correspond to the current viewport dimensions, which can be thought of as the *view space* width and height. These values are commonly used by methods to create projection matrices, such as [CreatePerspectiveFieldOfView](#). When creating a camera class, you would set the **Viewport** width and height to correspond to the size of the camera viewport.

The dimensions of a viewport default to the dimensions of the render target, but may be a subset of the render target. For example, you might render multiple viewports to a single render target to create a split screen game.

The **Viewport** dimensions do not correspond to the size of the game window (see [ClientBounds](#) for this information) or the display (see [DisplayMode](#) for this information).

Back Buffer Width and Height

The back buffer is a specific render target that has been set to be the next render target presented when [GraphicsDevice.Present](#) is called. To obtain the dimensions of the back buffer, use the [GraphicsDevice.PresentationParameters.BackBufferWidth](#) and [BackBufferHeight](#) properties.

On Windows, the back buffer is created to match the dimensions of the [ClientBounds](#) by default. For Xbox 360 game projects, the back buffer is created with the dimensions that have been specified by the user.

When going into full-screen mode on Windows, it is often desirable to set the back buffer dimensions to match the [DisplayMode](#) dimensions so that the game ("display") resolution does not change when going into full-screen mode.

The graphics back buffer created for an Xbox 360 game project is not necessarily the same size as the final resolution on the television connected to the Xbox 360. The Xbox 360 automatically scales output to the television resolution selected by the user in the System Blade. If the aspect ratio of the back buffer is different than the aspect ratio of the television display mode, the Xbox 360 will automatically add "black bars" (letterboxing) if the user's display is not widescreen.

In addition, if you request a back-buffer resolution that is not supported by the output device, the XNA framework automatically selects the highest resolution supported by the output device. For example, if a graphics back-buffer, with a resolution of 1920x1080 (e.g. 1080p or 1080i), is created and displayed on a device with 480i resolution, the back-buffer is automatically resized to 480i.

Render Targets

Describes how render targets can be an important part of your XNA Framework game when you render simple or complex scenes. For a description of a render target, see [What Is a Render Target?](#)

The following sections detail different aspects of render targets, useful when developing XNA Framework games.

- [Render Targets and Persistence](#)
- [Resolving a Render Target](#)
- [Multiple Render Targets](#)

Render Targets and Persistence

Before XNA Game Studio 3.0, the persistence of render targets depended on the target platform. You can specify the persistence behavior now by using [RenderTargetUsage](#) in the constructor. For example, the following line of code constructs a render target object that is never cleared when set.

 Note
Persistence behavior for the related depth-stencil buffer matches that of the render target.

```
discardTarget= new RenderTarget2D(GraphicsDevice, 200, 200, 1, SurfaceFormat.Color, RenderTargetUsage.PreserveContents);
```

The following tables list related persistence details, based on the target platform and the default value [RenderTargetUsage.DiscardContents](#) used by the constructor.

Creating the Render Target

Platform	Details
Xbox 360	Two surfaces are created: the render target and the resolve texture.
Windows	The default behavior creates two surfaces: the render target surface and the texture used as the output for resolve actions. If you specify persistence (for example, RenderTargetUsage.PreserveContents) and the render target does not have multisampling, you will create only one surface. This surface is a render target texture that is both the surface and the output texture for resolve actions.

Setting the Render Target

Platform	Details
Xbox 360	By default, the resolve texture data is deleted when you set the render target. If you enable persistence, the resolve texture data moves back into the render target (emulating a persisted render target) before you set the new render target.
Windows	The current resolve texture data is saved when you set the render target.

Resolving the Render Target

Platform	Details
Xbox 360	Resolution occurs when you set a new render target. The render target clears to a known, standard color rather than Color.TransparentBlack .
Windows	Resolution occurs when you set a new render target. However, by default, the render target (always a separate surface) is cleared to a known, standard color rather than Color.TransparentBlack . If persistence is enabled, no action is taken.

In addition to [RenderTargetUsage.PreserveContents](#) and [RenderTargetUsage.DiscardContents](#), there is a third option that is platform-specific: [RenderTargetUsage.PlatformContents](#).

This option creates a render target that has persistence for Windows, but not for Xbox 360. However, for games targeting Windows, if you create the render target without multisampling, you only create a single texture. This texture is both the render target surface as well as the resolved texture.

Resolving a Render Target

Before XNA Game Studio 3.0, you called **ResolveRenderTarget** to indicate that you were finished drawing to a render target. This method is now considered obsolete. It causes a compilation error if you use it in your code. The actual resolve operation occurs automatically when you set a new render target (for example, a call to [SetRenderTarget](#)). Note that calling [GetTexture](#) on the current render target throws an exception. This behavior ensures that a new render target has been set (and thus resolved) before you can use the texture for anything else.

Multiple Render Targets

Multiple Render Targets (MRT) refers to the ability to render to multiple surfaces with a single draw call. For games targeting Windows, this option is available on some graphics cards. For games targeting Xbox 360, this option is natively supported. You can use this feature to perform some very nice effects such as deferred shading, or effects such as depth of field or refraction.

The following restrictions apply to MRTs on both platforms.

- All render targets of an MRT must have the same bit depth. However, they can use different formats unless the [SupportsMultipleRenderTargetsIndependentBitDepths](#) property is **false**.
- All surfaces of an MRT should have the same width and height.
- Antialiasing is not supported for MRTs.
- Some MRT implementations do not apply the output write mask. Those that do (indicated by a value of **true** for the [SupportsColorWrite](#) property) have independent color write masks. The number of independent color write masks available is equal to the maximum number of elements the device is capable of supporting.
- Some MRT implementations do not perform post-pixel shader operations, such as dithering, alpha testing, fogging, and blending or masking (except for depth-buffer and depth-stencil testing). Those that do (indicated by a value of **true** for the [SupportsMultipleRenderTargetsPostPixelShaderBlending](#) property).

For those devices that support post-pixel shader operations, use [CheckDeviceFormat](#) (passing [PostPixelShaderBlending](#) for the *queryUsages* parameter value) to verify support for the specific surface format. If the result is **false**, you won't find any available post-pixel shader blending operations for that specific surface format. If **true**, the device is expected to apply the same state to all simultaneous render targets as follows:

- Alpha blend: The color value in αC_i is blended with the i th render target.
- Alpha test: Comparison uses αC_0 . If the comparison fails, the pixel test is terminated for all render targets.
- Fog: Render target 0 is fogged. Other render targets are undefined. Implementations can choose to fog all by using the same state.
- Dithering: Undefined.

Effect States

Provide a mechanism for effects to control the graphics device state. Setting a state through an effect file has exactly the same effect as setting the corresponding render state or sampler state from your C# code.

The syntax for setting an effect state from an effect file is:

```
effect_state [ [index] ] = expression;
```

Where:

effect_state

A graphics device render state or sampler state to set. A complete list of states is listed below.

[[index]]

Optional integer index. The index identifies a particular state within an array of effect states. The outer brackets indicate that an index is optional. If an index is used, be sure to use inner brackets.

expression

State assignment expression.

⚠ Caution

Effects that set render states that are not defined in this document may compile, but may fail to load due to run-time validation.

For Boolean render or sampler states, nonzero values are converted to **true** (1), and zero values are left alone (**false**).

Effect states can be divided into the following categories.

- [Render States](#)
 - [Pixel Pipe Render States](#)
 - [Vertex Pipe Render States](#)
- [Sampler States](#)
- [Sampler Stage States](#)
- [Shader States](#)
- [Shader Constant States](#)
 - [Pixel Shader Constant States](#)
 - [Vertex Shader Constant States](#)
- [Texture States](#)

Render States

There are two types of render states.

- [Pixel Pipe Render States](#)
- [Vertex Pipe Render States](#)

Pixel Pipe Render States

State	Type	Values
AlphaBlendEnable	bool	true or false . Equivalent to setting AlphaBlendEnable .
AlphaFunc	dword	Any value of CompareFunction . Equivalent to setting AlphaFunction .
AlphaRef	dword	Same values as ReferenceAlpha . Values can range from 0x00000000 through 0x000000FF.
AlphaTestEnable	dword	true or false . Equivalent to setting AlphaTestEnable .
BlendOp	dword	Same values as BlendFunction . Equivalent to setting BlendFunction .
ColorWriteEnable	dword	Bitwise combination of RED GREEN BLUE ALPHA. Equivalent to setting ColorWriteChannels .

DepthBias	int	Same values as DepthBias .
DestBlend	dwor d	Same values as Blend , excluding BothSourceAlpha and BothInverseSourceAlpha , which are not supported.
FillMode	dwor d	Same values as FillMode .
SrcBlend	dwor d	Same values as Blend , excluding BothSourceAlpha and BothInverseSourceAlpha , which are not supported.
StencilEnable	bool	true or false . Equivalent to setting StencilEnable .
StencilFail	dwor d	Keep, Zero, Replace, IncrSat, DecrSat, Invert, Incr, Dec, or TwoSided. Equivalent to setting StencilFail .
StencilFunc	dwor d	Same values as CompareFunction . Equivalent to setting StencilFunction .
StencilMask	dwor d	Same values as StencilMask .
StencilPass	dwor d	Keep, Zero, Replace, IncrSat, DecrSat, Invert, Incr, Dec, or TwoSided. Equivalent to setting StencilPass .
StencilRef	int	Same values as ReferenceStencil .
StencilWriteMask	dwor d	Same values as StencilWriteMask .
StencilZFail	dwor d	Keep, Zero, Replace, IncrSat, DecrSat, Invert, Incr, Dec, or TwoSided. Equivalent to setting StencilDepthBufferFail .
Wrap0–Wrap15	dwor d	Valid values are: <ul style="list-style-type: none"> • COORD0 (which corresponds to TextureWrapCoordinates.Zero) • COORD1 (which corresponds to TextureWrapCoordinates.One) • COORD2 (which corresponds to TextureWrapCoordinates.Two) • COORD3 (which corresponds to TextureWrapCoordinates.Three) • U • V • W
ZEnable	dwor d	true or false .
ZFunc	dwor d	Same values as CompareFunction . Equivalent to setting DepthBufferFunction .
ZWriteEnable	bool	true or false . Equivalent to setting DepthBufferWriteEnable .

Vertex Pipe Render States

State	Type	Values
ClipPlaneEnable	dwor d	<p>Valid values are any DWORD in which the status of each bit (set or not set) toggles the activation state of a corresponding user-defined clipping plane. The least significant bit (bit 0) controls the first clipping plane at index 0, and subsequent bits control the activation of clipping planes at higher indices. If a bit is set, the system applies the appropriate clipping plane during scene rendering. The default value is 0.</p> <p>User-defined clipping planes are enabled when the value set in this render state contains one or more set bits (that is, is not 0). The value of the render state is not important; the system does not interpret the value as a number. Rather, the value enables the clipping plane, whose corresponding bit is set. Bit 0 controls the state of the first clipping plane (at index 0), bit 1 the second plane, and so on.</p> <p>The bit patterns that these macros create can be combined by using a logical OR operation to simultaneously enable multiple clipping planes. Omitting one of these from the combination effectively disables the clipping plane at that index.</p>

Cull Mode	dw	Same values as CullMode .
MultiSampleAntiAlias	bool	true or false . Equivalent to setting MultiSampleAntiAlias .
MultiSampleMask	dw	Same values as MultiSampleMask .
PointSize	float	
PointSize_Min	float	
PointSize_Max	float	
PointSizeEnable	bool	True or False.

Sampler States

State	Type	Values
Sampler	sampler	null , or a sampler state block.

Sampler Stage States

Sampler stages are used to sample textures. Sampler state determines filtering types and texture addressing modes.

Sampler state	Type	Values
AddressU[16]	dw ord	Same values as TextureAddressMode . Equivalent to setting AddressU .
AddressV[16]	dw ord	Same values as TextureAddressMode . Equivalent to setting AddressV .
AddressW[16]	dw ord	Same values as TextureAddressMode . Equivalent to setting AddressW .
BorderColor[16]	DWORD	Either 0x00000000 (black) or 0xFFFFFFFF (white). Xbox 360 only supports a border color of either black or white. For Xbox 360, nonzero values are changed to 0xFFFFFFFF; zero values are left as is.
MagFilter[16]	dw ord	Point, Linear, or Anisotropic. Equivalent to setting MagFilter .
MaxAnisotropy[16]	dw ord	Values must be in the range [1, 16]. The default value is 1.
MaxMipLevel[16]	int	Values range from 0 to $(n - 1)$ where 0 is the largest. The default value is zero.
MinFilter[16]	dw ord	Point, Linear, or Anisotropic. Equivalent to setting MinFilter .
MipFilter[16]	dw ord	None, Point, or Linear. Equivalent to setting MipFilter .

MipMapLodBias[16]	float	Values must be in the range [-16.0f, 15.9375f]. This value is converted into a 5.5 fixed-point format, where 5 bits are used for a signed integer and 5 bits are reserved for the fractional part. The default value is zero.
-------------------	--------------	---

Shader States

There are only two effect shader states: one associated with a vertex shader object and/or associated with a pixel shader object.

Pixel Shader States

State	Type	Values
PixelShader	pixelshader	NULL, an assembly block, a compile target, or a pixel shader parameter.

Vertex Shader States

State	Type	Values
VertexShader	vertexshader	NULL, an assembly block, a compile target, or a pixel shader parameter.

Shader Constant States

Shader constant states are used for setting shader constant registers.

Pixel Shader Constant States

State	Type	Values
PixelShaderConstant	float [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of floats ; <i>m</i> and <i>n</i> are optional.
PixelShaderConstant1	float4	One 4D float .
PixelShaderConstant2	float4x2	Two 4D floats .
PixelShaderConstant3	float4x3	Three 4D floats .
PixelShaderConstant4	float4x4	Four 4D floats .
PixelShaderConstantB	bool [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of bools ; <i>m</i> and <i>n</i> are optional.
PixelShaderConstantI	int [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of ints ; <i>m</i> and <i>n</i> are optional.
PixelShaderConstantF	float [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of floats ; <i>m</i> and <i>n</i> are optional.

Vertex Shader Constant States

These shader states set vertex shader constants.

State	Type	Values
VertexShaderConstant	float [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of floats ; <i>m</i> and <i>n</i> are optional.
VertexShaderConstant1	float4	One 4D float .
VertexShaderConstant2	float4x2	Two 4D floats .
VertexShaderConstant3	float4x3	Three 4D floats .
VertexShaderConstant4	float4x4	Four 4D floats .
VertexShaderConstantB	bool [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of bools ; <i>m</i> and <i>n</i> are optional.
VertexShaderConstantI	int [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of ints ; <i>m</i> and <i>n</i> are optional.
VertexShaderConstantF	float [<i>m</i>][<i>n</i>]	<i>m</i> × <i>n</i> array of floats ; <i>m</i> and <i>n</i> are optional.

Texture States

State	Type	Values
Texture[8]	texture	NULL, or a texture parameter.

2D Graphics Overview

Sprites are 2D bitmaps drawn directly on the screen, as opposed to being drawn in 3D space. Sprites are commonly used to display information such as health bars, number of lives, or text such as scores. Some games, especially older games, are composed entirely of sprites. This topic discusses sprites in detail, covering the following areas.

- [Overview](#)
- [Sprite Origin](#)
- [Sprite Depth](#)
- [Sampling Textures](#)
- [Sprite Scaling](#)
- [Sprite Transformation Matrices](#)
- [Sprite Fonts](#)
- [Sprite Batching](#)
- [Render States](#)
- [Point Sprites](#)

Overview

Sprites are positioned on the screen by coordinates. The width and height of the screen is the same as the back buffer. The x-axis represents the screen width and the y-axis represents the screen height. It is important to note that the y-axis is measured from the top of the screen and increases as you move *down* the screen, and the x-axis is measured from left to right. For example, when the graphics back buffer is 800×600, 0,0 is the upper left of the screen, and 800,600 is the lower right of the screen (see Figure 1).

Figure 1. A sprite's location in screen coordinates (x-axis 400, y-axis 200)

To draw a sprite, you must create a [SpriteBatch](#) object, initialize it by calling [Begin](#), and then call [Draw](#) for each sprite. The bitmap information for a sprite is taken from a [Texture2D](#) object. The texture may contain alpha channel information to make part of the texture transparent or semi-transparent. You can tint, rotate, or scale sprites by using [Draw](#). This method also gives you the option of drawing only part of the texture on the screen. After you draw the sprites, call [End](#) before calling [Present](#).

Sprite Origin

When you draw sprites, the sprite *origin* is the most important concept. The origin is a specific point on the sprite, which is by default the upper-left corner of the sprite, or (0,0). [Draw](#) draws the origin of the sprite at the screen location you specify. For example, if you draw a 50×50 pixel sprite at location (400,200) without specifying an origin, the upper left of the sprite will be on pixel (400,200). If you use the center of the 50×50 sprite as the origin (25,25), to draw the sprite in the same position you must add the origin coordinates to the position. In this case, the position is (425,225) and the origin is (25,25), as shown in Figure 2.

Figure 2. The blue dot indicates the center coordinate of the sprite

When rotating a sprite, the method uses the origin as the center of the rotation. In these cases, it is common to use the center of the sprite as the origin when calculating where to draw the sprite on the screen.

Sprite Depth

Sprites also have a concept of *depth*. When drawing a sprite, you can specify a depth between 0 and 1 as a floating-point number. Sprites drawn at a depth of 0 are at the "front" of the screen, and will cover any sprites drawn at a lower depth. Sprites drawn at a depth of 1 are at the "back" of the screen, and will be covered by any sprites drawn at a depth less than 1.

Sampling Textures

A sprite is based on a [Texture2D](#) object—in other words, a bitmap. [Draw](#) can draw the entire texture, or a portion of the texture. To draw a portion of the texture, use the **sourceRectangle** parameter to specify which *texels* to draw as a sprite. A *texel* is a pixel in the texture. A 32×32 texture has 1024 texels, specified as x and y values similar to how screen coordinates are specified. Specifying a **sourceRectangle** of (0, 0, 16, 16) would select the upper-left quadrant of a 32×32 texture.

Sprite Scaling

[Draw](#) provides three methods of scaling sprites. [Draw](#) accepts either a uniform scaling parameter, a nonuniform scaling parameter, or a source and destination rectangle. The uniform scaling parameter is a floating-point number that multiplies the sprite size through both the x- and y-axes. This will shrink or expand the sprite along each axis equally, maintaining the original ratio between the sprite width and height.

To scale the x- and y-axes independently, [Draw](#) accepts a [Vector2](#) value as a scalar. This [Vector2](#) specifies nonuniform scaling: x- and y-axes are scaled independently according to the **X** and **Y** fields of the [Vector2](#).

[Draw](#) also accepts a source and destination rectangle. The destination rectangle is specified in screen coordinates, while the source rectangle is specified in texels. [Draw](#) takes the pixels on the texture specified in **sourceRectangle** and scales them independently along the x- and y-axes until they fit the screen coordinates specified by **destinationRectangle**.

Sprite Transformation Matrices

XNA Game Studio includes a feature for sprite batches—the ability to specify a transformation matrix that the batch can apply to each sprite before drawing. The transformation matrix can be any combination of translation, rotation, or scaling matrices multiplied together into a single matrix. This matrix is combined with the sprite position, rotation, scaling, and depth parameters supplied to [Draw](#). Because the matrix also applies to depth, any z-coordinate transformation that makes the sprite depth greater than 1.0 or less than 0.0 will cause the sprite to disappear.

See [How To: Rotate a Group of Sprites](#) for an example of matrix rotation, and [How To: Scale Sprites Based On Screen Size](#) for an example of matrix scaling.

Sprite Fonts

XNA Game Studio enables you to draw text using [SpriteBatch](#). The [DrawString](#) method will draw text on screen with position, color, rotation, origin, and scaling. [DrawString](#) also requires a special type of texture encapsulated by the [SpriteFont](#) class. A [SpriteFont](#) is created by the Content Pipeline when you add a Sprite Font file to your project. The Sprite Font file has information such as the name and point size of the font, and which Unicode characters to include in the [SpriteFont](#) texture. At run time, a [SpriteFont](#) is loaded with [ContentManager.Load](#) just like a [Texture2D](#) object.

See [How To: Draw Text](#) for an example of how to use [SpriteFont](#) to draw text, and [Sprite Font XML Schema Reference](#) for a list of Sprite Font tags. You can use the Content Pipeline to determine your character regions automatically. For more information, see [How To: Extend the Font Description Processor to Support Additional Characters](#).

Sprite Batching

In normal drawing, the [SpriteBatch](#) object does not change any render states or draw any sprites until you call [End](#). This is known as *Deferred* mode. In Deferred mode, [SpriteBatch](#) saves the information from each [Draw](#) call until you call [End](#). When you then call [End](#), [SpriteBatch](#) changes the graphics device settings and draws each sprite in the batch. [End](#) then resets the device settings, if you specified [SaveStateMode.SaveState](#).

If you call [Begin](#), specifying [SpriteSortMode.Immediate](#), it triggers *Immediate* mode. In Immediate mode, the [SpriteBatch](#) immediately changes the graphics device render states to begin drawing sprites. Thereafter, each call to [Draw](#) immediately draws the sprite using the current device settings. Calling [End](#) resets the device settings, if you specified [SaveStateMode.SaveState](#).

In Immediate mode, once you call [Begin](#) on one [SpriteBatch](#) instance, do not call it on any other [SpriteBatch](#) instance until you call [End](#) for the first [SpriteBatch](#).

Deferred mode is slower than Immediate mode, but it allows multiple instances of [SpriteBatch](#) to accept [Begin](#) and [Draw](#) calls without interfering with each other.

Render States

The [SpriteBatch](#) object sets the following render states on the graphics card when drawing sprites.

Render State	Value
GraphicsDevice.RenderState.CullMode	CullMode.CullCounterClockwiseFace
GraphicsDevice.RenderState.DepthBufferEnable	false
GraphicsDevice.RenderState.AlphaBlendEnable	true
GraphicsDevice.RenderState.AlphaBlendOperation	BlendFunction.Add
GraphicsDevice.RenderState.SourceBlend	Blend.SourceAlpha
GraphicsDevice.RenderState.DestinationBlend	Blend.InverseSourceAlpha
GraphicsDevice.RenderState.SeparateAlphaBlendEnabled	false
GraphicsDevice.RenderState.AlphaTestEnable	true
GraphicsDevice.RenderState.AlphaFunction	CompareFunction.Greater
GraphicsDevice.RenderState.ReferenceAlpha	0
GraphicsDevice.SamplerStates[0].AddressU	TextureAddressMode.Clamp
GraphicsDevice.SamplerStates[0].AddressV	TextureAddressMode.Clamp
GraphicsDevice.SamplerStates[0].MagFilter	TextureFilter.Linear
GraphicsDevice.SamplerStates[0].MinFilter	TextureFilter.Linear
GraphicsDevice.SamplerStates[0].MipFilter	TextureFilter.Linear
GraphicsDevice.SamplerStates[0].MipMapLevelOfDetailBias	0.0f
GraphicsDevice.SamplerStates[0].MaxMipLevel	0

The most important settings changed are [DepthBufferEnable](#) (normally **true**), [AlphaBlendEnable](#) (normally **false**), and [AlphaTestEnable](#) (normally **false**). You may also want to set [TextureAddressMode.Wrap](#) for the [AddressU](#) and [AddressV](#) sampler states.

The [SpriteBatch](#) object also sets the [Vertices](#), [Indices](#), [VertexDeclaration](#), [VertexShader](#), and [PixelShader](#) properties on the current [GraphicsDevice](#).

In Immediate mode, all of the render states can be changed before [Draw](#) is called, and [Draw](#) will use the new render states. [How To: Apply a Pixel Shader to Sprites](#) takes advantage of this to apply a custom pixel shader to [Draw](#).

Point Sprites

Point sprites are sprites drawn in 3D space. These sprites are specified by a position and a size. When a point sprite is rendered, it always appears the same size on screen (no matter where the point lies in 3D space relative to the camera) and faces the camera. Point sprites are used to render particle systems. [How To: Apply a Pixel Shader to Sprites](#) gives an example of how to render point sprites using a simple pixel and vertex shader.

Drawing a Sprite

To draw a sprite on screen

1. Derive a class from [Game](#).
2. Define a [SpriteBatch](#) object as a field on your game class.
3. In your [LoadContent](#) method, construct the [SpriteBatch](#) object, passing the current graphics device.
4. Load the textures that will be used for drawing sprites in [LoadContent](#).

In this case, the example uses the **Content** member to load a texture from the XNA Framework Content Pipeline. The texture must be in the project, with the same name passed to [Load](#).

C#

```
private Texture2D SpriteTexture;
private Rectangle TitleSafe;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    SpriteTexture = Content.Load<Texture2D>("Sprite");
    TitleSafe = GetTitleSafeArea(.8f);
}
```

5. In the overridden [Draw](#) method, call [Clear](#).
6. After [Clear](#), call [Begin](#) on your [SpriteBatch](#) object.
7. Create a [Vector2](#) to represent the screen position of the sprite.

On Xbox 360, be careful not to draw foreground sprites on the outer 10 or 20 percent of the screen. Some televisions may obscure the edge of the screen. The **GetTitleSafeArea** function calculates the area of the current [Viewport](#) that is safe, given a specified safety percentage.

C#

```
protected Rectangle GetTitleSafeArea( float percent )
{
    Rectangle retval = new Rectangle(
        graphics.GraphicsDevice.Viewport.X,
        graphics.GraphicsDevice.Viewport.Y,
        graphics.GraphicsDevice.Viewport.Width,
        graphics.GraphicsDevice.Viewport.Height );

    #if XBOX
        // Find Title Safe area of Xbox 360.
        float border = (1 - percent) / 2;
        retval.X = (int)(border * retval.Width);
        retval.Y = (int)(border * retval.Height);
        retval.Width = (int)(percent * retval.Width);
        retval.Height = (int)(percent * retval.Height);
        return retval;
    #endif
}
```

```
#else
    return retval;
#endif
}
```

8. Call `Draw` on your `SpriteBatch` object, passing the texture to draw, the screen position, and the color to apply.
9. Use `Color.White` to draw the texture without any color effects.
10. When all the sprites have been drawn, call `End` on your `SpriteBatch` object.

C#

```
protected override void Draw( gameTime )
{
    graphics.GraphicsDevice.Clear( Color.CornflowerBlue );
    spriteBatch.Begin();
    Vector2 pos = new Vector2( TitleSafe.Left, TitleSafe.Top );
    spriteBatch.Draw(SpriteTexture, pos, Color.White);
    spriteBatch.End();
    base.Draw( gameTime );
}
```

How To: Animate a Sprite

Demonstrates how to animate a sprite from a texture using a custom class.

The source code in this example assumes the texture you are loading is a *strip* of equal-sized images. In this example, the texture is a 256×64 texture with four frames. This example uses a class named **AnimatedTexture**, which is included with the sample.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download AnimatedSprite_Sample.zip.](#)

Drawing an Animated Sprite

To draw an animated sprite

1. Follow the steps of [How To: Draw a Sprite](#).
2. In your game's constructor, create an instance of the **AnimatedTexture** class.

This example uses (0,0) as the origin of the texture, no rotation, a scale of 2, and a depth of 0.5.

C#

```
private AnimatedTexture SpriteTexture;
private const float Rotation = 0;
private const float Scale = 2.0f;
private const float Depth = 0.5f;
public Game1()
{
    ...
    SpriteTexture = new AnimatedTexture(Vector2.Zero,
        Rotation, Scale, Depth);
#if ZUNE
    // Frame rate is 30 fps by default for Zune.
    TargetElapsedTime = TimeSpan.FromSeconds(1 / 30.0);
#endif
}
```

3. Load the texture or textures that provide the image data for the animation.

In this example, the **AnimatedTexture** class loads a single texture and divides it into frames of animation. It uses the last parameter to determine how many frames to draw each second. In this case, it draws four frames at 2 fps (frames per second).

C#

```
private Viewport viewport;
private Vector2 shipPos;
private const int Frames = 4;
private const int FramesPerSec = 2;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    // "shipanimated" is the name of the sprite asset in the project.
    SpriteTexture.Load(Content, "shipanimated", Frames, FramesPerSec);
    viewport = graphics.GraphicsDevice.Viewport;
    shipPos = new Vector2(viewport.Width / 2, viewport.Height / 2);
}
```

4. In your game's `Update` method, determine which frame of animation to display.

C#

```
protected override void Update(GameTime gameTime)
{
    ...
    float elapsed = (float)gameTime.ElapsedGameTime.TotalSeconds;

    // TODO: Add your game logic here.
    SpriteTexture.UpdateFrame(elapsed);
    base.Update(gameTime);
}
```

This is handled by `AnimatedTexture`'s **UpdateFrame** method, which takes the elapsed seconds between updates as a parameter.

C#

```
// class AnimatedTexture
public void UpdateFrame(float elapsed)
{
    if (Paused)
        return;
    TotalElapsed += elapsed;
    if (TotalElapsed > TimePerFrame)
    {
        Frame++;
        // Keep the Frame between 0 and the total frames, minus one.
        Frame = Frame % framecount;
        TotalElapsed -= TimePerFrame;
    }
}
```

5. In your game's `Draw` method, call `Draw` on the **AnimatedTexture** object.

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    // TODO: Add your drawing code here
    spriteBatch.Begin();
    SpriteTexture.DrawFrame(spriteBatch, shipPos);
    spriteBatch.End();

    base.Draw(gameTime);
}
```

AnimatedTexture will draw the sprite using the subrectangle of the texture that contains the desired animation.

C#

```
// class AnimatedTexture
public void DrawFrame(SpriteBatch batch, Vector2 screenPos)
{
    DrawFrame(batch, Frame, screenPos);
}
public void DrawFrame(SpriteBatch batch, int frame, Vector2 screenPos)
```

```
{  
    int FrameWidth = myTexture.Width / framecount;  
    Rectangle sourcerect = new Rectangle(FrameWidth * frame, 0,  
        FrameWidth, myTexture.Height);  
    batch.Draw(myTexture, screenPos, sourcerect, Color.White,  
        Rotation, Origin, Scale, SpriteEffects.None, Depth);  
}
```

How To: Draw a Masked Sprite over a Background

The foreground sprite in this example must include masking information.

Drawing a Foreground and Background Sprite

To draw a foreground and background sprite

1. Create the game class, and load your content as described in the procedures of [How To: Draw a Sprite](#).

C#

```
private Vector2 ViperPos; // Position of foreground sprite on screen
private int ScrollHeight; // Height of background sprite
private Viewport viewport;
Texture2D ShipTexture;
Texture2D StarTexture;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    StarTexture = Content.Load<Texture2D>("starfield");
    ShipTexture = Content.Load<Texture2D>("ship");
    viewport = graphics.GraphicsDevice.Viewport;

    ViperPos.X = viewport.Width / 2;
    ViperPos.Y = viewport.Height - 100;
    ScrollHeight = StarTexture.Height;
}
```

2. In [Draw](#), call [Begin](#) for the [SpriteBatch](#).
3. Specify [SpriteBlendMode.None](#).

This will tell the [SpriteBatch](#) to ignore alpha color values when drawing sprites. By default, the z-order of sprites is the order in which they are drawn.

4. Draw the background sprites, and then call [End](#).

C#

```
spriteBatch.Begin(SpriteBlendMode.None);
DrawBackground(spriteBatch);
spriteBatch.End();
```

5. Call [Begin](#) for the [SpriteBatch](#) again.
6. This time, specify [SpriteBlendMode.AlphaBlend](#).

This will cause pixels on the sprite with an alpha value less than 255 to become progressively transparent based on the magnitude of the alpha value. An alpha of 0 will make the pixel completely transparent. Calling [Begin](#) with no parameters causes [SpriteBatch](#) to default to [SpriteBlendMode.AlphaBlend](#).

7. Draw the foreground sprites, then call [End](#).

C#

```
spriteBatch.Begin(SpriteBlendMode.AlphaBlend);  
DrawForeground(spriteBatch);  
spriteBatch.End();
```

How To: Make a Scrolling Background

Demonstrates how to draw a scrolling background sprite using the [SpriteBatch](#) class.

The Complete Sample

[Download ScrollingBackground_Sample.zip.](#)

Drawing a Scrolling Background Sprite

To draw a scrolling background sprite

1. Create the game class.
2. Load resources as described in the procedures of [How To: Draw a Sprite](#).
3. Load the background texture.

C#

```
private ScrollingBackground myBackground;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    myBackground = new ScrollingBackground();
    Texture2D background = Content.Load<Texture2D>("starfield");
    myBackground.Load(GraphicsDevice, background);
}
```

4. Determine the size of the background texture and the size of the screen.

The texture size is determined using the [Height](#) and [Width](#) properties, and the screen size is determined using the [Viewport](#) property on the graphics device.

5. Using the texture and screen information, set the origin of the texture to the center of the top edge of the texture, and the initial screen position to the center of the screen.

C#

```
// class ScrollingBackground
private Vector2 screenpos, origin, texturesize;
private Texture2D mytexture;
private int screenheight;
public void Load( GraphicsDevice device, Texture2D backgroundTexture )
{
    mytexture = backgroundTexture;
    screenheight = device.Viewport.Height;
    int screenwidth = device.Viewport.Width;
    // Set the origin so that we're drawing from the
    // center of the top edge.
    origin = new Vector2( mytexture.Width / 2, 0 );
    // Set the screen position to the center of the screen.
    screenpos = new Vector2( screenwidth / 2, screenheight / 2 );
    // Offset to draw the second texture, when necessary.
    texturesize = new Vector2( 0, mytexture.Height );
}
```

6. To scroll the background, change the screen position of the background texture in your [Update](#) method.

This example moves the background down 100 pixels per second by increasing the screen position's Y value.

C#

```
protected override void Update(GameTime gameTime)
{
    ...
    // The time since Update was called last.
    float elapsed = (float)gameTime.ElapsedGameTime.TotalSeconds;

    // TODO: Add your game logic here.
    myBackground.Update(elapsed * 100);

    base.Update(gameTime);
}
```

The Y value is kept no larger than the texture height, making the background scroll from the bottom of the screen back to the top.

C#

```
public void Update( float deltaY )
{
    screenpos.Y += deltaY;
    screenpos.Y = screenpos.Y % mytexture.Height;
}
// ScrollingBackground.Draw
```

7. Draw the background using the origin and screen position calculated in [LoadContent](#) and [Update](#).

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    spriteBatch.Begin();
    myBackground.Draw(spriteBatch);
    spriteBatch.End();

    base.Draw(gameTime);
}
```

In case the texture doesn't cover the screen, another texture is drawn. This subtracts the texture height from the screen position using the **texture.size** vector created at load time. This creates the illusion of a loop.

C#

```
public void Draw( SpriteBatch batch )
{
    // Draw the texture, if it is still onscreen.
    if (screenpos.Y < screenheight)
    {
        batch.Draw( mytexture, screenpos, null,
            Color.White, 0, origin, 1, SpriteEffects.None, 0f );
    }
    // Draw the texture a second time, behind the first,
    // to create the scrolling illusion.
    batch.Draw( mytexture, screenpos - texture.size, null,
        Color.White, 0, origin, 1, SpriteEffects.None, 0f );
}
```

Drawing a Rotated Sprite

To draw a rotated sprite on screen

1. Follow the procedures of [How To: Draw a Sprite](#).
2. Determine the screen location of the sprite, and the point within the texture that will serve as the origin.

By default, the origin of a texture is (0,0), the upper-left corner. When you draw a sprite, the origin point in the texture is placed on the screen coordinate specified by the *at* parameter. In this example, the origin is the center of the texture, and the screen position is the center of the screen.

C#

```
private Texture2D SpriteTexture;
private Vector2 origin;
private Vector2 screenpos;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    SpriteTexture = Content.Load<Texture2D>("ship");
    Viewport viewport = graphics.GraphicsDevice.Viewport;
    origin.X = SpriteTexture.Width / 2;
    origin.Y = SpriteTexture.Height / 2;
    screenpos.X = viewport.Width / 2;
    screenpos.Y = viewport.Height / 2;
}
```

3. In your [Update](#) method, determine the rotation angle to use for the sprite.

The angle is specified in radians, and it can be greater than two times π , but does not need to be.

C#

```
private float RotationAngle;
protected override void Update(GameTime gameTime)
{
    // Allows the game to exit
    if (GamePad.GetState(PlayerIndex.One).Buttons.Back == ButtonState.Pressed)
        this.Exit();

    // The time since Update was called last.
    float elapsed = (float)gameTime.ElapsedGameTime.TotalSeconds;

    // TODO: Add your game logic here.
    RotationAngle += elapsed;
    float circle = MathHelper.Pi * 2;
    RotationAngle = RotationAngle % circle;

    base.Update(gameTime);
}
```

```
}
```

4. In your own [Draw](#) method, call [SpriteBatch.Draw](#) with the texture, angle, screen position, and origin of the texture.

C#

```
protected override void Draw(GameTime gameTime)
{
    graphics.GraphicsDevice.Clear(Color.CornflowerBlue);

    // TODO: Add your drawing code here
    spriteBatch.Begin();
    spriteBatch.Draw(SpriteTexture, screenpos, null, Color.White, RotationAngle,
        origin, 1.0f, SpriteEffects.None, 0f);
    spriteBatch.End();

    base.Draw(gameTime);
}
```

5. When all the sprites have been drawn, call [End](#) on your [SpriteBatch](#) object.

How To: Rotate a Group of Sprites

Demonstrates how to rotate a group of sprites around a single point using a rotation [Matrix](#). It uses two methods. It rotates the sprite positions manually during [Update](#), and it creates a rotation matrix during [Update](#) that [SpriteBatch](#) can use during [Draw](#).

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download RotateSpriteGroup_Sample.zip.](#)

Drawing a Rotated Group of Sprites

To draw a rotated group of sprites on screen

1. Follow the steps of [How To: Draw a Sprite](#).
2. Create one set of [Vector2](#) objects that represents the unrotated positions of the sprites, and one set to hold the rotated values.

C#

```
private Vector2[] myVectors;
private Vector2[] drawVectors;
protected override void Initialize()
{
    myVectors = new Vector2[9];
    drawVectors = new Vector2[9];

    base.Initialize();
}
```

3. After loading the sprite, calculate the positions of the unrotated group of sprites based on the sprite's size.

C#

```
private Texture2D SpriteTexture;
private Vector2 origin;
private Vector2 screenpos;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    SpriteTexture = Content.Load<Texture2D>("ship");
    origin.X = SpriteTexture.Width / 2;
    origin.Y = SpriteTexture.Height / 2;
    Viewport viewport = graphics.GraphicsDevice.Viewport;
    screenpos.X = viewport.Width / 2;
    screenpos.Y = viewport.Height / 2;
}
```

4. In your [Update](#) method, copy the unrotated vectors and determine the screen position around which all the sprites will rotate.

C#

```
private float RotationAngle = 0f;
private bool batchAutoRotate = false;
private Matrix rotationMatrix = Matrix.Identity;
protected override void Update(GameTime gameTime)
```

```

{
    ...
    float elapsed = (float)gameTime.ElapsedGameTime.TotalSeconds;

    RotationAngle += elapsed;
    float circle = MathHelper.Pi * 2;
    RotationAngle = RotationAngle % circle;

    // Copy and rotate the sprite positions.
    drawVectors = (Vector2[])myVectors.Clone();

    if (!batchAutoRotate)
        RotatePoints(ref screenpos, RotationAngle, ref drawVectors);
    else
        UpdateMatrix(ref screenpos, RotationAngle);

    base.Update(gameTime);
}

```

Now you need to transform each vector using a rotation matrix created for the rotation angle.

5. To rotate around the origin, transform each vector relative to the origin by subtracting the origin vector.
6. Add the origin vector to the transformed vector to create the final rotated vector.

C#

```

private static void RotatePoints(ref Vector2 origin, float radians,
    ref Vector2[] Vectors)
{
    Matrix myRotationMatrix = Matrix.CreateRotationZ(radians);

    for (int i = 0; i < 9; i++)
    {
        // Rotate relative to origin.
        Vector2 rotatedVector =
            Vector2.Transform(Vectors[i] - origin, myRotationMatrix);

        // Add origin to get final location.
        Vectors[i] = rotatedVector + origin;
    }
}

```

7. Draw each sprite using the rotated vectors as screen locations.

C#

```

private void DrawPoints()
{
    // Draw using manually rotated vectors
    spriteBatch.Begin();
    for (int i = 0; i < drawVectors.Length; i++)
        spriteBatch.Draw(SpriteTexture, drawVectors[i], null,
            Color.White, RotationAngle, origin, 1.0f,
            SpriteEffects.None, 0f);
    spriteBatch.End();
}

```

8. When all the sprites have been drawn, call `End`.

To draw a rotated group of sprites on screen using `SpriteBatch` transformation

1. Follow the steps of [How To: Draw a Sprite](#).
2. Create one set of [Vector2](#) objects that represents the unrotated positions of the sprites, and one set to hold the rotated values.

C#

```
private Vector2[] myVectors;
private Vector2[] drawVectors;
protected override void Initialize()
{
    myVectors = new Vector2[9];
    drawVectors = new Vector2[9];

    base.Initialize();
}
```

3. After loading the sprite, calculate the positions of the unrotated group of sprites based on the sprite's size.

C#

```
private Texture2D SpriteTexture;
private Vector2 origin;
private Vector2 screenpos;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    SpriteTexture = Content.Load<Texture2D>("ship");
    origin.X = SpriteTexture.Width / 2;
    origin.Y = SpriteTexture.Height / 2;
    Viewport viewport = graphics.GraphicsDevice.Viewport;
    screenpos.X = viewport.Width / 2;
    screenpos.Y = viewport.Height / 2;
}
```

4. In your [Update](#) method, copy the unrotated vectors and determine the screen position around which all the sprites will rotate.

C#

```
private float RotationAngle = 0f;
private bool batchAutoRotate = false;
private Matrix rotationMatrix = Matrix.Identity;
protected override void Update(GameTime gameTime)
{
    ...
    float elapsed = (float)gameTime.ElapsedGameTime.TotalSeconds;

    RotationAngle += elapsed;
    float circle = MathHelper.Pi * 2;
    RotationAngle = RotationAngle % circle;

    // Copy and rotate the sprite positions.
    drawVectors = (Vector2[])myVectors.Clone();

    if (!batchAutoRotate)
        RotatePoints(ref screenpos, RotationAngle, ref drawVectors);
    else
        UpdateMatrix(ref screenpos, RotationAngle);
}
```

```
    base.Update(gameTime);  
}
```

5. Create a rotation matrix for [SpriteBatch](#) to use during [Draw](#).
6. To rotate around a point that is not the upper-left corner of the screen, first subtract the origin of your rotation using a translation matrix.
7. Multiply that translation matrix by the rotation matrix.
8. Multiply the result by a translation matrix adding the origin of your rotation.

This is because a rotation matrix must rotate around (0,0,0).

C#

```
private void UpdateMatrix(ref Vector2 origin, float radians)  
{  
    // Translate sprites to center around screen (0,0), rotate them, and  
    // translate them back to their original positions  
    Vector3 matrixorigin = new Vector3(origin, 0);  
    rotationMatrix = Matrix.CreateTranslation(-matrixorigin) *  
        Matrix.CreateRotationZ(radians) *  
        Matrix.CreateTranslation(matrixorigin);  
}
```

9. In your [Draw](#) method, call [SpriteBatch.Begin](#), specifying your rotation matrix as the fourth parameter.

C#

```
private void DrawMatrix()  
{  
    // Draw using a rotation matrix with SpriteBatch  
    spriteBatch.Begin(SpriteBlendMode.AlphaBlend,  
        SpriteSortMode.Deferred, SaveStateMode.None, rotationMatrix);  
    for (int j = 0; j < myVectors.Length; j++)  
        spriteBatch.Draw(SpriteTexture, myVectors[j], null, Color.White,  
            0, origin, 1.0f, SpriteEffects.None, 0f);  
    spriteBatch.End();  
}
```

10. When all the sprites have been drawn, call [End](#).

Drawing a Scaled Sprite

To draw a scaled sprite with a uniform scale

1. Follow the procedures of [How To: Draw a Sprite](#).
2. In your **Update** method, determine how your sprite will be scaled.

The normal size of the sprite is multiplied by the scale specified. For example, a value of 1.0 draws the sprite full size, where 0.5 will draw it half-sized and 2.0 will draw it at twice its original size.

C#

```
protected float scale = 1f;
protected override void Update(GameTime gameTime)
{
    ...

    // The time since Update was called last.
    float elapsed = (float)gameTime.ElapsedGameTime.TotalSeconds;

    // TODO: Add your game logic here.
    scale += elapsed;
    scale = scale % 6;

    base.Update(gameTime);
}
```

3. When drawing the sprite, specify the scale of the sprite as a parameter to draw.

Specifying a floating-point scale parameter scales the sprite evenly in both the x and y directions.

C#

```
protected virtual void DrawForeground( SpriteBatch batch )
{
    Rectangle safeArea = GetTitleSafeArea( .8f );
    Vector2 position = new Vector2( safeArea.X, safeArea.Y );
    batch.Begin();
    batch.Draw( SpriteTexture, position, null,
        Color.White, 0f, Vector2.Zero, scale, SpriteEffects.None, 0f );
    batch.End();
}
```

4. When all the sprites have been drawn, call **End** on your [SpriteBatch](#) object.

To draw a scaled sprite using a nonuniform scale

1. Follow the procedures of [How To: Draw a Sprite](#).
2. In your **Update** method, determine how your sprite will be scaled along each axis, and store those values in a [Vector2](#) object.

C#

```
protected Vector2 nonuniformscale = Vector2.One;
protected override void Update(GameTime gameTime)
{
    base.Update(gameTime);
    float basescale = nonuniformscale.Y;
    basescale += (float)gameTime.ElapsedGameTime.TotalSeconds;
    basescale = basescale % 6;
    nonuniformscale.Y = basescale;
    nonuniformscale.X = basescale * .8f;
}
```

3. When drawing the sprite, specify the scale of the sprite using the [Vector2](#) object that you updated earlier.

Specifying a [Vector2](#) scales the sprite independently in both the x and y directions.

C#

```
protected override void DrawForeground(SpriteBatch batch)
{
    Rectangle safeArea = GetTitleSafeArea(.8f);
    Vector2 position = new Vector2(safeArea.X, safeArea.Y);
    batch.Begin();
    batch.Draw(SpriteTexture, position, null, Color.White, 0, Vector2.Zero,
        nonuniformscale, SpriteEffects.None, 0);
    batch.End();
}
```

4. When all of the sprites have been drawn, call [End](#) on your [SpriteBatch](#) object.

To draw a scaled sprite using a destination rectangle

1. Follow the procedures of [How To: Draw a Sprite](#).
2. In your **Update** method, construct a rectangle that defines where on screen the sprite will be drawn.

This rectangle does not need to be the same shape or size as the original sprite. Each dimension of the sprite is scaled independently to fit the destination rectangle.

C#

```
protected Rectangle destrect;
protected override void Update(GameTime gameTime)
{
    destrect = new Rectangle();
    Rectangle safeArea = GetTitleSafeArea(.8f);
    destrect.X = safeArea.X;
    destrect.Y = safeArea.Y;
    destrect.Width = (int)scale * 100;
    destrect.Height = (int)scale * 80;
    base.Update(gameTime);
}
```

3. When drawing the sprite, specify the destination rectangle as a parameter to [Draw](#).

The sprite will be drawn, filling the destination rectangle.

C#

```
protected override void DrawForeground(SpriteBatch batch)
{
    batch.Begin();
```

```
    batch.Draw(SpriteTexture, destrect, Color.White);  
    batch.End();  
}
```

4. When all of the sprites have been drawn, call [End](#) on your [SpriteBatch](#) object.

How To: Tile a Sprite

Demonstrates how to draw a sprite repeatedly in the x and y directions in one [Draw](#) call.

This sample takes advantage of the texture addressing modes of the graphics card to duplicate a texture across the area defined for drawing by [SpriteBatch.Draw](#). Using [SpriteSortMode.Immediate](#) allows us to set the [TextureAddressMode](#) directly and enable wrapping. Other address modes (such as mirroring) can create interesting results.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download TiledSprites_Sample.zip.](#)

Drawing a Tiled Sprite

To draw a tiled sprite on screen

1. Follow the procedures of [How To: Draw a Sprite](#).
2. In the [Draw](#) method, create a [Rectangle](#), defining how many pixels to fill with your sprite's image.

The total width of the [Rectangle](#) should be the number of times to tile your sprite in the x direction multiplied by the width of the sprite. The total height of the [Rectangle](#) should be the number of times to tile your sprite in the y direction multiplied by the height of the sprite.

C#

```
int TilesX = 2;
int TilesY = 2;
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    Rectangle source = new Rectangle(0, 0, xna.Width * TilesX,
        xna.Height * TilesY);
```

3. Call [SpriteBatch.Begin](#), and then select [SpriteSortMode.Immediate](#).
4. Set the [TextureAddressMode](#) of the first [SamplerState](#) to [TextureAddressMode.Wrap](#) for both the u and v directions.

C#

```
spriteBatch.Begin(SpriteBlendMode.AlphaBlend,
    SpriteSortMode.Immediate, SaveStateMode.None);
GraphicsDevice.SamplerStates[0].AddressU = TextureAddressMode.Wrap;
GraphicsDevice.SamplerStates[0].AddressV = TextureAddressMode.Wrap;
```

5. Call [SpriteBatch.Draw](#) with the sprite to tile, the starting position of the sprite, the source rectangle you created, and other relevant parameters.

C#

```
Vector2 pos = new Vector2(50);
spriteBatch.Draw(xna, pos, source, Color.White, 0,
    Vector2.Zero, 0.5f, SpriteEffects.None, 1.0f);
```

6. When all of the sprites have been drawn, call [End](#) on your [SpriteBatch](#) object.

C#

```
spriteBatch.End();

base.Draw(gameTime);
}
```

How To: Tint a Sprite

Demonstrates how to tint a sprite using a [Color](#) value.

Drawing a Tinted Sprite

To draw a tinted sprite on screen

1. Follow the procedures of [How To: Draw a Sprite](#).
2. In the [Update](#) method, determine how to tint the sprite.

In this example, we take the value of the game pad thumbsticks and determine Red, Green, Blue, and Alpha values to apply to the sprite.

C#

```
protected Color tint;
protected override void Update(GameTime gameTime)
{
    ...
    GamePadState input = GamePad.GetState(PlayerIndex.One);
    tint = new Color(GetColor(input.ThumbSticks.Left.X),
        GetColor(input.ThumbSticks.Left.Y),
        GetColor(input.ThumbSticks.Right.X),
        GetColor(input.ThumbSticks.Right.Y));

    base.Update(gameTime);
}
```

3. In the [Draw](#) method, pass the color value created in [Update](#) to [SpriteBatch.Draw](#).

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    spriteBatch.Begin();
    spriteBatch.Draw(SpriteTexture, position, tint);
    spriteBatch.End();

    base.Draw(gameTime);
}
```

4. When all of the sprites have been drawn, call [End](#) on your [SpriteBatch](#) object.

How To: Scale Sprites Based On Screen Size

Demonstrates how to scale sprites using a matrix that is created based on the viewport width.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download ScaleScreen_Sample.zip.](#)

Scaling Sprites Based on Screen Size

To scale sprites based on screen size

1. Use the [PreferredBackBufferHeight](#) and [PreferredBackBufferWidth](#) properties of [GraphicsDeviceManager](#) during your game's [Initialize](#) to set the default screen size of your game.
2. In your [LoadContent](#) method, use [Matrix.CreateScale](#) to create a scaling matrix.

This matrix is recreated any time the resolution of the [GraphicsDevice](#) changes.

Because you are scaling sprites, you should use only the x and y parameters to create the scaling matrix. Scaling the depth of sprites can result in their depth shifting above 1.0. If that happens, they will not render.

C#

```
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    ...

    // Default resolution is 800x600; scale sprites up or down based on
    // current viewport
    float screenscale =
        (float) graphics.GraphicsDevice.Viewport.Width / 800f;
    // Create the scale transform for Draw.
    // Do not scale the sprite depth (Z=1).
    SpriteScale = Matrix.CreateScale( screenscale, screenscale, 1 );
}
```

3. In your [Update](#) method, determine whether the game needs to change screen resolution.

This example uses game pad buttons to switch between two resolutions.

C#

```
protected override void Update(GameTime gameTime)
{
    ...
    // Change the resolution dynamically based on input
    if (GamePad.GetState(PlayerIndex.One).Buttons.A ==
        ButtonState.Pressed)
    {
        graphics.PreferredBackBufferHeight = 768;
        graphics.PreferredBackBufferWidth = 1024;
        graphics.ApplyChanges();
    }
    if (GamePad.GetState(PlayerIndex.One).Buttons.B ==
        ButtonState.Pressed)
    {
```

```
        graphics.PreferredBackBufferHeight = 600;
        graphics.PreferredBackBufferWidth = 800;
        graphics.ApplyChanges();
    }
    base.Update(gameTime);
}
```

4. In your `Draw` method, call `SpriteBatch.Begin`, passing the scaling matrix created in `LoadContent`.
5. Draw your scene normally, then call `SpriteBatch.End`.

All of the sprites you draw will be scaled according to the matrix.

C#

```
protected override void Draw(GameTime gameTime)
{
    ...
    // Initialize the batch with the scaling matrix
    spriteBatch.Begin(SpriteBlendMode.AlphaBlend,
        SpriteSortMode.Deferred, SaveStateMode.None, SpriteScale);
    // Draw a sprite at each corner
    for (int i = 0; i < spritepos.Length; i++)
    {
        spriteBatch.Draw(square, spritepos[i], null, Color.White,
            rotation, origin, scale, SpriteEffects.None, depth);
    }
    spriteBatch.End();
    base.Draw(gameTime);
}
```

How To: Draw Point Sprites

Demonstrates how to create and draw point sprites.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download PointSprites_Sample.zip.](#)

Using Point Sprites

To create a point sprite shader

- Verify that the shader for point sprites has a pixel shader that accepts a texture coordinate.

On Xbox 360, these are specified by the special SPRITETEXCOORD semantic. On Windows-based computers, any texture coordinate such as TEXCOORD0 will work. The pixel shader returns the color of the texel at the coordinate in the texture that is used to draw the sprite.

```
uniform extern texture SpriteTexture;
struct PS_INPUT
{
    #ifdef XBOX
        float2 TexCoord : SPRITETEXCOORD;
    #else
        float2 TexCoord : TEXCOORD0;
    #endif
};
sampler Sampler = sampler_state
{
    Texture = <SpriteTexture>;
};
float4 PixelShader(PS_INPUT input) : COLOR0
{
    float2 texCoord;

    texCoord = input.TexCoord.xy;

    return tex2D(Sampler, texCoord);
}
```

A vertex shader for point sprites only needs to return a POSITION0 for the vertex, transformed by the world-view-projection matrix.

```
uniform extern float4x4 WVPMatrix;
float4 VertexShader(float4 pos : POSITION0) : POSITION0
{
    return mul(pos, WVPMatrix);
}
```

To draw a group of point sprites

1. In [LoadContent](#), load an [Effect](#) object for your point sprites, and set the texture the point sprites will draw.

This example also creates a random set of point sprites to draw, using an array of [VertexPositionColor](#) elements.

C#

```

Effect pointSpritesEffect;
VertexPositionColor[] spriteArray;
VertexDeclaration vertexPosColDecl;
Random rand;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    pointSpritesEffect = Content.Load<Effect>("pointsprites");
    pointSpritesEffect.Parameters["SpriteTexture"].SetValue(
        Content.Load<Texture2D>("fire"));
    spriteArray = new VertexPositionColor[200];
    vertexPosColDecl = new VertexDeclaration(graphics.GraphicsDevice,
        VertexPositionColor.VertexElements);
    rand = new Random();
    for (int i = 0; i < spriteArray.Length; i++)
    {
        spriteArray[i].Position = new Vector3(rand.Next(100) / 10f,
            rand.Next(100) / 10f, rand.Next(100) / 10f);
        spriteArray[i].Color = Color.WhiteSmoke;
    }
}

```

- In [Draw](#), set the proper render states on the [GraphicsDevice](#).
- Set [PointSizeEnable](#) to **true** and [DepthBufferWriteEnable](#) to **false**.
- If your shader does not set the PSIZE semantic itself, set a [PointSize](#) here.

The [PointSize](#) is the width of the point sprite on screen, in pixels. Setting the PSIZE semantic in the shader allows the shader to vary the size of each point. Using the [PointSize](#) render state instead will cause each point to be rendered as the same size.

- Set up additive blending by setting [AlphaBlendEnable](#) to **true**, and the [SourceBlend](#) and [DestinationBlend](#) to [Blend.One](#).

C#

```

graphics.GraphicsDevice.RenderState.PointSpriteEnable = true;
graphics.GraphicsDevice.RenderState.PointSize = 64.0f;
graphics.GraphicsDevice.RenderState.AlphaBlendEnable = true;
graphics.GraphicsDevice.RenderState.SourceBlend = Blend.SourceAlpha;
graphics.GraphicsDevice.RenderState.DestinationBlend = Blend.One;
graphics.GraphicsDevice.RenderState.DepthBufferWriteEnable = false;

```

- Set the [VertexDeclaration](#) on the [GraphicsDevice](#) to the type of vertex you will be drawing (in this case, [VertexPositionColor](#)).

C#

```

graphics.GraphicsDevice.VertexDeclaration
    = vertexPosColDecl;

```

- Call [SetValue](#) for any draw-time parameters to your [Effect](#), such as the world-view-projection matrix.

C#

```

Matrix WVPMatrix = Matrix.Identity * viewMatrix * projectionMatrix;
pointSpritesEffect.Parameters["WVPMatrix"].SetValue(WVPMatrix);

```

- Call [Begin](#) on your [Effect](#), and for each pass in the effect, call [DrawUserPrimitives](#) for the point sprites.

C#

```
pointSpritesEffect.Begin();
foreach (EffectPass pass in
    pointSpritesEffect.CurrentTechnique.Passes)
{
    pass.Begin();
    graphics.GraphicsDevice.DrawUserPrimitives
        <VertexPositionColor>(
        PrimitiveType.PointList,
        spriteArray,
        0,
        spriteArray.Length);
    pass.End();
}
pointSpritesEffect.End();
```

9. Reset your render states for drawing any subsequent objects.

C#

```
graphics.GraphicsDevice.RenderState.PointSpriteEnable = false;
graphics.GraphicsDevice.RenderState.DepthBufferWriteEnable = true;
graphics.GraphicsDevice.RenderState.SourceBlend = Blend.SourceAlpha;
graphics.GraphicsDevice.RenderState.DestinationBlend =
    Blend.InverseSourceAlpha;
```

How To: Apply a Pixel Shader to Sprites

Demonstrates how to apply a pixel shader to sprites.

This example uses an offscreen render target to render a number of sprites, then applies a pixel shader to the full scene. This allows the pixel shader to shade the entire screen instead of each individual sprite separately.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download SpritePixelShader_Sample.zip.](#)

Applying a Pixel Shader to a Sprite

To create a sprite pixel shader

- Create a sampler object with a **Texture** member.

This is the texture that will be changed by the pixel shader. Although we declare the texture as an external parameter, actually the [SpriteBatch](#) populates the texture when it draws to the screen.

```
uniform extern texture ScreenTexture;

sampler ScreenS = sampler_state
{
    Texture = <ScreenTexture>;
};
```

A pixel shader is only required to return a color for the current pixel. This pixel shader uses the **tex2D** function to pick a pixel on the sampler to display. Because this is a distortion shader, the pixel chosen is not necessarily the "current" pixel.

```
float4 PixelShader(float2 texCoord: TEXCOORD0) : COLOR
{
    ...
    // pick a pixel on the screen for this pixel, based on
    // the calculated offset and direction
    float4 color = tex2D(ScreenS, texCoord+(sinoffset*sinsign));

    return color;
}
```

To apply a pixel shader to sprites

1. In [LoadContent](#), create a [SpriteBatch](#), load the [Effect](#) containing your pixel shader, and load any sprites you want to draw.
2. In the section of [LoadContent](#) for loading manual resources, create a [RenderTarget2D](#) for offscreen rendering, and create a [Texture2D](#) using the same settings.

The [Texture2D](#) will hold the scene that we later pass to the pixel shader.

C#

```
RenderTarget2D ShaderRenderTarget;
Texture2D ShaderTexture;
Effect ripple;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    grid = Content.Load<Texture2D>("grid");
}
```

```

    ripple = Content.Load<Effect>("ripple");
    ...

    ShaderRenderTarget = CloneRenderTarget(GraphicsDevice, 1);
    ShaderTexture = new Texture2D(GraphicsDevice,
        ShaderRenderTarget.Width, ShaderRenderTarget.Height, 1,
        TextureUsage.None, ShaderRenderTarget.Format);

    ...
}

```

3. In `Draw`, cache the current render target using `GetRenderTarget`, then switch to an offscreen render target using `SetRenderTarget`.
4. `Clear` the offscreen render target, and then draw all the sprites that comprise the scene.
5. Resolve the render target with `ResolveRenderTarget`, and retrieve the scene with `GetTexture`.
6. Reset the render target to the previous render target (normally the back buffer).

C#

```

// Change to our offscreen render target.
RenderTarget2D temp =
    (RenderTarget2D)GraphicsDevice.GetRenderTarget(0);
GraphicsDevice.SetRenderTarget(0, ShaderRenderTarget);

GraphicsDevice.Clear(Color.Black);
// Render a simple scene.
spriteBatch.Begin();
TileSprite(spriteBatch, grid);
spriteBatch.End();

// Change back to the back buffer, and get our scene
// as a texture.
GraphicsDevice.SetRenderTarget(0, temp);
ShaderTexture = ShaderRenderTarget.GetTexture();

```

7. Using the `Texture2D` containing the scene to shade, call `Begin` on your `SpriteBatch`, specifying `SpriteSortMode.Immediate`.
 8. Call `Begin` on the `Effect`, and `Begin` on the pass containing your pixel shader.
 9. Call `Draw` on the `SpriteBatch`.
- The pixel shader you specified will be used to render the sprite.
10. Call `End` on the `SpriteBatch`, the `EffectPass`, and the `Effect`.

C#

```

// Use Immediate mode and our effect to draw the scene
// again, using our pixel shader.
spriteBatch.Begin(SpriteBlendMode.None, SpriteSortMode.Immediate,
    SaveStateMode.None);
ripple.Begin();
ripple.CurrentTechnique.Passes[0].Begin();
spriteBatch.Draw(ShaderTexture, Vector2.Zero, Color.White);
spriteBatch.End();
ripple.CurrentTechnique.Passes[0].End();
ripple.End();

```

How To: Draw a Sprite Over a Model

Demonstrates how to draw a sprite so that it obscures a model. In this example, we are drawing an animated sprite representing an explosion over the current screen position of a 3D model.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download ViewportProjection_Sample.zip](#).

For this sample, the camera is a standard arc ball camera, implemented by camera.cs. The 3D model file is a simple ring, implemented by ring16b.x. The animated explosion sprite is implemented by explosion.dds. These files can be found in the complete sample. See [How To: Animate a Sprite](#) for an example of the AnimatedTexture class.

Drawing a Sprite Over a Model

To draw a sprite over a model

1. In your [Update](#) method, handle the input to move your camera, then call **UpdateFrame** on the **AnimatedTexture**.

C#

```
protected override void Update(GameTime gameTime)
{
    GamePadState PlayerOne = GamePad.GetState(PlayerIndex.One);

    // Move the camera using thumbsticks
    MoveCamera(PlayerOne);

    // Start or stop the animated sprite using buttons
    if (PlayerOne.Buttons.A == ButtonState.Pressed)
        explosion.Play();
    if (PlayerOne.Buttons.B == ButtonState.Pressed)
        explosion.Stop();

    // Update the animated sprite
    explosion.UpdateFrame((float)gameTime.ElapsedGameTime.TotalSeconds);
}
```

2. Use [CreateMerged](#) to create a [BoundingSphere](#) that contains all the [BoundingSphere](#) values for each [ModelMesh](#) in the [Model](#).
3. Use [Viewport.Project](#) to find the centerpoint of that sphere, which is the center of the model in screen coordinates.

C#

```
// Create a total bounding sphere for the mesh
BoundingSphere totalbounds = new BoundingSphere();
foreach (ModelMesh mesh in Ring.Meshes)
{
    totalbounds = BoundingSphere.CreateMerged(totalbounds,
        mesh.BoundingSphere);
}

// Project the center of the 3D object to the screen, and center the
// sprite there
Vector3 center = GraphicsDevice.Viewport.Project(totalbounds.Center,
    projectionMatrix, Camera1.ViewMatrix, Matrix.Identity);
explosionpos.X = center.X;
explosionpos.Y = center.Y;
```

4. Take the [BoundingSphere](#) for the model and use that to create a [BoundingBox](#) with [CreateFromSphere](#).
5. Find the corner of the box that is farthest from the center using [Project](#), and use that to scale the sprite appropriately.

C#

```
// Create a bounding box from the bounding sphere,
// and find the corner that is farthest away from
// the center using Project
BoundingBox extents = BoundingBox.CreateFromSphere(totalbounds);
float maxdistance = 0;
float distance;
Vector3 screencorner;
foreach (Vector3 corner in extents.GetCorners())
{
    screencorner = GraphicsDevice.Viewport.Project(corner,
        projectionMatrix, Camera1.ViewMatrix, Matrix.Identity);
    distance = Vector3.Distance(screencorner, center);
    if (distance > maxdistance)
        maxdistance = distance;
}

// Scale the sprite using the two points (the sprite is
// 75 pixels square)
explosion.Scale = maxdistance / 75;

base.Update(gameTime);
}
```

6. In your [Draw](#) method, draw the [Model](#) normally, then draw the animated sprite using the position calculated in [Update](#).

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    //Draw the model, a model can have multiple meshes, so loop
    foreach (ModelMesh mesh in Ring.Meshes)
    {
        //This is where the mesh orientation is set, as well as
        //our camera and projection
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.EnableDefaultLighting();
            effect.World = Matrix.Identity *
                Matrix.CreateRotationY( RingRotation ) *
                Matrix.CreateTranslation( RingPosition );
            effect.View = Camera1.ViewMatrix;
            effect.Projection = projectionMatrix;
        }
        //Draw the mesh, will use the effects set above.
        mesh.Draw();
    }

    // Draw the sprite over the 3D object
    spriteBatch.Begin( SpriteBlendMode.AlphaBlend,
        SpriteSortMode.Deferred, SaveStateMode.SaveState );
    explosion.DrawFrame( spriteBatch, explosionpos );
    spriteBatch.End();
}
```

```
    base.Draw( gameTime );  
}
```

How To: Draw Text

Demonstrates how to import a [SpriteFont](#) into a project and draw text using [DrawString](#).

Note

As with most types of software, font files are licensed rather than sold. Font licenses vary from vendor to vendor, but most do not allow redistribution of the fonts. That includes redistribution of reproductions such as bitmaps containing the rasterized character set. This is true of many of the licenses covering fonts that Microsoft supplies with applications and the Windows operating systems. Therefore, be careful to ensure that you have the required license rights to redistribute any font you include as a bitmap containing the rasterized character set in your game!

Note

The following list of fonts are installed by XNA Game Studio and are redistributable:

- Kooten.ttf
- Linds.ttf
- Miramo.ttf
- Bold Miramob.ttf
- Peric.ttf
- Pericl.ttf
- Pesca.ttf
- Pescab.ttf

These OpenType fonts, created by Ascender Corporation and licensed by Microsoft, are free for you to use in your XNA Game Studio game. You may redistribute these fonts in their original format as part of your game. These fonts were previously available only on the XNA Creators Club Online website.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download FontDemo_Sample.zip](#).

Adding a Sprite Font and Drawing Text

To add a sprite font

1. Right-click your Content project in Solution Explorer, click **Add**, and then click **New Item**.
2. From the **Add New Item** dialog box, click **Sprite Font**.

You may find it convenient at this point to change the name of the new file from "SpriteFont1" to the friendly name of the font you intend to load (leaving the file extension as ".spritefont"). The friendly name is the name that identifies the font once it is installed on your computer. For example, "Courier New" or "Times New Roman."

XNA Game Studio creates a new .spritefont file for your font and opens it.

3. If you did not name the new file with the font's friendly name, type the friendly name of the font to load into the FontName element.

Again, this is not the name of a font file, but rather the name that identifies the font once it is installed on your computer. You can use the Fonts folder in the **Control Panel** to see the names of fonts installed on your system, and to install new ones as well. The content pipeline supports the same fonts as the [System.Drawing.Font](#) class, including TrueType fonts, but not bitmap (.fon) fonts. You may find it convenient to save the new .spritefont file using this friendly name.

4. If necessary, change the **Size** entry to the point size you desire for your font.
5. If necessary, change the **Style** entry to the style of font to import.

You can specify **Regular**, **Bold**, **Italic**, or **Bold, Italic**. The **Style** entry is case sensitive.

6. Specify the character regions to import for this font.

Character regions specify which characters in the font are rendered by the [SpriteFont](#). You can specify the start and end of the region by using the characters themselves, or by using their decimal values with a `&#` prefix. The default character region includes all the characters between the space and tilde characters, inclusive.

To draw text on screen

1. Add a [Sprite Font](#) to your project as described above.
2. Create a [SpriteFont](#) object to encapsulate the imported font.
3. Create a [SpriteBatch](#) object for drawing the font onscreen.
4. In your [LoadContent](#) method, call [ContentManager.Load](#), specifying the [SpriteFont](#) class and the asset name of the imported font.
5. Create your [SpriteBatch](#) object, passing the current [GraphicsDevice](#).

C#

```
SpriteFont Font1;
Vector2 FontPos;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    Font1 = Content.Load<SpriteFont>("Courier New");

    // TODO: Load your game content here
    FontPos = new Vector2(graphics.GraphicsDevice.Viewport.Width / 2,
        graphics.GraphicsDevice.Viewport.Height / 2);
}
```

6. In your [Draw](#) method, call [Begin](#) on the [SpriteBatch](#) object.

If you select your own [SpriteBlendMode](#), [SpriteBlendMode.AlphaBlend](#) is recommended.

7. If necessary, determine the origin of your text.

If you want to draw your text centered on a point, you can find the center of the text by calling [MeasureString](#) and dividing the returned vector by 2.

8. Call [DrawString](#) to draw your output text, specifying the [SpriteFont](#) object for the font you want to use.

All other parameters of [DrawString](#) produce the same effects as a call to [SpriteBatch.Draw](#).

9. When you have drawn all your text, call [SpriteBatch.End](#).

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    spriteBatch.Begin();

    // Draw Hello World
    string output = "Hello World";

    // Find the center of the string
    Vector2 FontOrigin = Font1.MeasureString( output ) / 2;
    // Draw the string
    spriteBatch.DrawString( Font1, output, FontPos, Color.LightGreen,
        0, FontOrigin, 1.0f, SpriteEffects.None, 0.5f );

    spriteBatch.End();
    base.Draw( gameTime );
}
```

```
}
```

3D Graphics Overview

Provides an overview of 3D graphics. The [Microsoft.Xna.Framework.Graphics](#) namespace contains classes to use the graphics device to load and render resources and to apply effects to vertices and pixels. This overview covers the following topics as they apply to 3D graphics.

- [Getting Started with 3D](#)
- [The Graphics Device](#)
- [Resources](#)
- [Shaders and Effects](#)

Getting Started with 3D

In the examples in this section, you must provide the following three items for even the most simple 3D graphics application:

- A set of world, view, and projection transformation matrices
- A vertex buffer
- An effect that applies the world, view, and projection transformation matrices to the vertex data

This list of items enables you to render your first 3D content in an XNA application.

As you become comfortable with these ideas, you will want to learn more about the following:

- Manipulating the vertices you created
- Creating your own effects
- Applying textures
- Improving the performance of your application through such techniques as converting your vertex buffers to indexed vertex streams

The XNA Framework uses a shader-driven programmable pipeline. It requires a graphics card capable of at least Shader Model 1.1. Shader Model 2.0 is recommended. In the programmable pipeline, shaders and effects are used to apply transformations, textures, lighting, and materials. However, you do not need to write a custom shader for your first 3D XNA applications. The XNA Framework provides a class called [BasicEffect](#) that encapsulates most of these common operations.

The Graphics Device

When you create a game with XNA Game Studio, the XNA application model initializes a graphics device for you. You can use the [GraphicsDeviceManager.GraphicsDevice](#) property to gain access to the graphics device. To determine the capabilities of the graphics device, use the [GraphicsDevice.GraphicsDeviceCapabilities](#) property.

Graphics Device Initialization

The [GraphicsDeviceManager](#) initializes the [GraphicsDevice](#) before you call [Game.Initialize](#). Before you call [Initialize](#), there are three ways to change the [GraphicsDevice](#) settings:

1. Set the appropriate properties (e.g. [PreferredBackBufferHeight](#), [PreferredBackBufferWidth](#)) on the [GraphicsDeviceManager](#) in your game's constructor.
2. Handle the [PreparingDeviceSettings](#) event on the [GraphicsDeviceManager](#), and change the [PreparingDeviceSettingsEventArgs.GraphicsDeviceInformation.PresentationParameters](#) member properties.

Any changes made to the [PreparingDeviceSettingsEventArgs](#) will override the [GraphicsDeviceManager](#) preferred settings.

3. Handle the [DeviceCreated](#) event on the [GraphicsDeviceManager](#), and change the [PresentationParameters](#) of the [GraphicsDevice](#) directly.

When you call [Game.Initialize](#), [GraphicsDeviceManager](#) creates and configures [GraphicsDevice](#). You can safely access [GraphicsDevice](#) settings such as the backbuffer, depth/stencil buffer, viewport, and render states in [Initialize](#).

After you call [Game.Initialize](#), changes to the [PresentationParameters](#) of the [GraphicsDevice](#) will not take effect until you call [GraphicsDeviceManager.ApplyChanges](#). Other changes, such as render states, will take effect immediately.

Render States and the Graphics Device

Render states are an important part of the graphics device. They can affect game rendering significantly. When you first create a graphics device, the render states are set to their default values. For more information, see [RenderStates](#).

Commonly, the value of a render state is changed only if it is manually modified. For example, the following code sample sets the cull mode of the current graphics device to `None`. This causes all triangle faces to be drawn and differs from the default value of `CullMode.CounterClockwise`.

```
renderState.CullMode = CullMode.None;
```

However, there are cases where render states can change automatically. A common example is the rendering of sprites and 3D objects on the same graphics device. In this case, the [SpriteBatch](#) object changes various render states when you call [End](#). If you try any 3D rendering after this step, the results can be unpredictable.

For this reason, you should restore several key render states to their former settings before you try to render any 3D objects. The following code demonstrates this approach.

```
GraphicsDevice.RenderState.DepthBufferEnable = true;  
GraphicsDevice.RenderState.AlphaBlendEnable = false;  
GraphicsDevice.RenderState.AlphaTestEnable = false;
```

In addition, you should set the following render states, depending on the type of 3D content you are rendering.

```
GraphicsDevice.SamplerStates[0].AddressU = TextureAddressMode.Wrap;  
GraphicsDevice.SamplerStates[0].AddressV = TextureAddressMode.Wrap;
```

It is also possible to save the render state of the graphics device before rendering sprites by passing [SaveStateMode.SaveState](#) your [SpriteBatch.Begin](#) method call. However, this is not recommended because it is time intensive, and can slow down the rendering process.

Resources

A resource is a collection of data stored in memory that can be accessed by the CPU or GPU. Types of resources that an application might use include render targets, vertex buffers, index buffers, and textures.

Based on the resource management mode that was used when a resource is created, it should be reloaded when the device is reset. For more information, see [How To: Load Content](#).

Vertex and Index Buffers

A vertex buffer contains a list of 3D vertices to be streamed to the graphics device. Each vertex in a vertex buffer may contain data about not only the 3D coordinate of the vertex, but also other information describing the vertex, such as the vertex normal, color, or texture coordinate. The XNA Framework contains several classes to describe common vertex declaration types, such as [VertexPositionColor](#), [VertexPositionColorTexture](#), [VertexPositionNormalTexture](#), and [VertexPositionTexture](#). You may also use the [VertexElement](#) class to compose custom vertex types.

For a demonstration of low-level rendering of a 3D object from a vertex buffer, see [How To: Draw Points, Lines, and Other 3D Primitives](#).

Vertex buffers may contain either indexed or non-indexed vertex data.

If a vertex buffer is not indexed, all of the vertices are placed in the vertex buffer in the order they are to be rendered. Because 3D line lists or triangle lists often reference the same vertices multiple times, this can result in a large amount of redundant data.

Index buffers allow you to list each vertex only once in the vertex buffer. An index buffer is a list of indices into the vertex buffer, given in the order that you want the vertices to render.

To render a non-indexed vertex buffer, call the [GraphicsDevice.DrawPrimitives Method](#) or [GraphicsDevice.DrawUserPrimitives Generic Method](#). To render an indexed buffer, call the [GraphicsDevice.DrawIndexedPrimitives Method](#) or [GraphicsDevice.DrawUserIndexedPrimitives Method](#).

Textures

A texture resource is a structured collection of data designed to store texture data. The data in a texture resource is made up of one or more subresources that are organized into arrays and mipmap chains. Textures can be filtered by texture samplers as they are read by shaders. The type of texture influences how the texture is filtered.

You can apply textures by using the [Texture](#) property of the [BasicEffect](#) class, or choose to write your own effect methods to apply textures. For a demonstration of applying a texture from a user-created effect, see the example [How To: Create Custom](#)

[Texture Effects.](#)

Shaders and Effects

Shaders are programs that perform per-vertex or per-pixel processing of resources at run time. An effect is a combination of vertex and pixel shader code grouped together to encapsulate a particular rendering effect. Because shaders transform vertices and pixels at run time, they are used for lighting, materials, and textures. Unless you are using the [BasicEffect](#) class, you must first write shaders in either high-level shader language (HLSL) or assembly shader code (ASM), and then compile your shaders before your application can use the binary code.

For overviews of HLSL and the effect file format, see the [HLSL Shaders](#) and [Effects](#) DirectX Programming Guides on MSDN. Complete reference documentation for HLSL, shader ASM, and the effect file format is available in the [Direct3D API Reference](#).

For a simple demonstration of how to apply a vertex shader from an effect file, see [How To: Create and Apply Custom Effects](#).

Viewports and Frustums

Provides overview of viewports and frustums as related to 3D graphics concepts.

Conceptually, a viewport is a two-dimensional (2D) rectangle onto which a 3D scene is projected. In the XNA Framework, the rectangle exists as x - and y -coordinates within a 2D surface used by XNA as a rendering target. Properly positioning graphical objects on this surface requires a mathematical transform (known as a projection transform). This transform converts 3D vertices into the coordinate system of the viewport. Additionally, a viewport can specify the range of depth values for the render-target surface. This range usually lies between 0.0 and 1.0.

- [The Viewing Frustum](#)
- [Viewport Rectangle](#)
- [Clearing a Viewport](#)

The Viewing Frustum

A viewing frustum is a 3D volume positioned relative to the viewport's camera. The shape of the volume affects how models are projected from camera space onto the screen. The most common type of projection, a perspective projection, is responsible for making objects near the camera appear bigger than objects in the distance. For perspective viewing, the viewing frustum can be visualized as a pyramid, with the camera positioned at the tip. This pyramid is intersected by a front and back clipping plane. The volume within the pyramid between the front and back clipping planes is referred to as the viewing frustum. Objects are visible only when they are in this volume.

Imagine that you are standing in a dark room and looking through a square window. This is a good representation of a viewing frustum. In this analogy, the near clipping plane is the window, and the back clipping plane is whatever finally interrupts your view - the skyscraper across the street, the mountains in the distance, or nothing at all. You can see everything inside the truncated pyramid that starts at the window and ends with whatever interrupts your view, and nothing else.

The viewing frustum is defined by a field of view (fov), and by the distances of the front and back clipping planes, which are specified in z -coordinates. You can create a perspective fov using the [CreatePerspectiveFieldOfView](#) method. For more information on setting up a frustum and perspective transformation, see [How To: Make a Third-Person Camera](#).

Viewport Rectangle

You define a viewport rectangle in XNA by using the [Viewport](#) structure. For more information about using this structure in your game application, see [Displays, Client Bounds, Viewports, and Back Buffers](#).

The [Viewport](#) structure contains four members - X , Y , $Width$, $Height$ - that define the area of the render-target surface in which a scene is rendered. These values correspond to the destination rectangle, or viewport rectangle.

The specified values for the X , Y , $Width$, and $Height$ members are screen coordinates relative to the upper-left corner of the render-target surface. The structure defines two additional members ($MinDepth$ and $MaxDepth$), indicating the near and far view planes.

Tip

The depth buffer has a limited resolution which is distributed between the near and far clip planes. If these planes are too far apart, two objects could have the same depth value even though they lie on different depth planes. In cases like this, the depth buffer is unable to distinguish between them because of its limited resolution.

To avoid this situation, set your near clipping plane as high as possible without causing near-plane clipping issues. For instance, avoid settings such as 0.000001, which would certainly cause problems.

The XNA Framework assumes that the viewport clipping volume ranges from -1.0 to 1.0 in X, and from 1.0 to -1.0 in Y. These were the settings used most often by applications in the past. You can specify the viewport aspect ratio, used for the projection transform, with a call to [CreatePerspectiveFieldOfView](#).

The XNA Framework uses the viewport location and dimensions to scale the vertices to fit a rendered scene into the appropriate location on the target surface. An internal matrix is applied to each vertex to scale vertices according to the viewport dimensions and desired depth range and translate them to the appropriate location on the render-target surface. This matrix also reverses the y-coordinate to reflect a screen origin at the top-left corner with y increasing downward. After this matrix is applied, vertices are still homogeneous. That is, they still exist as $[x,y,z,w]$ vertices—and they must be converted to non-homogeneous coordinates before being sent to the rasterizer.

Note

The viewport scaling matrix incorporates the `MinDepth` and `MaxDepth` members of the [Viewport](#) structure to scale vertices to fit the specified depth range.

Clearing a Viewport

Clearing the viewport resets the contents of the viewport rectangle on the render-target surface. It can also clear the depth and stencil buffer surfaces.

Use [Clear](#) to clear the various components of the viewport. Overloaded versions accept various parameters such as a set of rectangles, defining the areas on the surface to be cleared, or a [ClearOptions](#) enumeration that specifies which buffers or render target to clear.

Use the [Clear](#) method to clear stencil bits within a depth buffer. Set the options parameter to determine which render-target components are cleared. The color argument sets the color value of the render target after it has been cleared. The depth parameter clears the depth buffer to the specified depth: 0.0 is the closest distance, and 1.0 is the farthest. Finally, the stencil parameter resets the stencil bits to the specified value. Use integers ranging from 0 to $2^n - 1$, where n is the stencil buffer bit depth.

Dynamic Vertex Buffers in XNA

Describes several techniques for implementing dynamic vertex buffers in an XNA Framework game.

Geometry in a 3D game ultimately is defined as a set of vertices. Commonly, a game either needs to modify the position of one or more existing vertices or generate the vertices at run time. Because the graphics device can access these buffers at any time, take care when you modify existing vertex buffers and render the resulting geometry defined by these buffers. The following sections discuss several techniques you can implement in your game.

Tip

For index or vertex buffers that are frequently updated during game run time, use the [DynamicIndexBuffer](#) and [DynamicVertexBuffer](#) classes. They are optimized to render faster when updated frequently.

Use [VertexBuffer](#) and [IndexBuffer](#) when index or vertex buffer data is infrequently updated.

Updating a Set of Primitives Dynamically

You can use the [DrawUserPrimitives](#) method as the basis for rendering a set of primitives that are generated dynamically each frame. The [Primitives Sample](#), located on the XNA Creators Club Online Web site, implements an abstraction layer around this method similar to the [SpriteBatch](#) class.

The sample renders primitives by first calling `Begin`, adding the necessary vertices, using the `Add` method, and then calling `End`. This forces the buffer to be drawn to the current device. The `Flush` method calls [DrawUserPrimitives](#) method when `End` is called or when the buffer has no room for new vertices. If there is no room, the buffer is written to the device, it is reset, and the pending vertices are added.

For a complete code listing, download the [Primitives Sample](#) from the XNA Creators Club Online Web site.

Dynamically Rendering a Persistent Set of Primitives

The [Particle 3D Sample](#), located on the XNA Creators Club Online Web site, implements a dynamic vertex buffer that contains custom vertices with a limited lifespan. The application adds particles and removes them to a fixed length buffer. The custom shader of the sample renders the active subset of vertices dynamically.

Because particles have a limited lifespan, the sample code must manage the vertex buffer in real time. The `ParticleSystem` class handles all adding, updating, and deleting.

Generating Geometry Programmatically

Sometimes, geometry to be rendered either is not known at design-time or it changes based on events during run time.

To generate geometry

1. Create a vertex buffer to store the vertices of the geometry to be generated.
2. Create an index buffer that stores the indices used to render the geometry represented by the vertex buffer.
3. Once the vertex and index data have been generated, call [SetData](#) for the vertex buffer and [SetData](#) for the index buffer.
4. In the method that renders your frame (the `Draw` method for a default XNA game project), set the vertex stream and index data of the current graphics device.

For a specific example of this, see [DrawIndexedPrimitives](#).

5. Call [DrawIndexedPrimitives](#).

For a more advanced solution for this problem, download the [Generated Geometry Sample](#) from the XNA Creators Club Online Web site. This sample uses the [MeshBuilder](#) helper class and a custom processor to generate a terrain map from a bitmap loaded by the content manager. Specifically, examine the `Process` method, located in `TerrainProcessor.cs`. This method programmatically creates the terrain geometry based on input from the specified bitmap.

Checking for Shader Model 2.0 Support

To check for Shader Model 2.0 support

1. Use the [GraphicsDevice.GraphicsDeviceCapabilities Property](#) to find the capabilities of the game's graphics device.
2. Compare [GraphicsDeviceCapabilities.MaxPixelShaderProfile](#) to the member of the [ShaderProfile](#) enumeration that represents pixel shader version ps_2_0.

In this example, if the graphics device does not support this shader model, the output window displays a message when you run the game in debug mode.

C#

```
// Check the graphics device used by the game
// for the necessary shader support.
GraphicsDeviceCapabilities caps =
    GraphicsDevice.GraphicsDeviceCapabilities;
if (caps.MaxPixelShaderProfile < ShaderProfile.PS_2_0)
{
    // This device does not support Shader Model 2.0.
    System.Diagnostics.Debug.WriteLine(
        "This adapter does not support Shader Model 2.0.");
}
```

How To: Enable Antialiasing (Multisampling)

Demonstrates how to use the [GraphicsDeviceManager](#) to enable antialiasing for your game. The [CheckDeviceMultiSampleType](#) method determines what kind of antialiasing your game computer supports.

Antialiasing is the process of smoothing the edges of triangles by averaging neighboring pixels in a render target. Because this process samples multiple pixels, it is also known as multisampling.

Note

Enabling antialiasing on the Xbox 360 will have a small performance impact. Enabling antialiasing on PCs may have a large impact on your game performance.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download AntiAliasing_Sample.zip](#).

Using Antialiasing

To enable antialiasing in your game

- Set [PreferMultiSampling](#) to **true** in your [Game](#) class constructor.

This will default to [MultiSampleType.TwoSamples](#) on Xbox 360 (2x antialiasing). On a PC, the [GraphicsDeviceManager](#) will query for [MultiSampleType.NonMaskable](#), and select that, if possible. Otherwise, it will choose the best available antialiasing.

C#

```
graphics.PreferMultiSampling = true;
```

To customize antialiasing in your game

- In your [Game](#) class constructor, add an event handler to the [PreparingDeviceSettings](#) event on your [GraphicsDeviceManager](#).

If [PreferMultiSampling](#) is **true**, a [MultiSampleType](#) will be chosen automatically before the event is raised. Whether or not a [MultiSampleType](#) is chosen when the event is raised, you can use the event handler to query and choose your own [MultiSampleType](#).

C#

```
public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";
    graphics.PreferMultiSampling = true;
    graphics.PreparingDeviceSettings +=
        new EventHandler<PreparingDeviceSettingsEventArgs>(
            graphics_PreparingDeviceSettings);
}
```

- Create a method to use as an event handler for the [PreparingDeviceSettings](#) event.

You will be using the [PreparingDeviceSettingsEventArgs](#) instance to access the [PresentationParameters](#) and set your antialiasing preferences.

C#

```
void graphics_PreparingDeviceSettings(object sender,
    PreparingDeviceSettingsEventArgs e)
{
```

3. If your game is running on Xbox 360, set directly the [MultiSampleQuality](#) and [MultiSampleType](#) properties, and then return from your event handler.

The Xbox supports [MultiSampleType.TwoSamples](#) and [MultiSampleType.FourSamples](#), each with a [MultiSampleQuality](#) of 0 or 1. [MultiSampleType.FourSamples](#) is 4x antialiasing; [MultiSampleType.TwoSamples](#) is 2x antialiasing.

C#

```
// Xbox 360 and most PCs support FourSamples/0
// (4x) and TwoSamples/0 (2x) antialiasing.
PresentationParameters pp =
    e.GraphicsDeviceInformation.PresentationParameters;

#if XBOX
    pp.MultiSampleQuality = 0;
    pp.MultiSampleType = MultiSampleType.FourSamples;
    return;
#else
```

4. If your game is running on a PC, use [CheckDeviceMultiSampleType](#) to query for antialiasing support.

Many PCs support 4x antialiasing, and most will support 2x antialiasing. Once you have determined that antialiasing is supported, set the [MultiSampleType](#) and [MultiSampleQuality](#) properties appropriately, and then return from the event handler.

C#

```
int quality = 0;
GraphicsAdapter adapter = e.GraphicsDeviceInformation.Adapter;
SurfaceFormat format = adapter.CurrentDisplayMode.Format;
// Check for 4xAA
if (adapter.CheckDeviceMultiSampleType(DeviceType.Hardware, format,
    false, MultiSampleType.FourSamples, out quality))
{
    // even if a greater quality is returned, we only want quality 0
    pp.MultiSampleQuality = 0;
    pp.MultiSampleType =
        MultiSampleType.FourSamples;
}
// Check for 2xAA
else if (adapter.CheckDeviceMultiSampleType(DeviceType.Hardware,
    format, false, MultiSampleType.TwoSamples, out quality))
{
    // even if a greater quality is returned, we only want quality 0
    pp.MultiSampleQuality = 0;
    pp.MultiSampleType =
        MultiSampleType.TwoSamples;
}
return;
#endif
}
```

How To: Use BasicEffect

Demonstrates how to create and initialize an instance of [BasicEffect](#), initialize a vertex buffer that can be rendered by [BasicEffect](#), apply the effect, and render the geometry.

Note

The steps described here apply to effects created with the [BasicEffect](#) class. In contrast, the [Effect](#) class is provided for users who wish to write custom effects. For more information, see [How To: Create and Apply Custom Effects](#).

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download UseBasicEffect_Sample.zip.](#)

Using BasicEffect

To use BasicEffect

Using the basic effect class requires a set of world, view, and projection matrices, a vertex buffer, a vertex declaration, and an instance of the [BasicEffect](#) class.

1. Declare these objects at the beginning of the game.

C#

```
Matrix worldMatrix;
Matrix viewMatrix;
Matrix projectionMatrix;
VertexPositionNormalTexture[] cubeVertices;
VertexDeclaration basicEffectVertexDeclaration;
VertexBuffer vertexBuffer;
BasicEffect basicEffect;
```

2. Initialize the world, view, and projection matrices.

In this example, you create a world matrix that rotates the geometry 22.5 degrees along the x and y axes. The view matrix is a look-at matrix with a camera position at (0, 0, 5), pointing at the origin. The projection matrix is a perspective projection matrix based on a 45-degree field of view, an aspect ratio equal to the client window, and a set of near and far planes.

C#

```
float tilt = MathHelper.ToRadians(22.5f); // 22.5 degree angle
// Use the world matrix to tilt the cube along x and y axes.
worldMatrix = Matrix.CreateRotationX(tilt) *
    Matrix.CreateRotationY(tilt);

viewMatrix = Matrix.CreateLookAt(new Vector3(0, 0, 5), Vector3.Zero,
    Vector3.Up);

projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
    MathHelper.ToRadians(45), // 45 degree angle
    (float)GraphicsDevice.Viewport.Width /
    (float)GraphicsDevice.Viewport.Height,
    1.0f, 100.0f);
```

3. Initialize [BasicEffect](#) to the desired values.

C#

```
basicEffect = new BasicEffect(graphics.GraphicsDevice, null);
basicEffect.Alpha = 1.0f;
```

```

basicEffect.DiffuseColor = new Vector3(1.0f, 0.0f, 1.0f);
basicEffect.SpecularColor = new Vector3(0.25f, 0.25f, 0.25f);
basicEffect.SpecularPower = 5.0f;
basicEffect.AmbientLightColor = new Vector3(0.75f, 0.75f, 0.75f);

basicEffect.DirectionalLight0.Enabled = true;
basicEffect.DirectionalLight0.DiffuseColor = Vector3.One;
basicEffect.DirectionalLight0.Direction =
    Vector3.Normalize(new Vector3(1.0f, -1.0f, -1.0f));
basicEffect.DirectionalLight0.SpecularColor = Vector3.One;

basicEffect.DirectionalLight1.Enabled = true;
basicEffect.DirectionalLight1.DiffuseColor =
    new Vector3(0.5f, 0.5f, 0.5f);
basicEffect.DirectionalLight1.Direction =
    Vector3.Normalize(new Vector3(-1.0f, -1.0f, 1.0f));
basicEffect.DirectionalLight1.SpecularColor =
    new Vector3(0.5f, 0.5f, 0.5f);

basicEffect.LightingEnabled = true;

basicEffect.World = worldMatrix;
basicEffect.View = viewMatrix;
basicEffect.Projection = projectionMatrix;

```

4. Implement [BasicEffect](#) so it can use the vertex type that is appropriate for the options you will enable for the effect.

- If lighting is enabled, the vertex must have a normal type.
- If vertex colors are enabled, the vertex must have colors.
- If texturing is enabled, the vertex must have a texture coordinate.

The following code shows a cube created with vertices of type [VertexPositionNormalTexture](#).

C#

```

cubeVertices = new VertexPositionNormalTexture[36];

Vector3 topLeftFront = new Vector3(-1.0f, 1.0f, 1.0f);
Vector3 bottomLeftFront = new Vector3(-1.0f, -1.0f, 1.0f);
Vector3 topRightFront = new Vector3(1.0f, 1.0f, 1.0f);
Vector3 bottomRightFront = new Vector3(1.0f, -1.0f, 1.0f);
Vector3 topLeftBack = new Vector3(-1.0f, 1.0f, -1.0f);
Vector3 topRightBack = new Vector3(1.0f, 1.0f, -1.0f);
Vector3 bottomLeftBack = new Vector3(-1.0f, -1.0f, -1.0f);
Vector3 bottomRightBack = new Vector3(1.0f, -1.0f, -1.0f);

Vector2 textureTopLeft = new Vector2(0.0f, 0.0f);
Vector2 textureTopRight = new Vector2(1.0f, 0.0f);
Vector2 textureBottomLeft = new Vector2(0.0f, 1.0f);
Vector2 textureBottomRight = new Vector2(1.0f, 1.0f);

Vector3 frontNormal = new Vector3(0.0f, 0.0f, 1.0f);
Vector3 backNormal = new Vector3(0.0f, 0.0f, -1.0f);
Vector3 topNormal = new Vector3(0.0f, 1.0f, 0.0f);
Vector3 bottomNormal = new Vector3(0.0f, -1.0f, 0.0f);
Vector3 leftNormal = new Vector3(-1.0f, 0.0f, 0.0f);
Vector3 rightNormal = new Vector3(1.0f, 0.0f, 0.0f);

// Front face.

```

```

cubeVertices[0] =
    new VertexPositionNormalTexture(
        topLeftFront, frontNormal, textureTopLeft);
cubeVertices[1] =
    new VertexPositionNormalTexture(
        bottomLeftFront, frontNormal, textureBottomLeft);
cubeVertices[2] =
    new VertexPositionNormalTexture(
        topRightFront, frontNormal, textureTopRight);
cubeVertices[3] =
    new VertexPositionNormalTexture(
        bottomLeftFront, frontNormal, textureBottomLeft);
cubeVertices[4] =
    new VertexPositionNormalTexture(
        bottomRightFront, frontNormal, textureBottomRight);
cubeVertices[5] =
    new VertexPositionNormalTexture(

// Back face.
cubeVertices[6] =
    new VertexPositionNormalTexture(
        topLeftBack, backNormal, textureTopRight);
cubeVertices[7] =
    new VertexPositionNormalTexture(
        topRightBack, backNormal, textureTopLeft);
cubeVertices[8] =
    new VertexPositionNormalTexture(
        bottomLeftBack, backNormal, textureBottomRight);
cubeVertices[9] =
    new VertexPositionNormalTexture(
        bottomLeftBack, backNormal, textureBottomRight);
cubeVertices[10] =
    new VertexPositionNormalTexture(
        topRightBack, backNormal, textureTopLeft);
cubeVertices[11] =
    new VertexPositionNormalTexture(
        bottomRightBack, backNormal, textureBottomLeft);

// Top face.
cubeVertices[12] =
    new VertexPositionNormalTexture(
        topLeftFront, topNormal, textureBottomLeft);
cubeVertices[13] =
    new VertexPositionNormalTexture(
        topRightBack, topNormal, textureTopRight);
cubeVertices[14] =
    new VertexPositionNormalTexture(
        topLeftBack, topNormal, textureTopLeft);
cubeVertices[15] =
    new VertexPositionNormalTexture(
        topLeftFront, topNormal, textureBottomLeft);
cubeVertices[16] =
    new VertexPositionNormalTexture(
        topRightFront, topNormal, textureBottomRight);
cubeVertices[17] =
    new VertexPositionNormalTexture(
        topRightBack, topNormal, textureTopRight);

```

```

// Bottom face.
cubeVertices[18] =
    new VertexPositionNormalTexture(
        bottomLeftFront, bottomNormal, textureTopLeft);
cubeVertices[19] =
    new VertexPositionNormalTexture(
        bottomLeftBack, bottomNormal, textureBottomLeft);
cubeVertices[20] =
    new VertexPositionNormalTexture(
        bottomRightBack, bottomNormal, textureBottomRight);
cubeVertices[21] =
    new VertexPositionNormalTexture(
        bottomLeftFront, bottomNormal, textureTopLeft);
cubeVertices[22] =
    new VertexPositionNormalTexture(
        bottomRightBack, bottomNormal, textureBottomRight);
cubeVertices[23] =
    new VertexPositionNormalTexture(
        bottomRightFront, bottomNormal, textureTopRight);

// Left face.
cubeVertices[24] =
    new VertexPositionNormalTexture(
        topLeftFront, leftNormal, textureTopRight);
cubeVertices[25] =
    new VertexPositionNormalTexture(
        bottomLeftBack, leftNormal, textureBottomLeft);
cubeVertices[26] =
    new VertexPositionNormalTexture(
        bottomLeftFront, leftNormal, textureBottomRight);
cubeVertices[27] =
    new VertexPositionNormalTexture(
        topLeftBack, leftNormal, textureTopLeft);
cubeVertices[28] =
    new VertexPositionNormalTexture(
        bottomLeftBack, leftNormal, textureBottomLeft);
cubeVertices[29] =
    new VertexPositionNormalTexture(
        topLeftFront, leftNormal, textureTopRight);

// Right face.
cubeVertices[30] =
    new VertexPositionNormalTexture(
        topRightFront, rightNormal, textureTopLeft);
cubeVertices[31] =
    new VertexPositionNormalTexture(
        bottomRightFront, rightNormal, textureBottomLeft);
cubeVertices[32] =
    new VertexPositionNormalTexture(
        bottomRightBack, rightNormal, textureBottomRight);
cubeVertices[33] =
    new VertexPositionNormalTexture(
        topRightBack, rightNormal, textureTopRight);
cubeVertices[34] =
    new VertexPositionNormalTexture(
        topRightFront, rightNormal, textureTopLeft);
cubeVertices[35] =
    new VertexPositionNormalTexture(
        bottomRightBack, rightNormal, textureBottomRight);

```

```
vertexBuffer = new VertexBuffer(  
    graphics.GraphicsDevice,  
    VertexPositionNormalTexture.SizeInBytes * cubeVertices.Length,  
    BufferUsage.None  
);  
  
vertexBuffer.SetData<VertexPositionNormalTexture>(cubeVertices);
```

5. Create a vertex declaration for the type [VertexPositionNormalTexture](#).

This vertex declaration is used in the render loop in the next step.

C#

```
basicEffectVertexDeclaration = new VertexDeclaration(  
    graphics.GraphicsDevice, VertexPositionNormalTexture.VertexElements);
```

6. Call the [Effect.Begin](#) to begin applying the [BasicEffect](#).
7. Draw the desired geometry between calls to [EffectPass.Begin](#) and [EffectPass.End](#).
8. Call [Effect.End](#) to stop application of the technique.

C#

```
graphics.GraphicsDevice.VertexDeclaration =  
    basicEffectVertexDeclaration;  
graphics.GraphicsDevice.Vertices[0].SetSource(vertexBuffer, 0,  
    VertexPositionNormalTexture.SizeInBytes);  
  
// This code would go between a device  
// BeginScene-EndScene block.  
basicEffect.Begin();  
foreach (EffectPass pass in basicEffect.CurrentTechnique.Passes)  
{  
    pass.Begin();  
  
    graphics.GraphicsDevice.DrawPrimitives(  
        PrimitiveType.TriangleList,  
        0,  
        12  
    );  
  
    pass.End();  
}  
basicEffect.End();
```

How To: Render a Model

Demonstrates how to load and render a model using the XNA Framework Content Pipeline. It is assumed that an existing Windows game project is loaded in XNA Game Studio. In this example, the project is called "CPModel."

This example has three main parts: importing and processing the model (design-time code), drawing the resultant managed object as a model with full lighting effect in the game (run-time code), and enabling movement of the model with the Xbox 360 game pad (run-time code).

Tip

This technique is implemented in the FuelCell game, a game developed by following a series of focused articles that discuss basic 3D game development. For more information, see [FuelCell: Setting the Scene](#).

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download CPModel_Sample.zip](#).

Adding and Rendering a Model

To add the model to the game

1. Right-click the **Content** project, click **Add**, and then click **Existing Item**.
2. From the **Files of type**: control, click **XNA Content Files**.
3. Navigate to the correct folder and select the model to be added.

For this example, use the wedge_player1.x file.

4. Click the small arrow to the right of the **Add** button, and then click **Add as Link**.

This creates a reference to the selected asset (and not a copy) in your Content project.

Tip

Making a reference to an existing file in your project is quite different from adding an existing item to your project. A file reference only stores the path to the file in question, not a copy of the contents. This is useful if the referenced file is dependent on additional external files and ensures that the solution always uses the latest version. This differs from adding a copy of the file to the project. In this case, it is possible to break external file dependencies and create extra work if the original content changes but the copy is not updated.

For these reasons, it is recommended that you place any media used by the solution in a subfolder of the solution, and that you add a reference to the media and not a copy of the media.

5. After you add the asset, open the **Properties** window and verify that the correct importer and processor are specified.

For this example, the **Content Importer** is X File-XNA Framework and the **Content Processor** is Model-XNA Framework. For ease of reference, the asset name value was manually changed to "ship" using the **Properties** window.

For more information on the **Properties** window of a game asset, see [Game Asset Properties](#).

6. Save the solution.

At this point, build the solution.

This completes the design-time portion of the example. The remaining parts render the model using the managed object (called "ship") and add some user control of the model. All code modifications for this part occur within the game1.cs file of the game project.

To render the model

1. From Solution Explorer, double-click the game1.cs file.
2. Modify the **Game1** class by adding the following code at the beginning of the declaration.

C#

```
private Model gameShip;
```

This member is used to hold the ship model.

3. Modify the **LoadGraphicsContent** method by adding the following code.

C#

```
gameShip = Content.Load<Model>("ship");
```

This code loads the model into the `gameShip` member (using [Load](#)).

4. Create a new **private** method (called **DrawModel**) in the **Game1** class by adding the following code before the existing [Draw](#) method.

C#

```
private void DrawModel(Model m)
{
    Matrix[] transforms = new Matrix[m.Bones.Count];
    float aspectRatio = graphics.GraphicsDevice.Viewport.Width /
        graphics.GraphicsDevice.Viewport.Height;
    m.CopyAbsoluteBoneTransformsTo(transforms);
    Matrix projection =
        Matrix.CreatePerspectiveFieldOfView(MathHelper.ToRadians(45.0f),
        aspectRatio, 1.0f, 10000.0f);
    Matrix view = Matrix.CreateLookAt(new Vector3(0.0f, 50.0f, Zoom),
        Vector3.Zero, Vector3.Up);

    foreach (ModelMesh mesh in m.Meshes)
    {
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.EnableDefaultLighting();

            effect.View = view;
            effect.Projection = projection;
            effect.World = gameWorldRotation *
                transforms[mesh.ParentBone.Index] *
                Matrix.CreateTranslation(Position);
        }
        mesh.Draw();
    }
}
```

This code sets up the lighting effects for each sub-mesh of the model. The `gameWorldRotation` and `Zoom` variables are used for player control. This functionality is added later.

Note

This render code is designed for only those models with a [BasicEffect](#). For custom effects, the inner `for-each` loop should be changed to use [Effect](#) instead of [BasicEffect](#). In addition, you must use [EffectParameter](#) objects to manually set the world, view, and projection matrices.

5. Modify the **Game1.Draw** method by replacing the following code // `TODO: Add your drawing code here` with the following code:

C#

```
DrawModel(gameShip);
```

This causes the effects initialization of the model before the entire model is rendered.

6. Save the solution.

At this point, the rendering code for the model is complete, but the user control code still needs implementation.

To move the model:

1. Modify the **Game1** class by adding the following code after the `gameShip` declaration.

C#

```
private Vector3 Position = Vector3.One;
private float Zoom = 2500;
private float RotationY = 0.0f;
private float RotationX = 0.0f;
private Matrix gameWorldRotation;
```

These members store the current position, zoom, and rotation values. In addition, the `gameWorldRotation` simplifies the `UpdateGamePad` code.

2. Add a private method (called **UpdateGamePad**) before the call to `Update`.

C#

```
private void UpdateGamePad()
{
    GamePadState state = GamePad.GetState(PlayerIndex.One);

    if (state.Buttons.A == ButtonState.Pressed)
    {
        Exit();
    }

    Position.X += state.ThumbSticks.Left.X * 10;
    Position.Y += state.ThumbSticks.Left.Y * 10;
    Zoom += state.ThumbSticks.Right.Y * 10;
    RotationY += state.ThumbSticks.Right.X;
    if (state.DPad.Up == ButtonState.Pressed)
    {
        RotationX += 1.0f;
    }
    else if (state.DPad.Down == ButtonState.Pressed)
    {
        RotationX -= 1.0f;
    }
    gameWorldRotation =
        Matrix.CreateRotationX(MathHelper.ToRadians(RotationX)) *
        Matrix.CreateRotationY(MathHelper.ToRadians(RotationY));
}
```

This code implements an exit method for the game (pressing the **A** button), and updates the position members with the current input of the game controller.

3. Modify the **Update** method by adding a call to `UpdateGamePad`, before the call to `Update`.

C#

```
UpdateGamePad();
```

This code updates the state of the position variables with the latest input.

4. Save the solution.

At this point, all development is complete. You can control the ship location with the game pad, and exit by pressing the **A** button.

How To: Create and Use a Custom Vertex

Demonstrates how to create a custom vertex and use it to render a 3D primitive object. It extends the concepts discussed in [How To: Use BasicEffect](#) and [How To: Draw Points, Lines, and Other 3D Primitives](#).

A custom vertex can include any standard and custom data types. This enables you to provide functionality beyond the standard XNA Framework vertex declarations, declarations such as [VertexPositionColor](#).

This topic shows you the concept with a custom vertex (of type `VertexPositionColoredNormal`) with three properties: a [Vector3](#) position, a [Color](#) color, and a [Vector3](#) normal. With this information, you can render 3D primitives with basic color and lighting effects.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download UseCustomVertex_Sample.zip](#).

Declaring the Custom Vertex

The requirements for a custom vertex are:

- Properties, implemented using both standard and user-defined data types, containing the values for the custom vertex. For this example, three properties are declared representing the position, color, and normal of the vertex.
- A public method called **SizeInBytes**.
- An array of type [VertexElement](#) with each element representing a property of the custom vertex. For this example, the properties are represented by two [Vector3](#) types and a [Color](#) type.

In addition, you can implement some standard methods, such as constructors and public property accessors. For this example, a constructor and public methods for the three properties are implemented.

To declare the custom vertex

1. At the top of the source file declaring your game class, declare a structure containing the necessary components, based on the requirements listed previously.

This part of the structure declaration declares a custom vertex with properties for the position, color, and vertex normal.

C#

```

Vector3 vertexPosition;
Color vertexColor;
Vector3 vertexNormal;

public static int SizeInBytes { get { return 28; } }

//Declares the elements of the custom vertex.
//Each vertex stores information on the current
//position, color, and normal.
public static readonly VertexElement[] VertexElements =
    new VertexElement[] {
        new VertexElement(0, 0, VertexElementFormat.Vector3,
            VertexElementMethod.Default,
            VertexElementUsage.Position, 0),
        new VertexElement(0, sizeof(float) * 3,
            VertexElementFormat.Color, VertexElementMethod.Default,
            VertexElementUsage.Color, 0),
        new VertexElement(0, sizeof(float) * 3 + 4,
            VertexElementFormat.Vector3,
            VertexElementMethod.Default, VertexElementUsage.Normal,
            0) };

```

2. Declare any additional methods you think are necessary.

This part of the structure declaration declares a constructor and three public methods. There is a method for each custom vertex property.

C#

```
public VertexPositionColoredNormal(Vector3 pos, Color color,
    Vector3 normal)
{
    vertexPosition = pos;
    vertexColor = color;
    vertexNormal = normal;
}

//Public methods for accessing the components of the custom vertex.
public Vector3 Position { get { return vertexPosition; }
    set { vertexPosition = value; } }
public Color Color { get { return vertexColor; }
    set { vertexColor = value; } }
public Vector3 Normal { get { return vertexNormal; }
    set { vertexNormal = value; } }
```

The custom vertex structure declaration is now complete. Initializing the basic effect is next.

Initializing the Effect and Camera

The next step initializes an effect (of type [BasicEffect](#)) and the related camera. These are used for basic coloring and lighting effects, and for viewing the 3D object. Although this step is not strictly necessary for implementing a custom vertex, it is provided to show you a common usage scenario for this custom vertex, which is the rendering of a simple 3D object with color and light effects.

To initialize the basic effect and camera

1. Declare variables for the basic effect and various projection matrices.

C#

```
BasicEffect basicEffect;
Matrix worldMatrix;
Matrix viewMatrix;
Matrix projectionMatrix;
```

2. Initialize the matrices of the camera object.

In this topic, a translation matrix is created to place the primitive at the center of the viewport of the game. The camera is oriented to look at (0, 0, 0) from a short distance away.

C#

```
//Centers the triangle strip in the game's viewport.
worldMatrix = Matrix.CreateTranslation(-1.5f, -0.5f, 0.0f);

viewMatrix = Matrix.CreateLookAt(
    new Vector3(0.0f, 0.0f, 5.0f),
    Vector3.Zero,
    Vector3.Up
);

projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
    MathHelper.ToRadians(45),
    (float)GraphicsDevice.Viewport.Width /
    (float)GraphicsDevice.Viewport.Height,
```

```
1.0f, 100.0f
);
```

3. Initialize the effect to display a colored 3D primitive with default lighting.

In this topic, vertex coloring and lighting are enabled. In addition, the default lighting scenario lights the primitive. This is the minimum needed to properly color and light the primitive.

C#

```
basicEffectVertexDeclaration =
    new VertexDeclaration(GraphicsDevice,
        VertexPositionColoredNormal.VertexElements);

//Enables some basic effect characteristics, such as vertex
//coloring and default lighting.
basicEffect = new BasicEffect(graphics.GraphicsDevice, null);
basicEffect.VertexColorEnabled = true;
basicEffect.LightingEnabled = true;
basicEffect.EnableDefaultLighting();

basicEffect.World = worldMatrix;
basicEffect.View = viewMatrix;
basicEffect.Projection = projectionMatrix;
```

This completes the initialization of the camera and basic effect. The next step sets up a basic triangle strip using the custom vertex declared earlier in this topic.

Initializing the 3D Primitive

In this step, you initialize a vertex array with custom vertices implemented by `VertexPositionColoredNormal`. In addition to an indices array, the vertex array later renders a colored triangle strip with default lighting effects.

To initialize the triangle strip

1. Declare an array (of type `VertexPositionColoredNormal`), and then initialize the various properties of the vertex elements.

In this topic, a triangle strip (from 0,0 to 3,0 and on the plane $z = 0$) is drawn.

C#

```
triangleStripVertices = new VertexPositionColoredNormal[8];

//Initialize the custom vertex values for the triangle strip.
for (int x = 0; x < 4; x++)
{
    for (int y = 0; y < 2; y++)
    {
        triangleStripVertices[(x * 2) + y] =
            new VertexPositionColoredNormal(
                new Vector3(x, y, 0.0f),
                Color.Red,
                new Vector3(0.0f, 0.0f, 1)
            );
    }
}
```

2. Create and initialize the indices buffer for the primitive.

Because a triangle strip is being used, the buffer is relatively small.

C#

```
triangleStripIndices = new short[8];
for (int i = 0; i < 8; i++)
{
    triangleStripIndices[i] = (short)i;
}
```

Initialization of the triangle strip is complete and the final step of rendering the triangle strip is next.

Drawing the 3D Primitive

In this step, a red triangle strip is rendered with some basic lighting effects. This code is commonly placed inside the [Draw](#) method of your game.

To draw the triangle strip

- Declare the proper vertex declaration for the graphics device, and call the [DrawUserIndexedPrimitives](#) method.

C#

```
GraphicsDevice.VertexDeclaration = basicEffectVertexDeclaration;

basicEffect.Begin();
foreach (EffectPass pass in basicEffect.CurrentTechnique.Passes)
{
    pass.Begin();

    GraphicsDevice.DrawUserIndexedPrimitives
        <VertexPositionColoredNormal>(
        PrimitiveType.TriangleStrip,
        triangleStripVertices,
        0, // vertex buffer offset
           // (to add to each element of the index buffer)
        8, // number of vertices to draw
        triangleStripIndices,
        0, // first index element to read
        6 // number of primitives to draw
    );

    pass.End();
}
basicEffect.End();
```

These simple lighting effects are the reason the `VertexPositionColoredNormal` custom vertex type was created. Because each vertex has a normal, along with a position and color, the basic effect determines where the triangle strip is highlighted and where any shadows lie. If you had instead used vertices of type `VertexPositionColor`, there would be no normals to determine any lighting effects.

How To: Draw Points, Lines, and Other 3D Primitives

Demonstrates how to draw points, lines, and other 3D primitives.

In the XNA Framework, a 3D primitive is a special type of 3D shape that describes how the graphics device interprets vertices stored in a vertex array or vertex stream. The following example shows you how to use the point, line, and triangle primitive types that are the basis for all low-level drawing calls in the XNA Framework.

Note

To render primitives, you need to create a basic effect and several transformation matrices. This topic follows the steps described in [How To: Use BasicEffect](#) to create an instance of [BasicEffect](#). This sample uses orthographic projection, but you can also use perspective projection to render primitives.

The vertices used in the sample are of type [VertexPositionColor Structure](#). Vertices of this type contain position and color information.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download DrawUserPrimitives_Sample.zip.](#)

The major steps for this example are listed below:

- [The Complete Sample](#)
- [Drawing Points](#)
- [Drawing Lines](#)
- [Drawing a Line Strip](#)
- [Drawing Triangles](#)
- [Drawing a Triangle Strip](#)

Drawing Points

To draw a point list

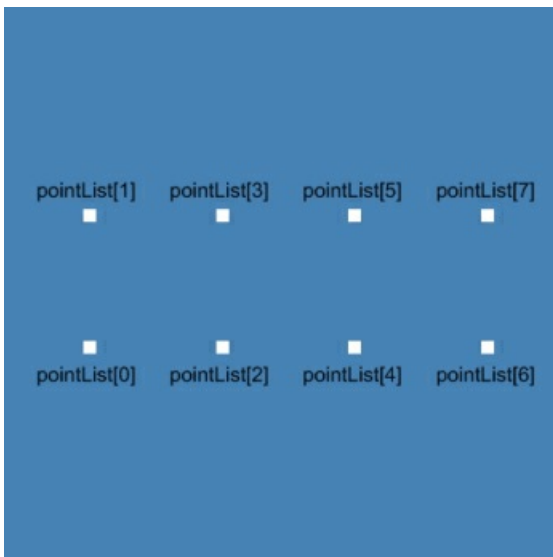

1. Create a list of vertices in 3D space that represent the points to draw.

The following code initializes eight points, and stores them in an array of type **VertexPositionColor**. This results in an array with the following vertex positions.

C#

```
pointList = new VertexPositionColor[points];

for (int x = 0; x < points / 2; x++)
{
    for (int y = 0; y < 2; y++)
    {
        pointList[(x * 2) + y] = new VertexPositionColor(
            new Vector3(x * 100, y * 100, 0), Color.White);
    }
}
```

These eight points form a triangle strip consisting of six triangles drawn along the plane $z = 0$, with the first point at $(0, 0, 0)$. The camera is positioned at $(0, 0, 1)$ looking at $(0, 0, 0)$. An orthogonal projection matrix is created with the upper-left point at $(0, 0)$ and the lower-right point at $(800, 600)$. In addition, a translation matrix shifts the point set to the center of the screen. The following code implements the positioning of the points, the camera, and the required transformations:

C#

```
viewMatrix = Matrix.CreateLookAt(  
    new Vector3(0.0f, 0.0f, 1.0f),  
    Vector3.Zero,  
    Vector3.Up  
);  
  
projectionMatrix = Matrix.CreateOrthographicOffCenter(  
    0,  
    (float)GraphicsDevice.Viewport.Width,  
    (float)GraphicsDevice.Viewport.Height,  
    0,  
    1.0f, 1000.0f);
```

2. Render the size of a point from a point list by setting the property [RenderState.PointSize](#).

The point size here is 10. You will see a 10-pixel square at each point in the list.

C#

```
GraphicsDevice.RenderState.PointSize = 10;
```

3. Render the points by calling [DrawUserPrimitives](#), which specifies [PrimitiveType.PointList](#) to determine how the data in the vertex array is interpreted.

C#

```
GraphicsDevice.DrawUserPrimitives<VertexPositionColor>(  
    PrimitiveType.PointList,  
    pointList,  
    0, // index of the first vertex to draw  
    8 // number of primitives  
);
```

Drawing Lines

The following example uses the sample vertex list created in step 1 of "To draw a point list."

To draw a line list

1. Create an index array that indexes into the vertex buffer.

This identifies a series of lines.

C#

```
// Initialize an array of indices of type short.
lineListIndices = new short[(points * 2) - 2];

// Populate the array with references to indices in the vertex buffer
for (int i = 0; i < points - 1; i++)
{
    lineListIndices[i * 2] = (short)(i);
    lineListIndices[(i * 2) + 1] = (short)(i + 1);
}
```

This is equivalent to setting `lineListIndices` to the following array, which consists of a series of lines between `pointList[0]` and `pointList[1]`, `pointList[1]` and `pointList[2]`, and so forth.

C#

```
lineListIndices = new short[14]{ 0, 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, 6, 6, 7 };
```

2. Render the lines by calling `DrawUserIndexedPrimitives`, which specifies `PrimitiveType.LineList` to determine how to interpret the data in the vertex array.

C#

```
GraphicsDevice.DrawUserIndexedPrimitives<VertexPositionColor>(
    PrimitiveType.LineList,
    pointList,
    0, // vertex buffer offset to add to each element of the index buffer
    8, // number of vertices in pointList
    lineListIndices, // the index buffer
    0, // first index element to read
    7 // number of primitives to draw
);
```

Drawing a Line Strip

The following example uses the same point list and renders the same output as "To draw a line list." However, it uses a line strip primitive type when it identifies the indices of the vertex array to draw. You store fewer indices when you use a line strip.

To draw a line strip

1. Create a list of indices to identify the order in which to draw the points in the specified point list.

You need only half the number of indices here as you used for the line list because the data consist of a series of connected lines.

C#

```
// Initialize an array of indices of type short.
lineStripIndices = new short[points];

// Populate the array with references to indices in the vertex buffer.
for (int i = 0; i < points; i++)
{
    lineStripIndices[i] = (short)(i);
}
```

This is equivalent to setting `lineStripIndices` to the following array, which consists of a series of *connected* lines between `pointList[0]`, `pointList[1]`, and `pointList[2]`, and so forth.

C#

```
lineStripIndices = new short[8]{ 0, 1, 2, 3, 4, 5, 6, 7 };
```

2. Render the line strip by calling `DrawUserIndexedPrimitives`, which specifies `PrimitiveType.LineStrip` to determine how to interpret the data in the vertex array.

Note that you use fewer vertices to render the same number of primitives rendered earlier by the line list.

Note

In the example code, the line strip is rendered by a series of red lines, instead of the white lines used for the previous line list. This is accomplished by changing the vertex color before you draw the line strip. After you complete the drawing, it reverts to the original color. In addition, vertex coloring was enabled for the basic effect (using `BasicEffect.VertexColorEnabled` Property).

The color change indicates a different primitive type was used to achieve the same result.

C#

```
for (int i = 0; i < pointList.Length; i++)
    pointList[i].Color = Color.Red;

GraphicsDevice.DrawUserIndexedPrimitives<VertexPositionColor>(
    PrimitiveType.LineStrip,
    pointList,
    0, // vertex buffer offset to add to each element of the index buffer
    8, // number of vertices to draw
    lineStripIndices,
    0, // first index element to read
    7 // number of primitives to draw
);
for (int i = 0; i < pointList.Length; i++)
    pointList[i].Color = Color.White;
```

Drawing Triangles

Like a line list, a triangle list is a primitive type that indicates you need to interpret the vertices in the vertex buffer as a series of separately drawn triangles.

To draw a triangle list

1. Create an array to hold the list of indices that identify a series of triangles to draw from the specified point list.

C#

```
triangleListIndices = new short[(width - 1) * (height - 1) * 6];

for (int x = 0; x < width - 1; x++)
{
    for (int y = 0; y < height - 1; y++)
    {
        triangleListIndices[(x + y * (width - 1)) * 6] = (short)(2 * x);
        triangleListIndices[(x + y * (width - 1)) * 6 + 1] = (short)(2 * x + 1);
        triangleListIndices[(x + y * (width - 1)) * 6 + 2] = (short)(2 * x + 2);

        triangleListIndices[(x + y * (width - 1)) * 6 + 3] = (short)(2 * x + 2);
        triangleListIndices[(x + y * (width - 1)) * 6 + 4] = (short)(2 * x + 1);
        triangleListIndices[(x + y * (width - 1)) * 6 + 5] = (short)(2 * x + 3);
    }
}
```

This is equivalent to setting `triangleListIndices` to the following array, which consists of a series of triangles between `pointList[0]`, `pointList[1]`, and `pointList[2]`, and so forth.

C#

```
triangleListIndices = new short[18]{ 0, 1, 2, 2, 1, 3, 2, 3, 4, 4, 3, 5, 4, 5, 6, 6, 5, 7 };
```

2. Render the lines by calling `DrawUserIndexedPrimitives`

This specifies `PrimitiveType.TriangleList`, which determines how the data in the vertex array is interpreted.

C#

```
GraphicsDevice.DrawUserIndexedPrimitives<VertexPositionColor>(
    PrimitiveType.TriangleList,
    pointList,
    0, // vertex buffer offset to add to each element of the index buffer
    8, // number of vertices to draw
    triangleListIndices,
    0, // first index element to read
    6 // number of primitives to draw
);
```

Drawing a Triangle Strip

A triangle strip is a set of triangles that share multiple vertices. This example shows you how to render an object that looks the same as the object rendered with a triangle list. However, fewer vertices are needed because the triangles share multiple vertices.

To draw a triangle strip

1. Create an array to hold the list of indices that identify a strip of triangles.

C#

```
// Initialize an array of indices of type short.
triangleStripIndices = new short[points];

// Populate the array with references to indices in the vertex buffer.
for (int i = 0; i < points; i++)
{
    triangleStripIndices[i] = (short)i;
}
```

This is equivalent to setting `triangleStripIndices` to the following array, which consists of a series of *connected* triangles between `pointList[0]`, `pointList[1]`, and `pointList[2]`, and so forth.

C#

```
triangleStripIndices = new short[8]{ 0, 1, 2, 3, 4, 5, 6, 7 };
```

2. Render the lines by calling `DrawUserIndexedPrimitives`.

This specifies `PrimitiveType.TriangleStrip` to determine how to interpret the data in the vertex array. Note that you use fewer vertices to render the same number of primitives rendered earlier by the triangle list.

Note

In the example code, the triangle strip is rendered by a series of red lines, instead of the white lines used for the previous triangle list. The color change indicates a different primitive type was used to achieve the same result.

C#

```
for (int i = 0; i < pointList.Length; i++)
```

```
    pointList[i].Color = Color.Red;

GraphicsDevice.DrawUserIndexedPrimitives<VertexPositionColor>(
    PrimitiveType.TriangleStrip,
    pointList,
    0, // vertex buffer offset to add to each element of the index buffer
    8, // number of vertices to draw
    triangleStripIndices,
    0, // first index element to read
    6 // number of primitives to draw
);
for (int i = 0; i < pointList.Length; i++)
    pointList[i].Color = Color.White;
```

How To: Create and Apply Custom Effects

Demonstrates how to create a simple effect to set the diffuse color and world, view, and projection transformation of a 3D object.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

Applying an Effect

Note

The steps described here apply to effects created with the [Effect](#) class. In contrast, the [BasicEffect](#) class is provided for users who want basic lighting, materials, texture, and transformation functionality, but do not want to write custom effects. For more information, see [How To: Use BasicEffect](#).

To apply an effect

1. Compose the effect description using either shader assembly language (ASM) or high-level shader language (HLSL).

In this example, the effect file contains a vertex shader named **Transform** and a technique named **TransformTechnique**, which applies the vertex shader in a single pass.

```
uniform extern float4x4 WorldViewProj : WORLDVIEWPROJECTION;

struct VS_OUTPUT
{
    float4 position : POSITION;
    float4 color : COLOR0;
};

VS_OUTPUT Transform(
    float4 Pos : POSITION,
    float4 Color : COLOR0 )
{
    VS_OUTPUT Out = (VS_OUTPUT)0;

    Out.position = mul(Pos, WorldViewProj);
    Out.color = Color;

    return Out;
}

float4 PixelShader( VS_OUTPUT vsout ) : COLOR
{
    return vsout.color;
}

technique TransformTechnique
{
    pass P0
    {
        vertexShader = compile vs_2_0 Transform();
        pixelShader = compile ps_1_1 PixelShader();
    }
}
```

2. Add the effect file to the Content directory of your XNA Framework game.

3. Right-click your Content node, point to **Add**, and then click **Existing Item**.
4. In the **Files of type:** drop-down list, click **All Files**.
5. Navigate to your .fx file, and click **Add**.

Tip

To create a new .fx file, point to **Add**, click **New Item**, and then select the **Text File** template. For the name of the file, use the .fx file extension.

6. Create a new [Effect](#) by using the [ContentManager.Load<Effect>](#) method to load the asset.

C#

```
effect = Content.Load<Effect>("ReallySimpleEffect");
```

In the effect file, there is a parameter named *WorldViewProj*, which is a matrix used by the vertex shader. The following code looks up the *WorldViewProj* parameter in [Effect.Parameters](#), and calls [EffectParameter.SetValue](#) to initialize the value of the transform matrix.

C#

```
effect.Parameters["WorldViewProj"].SetValue(worldViewProjection);
```

7. Set [Effect.CurrentTechnique](#) to the technique from the effect file you wish to apply.

In this case, use [Effect.Techniques](#) to look up the technique named **TransformTechnique** from the effect file.

C#

```
effect.CurrentTechnique = effect.Techniques["TransformTechnique"];
```

8. Call the [Effect.Begin](#) to begin applying the technique.
9. For each pass in the technique, draw the desired geometry between calls to [EffectPass.Begin](#) and [EffectPass.End](#).
10. Call [Effect.End](#) to stop applying the technique.

C#

```
// The effect is a compiled effect created and compiled elsewhere
// in the application.

effect.Begin();
foreach (EffectPass pass in effect.CurrentTechnique.Passes)
{
    pass.Begin();

    GraphicsDevice.DrawIndexedPrimitives(
        PrimitiveType.TriangleList,
        0,
        0,
        cubeVertices.Length,
        0,
        12);

    pass.End();
}
effect.End();
```

Drawing a Model With a Custom Effect

When you load a [Model](#), the model is set by default to use the [BasicEffect](#). You can change this by customizing the content pipeline, or you can apply a new [Effect](#) to the [Model](#) when you load the [Model](#).

To draw a model with a custom effect

1. In your game's [LoadContent](#) method, load your [Model](#), typically using the [ContentManager](#).

C#

```
terrain = Content.Load<Model>("terrain");
```

2. In [LoadContent](#), load your [Effect](#), typically using the [ContentManager](#).

C#

```
MyEffect = content.Load<Effect>("CustomEffect");
```

3. Iterate through each [ModelMeshPart](#) in your model, and assign your [Effect](#) to the [Effect](#) property of the [ModelMeshPart](#).

C#

```
public static void RemapModel(Model model, Effect effect)
{
    foreach (ModelMesh mesh in model.Meshes)
    {
        foreach (ModelMeshPart part in mesh.MeshParts)
        {
            part.Effect = effect;
        }
    }
}
```

4. Draw the [Model](#), using the steps outlined in [How To: Render a Model](#) with one exception: instead of using [BasicEffect](#), use the [Effect](#) attached to the model.

C#

```
foreach (ModelMesh mesh in terrain.Meshes)
{
    foreach (Effect effect in mesh.Effects)
    {
        mesh.Draw();
    }
}
```

How To: Create Custom Texture Effects

Demonstrates how to create an effect to apply a texture to a 3D primitive object. This topic builds on the demonstrations [How To: Draw Points, Lines, and Other 3D Primitives](#) and [How To: Create and Apply Custom Effects](#).

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download ApplyTextures_Sample.zip.](#)

The major steps for this example are listed below:

- [Composing the Texture](#)
- [Associating Vertices with Texture Coordinates](#)
- [Initializing the Texture](#)
- [Initializing the Effect](#)
- [Applying the Effect Technique](#)

Composing the Texture

To compose the texture effect

- Compose the effect description using either shader assembly language (ASM) or high-level shader language (HLSL).

In this example, the effect file contains a vertex shader to transform the object and a pixel shader to apply the texture to the object.

Note

In this effect file, even though the vertex shader does not manipulate the texture coordinate, it returns the texture coordinate so that it will be available to the pixel shader.

```
uniform extern float4x4 WorldViewProj : WORLDVIEWPROJECTION;
uniform extern texture UserTexture;

struct VS_OUTPUT
{
    float4 position : POSITION;
    float4 textureCoordinate : TEXCOORD0;
};

sampler textureSampler = sampler_state
{
    Texture = <UserTexture>;
    mipfilter = LINEAR;
};

VS_OUTPUT Transform(
    float4 Position : POSITION,
    float4 TextureCoordinate : TEXCOORD0 )
{
    VS_OUTPUT Out = (VS_OUTPUT)0;

    Out.position = mul(Position, WorldViewProj);
    Out.textureCoordinate = TextureCoordinate;

    return Out;
}

float4 ApplyTexture(VS_OUTPUT vsout) : COLOR
```

```

{
    return tex2D(textureSampler, vsout.textureCoordinate).rgba;
}

technique TransformAndTexture
{
    pass P0
    {
        vertexShader = compile vs_2_0 Transform();
        pixelShader  = compile ps_2_0 ApplyTexture();
    }
}

```

Associating Vertices with Texture Coordinates

To associate texture coordinates with vertices

1. Create a vertex declaration of type [VertexPositionTexture](#).

C#

```

cubeVertexDeclaration = new VertexDeclaration(
    GraphicsDevice, VertexPositionTexture.VertexElements);

```

2. Initialize the points to be used to draw each side of the cube.

C#

```

Vector3 topLeftFront = new Vector3(-1.0f, 1.0f, 1.0f);
Vector3 bottomLeftFront = new Vector3(-1.0f, -1.0f, 1.0f);
Vector3 topRightFront = new Vector3(1.0f, 1.0f, 1.0f);
Vector3 bottomRightFront = new Vector3(1.0f, -1.0f, 1.0f);
Vector3 topLeftBack = new Vector3(-1.0f, 1.0f, -1.0f);
Vector3 topRightBack = new Vector3(1.0f, 1.0f, -1.0f);
Vector3 bottomLeftBack = new Vector3(-1.0f, -1.0f, -1.0f);
Vector3 bottomRightBack = new Vector3(1.0f, -1.0f, -1.0f);

```

3. Initialize the texture coordinates.

C#

```

Vector2 textureTopLeft = new Vector2(0.0f, 0.0f);
Vector2 textureTopRight = new Vector2(1.0f, 0.0f);
Vector2 textureBottomLeft = new Vector2(0.0f, 1.0f);
Vector2 textureBottomRight = new Vector2(1.0f, 1.0f);

```

4. Declare an array to hold the list of vertices.

This array will be used to assign data to the vertex buffer.

C#

```

cubeVertices = new VertexPositionTexture[36];

```

5. Assign the position and texture coordinate data to each element of the vertex array.

C#

```

// Vertices for the front of the cube.
cubeVertices[0] =
    new VertexPositionTexture(
        topLeftFront, textureTopLeft); // 0
cubeVertices[1] =

```

```

    new VertexPositionTexture(
        bottomLeftFront, textureBottomLeft); // 1
cubeVertices[2] =
    new VertexPositionTexture(
        topRightFront, textureTopRight); // 2
cubeVertices[3] =
    new VertexPositionTexture(
        bottomRightFront, textureBottomRight); // 3

// Vertices for the back of the cube.
cubeVertices[4] =
    new VertexPositionTexture(
        topLeftBack, textureTopRight); // 4
cubeVertices[5] =
    new VertexPositionTexture(
        topRightBack, textureTopLeft); // 5
cubeVertices[6] =
    new VertexPositionTexture(
        bottomLeftBack, textureBottomRight); //6
cubeVertices[7] =
    new VertexPositionTexture(
        bottomRightBack, textureBottomLeft); // 7

// Vertices for the top of the cube.
cubeVertices[8] =
    new VertexPositionTexture(
        topLeftFront, textureBottomLeft); // 8
cubeVertices[9] =
    new VertexPositionTexture(
        topRightBack, textureTopRight); // 9
cubeVertices[10] =
    new VertexPositionTexture(
        topLeftBack, textureTopLeft); // 10
cubeVertices[11] =
    new VertexPositionTexture(
        topRightFront, textureBottomRight); // 11

// Vertices for the bottom of the cube.
cubeVertices[12] =
    new VertexPositionTexture(
        bottomLeftFront, textureTopLeft); // 12
cubeVertices[13] =
    new VertexPositionTexture(
        bottomLeftBack, textureBottomLeft); // 13
cubeVertices[14] =
    new VertexPositionTexture(
        bottomRightBack, textureBottomRight); // 14
cubeVertices[15] =
    new VertexPositionTexture(
        bottomRightFront, textureTopRight); // 15

// Vertices for the left side of the cube.
cubeVertices[16] =
    new VertexPositionTexture(
        topLeftFront, textureTopRight); // 16
cubeVertices[17] =
    new VertexPositionTexture(
        bottomLeftFront, textureBottomRight); // 17
cubeVertices[18] =

```

```
    new VertexPositionTexture(
        topRightFront, textureTopLeft); // 18
cubeVertices[19] =
    new VertexPositionTexture(
        bottomRightFront, textureBottomLeft); // 19
```

6. Create a vertex buffer to hold the vertex data.

C#

```
vertexBuffer = new VertexBuffer(GraphicsDevice,
    VertexPositionTexture.SizeInBytes * cubeVertices.Length,
    BufferUsage.None
);
```

7. Add the data to the vertex buffer.

C#

```
vertexBuffer.SetData<VertexPositionTexture>(cubeVertices);
```

8. Create indices to index into the **cubeVertices** array.

C#

```
cubeIndices = new short[] {
    0, 1, 2, // front face
    1, 3, 2,
    4, 5, 6, // back face
    6, 5, 7,
    8, 9, 10, // top face
    8, 11, 9,
    12, 13, 14, // bottom face
    12, 14, 15,
    16, 13, 17, // left face
    10, 13, 16,
    18, 19, 14, // right face
    9, 18, 14 };
```

9. Create an index buffer to hold the index array data.

C#

```
indexBuffer = new IndexBuffer(GraphicsDevice,
    sizeof(short) * cubeIndices.Length,
    BufferUsage.None,
    IndexElementSize.SixteenBits
);
```

10. Add the data to the index buffer.

C#

```
indexBuffer.SetData<short>(cubeIndices);
```

Initializing the Texture

Now you will want to add texture to the Content directory of your game project.

To initialize the texture

1. From Solution Explorer, right-click the Content node of your game project, click **Add**, and then click **Existing Item**.

2. In the **Files of type:** drop-down list, select **All Files**.
3. Navigate to your texture file and click **Add**.

In this example, a texture named xna.jpg is added and assigned a corresponding asset name of **xna**. For more information about game asset properties, see [Game Asset Properties](#).

4. Create a new [Texture2D](#) object using the [ContentManager.Load<Texture2D>](#) method to load the asset.

C#

```
Texture2D texture = Content.Load<Texture2D>("xna");
```

Initializing the Effect

This effect has two parameters, a transformation matrix named **WorldViewProj** to use in the vertex shader, and the texture named **UserTexture** to use in the texture sampler to be applied to the pixel shader. You need to set these parameters to the corresponding objects in the application: the [Matrix](#) object named **worldViewProjection**, and the [Texture2D](#) object named **texture**.

C#

```
effect.Parameters["WorldViewProj"].SetValue(worldViewProjection);  
effect.Parameters["UserTexture"].SetValue(texture);
```

Applying the Effect Technique

There is only one technique available in the effect file, so in this example [CurrentTechnique](#) is set to **TransformAndTexture**, which is the name of the technique in the effect file.

C#

```
effect.CurrentTechnique = effect.Techniques["TransformAndTexture"];
```

To select and apply a texture technique

1. Set the device vertex stream, indices, and vertex declaration to correspond to the vertices for which the texture is to be applied.

C#

```
GraphicsDevice.VertexDeclaration = cubeVertexDeclaration;  
GraphicsDevice.Indices = indexBuffer;  
GraphicsDevice.Vertices[0].SetSource(  
    vertexBuffer,  
    0,  
    VertexPositionTexture.SizeInBytes);
```

2. Apply the technique by placing the drawing calls between [EffectPass.Begin](#) and [EffectPass.End](#) inside an [Effect.Begin ... Effect.End](#) block.

C#

```
// This code would go between a device BeginScene-EndScene block.  
effect.Begin();  
foreach (EffectPass pass in effect.CurrentTechnique.Passes)  
{  
    pass.Begin();  
  
    GraphicsDevice.DrawIndexedPrimitives(  
        PrimitiveType.TriangleList,  
        0,  
        0,  
        cubeVertices.Length,  
        0,
```

12

);

pass.End();

}

effect.End();

How To: Draw a Textured Quad

Demonstrates how to create and draw a simple quad using `DrawUserIndexedPrimitives`.

A quad is two triangles that form a rectangle or square. This sample introduces the **Quad** class. This class constructs a quad with a list of vertices and indices suitable for drawing with `DrawUserIndexedPrimitives`. This sample also demonstrates how to use `BasicEffect` to apply a texture to the primitive.

Note

To render the quad, this sample uses the `BasicEffect` class. For a discussion of `BasicEffect` see [How To: Use BasicEffect](#).

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download TexturedQuad_Sample.zip](#).

The Textured Quad

To Create a Quad

1. Determine the location of each of the four vertices in the quad.

The Quad constructor calculates the four corners given the origin, width, height, and facing information supplied by the caller.

C#

```
public Quad( Vector3 origin, Vector3 normal, Vector3 up,
            float width, float height )
{
    Vertices = new VertexPositionNormalTexture[4];
    Indexes = new int[6];
    Origin = origin;
    Normal = normal;
    Up = up;

    // Calculate the quad corners
    Left = Vector3.Cross( normal, Up );
    Vector3 uppercenter = (Up * height / 2) + origin;
    UpperLeft = uppercenter + (Left * width / 2);
    UpperRight = uppercenter - (Left * width / 2);
    LowerLeft = UpperLeft - (Up * height);
    LowerRight = UpperRight - (Up * height);

    FillVertices();
}
```

2. Determine the UV coordinates for the texture you want to apply to the quad.

The Quad constructor calls `FillVertices`, which assigns UV coordinates ranging from (0,0) to (1,1). This will make the entire texture appear on the quad.

C#

```
private void FillVertices()
{
    // Fill in texture coordinates to display full texture
    // on quad
    Vector2 textureUpperLeft = new Vector2( 0.0f, 0.0f );
    Vector2 textureUpperRight = new Vector2( 1.0f, 0.0f );
    Vector2 textureLowerLeft = new Vector2( 0.0f, 1.0f );
}
```

```
Vector2 textureLowerRight = new Vector2( 1.0f, 1.0f );
```

- Determine the normals for your vertices.

FillVertices copies the normal vector you provide to each vertex.

C#

```
// Provide a normal for each vertex
for (int i = 0; i < Vertices.Length; i++)
{
    Vertices[i].Normal = Normal;
}
```

- Copy the position and texture coordinate data to your vertex array.

C#

```
// Set the position and texture coordinate for each
// vertex
Vertices[0].Position = LowerLeft;
Vertices[0].TextureCoordinate = textureLowerLeft;
Vertices[1].Position = UpperLeft;
Vertices[1].TextureCoordinate = textureUpperLeft;
Vertices[2].Position = LowerRight;
Vertices[2].TextureCoordinate = textureLowerRight;
Vertices[3].Position = UpperRight;
Vertices[3].TextureCoordinate = textureUpperRight;
```

- Fill out the index buffer to determine what order your vertices are drawn by the graphics hardware.

Drawing two triangles requires four vertices, but six index entries if you are using [PrimitiveType.TriangleList](#). The indices are specified in clockwise order. Because XNA is a right-handed system, triangles drawn in counter-clockwise order are assumed to be facing away from the camera, and are automatically culled by default.

C#

```
// Set the index buffer for each vertex, using
// clockwise winding
Indexes[0] = 0;
Indexes[1] = 1;
Indexes[2] = 2;
Indexes[3] = 2;
Indexes[4] = 1;
Indexes[5] = 3;
}
```

To Draw a Quad

- In your game's [Initialize](#) method, create a new **Quad** object specifying the location, the normal (the direction the Quad faces), the Up vector, and the width and height of the quad.

You can also create a View and Projection matrix to use when rendering.

C#

```
Quad quad;
VertexDeclaration quadVertexDecl;
Matrix View, Projection;
protected override void Initialize()
{
    quad = new Quad(Vector3.Zero, Vector3.Backward, Vector3.Up, 1, 1);
    View = Matrix.CreateLookAt(new Vector3(0, 0, 2), Vector3.Zero,
```

```

        Vector3.Up);
    Projection = Matrix.CreatePerspectiveFieldOfView(
        MathHelper.PiOver4, 4.0f / 3.0f, 1, 500);

    base.Initialize();
}

```

- In your game's `LoadContent` method, load the texture you want to apply to the quad using the `ContentManager`.
- Create and initialize a new `BasicEffect` object.
- Set `TextureEnabled` to `true`, and assign the texture to draw to the `Texture` property.

C#

```

Texture2D texture;
BasicEffect quadEffect;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    texture = Content.Load<Texture2D>("Glass");
    quadEffect = new BasicEffect(graphics.GraphicsDevice, null);
    quadEffect.EnableDefaultLighting();

    quadEffect.World = Matrix.Identity;
    quadEffect.View = View;
    quadEffect.Projection = Projection;
    quadEffect.TextureEnabled = true;
    quadEffect.Texture = texture;
}

```

- In `LoadContent`, create a `VertexDeclaration` for the vertex type used to define the quad, in this case, `VertexPositionNormalTexture`.

C#

```

quadVertexDecl = new VertexDeclaration(graphics.GraphicsDevice,
    VertexPositionNormalTexture.VertexElements);
}

```

- In your game's `Draw` method, set the `VertexDeclaration` on the `GraphicsDevice` to the `VertexDeclaration` object you created in `LoadContent`.

C#

```

protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);
    GraphicsDevice.VertexDeclaration = quadVertexDecl;
}

```

- Call `Begin` on the effect.
- Use `DrawUserIndexedPrimitives` in each `EffectPass` to draw the quad.
- Use the `Vertices` and `Indices` properties on the `Quad` structure to supply the primitive data, and specify two triangles to draw.
- Call `End` on the effect.

C#

```

quadEffect.Begin();
foreach (EffectPass pass in quadEffect.CurrentTechnique.Passes)

```

        PrimitiveType.TriangleList,
        quad.Vertices, 0, 4,

    pass.End();
}
quadEffect.End();

base.Draw(gameTime);

How To: Use Viewports for Split Screen Gaming

Demonstrates how to use the [Viewport](#) property to display different scenes to different parts of the screen. This sample assumes there are two camera classes in use, **Camera1** and **Camera2**.

Creating a Split Screen

To create a split screen

1. In your [LoadContent](#) method, create two new [Viewport](#) objects to define the two new "split" regions of the screen.

In this example, the screen is split in half vertically.

C#

```
Viewport defaultViewport;
Viewport leftViewport;
Viewport rightViewport;
Matrix projectionMatrix;
Matrix halfprojectionMatrix;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);

    defaultViewport = GraphicsDevice.Viewport;
    leftViewport = defaultViewport;
    rightViewport = defaultViewport;
    leftViewport.Width = leftViewport.Width / 2;
    rightViewport.Width = rightViewport.Width / 2;
    rightViewport.X = leftViewport.Width + 1;
}
```

2. Create a projection matrix to fit each new viewport.

In this case, because the screen is split in half, only one new projection matrix is necessary. It has the same settings as the 4:3 full screen projection matrix, except the aspect ratio is now 2:3.

C#

```
projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
    MathHelper.PiOver4, 4.0f / 3.0f, 1.0f, 10000f);
halfprojectionMatrix = Matrix.CreatePerspectiveFieldOfView(
    MathHelper.PiOver4, 2.0f / 3.0f, 1.0f, 10000f);
}
```

3. In your [Draw](#) method, assign one of the viewports to draw as the [GraphicsDevice Viewport](#).
4. Draw your scene as normal, using the camera (or view matrix) associated with this perspective along with the proper projection matrix.

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Viewport = defaultViewport;
    GraphicsDevice.Clear(Color.CornflowerBlue);
}
```

```
GraphicsDevice.Viewport = leftViewport;  
DrawScene(gameTime, Camera1.ViewMatrix, halfprojectionMatrix);
```

5. After drawing the first scene, assign the other viewport to the [Viewport](#) property.
6. Draw your scene again with the associated camera or view matrix, and the proper projection matrix.

C#

```
GraphicsDevice.Viewport = rightViewport;  
DrawScene(gameTime, Camera2.ViewMatrix, halfprojectionMatrix);  
  
base.Draw(gameTime);  
  
}
```

How To: Create a SkySphere

Demonstrates how to create an effect that will apply a skybox-style TextureCube ("cube map") to a sphere.

This example assumes you have a Camera object for handling the position and view matrix of the 3D camera, along with a simple [Model](#) to display. The SkySphere effect also requires a sphere model and a skybox cube map.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download SkySphere_Sample.zip.](#)

The Skysphere Effect

The vertex shader for the SkySphere effect takes the position of each vertex and extracts the rotation of the camera from the view matrix. It then applies the projection matrix to that for the final vertex position. For calculating the pixel values between the vertices, the vertex shader passes the unmodified position.

C#

```
uniform extern float4x4 ViewMatrix;
uniform extern float4x4 ProjectionMatrix;

void SkyboxVertexShader( float3 pos : POSITION0,
                        out float4 SkyPos : POSITION0,
                        out float3 SkyCoord : TEXCOORD0 )
{
    // Calculate rotation. Using a float3 result, so translation is ignored
    float3 rotatedPosition = mul(pos, ViewMatrix);
    // Calculate projection, moving all vertices to the far clip plane
    // (w and z both 1.0)
    SkyPos = mul(float4(rotatedPosition, 1), ProjectionMatrix).xyww;

    SkyCoord = pos;
};
```

The pixel shader for the SkySphere effect uses the texCUBE function to choose a pixel on the cube map.

To Create the SkySphere Effect

1. Imagine the sphere model surrounding the camera viewpoint, and the cube map surrounding the sphere model (as a cube).
2. Draw a line from the camera position to a point on the sphere model, and continue that line until it hits the cube map.

This is the pixel returned by texCUBE. This has the effect of transforming the cube into a different shape, which makes the sky look more realistic (the cube often has obvious corners). You do not have to use a sphere for this effect. A flattened or oblong sphere may look better for some applications.

C#

```
uniform extern texture SkyboxTexture;
sampler SkyboxS = sampler_state
{
    Texture = <SkyboxTexture>;
    MinFilter = LINEAR;
    MagFilter = LINEAR;
    MipFilter = LINEAR;
    AddressU = CLAMP;
    AddressV = CLAMP;
};
float4 SkyboxPixelShader( float3 SkyCoord : TEXCOORD0 ) : COLOR
{
```

```

    // grab the pixel color value from the skybox cube map
    return texCUBE(SkyboxS, SkyCoord);
};

```

The technique for the SkySphere effect has one pass. Because you want all the triangles on the sphere to render, the technique has to disable culling. Since the camera is inside the sphere, normal culling would result in no vertices to shade. Depth writes are also disabled because we want the environment to render behind everything else, without appearing to clip any objects.

C#

```

technique SkyboxTechnique
{
    pass P0
    {
        vertexShader = compile vs_2_0 SkyboxVertexShader();
        pixelShader = compile ps_2_0 SkyboxPixelShader();

        // We're drawing the inside of a model
        CullMode = None;
        // We don't want it to obscure objects with a Z < 1
        ZWriteEnable = false;
    }
}

```

To Apply the SkySphere Effect

1. In your `Game.LoadContent`, load the content that you normally draw in your scene.

C#

```

Vector3 ModelPosition;
float ModelRotation = 0.0f;
Model Model;
Model SkySphere;
Effect SkySphereEffect;
Matrix projectionMatrix;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    Model = Content.Load<Model>("redtorus");
    ModelPosition = Vector3.Zero;
    projectionMatrix = Matrix.CreatePerspectiveFieldOfView(
        MathHelper.PiOver4, 4.0f / 3.0f, 1.0f, 10000f);
}

```

2. Load the SkySphere effect from the Content Manager.
3. Load a cube map into a `TextureCube` object.

A cube map is a texture with six sides that form a cube. For a skybox (or sphere), the cube map is a picture of the far distance in the scene.

4. Set the parameters the SkySphere requires, including the `TextureCube` to draw.

C#

```

// Load the effect, the texture it uses, and
// the model used for drawing it
SkySphereEffect = Content.Load<Effect>("SkySphere");
TextureCube SkyboxTexture =
    Content.Load<TextureCube>("uffizi_cross");

```

```

SkySphere = Content.Load<Model>("SphereHighPoly");

// Set the parameters of the effect
SkySphereEffect.Parameters["ViewMatrix"].SetValue(
    myCamera.ViewMatrix);
SkySphereEffect.Parameters["ProjectionMatrix"].SetValue(
    projectionMatrix);
SkySphereEffect.Parameters["SkyboxTexture"].SetValue(
    SkyboxTexture);

```

5. Since the [Effect](#) and the [Model](#) are loaded separately, apply the SkySphere effect to each [Effect](#) property on the [ModelMeshPart](#) of the SkySphere model.

C#

```

// Set the Skysphere Effect to each part of the Skysphere model
foreach (ModelMesh mesh in SkySphere.Meshes)
{
    foreach (ModelMeshPart part in mesh.MeshParts)
    {
        part.Effect = SkySphereEffect;
    }
}

```

6. In your [Game.Draw](#), draw your scene as normal.

C#

```

protected override void Draw(GameTime gameTime)
{
    graphics.GraphicsDevice.Clear(Color.CornflowerBlue);

    //Draw the model, a model can have multiple meshes, so loop
    foreach (ModelMesh mesh in Model.Meshes)
    {
        //This is where the mesh orientation is set,
        //as well as our camera and projection
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.EnableDefaultLighting();
            effect.World = Matrix.Identity *
                Matrix.CreateRotationY(ModelRotation) *
                Matrix.CreateTranslation(ModelPosition);
            //effect.View = myCamera.View;
            effect.View = myCamera.ViewMatrix;
            effect.Projection = projectionMatrix;
        }
        //Draw the mesh, will use the effects set above.
        mesh.Draw();
    }
}

```

7. Draw the SkySphere by setting parameters to the SkySphere [Effect](#).
8. Draw the SkySphere [Model](#).

In this case we set the View and Projection matrices.

C#

```
// Set the View and Projection matrix for the effect
SkySphereEffect.Parameters["ViewMatrix"].SetValue(
    myCamera.ViewMatrix);
SkySphereEffect.Parameters["ProjectionMatrix"].SetValue(
    projectionMatrix);
// Draw the sphere model that the effect projects onto
foreach (ModelMesh mesh in SkySphere.Meshes)
{
    mesh.Draw();
}
```

9. Because this shader sets some render states before it runs, reset the affected render states to the values we want to use for further rendering.

C#

```
// Undo the renderstate settings from the shader
GraphicsDevice.RenderState.CullMode =
    CullMode.CullCounterClockwiseFace;
GraphicsDevice.RenderState.DepthBufferWriteEnable = true;
base.Draw(gameTime);
```

How To: Draw a Shadow

Demonstrates how to draw a shadow using [Matrix.CreateShadow](#) and the stencil buffer.

To draw a shadow, you use the shadow matrix to draw the original object without lighting. This sample demonstrates how to set up the shadow matrix and how to use the stencil buffer to avoid an uneven shadow.

Note

To render the scene, this sample uses the [BasicEffect](#) class. For a discussion of [BasicEffect](#) see [How To: Use BasicEffect](#). This sample also uses the **Quad** class introduced in [How To: Draw a Textured Quad](#).

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download StencilShadow_Sample.zip](#).

Drawing a Shadow

To draw a shadow

1. Use [PreferredDepthStencilFormat](#) to choose a depth buffer format that has some bits reserved for stencil buffering.

You can do this by checking each depth stencil format with [CheckDepthStencilMatch](#), and picking the best depth/stencil format for your needs.

C#

```
GraphicsDeviceManager graphics;
SpriteBatch spriteBatch;

public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";
    graphics.PreferredDepthStencilFormat = SelectStencilMode();
}
private static DepthFormat SelectStencilMode()
{
    // Check stencil formats
    GraphicsAdapter adapter = GraphicsAdapter.DefaultAdapter;
    SurfaceFormat format = adapter.CurrentDisplayMode.Format;
    if (adapter.CheckDepthStencilMatch(DeviceType.Hardware, format,
        format, DepthFormat.Depth24Stencil8))
        return DepthFormat.Depth24Stencil8;
    else if (adapter.CheckDepthStencilMatch(DeviceType.Hardware, format,
        format, DepthFormat.Depth24Stencil8Single))
        return DepthFormat.Depth24Stencil8Single;
    else if (adapter.CheckDepthStencilMatch(DeviceType.Hardware, format,
        format, DepthFormat.Depth24Stencil4))
        return DepthFormat.Depth24Stencil4;
    else if (adapter.CheckDepthStencilMatch(DeviceType.Hardware, format,
        format, DepthFormat.Depth15Stencil1))
        return DepthFormat.Depth15Stencil1;
    else
        throw new InvalidOperationException(
            "Could Not Find Stencil Buffer for Default Adapter");
}
```

2. Create a [Plane](#) that represents the surface the shadow falls upon.

In this case, the shadow falls upon a textured quad drawn with the **Quad** class. Thus, we create a plane using three vertices of the quad.

C#

```
Quad wall;
Plane wallPlane;
protected override void Initialize()
{
    ...
    // Create a new Textured Quad to represent a wall
    wall = new Quad(Vector3.Zero, Vector3.Backward, Vector3.Up, 7, 7);
    // Create a Plane using three points on the Quad
    wallPlane =
        new Plane(wall.UpperLeft, wall.UpperRight, wall.LowerLeft);

    base.Initialize();
}
```

3. Use [CreateShadow](#) to create a shadow matrix based on the direction of your key light and the plane on which the shadow falls.

In this case, it is the [Plane](#) you created previously from a textured quad. The shadow matrix also contains a translation to make sure it does not intersect the quad. If the shadow used exactly the same plane as an object, the two objects would both be displayed intermittently. This is called the z-fighting effect.

C#

```
Vector3 shadowLightDir;
Matrix shadow;
protected override void LoadContent()
{
    ...
    shadowLightDir = quadEffect.Directionallight0.Direction;
    // Use the wall plane to create a shadow matrix,
    // and make the shadow slightly higher than the wall.
    // The shadow is based on the strongest light
    shadow = Matrix.CreateShadow(shadowLightDir, wallPlane) *
        Matrix.CreateTranslation(wall.Normal / 100);
    ...
}
```

4. In your game's [Draw](#) method, first draw your scene as normal.

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    // Draw floor, and draw model
    DrawQuad();

    foreach (ModelMesh mesh in model.Meshes)
    {
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.EnableDefaultLighting();

            effect.View = View;
            effect.Projection = Projection;
        }
    }
}
```

```

        effect.World = modelWorld;
    }
    mesh.Draw();
}

```

5. Draw the shadow using a stencil buffer.

The stencil buffer ensures that the shadow appears one-dimensional. Our first step is to set [StencilEnable](#) to **true** and [Clear](#) the stencil buffer.

C#

```

// Draw shadow, using the stencil buffer to
// prevent drawing overlapping polygons

// Clear stencil buffer to zero.
GraphicsDevice.Clear(ClearOptions.Stencil, Color.Black, 0, 0);
GraphicsDevice.RenderState.StencilEnable = true;

```

6. Set up the stencil buffer test for the shadow by setting the [StencilFunction](#) to [CompareFunction.Equal](#) with a [ReferenceStencil](#) of 0.

This means you only draw a pixel when the stencil buffer value is 0. Setting [StencilPass](#) to [StencilOperation.Increment](#) means that after a pixel is drawn, the stencil buffer value becomes 1, so no more pixels will be drawn.

C#

```

// Draw on screen if 0 is the stencil buffer value
GraphicsDevice.RenderState.ReferenceStencil = 0;
GraphicsDevice.RenderState.StencilFunction =
    CompareFunction.Equal;
// Increment the stencil buffer if we draw
GraphicsDevice.RenderState.StencilPass =
    StencilOperation.Increment;

```

7. Set up the alpha blending for the shadow by setting [AlphaBlendEnable](#) to **true**, and setting the [SourceBlend](#) and [DestinationBlend](#) modes to use the alpha value.

C#

```

// Setup alpha blending to make the shadow semi-transparent
GraphicsDevice.RenderState.AlphaBlendEnable = true;
GraphicsDevice.RenderState.SourceBlend =
    Blend.SourceAlpha;
GraphicsDevice.RenderState.DestinationBlend =
    Blend.InverseSourceAlpha;

```

8. Draw the model again, this time as a shadow.

To make a shadow, we turn the ambient light color to black, disable other lights, and set an alpha transparency to make the ground below the shadow show through. The shape of the shadow is created by multiplying the model's world matrix with the shadow matrix.

C#

```

// Draw the shadow without lighting
foreach (ModelMesh mesh in model.Meshes)
{
    foreach (BasicEffect effect in mesh.Effects)
    {
        effect.AmbientLightColor = Vector3.Zero;
        effect.Alpha = 0.5f;
    }
}

```

```
        effect.DirectionalLight0.Enabled = false;
        effect.DirectionalLight1.Enabled = false;
        effect.DirectionalLight2.Enabled = false;
        effect.View = View;
        effect.Projection = Projection;
        effect.World = modelWorld * shadow;
    }
    mesh.Draw();
}
```

9. Reset the render states to normal, disabling stencil testing and alpha blending.

C#

```
// Return render states to normal

// turn stencilling off
GraphicsDevice.RenderState.StencilEnable = false;
// turn alpha blending off
GraphicsDevice.RenderState.AlphaBlendEnable = false;
```

How To: Use EffectParameters and EffectTechniques

Demonstrates how to use [EffectParameters](#) objects to interact with effect variables, and to use [EffectTechniques](#) to access different techniques in an [Effect](#).

In this example, a wrapper class is created to expose [EffectParameters](#) and [EffectTechniques](#) for the custom effect. The example shows you how to use the [EffectParameters](#) and [EffectTechniques](#). This class is used in the [How To: Implement Shadow Mapping](#) sample.

Using EffectParameters and EffectTechniques

To Use EffectParameters

1. In your game's [LoadContent](#) method, load your [Effect](#) from the Content Manager.
2. Create an [EffectParameter](#) instance for each parameter in your effect that will be accessed during [Draw](#) or [Update](#).

You can use the [Parameters](#) indexed property on [Effect](#) to access any effect parameter, but this is slower than using [EffectParameters](#). For this reason, you should create an [EffectParameter](#) for each effect parameter that changes frequently.

C#

```
public EffectParameter mWorld;
public EffectParameter mCameraView;
public EffectParameter CameraPos;
public EffectParameter mCameraProj;
```

3. Use the [Parameters](#) indexed property on [Effect](#) to access the effect parameter, and then assign it to your [EffectParameter](#).

C#

```
mWorld = effect.Parameters["g_mWorld"];
mCameraView = effect.Parameters["g_mCameraView"];
CameraPos = effect.Parameters["g_CameraPos"];
mCameraProj = effect.Parameters["g_mCameraProj"];
```

4. Call [SetValue](#) on [EffectParameter](#) whenever you want to set a new value for the effect parameter.

You must call [SetValue](#) before calling [Begin](#) on your [Effect](#). If you change the value of an [EffectParameter](#) after calling [Begin](#) and before calling [End](#), you must call [CommitChanges](#) for the new value to take effect.

C#

```
MyEffect.CameraPos.SetValue(CameraPos);
MyEffect.mCameraView.SetValue(view);
MyEffect.mCameraProj.SetValue(projection);
MyEffect.LightPos.SetValue(LightPos);
MyEffect.mLightView.SetValue(Matrix.CreateLookAt(LightPos,
    bounds.Center, Vector3.Up));
```

To Use EffectTechniques

1. In your game's [LoadContent](#) method, load your [Effect](#) from the Content Manager.
2. Create an [EffectTechnique](#) instance for each technique in your [Effect](#) that you will use during [Update](#) or [Draw](#).

You can use the [Techniques](#) indexed property on [Effect](#) to access any effect technique, but this is slower than using

[EffectTechniques](#). For this reason, you should create an [EffectTechnique](#) for each effect technique that you use.

C#

```
public EffectTechnique texture;  
public EffectTechnique shadows;  
public EffectTechnique shadowMap;
```

3. Use the [Techniques](#) indexed property on [Effect](#) to access the effect technique, and then assign it to your [EffectTechnique](#).

C#

```
texture = effect.Techniques["TextureRender"];  
shadowMap = effect.Techniques["ShadowMapRender"];  
shadows = effect.Techniques["ShadowRender"];
```

4. Set the [CurrentTechnique](#) property on your [Effect](#) to the technique you wish to use when drawing.

You can use your [Effect](#) multiple times per [Draw](#) with different techniques.

C#

```
private void DrawScene(EffectTechnique technique)  
{  
    MyEffect.mWorld.SetValue(terrainWorld);  
    MyEffect.MeshTexture.SetValue(terrainTex);  
    foreach (ModelMesh mesh in terrain.Meshes)  
    {  
        foreach (Effect effect in mesh.Effects)  
        {  
            effect.CurrentTechnique = technique;  
            mesh.Draw();  
        }  
    }  
}
```

How To: Create a Depth Texture

Demonstrates how to create a texture that contains depth information for a scene using a customized `RenderTarget2D`, `DepthStencilBuffer`, and a simple Effect.

To render the depth to a texture, you create a new `RenderTarget2D` and a `DepthStencilBuffer` with your desired depth format. Then you render your scene by using a shader that draws each pixel in the render target as a depth value instead of a normal color. Finally, you use `GetTexture` on the `RenderTarget2D` to save that information to a `Texture2D`.

Note

To render the scene, this sample uses a technique from a customized Effect file. For more information, see [How To: Use Effect Parameters and Effect Techniques](#).

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download ShadowMapping_Sample.zip](#).

Creating a Depth Texture

To create a depth texture

1. In your game's `LoadContent` method, create a new `RenderTarget2D` for rendering the depth in your scene.

You may want to choose a surface format that gives you the most depth information. In this example, you will use `SurfaceFormat.Single` if the game computer supports it. Use `CheckDeviceFormat` on the computer to see if your chosen `SurfaceFormat` is supported on your game computer. Otherwise, consult [Xbox 360 Surface Formats](#) for supported `SurfaceFormats` on Xbox 360.

`SurfaceFormat.Single` creates a 32-bit floating point value for each pixel, representing the red channel. No bits are used for the green, blue, or alpha channels. Using floating point values for depth allows more precision for the shadow calculations. This results in smoother shadows. Using a large render target and enabling antialiasing for the render target also improves the quality of the shadow rendering.

To create the render target, there are four variables to consider: the proposed width of the texture, the proposed height of the texture, the surface format of the texture, and whether to use anti-aliasing. Not all PC video cards will accept all configurations of these four parameters. `CreateRenderTarget` tries to find the best match by first using `CheckDeviceFormat` to determine if the caller's preferred surface format is supported (in this case, a floating point texture). Next, it uses `CheckDeviceMultiSampleType` to confirm the anti-aliasing setting with the chosen surface format.

C#

```
shadowRenderTarget = GfxComponent.CreateRenderTarget(GraphicsDevice,
    1, SurfaceFormat.Single);
```

C#

```
public static RenderTarget2D CreateRenderTarget(GraphicsDevice device,
    int numberLevels, SurfaceFormat surface)
{
    MultiSampleType type =
        device.PresentationParameters.MultiSampleType;

    // If the card can't use the surface format
    if (!GraphicsAdapter.DefaultAdapter.CheckDeviceFormat(
        DeviceType.Hardware,
        GraphicsAdapter.DefaultAdapter.CurrentDisplayMode.Format,
        TextureUsage.None,
        QueryUsages.None,
        ResourceType.RenderTarget,
        surface))
```

```

{
    // Fall back to current display format
    surface = device.DisplayMode.Format;
}
// Or it can't accept that surface format
// with the current AA settings
else if (!GraphicsAdapter.DefaultAdapter.CheckDeviceMultiSampleType(
    DeviceType.Hardware, surface,
    device.PresentationParameters.IsFullScreen, type))
{
    // Fall back to no antialiasing
    type = MultiSampleType.None;
}

int width, height;

// See if we can use our buffer size as our texture
CheckTextureSize(device.PresentationParameters.BackBufferWidth,
    device.PresentationParameters.BackBufferHeight,
    out width, out height);

// Create our render target
return new RenderTarget2D(device,
    width, height, numberLevels, surface,
    type, 0);
}

```

Lastly, before creating the texture, **CreateRenderTarget** calls **CheckTextureSize**, which uses [GraphicsDeviceCapabilities](#) to see if the video card supports the chosen texture size (some video cards expect all textures to be powers of two, or square, or both). **CheckTextureSize** adjusts the texture size to fit the listed capabilities.

C#

```

public static bool CheckTextureSize(int width, int height,
    out int newwidth, out int newheight)
{
    bool retval = false;

    GraphicsDeviceCapabilities Caps;
    Caps = GraphicsAdapter.DefaultAdapter.GetCapabilities(
        DeviceType.Hardware);

    if (Caps.TextureCapabilities.RequiresPower2)
    {
        retval = true; // Return true to indicate the numbers changed

        // Find the nearest base two log of the current width,
        // and go up to the next integer
        double exp = Math.Ceiling(Math.Log(width)/Math.Log(2));
        // and use that as the exponent of the new width
        width = (int)Math.Pow(2, exp);
        // Repeat the process for height
        exp = Math.Ceiling(Math.Log(height)/Math.Log(2));
        height = (int)Math.Pow(2, exp);
    }
    if (Caps.TextureCapabilities.RequiresSquareOnly)
    {
        retval = true; // Return true to indicate numbers changed
        width = Math.Max(width, height);
    }
}

```

```

        height = width;
    }

    newwidth = Math.Min(Caps.MaxTextureWidth, width);
    newheight = Math.Min(Caps.MaxTextureHeight, height);
    return retval;
}

```

- Next in your `LoadContent` method, create a new `DepthStencilBuffer` for your custom `RenderTarget2D`.

The `DepthStencilBuffer` settings for width, height, and multisample quality should be the same as the values chosen for your render target. You may want to choose a depth format that gives you the most depth information. In this example, you will use `DepthFormat.Depth24Stencil8Single` if the game computer supports it. Use `CheckDepthStencilMatch` on Windows-based computers to see if your chosen `DepthFormat` is supported. Otherwise, consult [Xbox 360 Surface Formats](#) for supported `DepthFormats` on Xbox 360. `DepthFormat.Depth24Stencil8Single` creates a 24-bit floating-point value for depth. This allows more depth precision than the normal 24-bit fixed-point buffer. Still, you must be careful with floating-point values to guard against floating-point errors for depth values that are nearly identical.

C#

```

shadowDepthBuffer =
    GfxComponent.CreateDepthStencil(shadowRenderTarget,
    DepthFormat.Depth24Stencil8Single);

```

C#

```

public static DepthStencilBuffer CreateDepthStencil(
    RenderTarget2D target)
{
    return new DepthStencilBuffer(target.GraphicsDevice, target.Width,
        target.Height, target.GraphicsDevice.DepthStencilBuffer.Format,
        target.MultiSampleType, target.MultiSampleQuality);
}
public static DepthStencilBuffer CreateDepthStencil(
    RenderTarget2D target, DepthFormat depth)
{
    if (GraphicsAdapter.DefaultAdapter.CheckDepthStencilMatch(
        DeviceType.Hardware,
        GraphicsAdapter.DefaultAdapter.CurrentDisplayMode.Format,
        target.Format,
        depth))
    {
        return new DepthStencilBuffer(target.GraphicsDevice,
            target.Width, target.Height, depth,
            target.MultiSampleType, target.MultiSampleQuality);
    }
    else
        return CreateDepthStencil(target);
}

```

- In your game's `Update` method, when you calculate a projection matrix from the point of view of the light source, include as many objects in the scene as possible if they are visible to the camera.

In this example, both objects are always visible to the camera and do not move, so the bounding sphere used is the bounding sphere of both objects combined.

- Set the near and far plane of the projection matrix as close as possible to the objects in the scene.

This will result in more accurate depth values for the depth map. The projection matrix is passed to the effect.

C#

```
protected override void Update(GameTime gameTime)
{
    ...
    Matrix proj =
        CalcLightProjection(LightPos, bounds, defaultViewport);
    MyEffect.mLightProj.SetValue(proj);
    base.Update(gameTime);
}
```

- In your `Draw` method, use `CompareFunction.LessEqual` to set the appropriate `DepthBufferFunction` for your depth texture effect.

When you depth-test a pixel, `CompareFunction.LessEqual` preserves lower depth values while discarding any pixels with a depth value higher than the current lowest value.

C#

```
GraphicsDevice.RenderState.DepthBufferFunction =
    CompareFunction.LessEqual;
```

- In your `Draw` method, call `GraphicsDevice.SetRenderTarget` to set the current render target (target 0) to the render target you created in Step 1.
- Make a copy of the current `DepthStencilBuffer` on the `GraphicsDevice` before assigning the `DepthStencilBuffer` you created previously to the `DepthStencilBuffer` property on `GraphicsDevice`.

C#

```
GraphicsDevice.SetRenderTarget(0, shadowRenderTarget);
// Cache the current depth buffer
DepthStencilBuffer old = GraphicsDevice.DepthStencilBuffer;
// Set our custom depth buffer
GraphicsDevice.DepthStencilBuffer = shadowDepthBuffer;
```

- Render your scene using an effect that will draw the depth value of each pixel to your render target.

The following code shows a simple vertex and pixel shader for such an effect.

C#

```
// Render the shadow map
GraphicsDevice.Clear(Color.Black);
DrawScene(MyEffect.shadowMap);
```

- After you have rendered the depth values to the render target, call `SetRenderTarget` again

This sets the current render target (target 0) to **null**. Also, it resets the current render target to the display buffer.

- Set the `DepthStencilBuffer` on the `GraphicsDevice` to its former value.

C#

```
// Set render target back to the back buffer
GraphicsDevice.SetRenderTarget(0, null);
// Reset the depth buffer
GraphicsDevice.DepthStencilBuffer = old;
```

- Call `GetTexture` on your `RenderTarget2D` to get a `Texture2D` containing the depth values for your scene.

This is your depth texture.

C#

```
// Return the shadow map as a texture
return shadowRenderTarget.GetTexture();
```

Rendering Depth in HLSL

To render depth in HLSL

1. Use a custom vertex shader to render depth values in HLSL.

The vertex shader returns two values to the pixel shader. The first value is a POSITION that transforms the incoming POSITION into the view and projection space of the light source. The second value is the depth value of the transformed POSITION. The depth is calculated by dividing the z coordinate by the w coordinate. Dividing by w gives you a depth between 0 and 1. The depth is subtracted from 1 to get more precision from the floating point format. The depth is packed into a TEXCOORD semantic (in this case, TEXCOORD0) to be returned by the pixel shader.

```
struct VS_SHADOW_OUTPUT
{
    float4 Position : POSITION;
    float Depth : TEXCOORD0;
};
float4 GetPositionFromLight(float4 position)
{
    float4x4 WorldViewProjection =
        mul(mul(g_mWorld, g_mLightView), g_mLightProj);
    return mul(position, WorldViewProjection);
}
VS_SHADOW_OUTPUT RenderShadowMapVS(float4 vPos: POSITION)
{
    VS_SHADOW_OUTPUT Out;
    Out.Position = GetPositionFromLight(vPos);
    // Depth is Z/W. This is returned by the pixel shader.
    // Subtracting from 1 gives us more precision in floating point.
    Out.Depth.x = 1-(Out.Position.z/Out.Position.w);
    return Out;
}
```

2. Use a custom pixel shader to render depth values in HLSL.

The pixel shader returns one value, the depth of the pixel. This is calculated by the pixel shader and passed in the TEXCOORD0 semantic.

The depth is returned as the red value by the pixel shader. If you are using [SurfaceFormat.Single](#), this holds a 32-bit floating point value. More bits give you smoother shadows. Floating point will create smoother shadows than fixed point. However, this shader will create shadows using almost any SurfaceFormat value.

```
float4 RenderShadowMapPS( VS_SHADOW_OUTPUT In ) : COLOR
{
    // The depth is Z divided by W. We return
    // this value entirely in a 32-bit red channel
    // using SurfaceFormat.Single. This preserves the
    // floating-point data for finer detail.
    return float4(In.Depth.x,0,0,1);
}
```

How To: Implement Shadow Mapping

Demonstrates how to use [depth textures](#) (that is, shadow maps) to create dynamic shadows in a scene. These shadows move when a light source moves, and are accurate against both flat and irregular surfaces.

To create shadows with shadow mapping, first you need to create a depth texture showing the depth of all objects in the scene from the point of view of the light source. Once you render pixels in your final scene from the camera's point of view, compare the distance from the pixel to the light source with the depth value encoded in the shadow map. When the depth of the rendered pixel is higher than the value in the shadow map, that pixel is in shadow.

Note

To render the scene, this sample uses a technique from a customized Effect file. For more information, see [How To: Draw a Model with a Custom Effect](#).

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

Working With Shadow Mapping

To create a shadow map effect

1. Load a custom effect that supports shadow mapping.

In this example, the effect has two major techniques: one for creating a shadow map, and the other for rendering a scene using the shadow map to draw shadows. A simple third technique is used to draw the light source. The effect is encapsulated in its own class.

C#

```
MyEffect = ShadowMapEffect.LoadEffect(Content);
```

2. In your game's [LoadContent](#) method, load the [Models](#) and [Effect](#) for your scene.
3. Remap the Models to use your custom [Effect](#) according to [How To: Draw a Model with a Custom Effect](#).
4. In [LoadContent](#), use the techniques described in [How To: Create a Depth Texture](#) to create a [RenderTarget2D](#) and [DepthStencilBuffer](#) for your shadow map.
5. In your game's [Update](#) method, set the position of your light source and your camera as parameters to the [Effect](#).

You must also set the view and projection matrices for both the shadow map and the camera itself.

C#

```
MyEffect.CameraPos.SetValue(CameraPos);
MyEffect.mCameraView.SetValue(view);
MyEffect.mCameraProj.SetValue(projection);
MyEffect.LightPos.SetValue(LightPos);
MyEffect.mLightView.SetValue(Matrix.CreateLookAt(LightPos,
    bounds.Center, Vector3.Up));
```

6. In your game's [Draw](#) method, use the techniques described in [How To: Create a Depth Texture](#) to create a shadow map for the scene.

C#

```
map = CreateShadowMap();
```

7. After creating the depth texture in [Draw](#), set it to an appropriate sampler value in your shadow mapping effect.

C#

```
// Set our shadow map into our effect
MyEffect.ShadowMapTexture.SetValue(map);
```

8. Draw your scene using a shader that supports shadow mapping.

The shader will apply ambient light only where the light casts a shadow.

C#

```
// Render our scene
GraphicsDevice.Clear(Color.CornflowerBlue);
DrawScene(MyEffect.shadows);
```

To render shadows in HLSL with a shadow map

- Use per-pixel lighting to render shadows with a shadow map in HLSL.

The vertex shader for this effect performs a normal world-view-projection transformation on the POSITION supplied by the video card. It also transforms the NORMAL. Both of these values are passed as output. The UV coordinate for the texture is passed through to the pixel shader, along with a copy of the untransformed POSITION value.

```
VS_OUTPUT RenderShadowsVS(
    float3 position : POSITION,
    float3 normal : NORMAL,
    float2 vTexCoord0 : TEXCOORD0 )
{
    VS_OUTPUT Output;

    //generate the world-view-projection matrix
    float4x4 wvp = mul(mul(g_mWorld, g_mCameraView), g_mCameraProj);

    //transform the input position to the output
    Output.Position = mul(float4(position, 1.0), wvp);

    //transform the normal to world space
    Output.vNormal = mul(normal, g_mWorld);

    //do not transform the position needed for the
    //shadow map determination
    Output.vPos = float4(position,1.0);

    //pass the texture coordinate as-is
    Output.TextureUV = vTexCoord0;

    //return the output structure
    return Output;
}
```

The first task for the pixel shader is calculating the normal lighting equation for the pixel. In this example, only diffuse lighting is calculated.

```
PS_OUTPUT RenderShadowsPS( PS_INPUT In )
{
    PS_OUTPUT Output;

    // Standard lighting equation
    float4 vTotalLightDiffuse = float4(0,0,0,1);
    float3 lightDir = normalize(g_LightPos-In.vPos); // direction of light
```

```
vTotalLightDiffuse += g_LightDiffuse * max(0,dot(In.vNormal, lightDir));
vTotalLightDiffuse.a = 1.0f;
```

Next, the pixel shader gets the position of this pixel on the shadow map. This is necessary because the shadow map is rendered from the light's perspective, and this pixel is rendered from the camera's perspective. The result of `GetPositionFromLight` is a screen coordinate. The screen coordinate is then converted into a UV coordinate so it can be accessed from the sampler containing the shadow map.

```
// Now, consult the ShadowMap to see if we're in shadow
float4 lightingPosition
    = GetPositionFromLight(In.vPos);// Get our position on the shadow map

// Get the shadow map depth value for this pixel
float2 ShadowTexC =
    0.5 * lightingPosition.xy / lightingPosition.w + float2( 0.5, 0.5 );
ShadowTexC.y = 1.0f - ShadowTexC.y;
```

Next, the shadow depth of this pixel is accessed using the `tex2D` function to access the shadow map. Then the depth of this pixel is determined by dividing the Z value of the position with the W value. This is subtracted from 1.0 before comparison because the shadow depths are similarly subtracted from 1.0. For more information, see `CreateDepthTexture`.

```
float shadowdepth = tex2D(ShadowMapSampler, ShadowTexC).r;

// Check our value against the depth value
float ourdepth = 1 - (lightingPosition.z / lightingPosition.w);
```

Now the shadow depth and true depth are compared. Floating-point precision errors can cause a banding effect if the two values are compared directly. The shadow depth is decreased slightly to ensure that pixels that should be lighted are lighted. If this pixel is indeed in shadow, the diffuse portion of the lighting is reset to black.

```
// Check the shadowdepth against the depth of this pixel
// a fudge factor is added to account for floating-point error
if (shadowdepth-0.03 > ourdepth)
{
    // we're in shadow, cut the light
    vTotalLightDiffuse = float4(0,0,0,1);
};
```

Finally, the total lighting equation is computed by adding the diffuse and ambient components together. This is the output returned from the pixel shader.

```
Output.RGBColor = tex2D(MeshTextureSampler, In.TextureUV) *
    (vTotalLightDiffuse + g_LightAmbient);

return Output;
}
```

[What Is a Stencil Buffer?](#)

A stencil buffer is similar to a [depth buffer](#). In fact, it uses part of the depth buffer (for this reason, the depth buffer is often called the *depth-stencil buffer*). The stencil buffer allows the programmer to set a stencil function that will test the "reference" stencil value - a global value - against the value already in the stencil buffer each time a pixel is rendered.

[What Is Texture Mapping?](#)

Texture mapping is the process of determining where in a particular space a texture will be applied.

What Is Antialiasing?

Antialiasing is the process of softening hard edges in an image so that polygons appear less jagged.

Antialiasing is normally accomplished by *multisampling*, which means you use more than one pixel ("sample") from an image to determine the color of a pixel in your final image. The more samples per pixel, the smoother the resulting image.

Both PC and Xbox 360 platforms support Full Screen Antialiasing (FSAA) modes, where extra pixels are rendered to a render target and used as samples to create an antialiased final image. 4x FSAA uses four samples per pixel by rendering the scene to a render target with twice the height and width of the backbuffer. It uses the extra samples in the render target to create an antialiased final image. 2x FSAA is also common on PCs and supported by the Xbox 360.

Use the [CheckDeviceMultiSampleType](#) method to query for antialiasing support on your game machine. Also, use the [MultiSampleQuality](#) and [MultiSampleType](#) properties of the [PresentationParameters](#) to select an antialiasing mode for your backbuffer. For more information, see [How To: Enable Antialiasing \(Multisampling\)](#). You can set [PreferMultiSampling](#) on the [GraphicsDeviceManager](#) to **true** to let the [GraphicsDeviceManager](#) choose the antialiasing mode.

You can use the [RenderState](#) property [MultiSampleAntiAlias](#) to enable or disable multisampling at run time.

What Is Color Blending?

Color blending is the process of mixing two colors together to produce a third color.

The first color is called the *source color*. This is the new color being added. The second color is called the *destination color*. This is the color that already exists (in the backbuffer, for example). Each color has a separate blend factor that determines how much of each color is combined into the final product. Once the source and destination colors have been multiplied by their blend factors, the results are combined according to the specified blend function. The normal blend function is simple addition.

The full formula looks like this:

$$(source \times source \text{ blend factor}) \text{ (blend function) } (destination \times destination \text{ blend factor})$$

The source blend factor is specified by the [SourceBlend](#) property, and the destination blend factor is specified by the [DestinationBlend](#) property. The [BlendFunction](#) property specifies the blend function to use, normally [BlendFunction.Add](#). In that case the formula looks like this:

$$(source \times \mathbf{SourceBlend}) + (destination \times \mathbf{DestinationBlend})$$

When the [AlphaBlendEnable](#) property is **false**, no blending occurs during rendering. In this case, the source pixel overwrites the destination pixel. When [AlphaBlendEnable](#) is **true**, you can create a lot of special effects using the [SourceBlend](#) and [DestinationBlend](#) properties:

Blend Type	Blend Settings
Alpha Blending	$(source \times \text{Blend.SourceAlpha}) + (destination \times \text{Blend.InvSourceAlpha})$
Additive Blending	$(source \times \text{Blend.One}) + (destination \times \text{Blend.One})$
Multiplicative Blending	$(source \times \text{Blend.Zero}) + (destination \times \text{Blend.SourceColor})$
2X Multiplicative Blending	$(source \times \text{Blend.DestinationColor}) + (destination \times \text{Blend.SourceColor})$

Figure 1. This picture illustrates four common blend modes. From left to right: Alpha blending, Additive blending, Multiplicative blending, and 2X Multiplicative blending. The top image in each column is the source image and below, it's effect when added to the destination.

Alpha blending uses the alpha channel of the source color to create a transparency effect so that the destination color appears through the source color. For example, if you clear your backbuffer to [Color.Gray](#), it will be colored (0.5,0.5,0.5,1). If you then take a [Color.White](#) color with a partial alpha value (1,1,1,0.4), the result will be 60 percent of the destination color and 40 percent of the source: $(0.5 \times 0.6) + (1 \times 0.4)$. The resulting color will be (0.7,0.7,0.7, 1). The alpha values are multiplied as well - $(.6 \times 1) + .4$ gives us an alpha value of 1.

In some cases, alpha blending is automatic. When drawing sprites using the [SpriteBatch](#) class, choosing [SpriteBlendMode.AlphaBlend](#) configures alpha blending for you.

By default, the alpha channel is blended along with the red, green, and blue channels using the [SourceBlend](#) and [DestinationBlend](#) properties. You can choose to customize the blending for just the alpha channel by using the [AlphaSourceBlend](#) and [AlphaDestinationBlend](#) properties. When you compute the alpha channel, these properties are used as blending factors if the [SeparateAlphaBlendEnabled](#) property is **true**.

What Is a Depth Buffer?

A depth buffer is a buffer that is the same width and height as your render target. This buffer records the depth of each pixel that is rendered.

When a pixel is rendered a second time - such as when one object is rendered behind another - the depth buffer will keep either the previous depth value, or replace it with the depth value for the second pixel. Which depth is preserved and which depth is discarded depends on the depth function you select. For example, if [CompareFunction.LessEqual](#) is the current depth function, depth values that are less than or equal to the current value are preserved. Any value greater than the current depth value is discarded. This is called the *depth test*. The depth test occurs every time a pixel is rendered. When a pixel passes the depth test, its color is written to the render target and its depth is written to the depth buffer.

The depth of a pixel is determined based on the size of the view and projection matrix selected for rendering. A pixel that touches the near plane of the projection has depth 0. A pixel that touches the far plane of the projection has depth 1. As each object in the scene is rendered, normally the pixels that are closest to the camera are kept, as those objects block the view of the objects behind them.

The depth buffer may also contain stencil bits - for this reason it's often called the *depth-stencil buffer*. The depth format describes the composition of the depth buffer. The depth buffer is always 32 bits, but those bits can be arranged in different ways, similar to how texture formats can vary. A common depth format is `Depth32`, where all 32 bits are reserved for depth information. Another common format is `DepthFormat.Depth24Stencil8`, where 24 bits are used for depth calculation and 8 bits are used by the stencil buffer. `DepthFormat.Depth24Stencil8Single` is a more unusual format where the 24 bits for the depth buffer are arranged as a floating point value. Use the `AutoDepthStencilFormat` property on `PresentationParameters` to set the default depth format.

Use `RenderState.DepthBufferEnable` to enable or disable depth buffering. Use `RenderState.DepthBufferFunction` to change the comparison function used for the depth test. The depth buffer can be cleared separately by passing `ClearOptions.DepthBuffer` to the `GraphicsDevice.Clear` method. Use the `DepthStencilBuffer` class to create your own depth buffer. [How To: Create a Depth Texture](#) provides an example of how to create a custom `DepthStencilBuffer`.

What Is a Depth Texture?

A depth texture is a texture that contains the data from the [depth buffer](#) for a particular scene.

The color of each pixel in the texture represents the depth of the polygon under that pixel, taken from the depth buffer. You can use depth textures to render accurate shadows using a technique called shadow mapping. For this reason, depth textures are also known as *shadow maps*.

There are two common ways to encode the depth information into a texture. The first is to use a standard RGBA surface format for your texture, and treat all four colors as one 32-bit buffer and copy the depth into that buffer (depth formats normally assign 24 or 32 bits for depth data). The second is to use a floating-point surface format for your texture combined with a floating-point depth buffer. Depth buffers are normally fixed-point. When using the floating-point approach, it is more accurate to subtract the depth from 1.0 before storing it, due to the way floating-point numbers are encoded.

Both of these techniques require a custom vertex and pixel shader. [How To: Create a Depth Texture](#) provides an example of a depth texture shader and the code necessary to use it.

What Is a Model Bone?

A model bone is a matrix that represents the position of a mesh relative to other bones in a 3D model.

In the XNA Framework, the [Model](#) class represents the whole model. The [Model](#) contains a [ModelMesh](#) for each separate mesh in the model. Each [ModelMesh](#) contains a [ParentBone](#), which controls the mesh's position and orientation relative to the model. The [Model](#) has a [Root](#) bone, which determines the model's position and orientation. Every [ModelBone](#) can have one parent and many children. The [Root](#) bone on the [Model](#) object is the ultimate parent. Its children are bones on [ModelMesh](#) objects—objects which might have other [ModelMesh](#) bones as their children, and so on. In any given family of bones, rotating the parent bone also rotates the children, and their children, and so on.

Every bone has a transformation matrix (called [Transform](#)) that defines its position and rotation relative to the position of the parent bone. This rotation and translation applies to all the vertices in the [ModelMesh](#) (for example, all the vertices that connect to that bone). To animate a bone, you multiply the default bone transform by a new matrix. When you draw the [ModelMesh](#), you then base your world matrix on the bone's transform.

The easiest way to incorporate transformed bones into drawing is to use the [CopyAbsoluteBoneTransformsTo](#) method. This method takes the bone transforms, which are relative to each other, and iterates over them to make them relative to the [Root](#) bone of the [Model](#). Then it returns a copy of these transforms. When you draw each [ModelMesh](#), you can use the absolute bone transform as the first part of your world matrix. This way you won't have to worry about parent bones and their relationships.

What Is a Render Target?

A render target is a buffer where the video card draws pixels for a scene that is being rendered by an [Effect Class](#).

The default render target is called the back buffer - this is the part of video memory that contains the next frame to be drawn. You can create other render targets with the [RenderTarget2D](#) class - in effect, reserving new regions of video memory for drawing. Most games render a lot of content to other render targets besides the back buffer ("offscreen"), then assemble the different graphical elements in stages, combining them to create the final product in the back buffer.

A render target has a width and height. The width and height of the back buffer are the final resolution of your game (although on Xbox 360 that final result is scaled to match the user's screen). An offscreen render target does not need to have the same width and height as the back buffer. Small parts of the final image can be rendered in small render targets, then copied to another render target later. A render target also has a surface format, which describes how many bits are allocated to each pixel and how they are divided between red, green, blue, and alpha. For example, [SurfaceFormat.Bgr32](#) allocates 32 bits per pixel: 8 bits for each color and 8 bits for the alpha channel. As an option, render targets can perform antialiasing on all the images that are rendered into them.

To use a render target, create a [RenderTarget2D](#) object with the width, height, and other options you prefer. Then call [GraphicsDevice.SetRenderTarget](#) to make your render target the current render target. From this point on, any **Draw** calls you make will draw into your render target. When you are finished with the render target, call [GraphicsDevice.SetRenderTarget](#) to a new render target (or null for the back buffer). Then at any time you can call [RenderTarget2D.GetTexture](#) to get the contents of the render target for further processing.

Render targets work in conjunction with the depth-stencil buffer. If you set a new render target, it will use the existing depth-stencil buffer. If the new render target has different multisampling settings than the depth-stencil buffer, or a larger width and height, you will need a new depth-stencil buffer to match. You must also use a depth format in your depth-stencil buffer that is compatible with the surface format of your render target.

You can sometimes render to more than one render target at the same time. The number of simultaneous render targets your graphics device supports is given by the [MaxSimultaneousRenderTargets](#) property. There are numerous caveats for using multiple render targets. For more information, see [Render Targets](#).

What Is a Stencil Buffer?

A stencil buffer is similar to a [depth buffer](#). In fact, it uses part of the depth buffer (for this reason, the depth buffer is often called the *depth-stencil buffer*). The stencil buffer allows the programmer to set a stencil function that will test the "reference" stencil value - a global value - against the value already in the stencil buffer each time a pixel is rendered.

The outcome of that stencil test determines if the color value of the pixel is written to the render target, and if the depth value of that pixel is written to the depth buffer.

For example, if you render some objects to a scene while the reference stencil is 0, and the stencil buffer has been cleared to 1, the stencil buffer will contain a cut-out pattern of zeros where those objects were rendered. If the reference value was then set to 1, and the [StencilFunction](#) was set to [CompareFunction.LessEqual](#), the only pixels that could be rendered to the scene are those that are not in the same location where the stencil value was set to 0. This is a basic way to use the stencil buffer to create an area that is off-limits to the current rendering pass.

The stencil buffer can be used in more sophisticated ways. It is possible to specify [StencilOperations](#) that go beyond replace or discard, to increment or decrement the stencil buffer after each successful stencil test. This can be combined with the [StencilMask](#) value to ensure that the stencil test only operates on a part of the stencil buffer.

To use the stencil buffer, the [DepthFormat](#) must reserve some bits for the stencil buffer. The [DepthFormat.Depth24Stencil8](#) depth format allows 8 bits for a stencil buffer. When you combine this with the [RenderState.StencilMask Property](#), this can provide eight different stencil buffers for the programmer. The [DepthFormat.Depth24Stencil4](#) depth format uses 4 bits for the stencil buffer, while the [DepthFormat.Depth15Stencil1](#) format only allows one bit. The stencil buffer can be cleared separately by passing [ClearOptions.StencilBuffer](#) to the [GraphicsDevice.Clear](#) method.

You can use the [DepthStencilBuffer](#) class to create your own depth-stencil buffer. You may need to create your own depth-stencil buffer when you create a custom render target

What Is Texture Mapping?

Texture mapping is the process of determining where in a particular space a texture will be applied.

A texture consists of a series of pixels (also called *texels*), each occupying a texture coordinate determined by the width and height of the texture. These texture coordinates are then mapped into values ranging from 0 to 1 along a u and v axes (u is width, v is height). This process is called UV mapping. The resulting coordinates are UV coordinates.

Whenever you render a polygon, a UV coordinate is calculated for each vertex in the triangle. These three UV coordinates dictate how a texture is applied to the polygon by the pixel shader. When the u or v values move below 0 or above 1, the polygon is applied according to the texture address mode that has been set. When [TextureAddressMode.Border](#) is in effect, any pixels where the UV mapping is outside the 0-1 range are colored with the border color. When [TextureAddressMode.Clamp](#) is in effect, the color of the nearest pixel is used. [TextureAddressMode.Wrap](#) indicates that the texture should repeat across the triangle. When you specify [TextureAddressMode.Mirror](#), the texture wraps, but reverses itself when it crosses a UV boundary. Texture-addressing modes are specified for each axis separately, so you could wrap along the u-axis while clamping the v-axis.

If the texture is too large or too small for the polygon, the texture must be filtered to fit the space. There are two types of filtering that can be applied to textures: magnification and minification. A magnification filter enlarges a texture to fit a polygon. A minification filter reduces the texture to fit into a smaller area. Texture magnification is normally straightforward, and results in a blurrier image. Texture minification is more complicated, and improper minification can result in aliasing – that is, jagged edges.

The most popular approach to minification is to create mipmaps for each texture. A mipmap is a pre-shrunk texture, normally half the size of the original. The mipmap itself then gets mipmapped, and this process continues until a 1x1 texture is created. This is the final mipmap for the texture. You can think of mipmaps as a chain, starting with the original texture and becoming smaller and smaller until the 1 texel texture is reached. When minification is needed, first the appropriate mipmapped texture is chosen, then that mipmap is applied to the object, with real-time texture filtering if needed. The default Texture processor for the Content Pipeline has an option to generate mipmaps automatically.

XNA supports five texture filters. [TextureFilter.Point](#) uses the nearest corresponding point on the texture, with no filtering. [TextureFilter.Linear](#) uses bilinear interpolation to sample four neighboring texels and create an average value. [TextureFilter.PyramidalQuad](#) also uses four samples and favors texels nearer to the center of the resulting pixel when calculating the final result. The [TextureFilter.GaussianQuad](#) works the same way, using a different mathematical weighting - similar to a bell curve where the top of the curve is the center of the resulting pixel. [TextureFilter.Anisotropic](#) is a filtering method designed for surfaces that are not facing the camera (such as the ground near a horizon).

Math Overview

The XNA Framework Math Libraries can be found in the [Microsoft.Xna.Framework](#) namespace, alongside a number of additional types that deal with the XNA Framework Application model.

- [Coordinate system](#)
- [Mathematical Constants and Scalar Manipulation](#)
- [Basic Geometric Types](#)
- [Precision and Performance](#)

Coordinate system

The XNA Framework uses a right-handed coordinate system, with the positive z-axis pointing toward the observer when the positive x-axis is pointing to the right, and the positive y-axis is pointing up.

Mathematical Constants and Scalar Manipulation

The XNA Framework provides the [MathHelper Members](#) class for [manipulating scalar values](#) and retrieving some [common mathematical constants](#). This includes methods such as the [ToDegrees](#) and [ToRadians](#) utility methods for converting between degrees and radians.

Basic Geometric Types

The XNA Framework Math library has multiple basic geometric types that can be used to manipulate objects in 2D or 3D space. The primitive objects in this library represent the data required to represent a geometric object or an operation on that object. Each geometric type has a number of mathematical operations that are supported for the type.

Vectors

The XNA Framework provides the [Vector2](#), [Vector3](#) and [Vector4](#) classes for representing and manipulating vectors. A vector is typically used to represent a direction and magnitude. However, in the XNA framework it might also be used to store a coordinate or some other data type with the same storage requirements.

Each vector class has methods for performing standard vector operations such as:

- [Dot product](#)
- [Cross product](#)
- [Normalization](#)
- [Transformation](#)
- [Linear](#), [Cubic](#), [Catmull-Rom](#), or [Hermite spline](#) interpolation.

Matrices

The XNA Framework provides the [Matrix](#) class for transformation of geometry. The [Matrix](#) class uses a row major order to address matrices, which means that the row is specified before the column when describing an element of a two-dimensional matrix. The [Matrix](#) class provides methods for performing standard matrix operations such as calculating the [determinate](#) or [inverse](#) of a matrix, in addition to helper methods for creating scale, translation, and rotation matrices.

Quaternions

The XNA Framework provides the [Quaternion](#) structure to represent and calculate the efficient rotation about a vector around a specified angle.

Curves

The [Curve](#) class represents a hermite curve that allows you to interpolate varying positions at different times without having to explicitly define each position. The curve is defined by a collection of [CurveKey](#) points representing each varying position at different times.

This class can be used not only for spatial motion, but also to represent any response that changes over time.

Bounding Volumes

The XNA Framework provides the [BoundingBox](#), [BoundingFrustum](#), [BoundingSphere](#), [Plane](#), and [Ray](#) classes for representing simplified versions of geometry for the purpose of efficient collision and hit-testing. These classes have methods for checking for intersection and containment with each other.

Precision and Performance

The XNA Framework Math libraries are single-precision. This means that the primitives and operations contained in this library use 32-bits to represent floating-point numbers in order to achieve a balance between precision and efficiency when performing large numbers of calculations.

The 32-bit floating-point numbers can represent a range of values from negative $3.402823e38$ to positive $3.402823e38$. The 32-bits of a floating-point number are used to store the sign, mantissa, and exponent of the number. The result is seven digits of floating-point precision. Some numbers, such as π , $1/3$, or the square root of two, can only be approximated with a limited amount of memory. Because the number of bits used to represent a decimal number limit the range of numbers it can represent, floating-point numbers only approximate decimal numbers that require more than seven digits of precision. Consequently, rounding errors can occur under different conditions through the use of any binary-representation approximating a floating point number.

You can find more information about single-precision numbers in the documentation for the [Single](#) data type.

★Best Practice

Depending on the hardware platform your game is targeting, you may have multiple processors available to perform floating-point calculations. For example, on the Xbox 360 platform and on many Windows-based computers, you have a CPU, on which your game code is running, but you also have GPU, on which your shader code is running. Therefore, you can also perform floating point calculations on the GPU using shaders and [HLSL intrinsic functions](#). GPUs are very fast at performing large numbers of floating-point operations. This can be very useful, for example, if you need to perform a large number of floating point operations to animate a particle system.

However, you need to remember that the Zune platform does not have a GPU and does not support shaders. For Zune, you can use a conditional compilation directive `#if ZUNE` to write downlevel-code that behaves gracefully on this platform while still taking advantage of the performance gains on other types of hardware.

Collision Detection Overview

Overview of the collision-detection–related functionality provided by the XNA Framework.

Collision detection is the process of determining whether objects in a game world overlap each other. The XNA Framework provides several classes and methods to speed implementation of collision detection systems in games.

- [Bounding Volume Classes](#)
- [Non-Bounding Volume Classes](#)
- [Contains and Intersects Methods](#)
- [Adding New Collision Data Structures](#)

Bounding Volume Classes

The XNA Framework has three classes that represent three-dimensional areas in the world. You can use the bounding volume classes to approximate the volume occupied by models with shapes that are less expensive to do collision checks with. All of the bounding volume classes support intersection and containment tests with each other and the plane and ray classes.

Bounding Sphere

The [BoundingSphere Structure](#) represents the space occupied by a sphere.

There are several benefits of using a bounding sphere for collision detection.

- Sphere to sphere checks are very fast. To check for collision between two spheres, the distance between the centers of the spheres is compared to the sum of the radii of both spheres. If the distance is less than the combined radii of both spheres, the spheres intersect.
- The [BoundingSphere Structure](#) class is compact. It stores only a vector representing its center and its radius.
- Unlike a bounding box, a bounding sphere doesn't need to be recreated if the model rotates. If the model being bounded rotates, the bounding sphere will still be large enough to contain it.
- Moving a bounding sphere is inexpensive. Just add a value to the center.

There is one major drawback to using the bounding sphere class for collision detection.

- Unless the object being approximated is sphere shaped, the bounding sphere will have some empty space, which could result in false positive results. Long narrow objects will have the most empty space in their bounding spheres.

Bounding Box

The [BoundingBox Structure](#) represents the space occupied by a box. The bounding box class is axis aligned. Each face of the bounding box is perpendicular to the x-axis, the y-axis, or the z-axis.

There are several benefits of using the bounding box for collision detection.

- The bounding box class fits rectangular shapes aligned with the axis very well. Compared to the bounding sphere class, the bounding box class provides a much tighter fit for non-rotated rectangular objects.
- Because the bounding box class is axis aligned, you can make certain assumptions that result in collision checks between bounding boxes being quicker than a bounding box that can be rotated.

There are a few drawbacks of using the bounding box for collision detection.

- Rotating a bounding box causes it to no longer be axis aligned. Because of this, if you rotate a model being bounded, you will need to recreate the bounding box. Doing so can be slow, since all the points in an object are iterated through to get the bounding box. If the model has not changed orientation, you can translate the bounding box instead of recreating it.
- If the model being bounded is not aligned to the axis, the bounding box will have some empty space. The amount of empty space will be greatest when the object is rotated 45 degrees from an axis.
- Empty space in the bounding box can result in false positives when checking for collision.

Bounding Frustum

You can use [BoundingFrustum Class](#) to create a bounding volume that corresponds to the space visible to the camera. You create a bounding frustum from the combined view and projection matrix that the camera is using currently. If the camera moves or rotates, you need to recreate the bounding frustum. The bounding frustum isn't used to determine when two objects collide, but rather when an object is in collision with the volume of space viewable by the camera. Objects that do not intersect

and are not contained by the bounding frustum are not visible to the camera and don't need to be drawn. For complex models, this can save the graphics card a lot of work.

Non-Bounding Volume Classes

Plane

The [Plane Structure](#) describes a plane in space. The plane is defined by a vector perpendicular to the plane and a point on the plane. The plane class supports intersection tests with the bounding volume classes. The plane class's intersection test returns the tested object's position relative to the plane. The return value indicates whether the object intersects the plane. If the object does not intersect the plane, the return value indicates whether the object is on the plane's front side or back side.

Ray

The [Ray Structure](#) describes a ray starting at a point in space. The ray structure supports intersection tests with the bounding volume classes. The return value of the ray intersection tests is the distance the intersection occurred at, or null if no intersection occurred.

Model

In addition to the information needed to draw a model, the [Model Class](#) contains bounding volumes for its parts. When a model is imported, the content pipeline calculates the bounding sphere for each of the model's parts. To check for collision between two models, you can compare the bounding spheres for one model to all of the bounding spheres of the other model.

Contains and Intersects Methods

Bounding volume classes have methods to support two types of collision tests: intersection tests and containment tests. The intersects methods check whether the two objects being tested overlap in any way. As soon as the test finds that the objects do intersect, it returns without trying to determine the degree of the intersection. The contains methods determine whether the objects simply intersect or whether one of the objects is completely contained by the other. Since the intersects methods need only determine whether an intersection occurred, they tend to be faster than the contains methods. Use the contains methods only when the degree of intersection is relevant.

Adding New Collision Data Structures

When implementing other bounding volume classes and intersection tests, you will probably need to add a custom content pipeline processor. For example, your game might need to use convex hulls for collision detection. You could use a custom processor to determine the convex hull and then place it in the model's tag field. Then, when the model is loaded at run time, the convex hull information would be available in the model. For more information, see [Extending an XNA Framework Standard Processor](#).

How To: Transform a Point with a Matrix

This example demonstrates how to use the [Vector3](#) and [Matrix](#) classes to transform a point.

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

Transforming a Point with a Matrix

To transform a point

1. Create a [Matrix](#) by using [CreateRotationY](#) or one of the other **Create** methods.
2. Pass the point and the [Matrix](#) to the [Vector3.Transform](#) method.

C#

```
static Vector3 RotatePointOnYAxis(Vector3 point, float angle)
{
    // Create a rotation matrix that represents a rotation of angle radians.
    Matrix rotationMatrix = Matrix.CreateRotationY(angle);

    // Apply the rotation matrix to the point.
    Vector3 rotatedPoint = Vector3.Transform(point, rotationMatrix);

    return rotatedPoint;
}

How To: Rotate and Move a Camera

Demonstrates how to rotate and move a first-person camera in a 3D environment. You can rotate the camera about its y-axis, and move it forward and backward. You control the camera's position and orientation by using the directional keys on your keyboard or by using the D-pad of your Xbox 360 gamepad.

Note

This sample is the base for a more advanced sample that implements three camera types: first-person, first-person (offset), and third-person. For more information about this sample, see [How To: Make a Third-Person Camera](#).

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download FirstPersonCamera_Sample.zip](#).

Overview

This sample is based on several assumptions.

- The camera will move frequently, so the camera view [Matrix](#) is created and set every time [Game.Update](#) is called.
- The projection [Matrix](#) may also change frequently for effects such as zooming.
- You have added a model to the project as described in [How To: Render a Model](#).

For the sake of simplicity, the sample limits the camera object to an axis of rotation (y-axis) and forward and backward movement. This simplifies the process (and resultant code) for rendering the sample 3D scene. The following steps show you how to render the sample scene.

To render the sample scene

1. Determine the location and orientation of the camera object.
2. To create a view matrix as part of the standard world-view-projection matrix trilogy of 3D rendering using the camera position, orientation (also referred to as the "look at point"), and the world space's up vector, call [CreateLookAt](#).
3. Create a perspective matrix that determines the near and far clipping planes and the aspect of the projection with a call to [CreatePerspectiveFieldOfView](#).
4. In the [Draw](#) method of your game, initialize a [BasicEffect](#) object with the transformational matrices created earlier (world, view projection), and then render all existing 3D models.

Rotating and Moving a Camera

To rotate and move the camera

1. Determine the camera's position in world coordinates.
2. Determine the reference [Vector3](#) to which the rotation of the camera is relative.

The direction should not change during the game, and usually it will be (0, 0, 1) or (0, 0, -1).

C#

```
// Set the direction the camera points without rotation.
Vector3 cameraReference = new Vector3(0, 0, 1);
```

3. Create a rotation [Matrix](#) determining the current amount of rotation for the camera object.

Because the camera is limited to one axis of rotation, this matrix represents the rotation of the camera around its own y-axis. Use [CreateRotationY](#) to create a rotation [Matrix](#) representing the rotation around the y-axis.

C#

```
Matrix rotationMatrix = Matrix.CreateRotationY(avatarYaw);
```

- Use [Transform](#) and the rotation [Matrix](#) to transform a copy of the reference [vector](#).

This represents the direction the camera is pointing in transformed (or view) space.

C#

```
// Create a vector pointing the direction the camera is facing.
Vector3 transformedReference = Vector3.Transform(cameraReference, rotationMatrix);
```

- Add the camera's current position to the transformed direction [vector](#).

The result is the position to which the camera is pointing.

C#

```
// Calculate the position the camera is looking at.
Vector3 cameraLookat = cameraPosition + transformedReference;
```

- Create a new view [Matrix](#) using [CreateLookAt](#).

- Use [CreateLookAt](#) to pass the camera's current position and the transformed direction vector.

The third parameter of [CreateLookAt](#) is the up direction of the camera. Typically, it is [Vector3.Up](#) (0, 1, 0). This matrix [Matrix](#) controls how world coordinates are transformed to camera coordinates.

C#

```
// Set up the view matrix and projection matrix.
view = Matrix.CreateLookAt(cameraPosition, cameraLookat, new Vector3(0.0f, 1.0f, 0.0f)
);
```

- Use [CreatePerspectiveFieldOfView](#) to create a new projection [Matrix](#).

This [Matrix](#) controls how camera coordinate values are transformed to screen coordinates.

The first parameter is the field of view of the projection [Matrix](#) expressed in radians. A typical field of view of 45 degrees would be expressed as $\pi/4$ radians. The second parameter is the aspect ratio of the projection [Matrix](#); it corrects for the difference in width and height of a viewspace. The third and fourth parameters specify the near and far distances at which the objects will be visible.

C#

```
// Set distance from the camera of the near and far clipping planes.
static float nearClip = 1.0f;
static float farClip = 2000.0f;
Viewport viewport = graphics.GraphicsDevice.Viewport;
float aspectRatio = (float)viewport.Width / (float)viewport.Height;

proj = Matrix.CreatePerspectiveFieldOfView(viewAngle, aspectRatio, nearClip, farClip);
```

- Loop through each 3D model to be rendered as described in [How To: Render a Model](#) using the projection matrix and view matrix created above.

An identity matrix simplifies the code for the world matrix.

C#

```
void DrawModel(Model model, Matrix world, Texture2D texture)
{
    foreach (ModelMesh mesh in model.Meshes)
    {
        foreach (BasicEffect be in mesh.Effects)
        {
            be.Projection = proj;
            be.View = view;
        }
    }
}
```

```
        be.World = world;
        be.Texture = texture;
        be.TextureEnabled = true;
    }
    mesh.Draw();
}
```

How To: Make a First-Person Camera

Demonstrates how to create a first-person camera.

The example controls the camera by using the method shown in [How To: Rotate and Move a Camera](#), with an additional offset for the camera to place it where the game avatar's head should be. The example assumes a model has been added to the project as described in [How To: Render a Model](#).

Tip

This technique is implemented in the FuelCell game, a game developed by following a series of focused articles that discuss basic 3D game development. For more information, see [FuelCell: Setting the Scene](#).

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download FirstPersonCamera_Sample.zip](#).

Making a First-Person Camera

To make a first-person camera

1. Precalculate the camera's offset from the avatar.

The offset is used to place the camera roughly at the location of the avatar's head.

C#

```
Vector3 avatarHeadOffset = new Vector3(0, 10, 0);
```

2. Track the position and rotation of the avatar during gameplay.
3. Create a rotation [Matrix](#) using [CreateRotationY](#) and the avatar's current direction.

C#

```
Matrix rotationMatrix = Matrix.CreateRotationY(avatarYaw);
```

4. Use the rotation [Matrix](#) and [Vector3.Transform](#) to transform a copy of the camera's head offset.

C#

```
// Transform the head offset so the camera is
// positioned properly relative to the avatar.
Vector3 headOffset =
    Vector3.Transform(avatarHeadOffset, rotationMatrix);
```

5. Calculate the current position of the camera.

The position of the camera will be the position of the avatar, plus the avatar's transformed head offset.

C#

```
// Calculate the camera's current position.
Vector3 cameraPosition = avatarPosition + headOffset;
```

6. Use the rotation [Matrix](#) and [Vector3.Transform](#) to transform a copy of the camera's reference [vector](#).

C#

```
// Create a vector pointing the direction the camera is facing.
Vector3 transformedReference =
    Vector3.Transform(cameraReference, rotationMatrix);
```

- Calculate the position at which the camera is looking.

This "look-at" position will be the camera's position, plus the camera's transformed reference [vector](#).

C#

```
// Calculate the position the camera is looking at.
Vector3 cameraLookat = transformedReference + cameraPosition;
```

- Create a new view [Matrix](#).

You can create the new [Matrix](#) by passing the camera position and camera look-at to [CreateLookAt](#). The view [Matrix](#) controls how world coordinate values are transformed to camera coordinates.

C#

```
view = Matrix.CreateLookAt(cameraPosition, cameraLookat,
    new Vector3(0.0f, 1.0f, 0.0f));
```

- Use [CreatePerspectiveFieldOfView](#) to create a new projection [Matrix](#).

The projection [Matrix](#) controls how camera coordinate values are transformed to screen coordinates.

C#

```
Viewport viewport = graphics.GraphicsDevice.Viewport;
float aspectRatio = (float)viewport.Width / (float)viewport.Height;

proj = Matrix.CreatePerspectiveFieldOfView(viewAngle, aspectRatio,
    nearClip, farClip);
```

- Loop through each model in the world drawing it as described in [How To: Render a Model](#) using the projection matrix and view matrix created above.

For the world matrix, use [Matrix.CreateTranslation](#) and the object's current position in the world.

C#

```
void DrawBoxes()
{
    for (int z = 0; z < 9; z++)
    {
        for (int x = 0; x < 9; x++)
        {
            DrawModel(box,
                Matrix.CreateTranslation(x * 60, 0, z * 60),
                boxTexture);
        }
    }
}

    {
```

```
    foreach (BasicEffect be in mesh.Effects)
    {
        be.Projection = proj;
        be.View = view;
        be.World = world;
        be.Texture = texture;
        be.TextureEnabled = true;
    }
    mesh.Draw();
}

Demonstrates how to create a third-person camera.

The example controls the camera using the method shown in [How To: Rotate and Move a Camera](#), with an additional offset for the camera so it is looking down at the game avatar. Turning the avatar causes the camera to rotate around the avatar's position. The current camera type is displayed in the upper-left corner of the screen and updated whenever the TAB or left shoulder button is pressed.

The example assumes a model has been added to the project as described in [How To: Render a Model](#).

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download ThirdPersonCamera_Sample.zip](#).

Making a Third-Person Camera

To make a third-person camera

1. Decide on a camera offset [vector](#) from the avatar.

An offset of the form (0, N, -N) will put the camera above and behind the avatar at a 45-degree angle.

C#

```
Vector3 thirdPersonReference = new Vector3(0, 200, -200);
```

2. Track the position and rotation of the avatar.

Next, you need to create a rotation [Matrix](#) for the direction that the avatar is facing.

3. Create the rotation [Matrix](#) with [CreateRotationY](#), using the avatar's current rotation as its parameter.

C#

```
Matrix rotationMatrix = Matrix.CreateRotationY/avatarYaw);
```

4. Transform a copy of the camera offset [vector](#) by using the [Transform](#) method and the rotation [Matrix](#).

C#

```
// Create a vector pointing the direction the camera is facing.
Vector3 transformedReference =
    Vector3.Transform(thirdPersonReference, rotationMatrix);
```

5. Calculate the camera's position as the avatar's position, and calculate the transformed camera offset.

C#

```
// Calculate the position the camera is looking from.
Vector3 cameraPosition = transformedReference + avatarPosition;
```

6. Create a view [Matrix](#) with the [CreateLookAt](#) method.

The avatar's current position will be the *cameraTarget* parameter.

C#

```
view = Matrix.CreateLookAt(cameraPosition, avatarPosition,
    new Vector3(0.0f, 1.0f, 0.0f));
```

7. Create a new projection [Matrix](#) with [CreatePerspectiveFieldOfView](#).

The projection [Matrix](#) controls how camera coordinate values are transformed to screen coordinates.

C#

```
Viewport viewport = graphics.GraphicsDevice.Viewport;
float aspectRatio = (float)viewport.Width / (float)viewport.Height;

proj = Matrix.CreatePerspectiveFieldOfView(viewAngle, aspectRatio,
    nearClip, farClip);
```

8. Loop through each model in the world drawing it as described in [How To: Render a Model](#) using the projection matrix and view matrix created above.

For the world matrix, use [Matrix.CreateTranslation](#) and the object's current position in the world.

C#

```
void DrawBoxes()
{
    for (int z = 0; z < 9; z++)
    {
        for (int x = 0; x < 9; x++)
        {
            DrawModel(box,
                Matrix.CreateTranslation(x * 60, 0, z * 60),
                boxTexture);
        }
    }
}

/// <summary>
/// Draws the 3D specified model.
/// </summary>
/// <param name="model">The 3D model being drawn.</param>
/// <param name="world">Transformation matrix for world coords.
/// </param>
/// <param name="texture">Texture used for the drawn 3D model.
/// </param>
void DrawModel(Model model, Matrix world, Texture2D texture)
{
    foreach (ModelMesh mesh in model.Meshes)
    {
        foreach (BasicEffect be in mesh.Effects)
        {
            be.Projection = proj;
            be.View = view;
            be.World = world;
            be.Texture = texture;
            be.TextureEnabled = true;
        }
        mesh.Draw();
    }
}
```

How To: Script the Camera to Follow a Curve

Demonstrates how to use the [Curve](#) and [CurveKey](#) classes to script the movement of the camera.

Using [Curves](#) allows a path to be defined by a small number of control points with the [Curves](#) calculating the points on the path between the control points.

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download ScriptedCamera_Sample.zip](#).

Scripting the Camera to Follow a Curve

To script camera movement

1. Create an instance of the [Curve](#) class for each component being scripted.

In this case, you need two sets of three curves. One is for each of the x, y, and z components of the camera's position, and the other is for the position at which the camera is looking (the "look-at" position).

C#

```
class Curve3D
{
    public Curve curveX = new Curve();
    public Curve curveY = new Curve();
    public Curve curveZ = new Curve();
    ...
}
Curve3D cameraCurvePosition = new Curve3D();
Curve3D cameraCurveLookat = new Curve3D();
```

2. Set the [PreLoop](#) and [PostLoop](#) type of each [Curve](#).

The [PreLoop](#) and [PostLoop](#) types determine how the curve will interpret positions before the first key or after the last key. In this case, the values will be set to [CurveLoopType.Oscillate](#). Values past the ends of the curve will change direction and head toward the opposite side of the curve.

C#

```
curveX.PostLoop = CurveLoopType.Oscillate;
curveY.PostLoop = CurveLoopType.Oscillate;
curveZ.PostLoop = CurveLoopType.Oscillate;

curveX.PreLoop = CurveLoopType.Oscillate;
curveY.PreLoop = CurveLoopType.Oscillate;
curveZ.PreLoop = CurveLoopType.Oscillate;
```

3. Add [CurveKeys](#) to the [Curves](#).
4. Specify the time each [CurveKey](#) should be reached and the camera position when the [CurveKey](#) is reached.

In this case, each point in time will have three [CurveKeys](#) associated with it – one for each of the x, y, and z coordinates of the point on the [Curve](#).

C#

```
public void AddPoint(Vector3 point, float time)
{
    curveX.Keys.Add(new CurveKey(time, point.X));
    curveY.Keys.Add(new CurveKey(time, point.Y));
```

```

        curveZ.Keys.Add(new CurveKey(time, point.Z));
    }
    void InitCurve()
    {
        float time = 0;
        cameraCurvePosition.AddPoint(new Vector3(7.5f, 0, -45), time);
        cameraCurveLookat.AddPoint(new Vector3(9, 0, 9), time);
        time += 2000;
        cameraCurvePosition.AddPoint(new Vector3(3f, 0, -36), time);
        time += 2000;
        cameraCurvePosition.AddPoint(new Vector3(12f, 0, -30), time);
        time += 2000;
        cameraCurvePosition.AddPoint(new Vector3(3f, 0, -24), time);
        time += 2000;
        cameraCurvePosition.AddPoint(new Vector3(12f, 0, -18), time);
        time += 2000;
        ...
        cameraCurvePosition.SetTangents();
        cameraCurveLookat.SetTangents();
    }

```

5. Loop through each [Curve](#) setting the [TangentIn](#) and [TangentOut](#) of each [CurveKey](#).

The tangents of the [CurveKeys](#) control the shape of the [Curve](#). Setting the tangents of the [CurveKeys](#) to the slope between the previous and next [CurveKey](#) will give a curve that moves smoothly through each point on the curve.

C#

```

public void SetTangents()
{
    CurveKey prev;
    CurveKey current;
    CurveKey next;
    int prevIndex;
    int nextIndex;
    for (int i = 0; i < curveX.Keys.Count; i++)
    {
        prevIndex = i - 1;
        if (prevIndex < 0) prevIndex = i;

        nextIndex = i + 1;
        if (nextIndex == curveX.Keys.Count) nextIndex = i;

        prev = curveX.Keys[prevIndex];
        next = curveX.Keys[nextIndex];
        current = curveX.Keys[i];
        SetCurveKeyTangent(ref prev, ref current, ref next);
        curveX.Keys[i] = current;
        prev = curveY.Keys[prevIndex];
        next = curveY.Keys[nextIndex];
        current = curveY.Keys[i];
        SetCurveKeyTangent(ref prev, ref current, ref next);
        curveY.Keys[i] = current;

        prev = curveZ.Keys[prevIndex];
        next = curveZ.Keys[nextIndex];
        current = curveZ.Keys[i];
        SetCurveKeyTangent(ref prev, ref current, ref next);
        curveZ.Keys[i] = current;
    }
}

```

```

}
static void SetCurveKeyTangent(ref CurveKey prev, ref CurveKey cur,
    ref CurveKey next)
{
    float dt = next.Position - prev.Position;
    float dv = next.Value - prev.Value;
    if (Math.Abs(dv) < float.Epsilon)
    {
        cur.TangentIn = 0;
        cur.TangentOut = 0;
    }
    else
    {
        // The in and out tangents should be equal to the
        // slope between the adjacent keys.
        cur.TangentIn = dv * (cur.Position - prev.Position) / dt;
        cur.TangentOut = dv * (next.Position - cur.Position) / dt;
    }
}
}

```

6. Add code to evaluate the x, y, and z coordinates of the [Curves](#) at any given time by passing the elapsed time to the [Evaluate](#) method of each of the [Curves](#).

C#

```

public Vector3 GetPointOnCurve(float time)
{
    Vector3 point = new Vector3();
    point.X = curveX.Evaluate(time);
    point.Y = curveY.Evaluate(time);
    point.Z = curveZ.Evaluate(time);
    return point;
}

```

7. Create a variable to track the amount of time that has passed since the camera started moving.

C#

```

double time;

```

8. In [Game.Update](#), set the camera's position and look-at position based on the elapsed time since the camera started moving, and then set the camera's view and projection matrices as in [How To: Rotate and Move a Camera](#).

C#

```

// Calculate the camera's current position.
Vector3 cameraPosition =
    cameraCurvePosition.GetPointOnCurve((float)time);
Vector3 cameraLookat =
    cameraCurveLookat.GetPointOnCurve((float)time);

```

9. In [Game.Update](#), use [gameTime.ElapsedGameTime.TotalMilliseconds](#) to increment the time since the camera started moving.

C#

```

time += gameTime.ElapsedGameTime.TotalMilliseconds;

```

How To: Position the Camera to View All Objects in a Scene

Positioning the Camera to View All Objects in a Scene

To position the camera to view all objects in a scene

1. Create a [BoundingSphere](#) class that contains all of the objects in the scene. To create the sphere, loop through all of the objects in the scene, merging the [BoundingSphere](#) classes that contain them with [BoundingSphere.CreateMerged](#).
2. If you are not already tracking the [BoundingSphere](#) classes for collision detection, use [CreateFromBoundingBox](#) or [CreateFromPoints](#) to create them from [BoundingBox](#) classes or points.

In this example, the [BoundingSphere](#) classes are created from [BoundingBox](#) classes.

C#

```
BoundingSphere GetSceneSphere()
{
    BoundingSphere sceneSphere =
        new BoundingSphere(new Vector3(.5f, 1, .5f), 1.5f);
    for (int z = 0; z < 5; z++)
    {
        for (int x = 0; x < 5; x++)
        {
            BoundingSphere boundingSphere =
                sphere.Meshes[0].BoundingSphere;
            boundingSphere.Center = new Vector3(x * 3, 0, z * 3);

            sceneSphere = BoundingSphere.CreateMerged(
                sceneSphere, boundingSphere);
        }
    }

    return sceneSphere;
}
```

3. Set the position of the camera to the center of the [BoundingSphere](#) that contains the scene.

C#

```
cameraPosition = sceneSphere.Center;
```

4. Determine the distance from the center of the [BoundingSphere](#) that the camera needs to be to view the entire scene.

This distance is equal to the hypotenuse of the triangle formed by the center of the sphere, the desired camera position, and the point where the sphere touches the view frustum. One angle of the triangle is known to be the field of view of the camera divided by two. One leg of the triangle is known to be the radius of the sphere. Given these two measurements, you can calculate the hypotenuse as the radius of the sphere divided by the sine of half the field of view.

C#

```
float distanceToCenter =
    sceneSphere.Radius / (float)Math.Sin(FOV / 2);
```

5. Get the [Backward](#) vector of the view [Matrix](#) and flip its X component.

C#

```
Vector3 back = view.Backward;  
back.X = -back.X; //flip x's sign
```

6. To move the camera backward with respect to its orientation, multiply the desired distance by the adjusted back vector from the previous step.

The camera is now facing the center of the sphere containing the scene and is far enough back that the sphere fits in the camera's view frustum.

C#

```
cameraPosition += (back * distanceToCenter);
```

How To: Detect Whether Two Models Collide

Demonstrates how to use the [BoundingSphere](#) class to check whether two models are colliding.

Tip

This technique is implemented in the FuelCell game, a game developed by following a series of focused articles that discuss basic 3D game development. For more information, see [FuelCell: "Ships" Passing in the Night](#).

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download CollisionBetweenSpheres_Sample.zip](#).

Detecting Whether Two Models Collide

To check whether two objects are colliding

1. Track the position of a model as it moves about the game world.

C#

```

struct WorldObject
{
    public Vector3 position;
    public Vector3 velocity;
    public Model model;
    public Texture2D texture2D;
    public Vector3 lastPosition;
    public void MoveForward()
    {
        lastPosition = position;
        position += velocity;
    }
    public void Backup()
    {
        position -= velocity;
    }
    public void ReverseVelocity()
    {
        velocity.X = -velocity.X;
    }
}

```

2. Make a nested loop with the first model's meshes as the outer loop and the second model's meshes as the inner loop.
3. Inside the loop, follow these steps.
 - a. Get the bounding sphere for the current mesh of the first model and the current mesh of the second model.
 - b. Offset the bounding spheres by the current positions of the models.
 - c. Call the [BoundingSphere.Intersects](#) method to check the pairs of bounding spheres for collision.

If the method returns **true**, the objects are colliding.
 - d. If the models are colliding, break out of the loop.

C#

```

static void CheckForCollisions(ref WorldObject c1, ref WorldObject c2)
{
    for (int i = 0; i < c1.model.Meshes.Count; i++)
    {

```

```
// Check whether the bounding boxes of the two cubes intersect.
BoundingBox c1BoundingBox = c1.model.Meshes[i].BoundingBox;
c1BoundingBox.Center += c1.position;

for (int j = 0; j < c2.model.Meshes.Count; j++)
{
    BoundingBox c2BoundingBox = c2.model.Meshes[j].BoundingBox;
    c2BoundingBox.Center += c2.position;

    if (c1BoundingBox.Intersects(c2BoundingBox))
    {
        c2.ReverseVelocity();
        c1.Backup();
        c1.ReverseVelocity();
        return;
    }
}
}
```

Detecting Whether a User Clicked a 3D Object

To check whether the mouse is positioned over a 3D object

1. Get the current state of the mouse by using [GetState](#).

C#

```
MouseState mouseState = Mouse.GetState();
```

2. Get the current screen coordinates of the mouse from [X](#) and [Y](#).

C#

```
int mouseX = mouseState.X;
int mouseY = mouseState.Y;
```

3. Using [Viewport.Unproject](#), determine points in world space on the near and far clip plane. For the point on the near plane, pass a source vector with x and y set to the mouse position, and z set to 0.
4. For the point on the far plane, pass a source vector with x and y set to the mouse position, and z set to 1.
5. For both points, pass [Unproject](#) the current projection matrix, the view matrix, and a translation matrix for the point (0,0,0).

C#

```
Vector3 nearsource = new Vector3((float)mouseX, (float)mouseY, 0f);
Vector3 farsource = new Vector3((float)mouseX, (float)mouseY, 1f);

Matrix world = Matrix.CreateTranslation(0, 0, 0);

Vector3 nearPoint = GraphicsDevice.Viewport.Unproject(nearsource,
    proj, view, world);

Vector3 farPoint = GraphicsDevice.Viewport.Unproject(farsource,
    proj, view, world);
```

6. Create a [Ray](#) starting at the near point and pointing toward the far point.

C#

```
// Create a ray from the near clip plane to the far clip plane.
Vector3 direction = farPoint - nearPoint;
direction.Normalize();
Ray pickRay = new Ray(nearPoint, direction);
```

7. Use [Intersects](#) to loop through the objects in the world to check whether the [Ray](#) intersects each object.

8. If the [Ray](#) intersects an object, check whether it is the closest object intersected so far. If it is, store the object and the distance at which it was intersected, replacing any previously stored object.
9. When you completely loop through the objects, the last object stored will be the closest object underneath the area the user clicked.

Input Overview

Input is a general term referring to the process of receiving actions from the user. In XNA Game Studio, the [Microsoft.Xna.Framework.Input](#) namespace provides support for all input devices.

Note

APIs related to input devices physically not available in your game are always available to your code. For example, you can access the [Mouse](#) API on Zune, but you cannot retrieve the relevant mouse position. Also, you should not expect an exception or build error when you access APIs related to unavailable input devices.

Xbox 360 Controller, Mouse, and Keyboard

The Xbox 360 Controller, the keyboard, and the mouse are common input devices. What follows is the differences between these input devices and guidelines for how to use them with your game.

Digital vs. Analog

Input devices have two types of controls: digital and analog. Digital controls report only two possible states—on and off—and are represented by Boolean values. Examples of digital controls are the **START** button on the Xbox 360 Controller and any button on a keyboard.

Analog controls report a range of values, rather than just off and on. Examples of analog controls are the Xbox 360 Controller stick and the movements of the mouse. Analog values can be represented in a variety of ways. In XNA Game Studio, an analog value on the Xbox 360 Controller is represented as a floating-point value between -1.0 and 1.0 for the sticks, and between 0.0 and 1.0 for the triggers. For the mouse, XNA Game Studio reports mouse cursor values in pixels.

Polling and States

For all input devices in XNA Game Studio, input is received from the user by way of **polling**: each frame, call a function to receive the current state of an input device, and compare to previous states if necessary. A state is a snapshot of an input device's interactions from the user. At any given moment, a control may have a variety of buttons pressed, analog sticks or triggers held in a direction. The current positions of these buttons and analog controls are reported in a state structure. The following sections describe the methods for retrieving and using state for each input device.

Input Device Types

Each input device has specific advantages and disadvantages. The following table shows a brief comparison of three devices.

Input Device	Digital Buttons	Analog Controls	Vibration Effects	Supported on Windows	Supported on Xbox 360	Number Allowed on System
Xbox 360 Controller	14	4	Yes	Yes	Yes	4
Keyboard	> 100	0	No	Yes	Yes	1
Mouse	5	3	No	Yes	No	1

Xbox 360 Controller

The Xbox 360 Controller provides a good combination of digital buttons and analog sticks, so that many types of games can be played with it.

The controller can be used on either Windows or Xbox 360 systems. Up to four controllers are supported.

How to Use

1. Each frame of your game, call the static [GetState](#) method from the [GamePad](#) class.
2. Pass in the index of the player you wish to query. The player associated with a controller is visible on the Ring of Light on the controller.
3. Query the [GamePadState](#) structure you get back to retrieve information on the state of the controller. For more information on retrieving state, including how to determine whether the user has pressed or released a button since the last frame, see [How To: Detect Whether a Controller Button Is Pressed](#).

You may store a previous controller state if you wish to compare states to determine input changes from one frame to the next.

Note

Controllers may become disconnected during normal gameplay. For information on how to properly detect and handle this situation, see [How To: Detect Whether a Controller Is Disconnected](#).

Keyboard

The keyboard, with a multitude of digital buttons, is best for complicated simulations with many functions, or when typing text is necessary—but a keyboard has no analog controls for precise movement.

Not all keyboards support the entire range of buttons listed in [Keys](#); for example, older keyboards may not support the **VolumeDown**, **VolumeUp**, and **VolumeMute** members.

If the user's keyboard is connected via USB, it can be used on a Windows system, or on an Xbox 360.

How to Use

1. Each frame of your game, call the static [GetState](#) method from the [Keyboard](#) class.
2. Query the [KeyboardState](#) structure you get back to retrieve information on the state of the keyboard.

You may store a previous keyboard state if you wish to compare states to determine input changes from one frame to the next. See [How To: Detect Whether a Key Is Pressed](#) for more information.

Mouse

The mouse, with its precise analog control, is best for selecting objects, such as in a strategy game, or for moving a viewport, such as in a first-person action game—but a mouse has few digital buttons. Modern mouse devices have three extra buttons in addition to the standard left and right buttons: two digital buttons, usually on the side of the mouse, and a digital button that is activated by clicking down on the scroll wheel. The scroll wheel itself functions as an extra analog control in two directions, but does not provide precise input.

Not all mouse devices support all buttons; for example, older mouse devices may not support the [MiddleButton](#), [XButton1](#) and [XButton2](#) properties.

You can set the [Game.IsMouseVisible Property](#) to **true** to make the mouse cursor visible; use the default (**false**) if you are drawing your own cursor or don't want a cursor.

Mouse devices are used on Windows systems only. They are not supported on Xbox 360.

How to Use

1. Each frame of your game, call the static [GetState](#) method from the [Mouse](#) class.
2. Query the [MouseState](#) structure that is returned to retrieve information on the state of the mouse. Mouse coordinates are relative to the upper-left corner of the game window.

You may store a previous mouse state if you wish to compare states to determine input changes from one frame to the next.

For more information on mouse state, including an example, see [How To: Get the Current Mouse Position \(Windows\)](#).

Input on Zune

Zune devices have two digital buttons, and a ZunePad that is an analog control. The two buttons are the **Start** and **Back** buttons. The ZunePad features directional input that is retrieved with the [GamePad.GetState](#) method. The **Back** button maps to [GamePadState.Buttons.Back](#), and the **Play/pause** button maps to [GamePadState.Buttons.B](#).

For more information, see [Zune Programming Considerations](#).

Required and Optional Features

Support for the following features is required from all controller subtypes:

- The action buttons: **A**, **B**, **X**, and **Y**.
- The **Back**, **Start**, and **Xbox Guide** buttons.
- The directional pad (Up, Down, Left and Right), the Ring of Light, and voice support.

Support for the following features is optional:

- The serial port, which is part of the Expansion Port.
- The **Left/Right** stick buttons (that is, thumbsticks).
- The **Left/Right** triggers.
- The **Left/Right** shoulder buttons (that is, bumpers).

Alternate Guitar

This controller consists of a guitar with a vertical orientation sensor and whammy bar.

 Note
In addition to the standard control set, the standard and alternate guitar controllers implement additional vendor-specific effects.

Game Function	Gamepad	Guitar (alternate)
Game Dependent	Right Trigger	Accelerometer
Game Dependent	Left Trigger	Accelerometer
Game Dependent/Menu Navigation	Directional Pad (Up/Down/Left/Right)	Strum Up, Strum Down, DPad Left, DPad Right
Game Dependent	A, B, X, Y button	Green (1st Neck Button), Red (2nd Neck Button), Blue (4th Neck Button), Yellow (3rd Neck Button)
Game Dependent	Left Bumper	Orange (5th Neck Button)
Not used	Right Bumper	Optional Guitar Effect 3

Not used	Left Stick X-axis	Not used
Not used	Left Stick Y-axis	Not used
Game Dependent	Right Stick X-axis	Whammy Bar. When the whammy bar is held out from the base of the controller, it is in an Out (or neutral) position and returns a full negative value (-32,768). When the whammy bar is held against the base of the controller, it is in an In position and registers a full positive value (32,767).
Game Dependent	Right Stick Y-axis	Vertical Accelerometer When the controller is held at an angle of +55° or more, the Y-axis of the right stick registers a full positive max value. Values less than 55° register a positive value between 0 and 32,767. When the controller is held at an angle of -55° or more, the X-axis of the right stick registers a full negative max value. Values less than -55° register a negative value between 0 and -32,768.
Not used	Left and Right Stick buttons	Not used

Arcade Stick

This controller consists of a digital joystick and buttons, which are commonly used for arcade and fighting games.

Game Function	Gamepad	Arcade Stick
Game Dependent	Right Trigger	RT button (optional)
Game Dependent	Left Trigger	LT button (optional)
Game Dependent/Menu Navigation	Directional Pad (Up/Down/Left/Right)	Arcade Stick (Up/Down/Left/Right)
Game Dependent	A, B, X, Y button	Green/Red/Blue/Yellow button

Dance Pad

This controller consists of a floor mat, which is used exclusively with dance games. An optional headset extension cable might be bundled with the dance pad.

Game Function	Gamepad	Dance Pad
Not used	Right Trigger	Not used
Not used	Left Trigger	Not used
Game dependent	Directional Pad (Up/Down/Left/Right)	Top/North, Bottom/South, West/Left, East/Right pads
Game dependent	A, B, X, Y button	A Pad (North East), B Pad (North West), X Pad (South East), Y Pad (South West)

Drum Kit

This controller consists of a drum kit, which is used for music games. Bass drum control is implemented as a foot pedal with various drums represented by four (core kit) or seven (extended drum kit) pads.

Game Function	Gamepad	Drum Kit
Not used	Right Trigger	Not used
Not used	Left Trigger	Not used
Game Dependent/Menu Navigation	Directional Pad (Up/Down/Left/Right)	Directional Pad
Game Dependent	A, B, X, Y button	Green, Red, Blue, and Yellow pads.
Game Dependent	Left Bumper	Orange pedal
Game Dependent	Right Bumper	Extra Pad 3 (optional)
Pause/Wakes controller from standby and then signals console to wake up.	Start Button	Start Button
Back	Back button	Back button
Opens the on-screen Xbox 360 menu. Wakes controller from standby and then signals console to wake up.	Xbox Guide Button	Xbox Guide Button
Game Dependent	Left Stick button	Extra Pad 2 (optional)
Game Dependent	Right Stick button	Extra Pad 1 (optional)

Flight Stick

This controller consists of an aircraft joystick, which is used for flight simulation, air combat, and space combat games. The joystick's position is mapped to the Left Stick's X and Y-axes as on a Cartesian plane.

Game Function	Gamepad	Flight Stick
Throttle (Up/Down)	Right Trigger	Throttle Control (Forward/Backward)
Rudder (Left/Right)	Left Trigger	Twisting handle or rocker switch
Menu Navigation	Directional Pad (Up/Down/Left/Right)	Hat switch
Primary weapon, Secondary weapon, Action, Action	A, B, X, Y button	Joystick trigger, B, X, Y buttons
Optional	Left Bumper	Optional
Optional	Right Bumper	Optional

Point Of View	Right Stick X and Y-axis	Right Stick X and Y-axis
Optional	Left and Right Stick buttons	Optional

Gamepad

This is the standard Xbox 360 controller. It is suitable for emulating all other controller subtypes.

Game Function	Gamepad
Game Dependent	Right Trigger
Game Dependent	Left Trigger
Game Dependent/Menu Navigation	Directional Pad (Up/Down/Left/Right)
Game Dependent	A, B, X, Y button
Game Dependent	Left Bumper
Game Dependent	Right Bumper

Wheel

Several wheels (with associated pedals) are available for the Xbox 360 platform.

Game Function	Gamepad	Wheel
Accelerate	Right Trigger	Accelerator Pedal
Brake	Left Trigger	Brake Pedal
Game Dependent/Menu Navigation	Directional Pad (Up/Down/Left/Right)	Directional Pad (Up/Down/Left/Right)
Game Dependent	A, B, Y, X button	A, B, Y, X button
Gear Down	Left Bumper	Left Paddle/Shift Lever
Gear Up	Right Bumper	Right Paddle/Shift Lever

How To: Detect Whether a Controller Button Is Pressed

Demonstrates how to detect whether a user has pressed a digital button on a connected Xbox 360 Controller.

The topic shows you how to check whether the digital button currently is held in the down position. For every update loop in which the **A** button remains pressed, the controller will increase vibration. To detect only the first time a button has been pressed and ignore when the button is continuously held down, such as when you want to test how fast a player can rapidly press a button, see [How To: Detect Whether a Controller Button Has Been Pressed This Frame](#).

Tip

This technique is mentioned in the FuelCell game, a game developed by following a series of focused articles that discuss basic 3D game development. For more information, see [FuelCell: What's My Motivation](#).

Detecting the Current Position of the Controller Button

To detect whether a controller button is currently being pressed

1. Get the state of the Xbox 360 Controller by using [GetState](#).
2. Verify that the controller currently is connected by retrieving the [IsConnected](#) property.
3. Retrieve the values of the [Buttons](#) you wish to check.

If the current state is **Pressed**, the button is being pressed currently.

How To: Detect Whether a Controller Button Has Been Pressed This Frame

Demonstrates how to detect whether a user has just pressed a digital button on a connected Xbox 360 Controller. This topic ignores held buttons. It only activates when a button has been pressed in the current frame.

The example uses a stored [GamePadState](#) object and compares the value of the **A** button to determine whether the state of the button has changed from **Released** to **Pressed**. If it has changed, it indicates the user pressed the button.

Unlike the more basic example shown in [How To: Detect Whether a Controller Button Is Pressed](#), this topic only reports a digital button press, not when the button is simply held down. This can be useful in games where you want to test the user's ability to rapidly press a button. In a manner similar to [How To: Detect Whether a Controller Button Is Pressed](#), the result of this sample is vibration. However, the only way to increase the vibration amount is to rapidly press the **A** button. Holding the button will not increase the vibration.

Tip

This technique is implemented in the FuelCell game, a game developed by following a series of focused articles that discuss basic 3D game development. For more information, see [FuelCell: What's My Motivation](#).

Detecting Whether a Controller Button Has Been Pressed This Frame

To detect whether a controller button has just been pressed this frame

1. Get the state of the Xbox 360 Controller by using [GetState](#).
2. Verify that the controller is currently connected by retrieving the [IsConnected](#) property.
3. Compare the values of the [Buttons](#) you want to check between the current state and previous state.

If the current state is **Pressed** and the previous state is **Released**, the button has been pressed.

4. Update the previous state to the new state.

How To: Detect Whether a Controller Is Disconnected

Demonstrates how to detect whether an Xbox 360 Controller connected to the system at game start has become disconnected.

This topic shows you how to check the `IsConnected` property of a retrieved `GamePadState` object. If the value is **true**, the controller is still connected, and the game continues. If the value is **false**, the controller has become disconnected, and the game will pause until the user reconnects the controller.

Detecting Whether a Controller Has Been Disconnected

To detect whether a controller has been disconnected

1. At program start, present an interface for users to choose which controllers are connected, and store this information.
2. Proceed to the game loop.
3. In the game loop, get the state of each Xbox 360 Controller by using `GetState`.
4. Retrieve the `IsConnected` property to verify that each controller from the earlier list of connected controllers is still connected.

If the current value of `IsConnected` is **false** for a previously-connected controller, that controller has become disconnected.

5. Enter a pause loop and wait for the user to reconnect the controller.

How To: Get the Current Mouse Position (Windows)

Demonstrates how to get the current horizontal and vertical position of the mouse cursor relative to the upper-left corner a game window.

Note

This example applies only to Windows development. The [Mouse](#) and [MouseState](#) objects are not supported on Xbox 360.

The example queries the [Mouse](#) class to return a [MouseState](#) object that holds the button states and the current position of the mouse relative to the upper-left corner of the game window.

Retrieving the Current Mouse Position

To retrieve the current mouse position

1. Call [GetState](#) to get the current state of the mouse in a [MouseState](#) object.
2. Access the [X](#) and [Y](#) properties of the [MouseState](#) retrieved in the previous section to get the X (horizontal) and Y (vertical) mouse position, in pixels, relative to the upper-left corner of the game window.

How To: Detect Whether a Key Is Pressed

Demonstrates how to detect whether a user has pressed or released a key on the keyboard.

By using [GetState](#), a game can determine which keys are being held down. Often a game needs to detect when a user has pressed or released a button. For example, there is the case of an action title that requires users to press and release keys in rapid succession. The example uses a cached [KeyboardState](#) object to determine whether keys have been pressed or released in a given frame.

Depending on game design, there may be times when checking for a key press needs to occur more frequently, and other times when the check may not be needed as often. It is possible in the case of very fast key presses that more than one key press could occur within one frame. In this case, the last key press will be returned. Writing code that checks for key presses as often as possible when needed is the best way to handle this case.

Tip

This technique is implemented in the FuelCell game, a game developed by following a series of focused articles that discuss basic 3D game development. For more information, see [FuelCell: What's My Motivation](#).

Detecting Whether a Key is Pressed or Released

To detect whether a key is pressed or released

1. Declare a [KeyboardState](#) object to hold the last known keyboard state (in this example, the **oldState** object).
2. Assign this object a value in your constructor.
3. Call [GetState](#) to retrieve the current keyboard state (in this example, the **newState** object).
4. Compare the values in your **oldState** object to the values in the **newState** object.

Keys pressed in the **newState** object that were not pressed in the **oldState** object have been pressed during this frame. Conversely, keys pressed in the **oldState** object that are not pressed in the **newState** object have been released during this frame.

5. Update **oldState** object to the **newState** object before leaving **Update**.

Audio Overview

The XNA Framework provides audio playback through the Microsoft Cross-Platform Audio Creation Tool (XACT), and a simple [SoundEffect](#) class for audio playback that doesn't require XACT.

Audio Orientation

Some general terminology is provided below, followed by a more detailed discussion.

Wave

A wave is an audio data file used independently, or as a building block for creating game sound effects.

Wave Bank

A wave bank is multiple wave files logically grouped into a single file.

Sound Bank

A sound bank is a logically grouped collection of sounds (wave banks) and cues.

Cue

A cue allows a game programmer to play sounds. It is composed of one or more sounds, and is referenced through a sound bank.

Simple Audio Playback

The simplest way to play sounds for background music or sound effects is to use [SoundEffect](#) and [SoundEffectInstance](#). Source audio files are added to the project like any other game assets. For example code, see [How To: Play a Sound](#), [How To: Loop a Sound](#), and [How To: Change the Pitch or Volume of a Sound](#). For background music, see [How To: Play a Song](#).

[SoundEffect](#) and [SoundEffectInstance](#) are available on Windows, the Xbox 360, and Zune. However, these APIs are the only audio option on Zune.

Introducing XACT

XACT is at the heart of the XNA Framework Audio API. XACT combines two things. It combines a powerful graphical tool for authoring audio content with an API that is responsible for interpreting the authored XACT files and playing audio in response to game events. It is expected that core audio elements (waves) will be fully developed before using XACT.

Getting Started with XACT

Not all features of XACT are necessary for a game title that uses simple audio playback. To learn how to create a simple XACT project that contains only a few wave files, see [How To: Add a Sound File to Your Game Using XACT](#). To learn how to load and play cues from the XACT project you have built, see [How To: Play a Sound Using XACT](#). To create simple sound effects without using XACT at all, see [How To: Play a Sound](#).

What XACT Does

As a GUI-driven audio content creation system, XACT enables audio designers to load wave files into groups, organize the files into discrete *cues* that can be activated by in-game events, and create transitions between cues. XACT also enables designers to define variables that can be changed in-game to modify audio settings. With these advanced tools, an audio designer might, for example, design a set of car engine sounds for a racing game, and through the use of a variable, cause the car engine sounds to increase or decrease in pitch and volume as the variable is controlled in-game by the XACT engine.

To get started using XACT

1. Click the **Start** menu, and then click **All Programs**.
2. Click the **XNA Game Studio** folder, then **Tools**, and then click **Microsoft Cross-Platform Audio Creation Tool (XACT)**.

For detailed information about how to author audio in the XACT tool, including information about categories, variables, and other advanced features, see [XACT Audio Authoring](#).

Programming for XACT

Once you create an XACT project and save it as an .xap file, add the .xap file and any wave files the XACT project uses as input to your XNA Game Studio game. The Content Pipeline will build the needed files for you to access your content at run time.

An XACT project builds a set of files: a global settings file (.xgs), one or more wave banks (.xwb), and one or more sound banks (.xsb). These files may be provided to [AudioEngine](#), [WaveBank](#), and [SoundBank](#) constructors, respectively.

To initialize the XACT engine, you must create a new [AudioEngine](#), and provide the path to the global settings file. Then, load any wave banks you need by creating new [WaveBank](#) objects, and load any sound banks that you need by creating [SoundBank](#) objects. Once you load the necessary files, you can access cues created by the audio designer by calling [GetCue](#) on the [SoundBank](#) that contains the [Cue](#) that you want to retrieve. Each [Cue](#) instance that you retrieve is unique, even when you retrieve multiple cues with the same name. This allows multiple instances of the same [Cue](#) to exist and play simultaneously.

You can play, pause, resume, and stop [Cue](#) objects by using the [Play](#), [Pause](#), [Resume](#), and [Stop](#) methods, respectively. See [How To: Play a Sound Using XACT](#) for information about how to play a cue. For more information about how to pause, resume, and stop cues, see [How To: Stop or Pause a Sound Using XACT](#).

Periodically, you must call [Update](#) to allow the audio engine to process audio data.

For more advanced projects, you can also access [AudioCategory](#) objects for controlling the playback of sound categories by calling [AudioEngine.GetCategory](#). Also, to access variables that the audio designer has tied to playback changes in volume, pitch, or DSP effects, you can call [AudioEngine.GetGlobalVariable](#). For more information about how to use categories to change sound volume levels, see [How To: Change Sound Volume Levels Using XACT](#).

3D Audio

Both the [Cue](#) and [SoundEffect](#) classes provide the ability to place audio in a 3D space. By creating an [AudioEmitter](#) and [AudioListener](#) object, both sound playback APIs can position a sound in 3D, and change the 3D position of a sound during playback. Once you create and initialize the [AudioEmitter](#) and [AudioListener](#), call [Cue.Apply3D](#) or [SoundEffectInstance.Apply3D](#).

Attenuation and Doppler Pitch Shifting Overview

Provides an overview of attenuation and Doppler pitch shifting.

Attenuation

In 3D audio, *attenuation* refers to volume attenuation—the effect of having volume fade with distance between emitter and listener. By default, XACT does not automatically apply volume attenuation as a result of calculating distance, or Doppler effect as a result of relative emitter and listener velocity.

The programmer controls the position and velocity of game objects, and the sound designer determines how that affects sound. Because XACT is designed to partition and simplify the work of the programmer and sound designer, XACT determines emitted sound by combining effects specified by the sound designer with positional information supplied by the game.

XACT exposes variables as placeholders for runtime game information such as position and velocity. The sound designer uses XACT RPCs to define the relationships between those variables and sound effects. The variables are then set at run time, either by the game or by XACT itself, and produce the desired sounds.

The project tree region of the XACT tool shows the available variables:

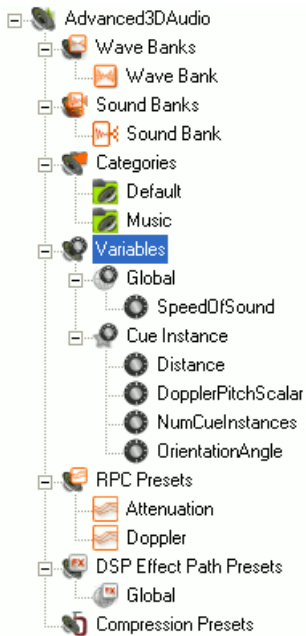

Figure 1. XACT Variables

Global variables are shared by all active sound cues. Only one of each global variable exists, and it is persisted the entire time the game is running. In contrast, a separate copy of each cue instance variable exists for every active cue. Cue instance variables persist only for the lifetime of an individual cue instance.

Global variables allow multiple audio elements to be controlled together. Cue instance variables provide individual control or information for each instance of a cue, and for each copy of the same cue.

Figure 2. Cue Instance Variables

The variables used for 3D audio effects are the cue instance variables *Distance*, *DopplerPitchScalar*, and *OrientationAngle*. XACT updates these variables automatically for the cue when the game calls [Apply3D](#).

The variables provide the following information.

Variable	Description
<i>Distance</i>	The distance between the emitter and listener.
<i>DopplerPitchScalar</i>	A value calculated by comparing the relative velocities of the emitter and listener; used for Doppler pitch shifting.

<i>OrientationAngle</i>	The angle difference between the emitter and listener.
-------------------------	--

XACT updates the cue's *Distance* variable. However, by default, it does not adjust the volume for that cue. It isn't the developer's job to try to determine and set the appropriate volume. Instead, the sound designer defines the attenuation, which is the relationship between distance and volume. To do so, the designer uses the XACT tool to create an RPC. An RPC defines the mapping between an input variable, such as *Distance*, and an output parameter, such as sound volume.

The programmer might be tempted to query distance with `Cue.GetVariable("Distance")`, and then, based on distance, try to set the volume of the cue. However, volume can normally be set only for categories of cues, defined by the sound designer. See [How To: Change Sound Volume Levels Using XACT](#). The game code would also have to calculate the proper volume change based on distance. To avoid these issues, simply use an RPC as described in this topic and let XACT perform attenuation automatically, as designed.

Defining the Distance Scale

To define the Distance scale

1. Click once on the **Distance** variable in the tree.

The properties pane, below the project tree, will display properties for the *Distance* variable. Look for the section named **General**.

2. Inside the **General** section, find **Variable Range**.

The left box is the minimum value, and the right box is the maximum value.

3. Enter values into these boxes that are appropriate to the game's world scale (or whatever scale is used when calling [Apply3D](#)).

Distances outside the specified range are clamped to the range. The designer need not worry about extreme values when determining the curve. For example, a game uses a 1 m (one meter) game scale, and sounds trail off completely near 1000 m. The minimum value would be 0, and the maximum value would be 1000.

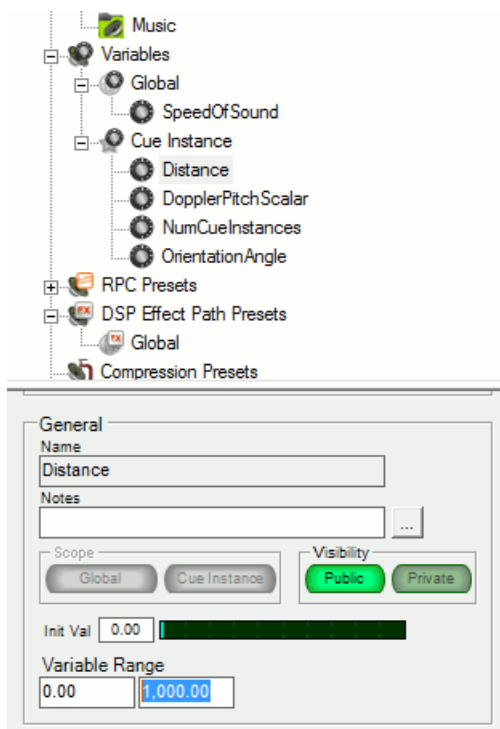

Figure 3. The Variable Range

Creating a Distance::Volume RPC

To create a Distance::Volume RPC

1. Right-click the **RPC Presets** node in the project tree, and select **New RPC Preset**.

XACT creates and displays a new RPC, and opens it for editing.

2. Set the **Variable** drop-down to **Distance** (the default is *OrientationAngle*).
3. Set the **Object** drop-down to **Sound**.

- Set the **Parameter** drop-down to **Volume**.

The RPC now adjusts volume based on distance. However, the curve is created flat, which means that volume will remain constant over distance. To change that, and define the attenuation, you must adjust the curve. In the curve plot window, distance is on the x-axis and volume, in decibels, is on the y-axis. To attenuate over distance, Y (volume) should decrease as X (distance) increases.

- To create a new control point, double-click anywhere on the plot line.

The curve is split and a new adjustable control point is added.

- Add and adjust as many curve points as needed to define the attenuation.

Different sounds may have different attenuation characteristics. These two example curves produce significantly different attenuation. The first creates a simple constant ramp from full volume (+0 dB) to silence (-96 dB) over the full distance range. The second has a fast rolloff after a short distance, then a fade out to full distance.

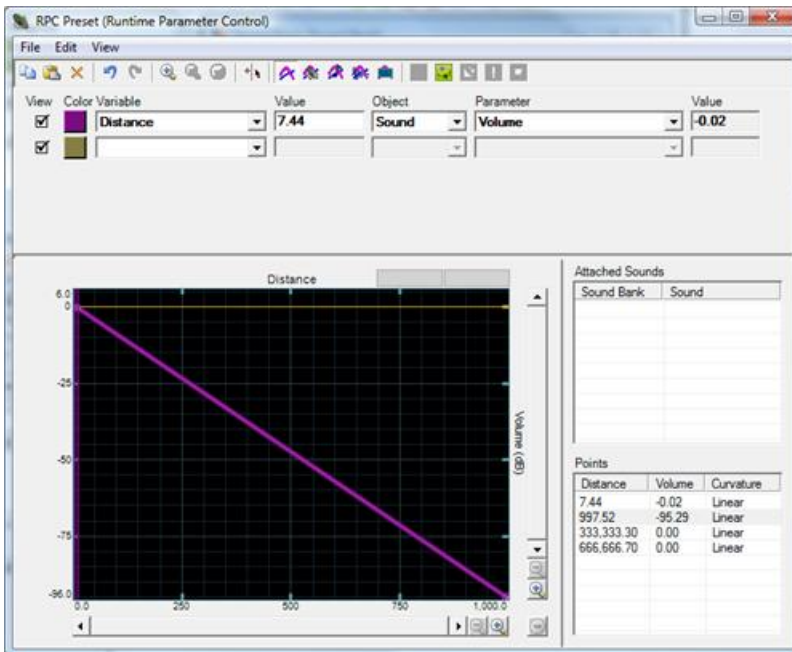

Figure 4. Attenuation RPC (Constant Rolloff)

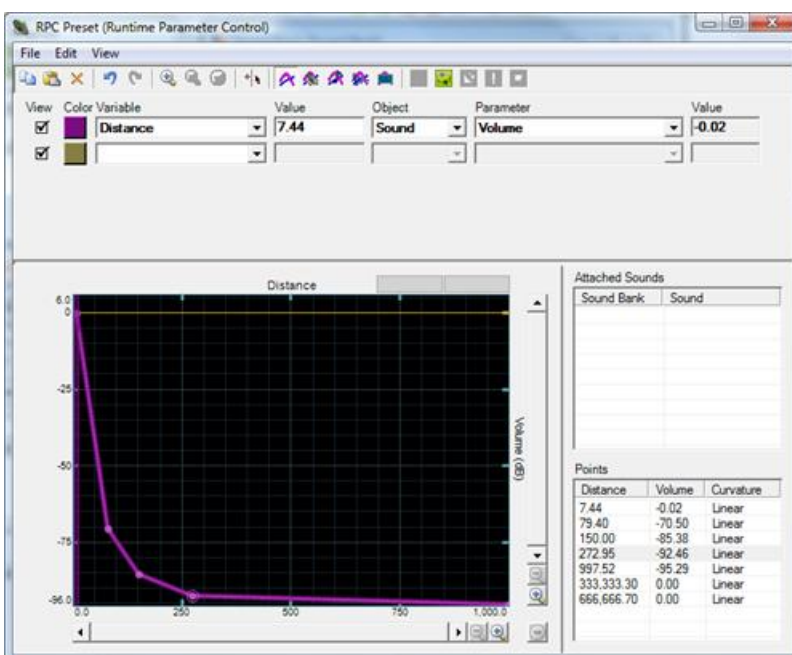

Figure 5. Attenuation RPC (Quick Rolloff)

- When finished, close the RPC window.

The new RPC is called "RPC Preset," but it can be renamed (for example, to "Attenuation") to make it easier to find in the

RPC list. The name given to the RPC does not affect the RPC or the game code.

8. To rename the RPC, right-click it and click **Rename**.

Applying the RPC to Sounds

To apply the RPC to sounds

The RPC is now defined, but no sounds are configured yet to use it. By default, sounds do not use any of the defined RPCs. Some sounds will not need attenuation (for example, narration or tutorial instructions), while others may need several different RPC effects.

1. Double-click on a sound bank listed in **Sound Banks** in the project tree.

The sound bank opens, showing the sounds and cues defined in that bank.

2. From **RPC Presets** in the project tree, drag the desired RPC onto the sound that will use that RPC.

Do this for as many sounds as will use the attenuation effect. You can apply more than one RPC to a sound. RPC curves that modify elements such as pitch and volume are additive, so if multiple parameters influence the sound, their results will be combined.

Removing an RPC from a Sound

To remove an RPC from a sound

1. To remove an RPC from a sound, either right-click the sound and click **Attach/Detach RPC(s)**, or right-click the RPC in the project tree and click **Attach/Detach Sounds**.
2. Right-click the sound and click **Attach/Detach RPC(s)**.

At this point, the attenuation RPC is defined and applied to the appropriate sounds. XACT will now use the curve to adjust emitter volume based on the distance between emitter and listener. Game code sets the [AudioEmitter.Position](#) and [AudioListener.Position](#) properties to specify the 3D location of the game objects. When the code then calls [Apply3D](#), XACT adjusts volume appropriately. See [How To: Apply Basic 3D Positional Effects to a Cue](#) for a description of the steps needed to use 3D positioning in a game.

Doppler Pitch Shifting

Doppler pitch shifting is the pitch shifting effect when a listener and an emitter are moving towards or away from each other. The relative velocities of the emitter and listener are compared and the result used to pitch up or down the emitter's sound.

Doppler pitch shifting is applied to sounds in the same way that attenuation is, except that the RPC adjusts pitch based on relative velocity rather than adjusting volume based on distance. The Doppler RPC ties the *DopplerPitchScalar* input variable to the *Sound::Pitch* output parameter.

Adding Doppler Pitch Shifting

To add doppler pitch shifting

1. Set the scale of the *DopplerPitchScalar* variable.

The default scale of 0–4 is appropriate, so leave **MinimumValue** at 0 and **MaximumValue** at 4.

The scale of *DopplerPitchScalar* is not based on the velocity scale used by the game. Instead, this value is the result of an XACT calculation to determine the pitch adjustment that should be applied due to Doppler effect. 0 indicates down 1 octave, 1 indicates unity pitch, and 4 indicates up 2 octaves.

2. To create a new RPC, right-click **RPC Presets**, and then click **New RPC Preset**.
3. Set **Variable** to **DopplerPitchScalar**, **Object** to **Sound**, and **Parameter** to **Pitch**.
4. Define the Doppler curve effect.

The y-axis is the pitch, in semitones, and ranges from down one octave (–12 semitones) to up one octave (+12 semitones).

For normal Doppler effect, the beginning of the curve would look like this:

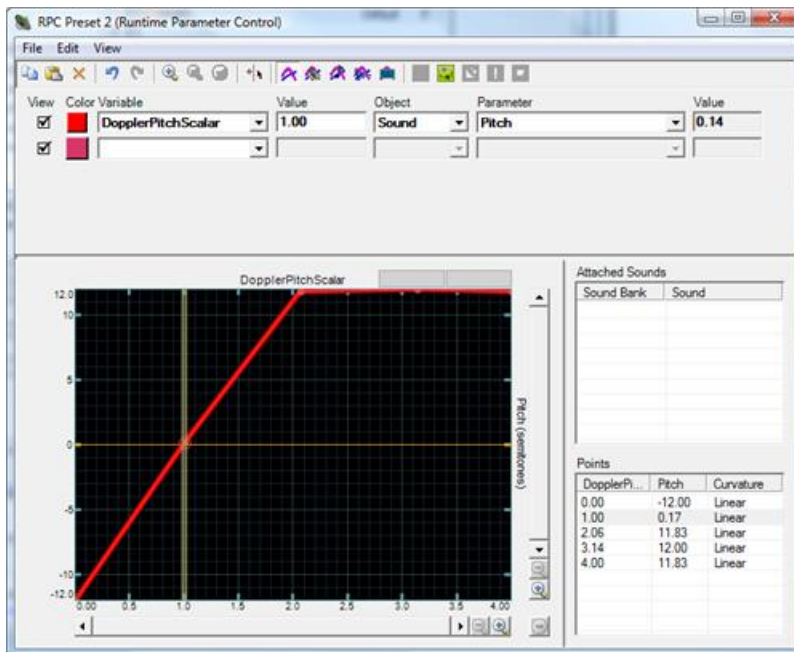

Figure 6. Doppler RPC

However, this curve limits the effect to +12 semitones. To enable a wider range effect, make the curve half as steep (+12 semitones at 4.0 rather than 2.0) and set the emitter's Doppler scale ([AudioEmitter.DopplerScale](#)) to 2.0f.

5. Close the RPC window and, if desired, rename the RPC.
6. To associate the RPC with sounds, open the sound bank, and then drag the RPC from the project tree onto the desired sound or sounds.

Code Changes to Support Doppler Pitch Shifting

XACT derives *DopplerPitchScalar* based on the relative velocities of the emitter and listener. The game informs XACT of these velocities by setting the [AudioListener.Velocity](#) and [AudioEmitter.Velocity](#) properties before calling [Apply3D](#).

The [AudioEmitter.DopplerScale](#) property can be used to exaggerate (values > 1.0) or diminish (values < 1.0) the Doppler effect.

The following example moves an object left and right. The gamepad triggers can be used to turn emitter and listener velocities on and off. Combined with an XACT project that defines RPCs as described in this topic, the code demonstrates the steps needed to enable attenuation and Doppler effects.

How To: Play a Sound

Demonstrates how to play a sound.

To play a sound without using XACT, use the [SoundEffect](#) or [SoundEffectInstance](#) classes. Using these classes is simpler than using XACT and the classes required by XACT.

Because XACT is not available on Zune, the [SoundEffect](#) and [SoundEffectInstance](#) will be the only option for Zune games.

[SoundEffect](#) and [SoundEffectInstance](#) are also available for Xbox and Windows XNA games.

The [SoundEffect.Play](#) method allows you to specify the pitch and volume of a sound for playing the sound. However, after you call [Play](#), you cannot modify the sound. Using [SoundEffectInstance](#) for a given [SoundEffect](#) allows you to change the pitch and volume of a sound at any time during playback.

Simple Sound Manipulation

1. Declare a [SoundEffect](#) using the method shown in [How To: Play a Sound](#).
2. Declare a [SoundEffectInstance](#), and set it to the return value of [SoundEffect.CreateInstance](#).

C#

```
SoundEffect soundEffect;  
SoundEffectInstance soundInstance;  
protected override void LoadContent()  
{  
    soundEffect = Content.Load<SoundEffect>("tx0_fire1");  
    soundInstance = soundEffect.CreateInstance();  
}
```

3. Call [SoundEffectInstance.Play](#) to play the sound.

C#

```
if (playerOne.Buttons.A == ButtonState.Pressed)  
{  
    // Play Sound  
    soundInstance.Play();  
}
```

4. Set [Pitch](#) and [Volume](#) to the desired values.

C#

```
// Pitch takes values from -1 to 1  
float pitch = playerOne.ThumbSticks.Left.X;  
// Volume only takes values from 0 to 1  
float volume = (playerOne.ThumbSticks.Right.X+1)/2;  
  
soundInstance.Pitch = pitch;  
soundInstance.Volume = volume;
```

How To: Apply Basic 3D Positional Effects to a SoundEffect

Demonstrates how to apply 3D positioning effects to SoundEffects.

The XNA Framework audio system contains support for 3D audio positioning effects. It uses the [AudioEmitter](#) and [AudioListener](#) classes, and the [SoundEffectInstance.Apply3D](#) method. The effects simulate 3D positioning for sound by adjusting speaker mix for cues that use the 3D values.

Note that speaker mix is the only effect that will be applied automatically using this method.

The Complete Sample

The following example uses a circular rotation around a stationary [AudioListener](#) to emphasize the 3D effect.

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

Applying Basic 3D Positional Effects to a SoundEffect

To retrieve and play a SoundEffect in 3D

1. Add a WAV file to a new XNA Game Studio project as described in [How To: Play a Sound](#).
The project should contain at least one [SoundEffect](#).
2. In code, create a [SoundEffectInstance](#) for the [SoundEffect](#) when it is initially loaded.
3. Create an [AudioEmitter](#), an [AudioListener](#), and a [Vector3](#) to store the 3D position of the sound entity.
4. Load the [SoundEffect](#), and create a [SoundEffectInstance](#) to play the sound.
5. Call [Apply3D](#) on the [SoundEffectInstance](#), passing the emitter and listener.
6. Call [Play](#) to play the sound. Set the [IsLooped](#) property to true before calling [Play](#) if you want the sound to repeat.

To process audio data

1. Set the [Vector3](#) to the position from which you want the sound to come.
2. Set the [AudioEmitter.Position](#) property to this vector.
3. As an option, set the [Vector3](#) to the position where you want the listener of the 3D sound to be, and then set the [AudioListener.Position](#) property to this vector.
4. Call [SoundEffectInstance.Apply3D](#) on the cue object you retrieved previously, passing in the [AudioEmitter](#), which is an [AudioListener](#).

Note

Calling the [SoundEffectInstance.Apply3D](#) method automatically sets the speaker mix for any sound played by this sound effect to a value calculated by the difference in [Position](#) values between *listener* and *emitter*. In preparation for the mix, the sound is converted to monoaural. Any stereo information in the sound is discarded.

How To: Add a Sound File to Your Game Using XACT

Demonstrates how to add wave (.WAV) files to an XACT project that can be built and interpreted by an XNA Game Studio game to play audio.

For detailed information about how to author audio in the XACT tool, including information on categories, variables, and other advanced features, see [XACT Audio Authoring](#).

Adding a Sound File to Your Game

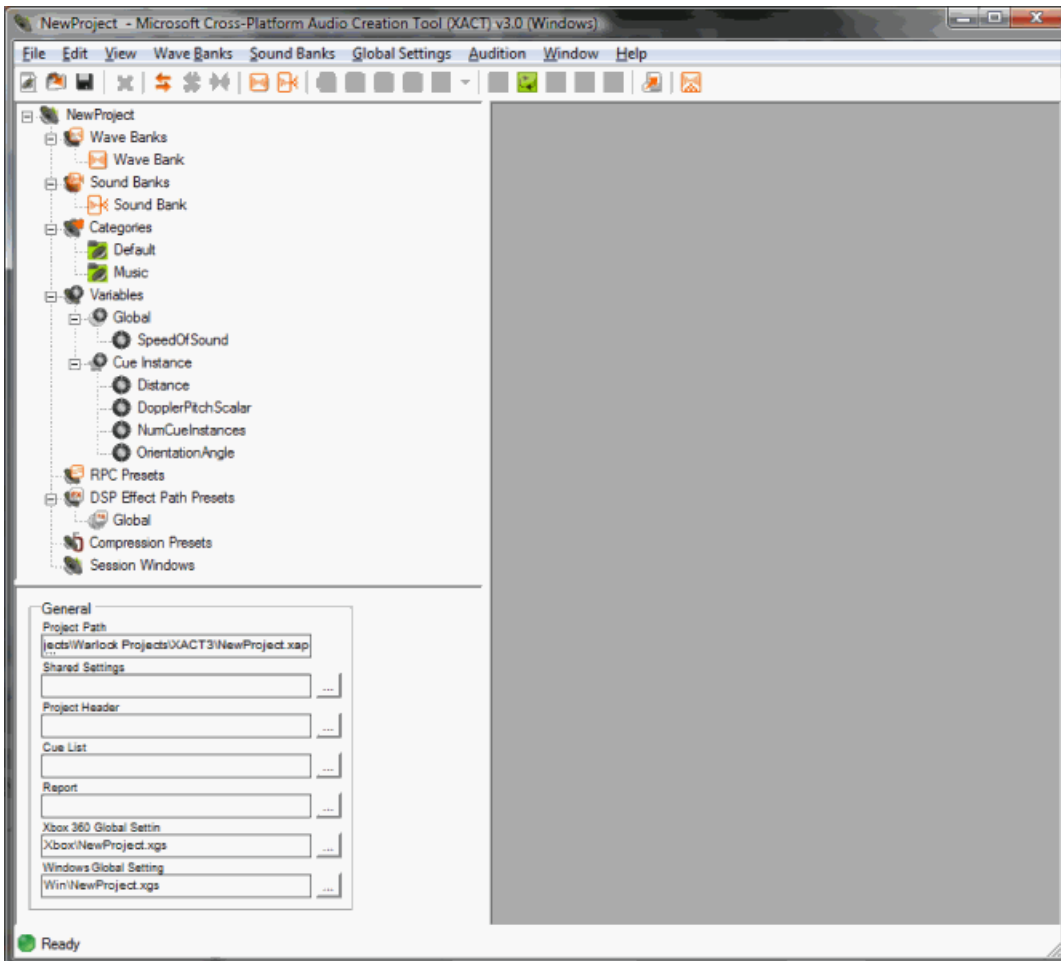

To create a wave bank and a sound bank

1. From the **Start** menu, click **All Programs**, click **XNA Game Studio 3.1**, click **Tools**, and then click **Microsoft Cross-Platform Audio Creation Tool (XACT)**.
2. To create a new project, click the **File** menu, and then click **New Project**.

You will be asked for a location and a name for your project.

3. Enter a name and a location that is easy for you to remember, and click **OK**.

The project will be created, and the screen will resemble the following:

4. In the empty project, create a wave bank. To do this, click **Wave Banks**, and then click **New Wave Bank**.

A new wave bank appears in the tree view under Wave Banks with the default name "Wave Bank."

5. Press **ENTER** to accept the default name.

6. To create a new sound bank, click **Sound Banks**, and then click **New Sound Bank**.

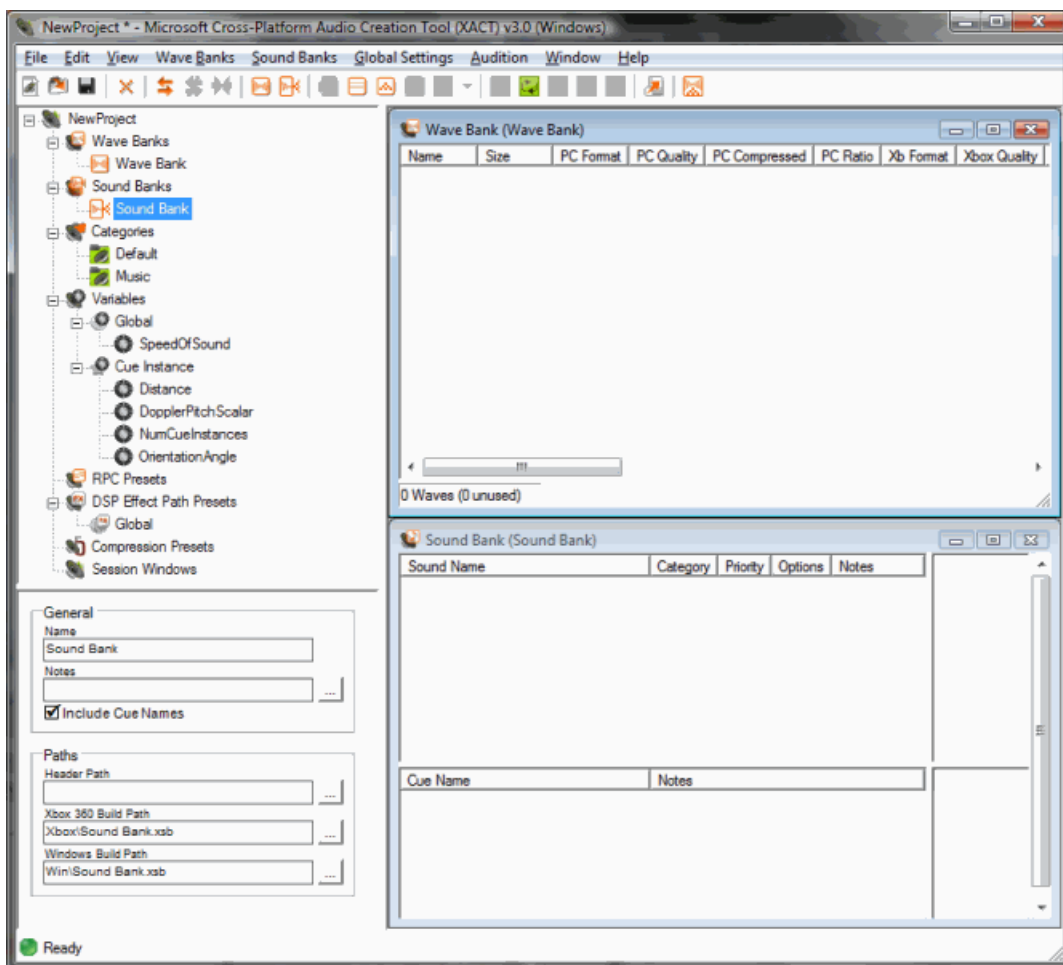

A new sound bank appears in the tree view under Sound Banks with the default name "Sound Bank."

7. Press **ENTER** to accept the default name.

At this point, two new windows have appeared: one for the wave bank and one for the sound bank.

8. To arrange these windows for easier viewing, click **Window**, and then click **Tile Horizontally**.

The windows should now look similar to the following:

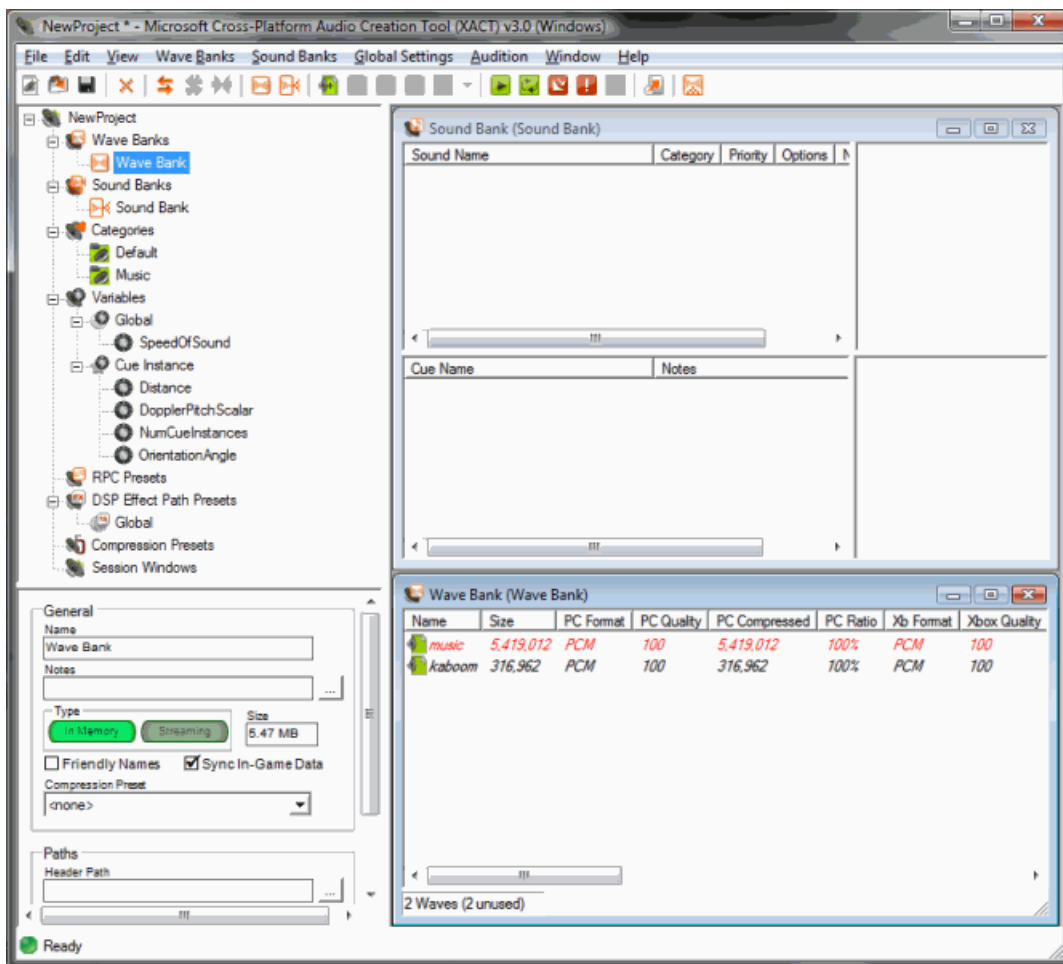

To add wave files to the wave bank window

Now you need to add your wave file to the wave bank window.

1. To make sure the wave bank window is active, click **Wave Banks**, and then click **Insert Wave File(s)**.
2. Insert one or more wave files into the wave bank.

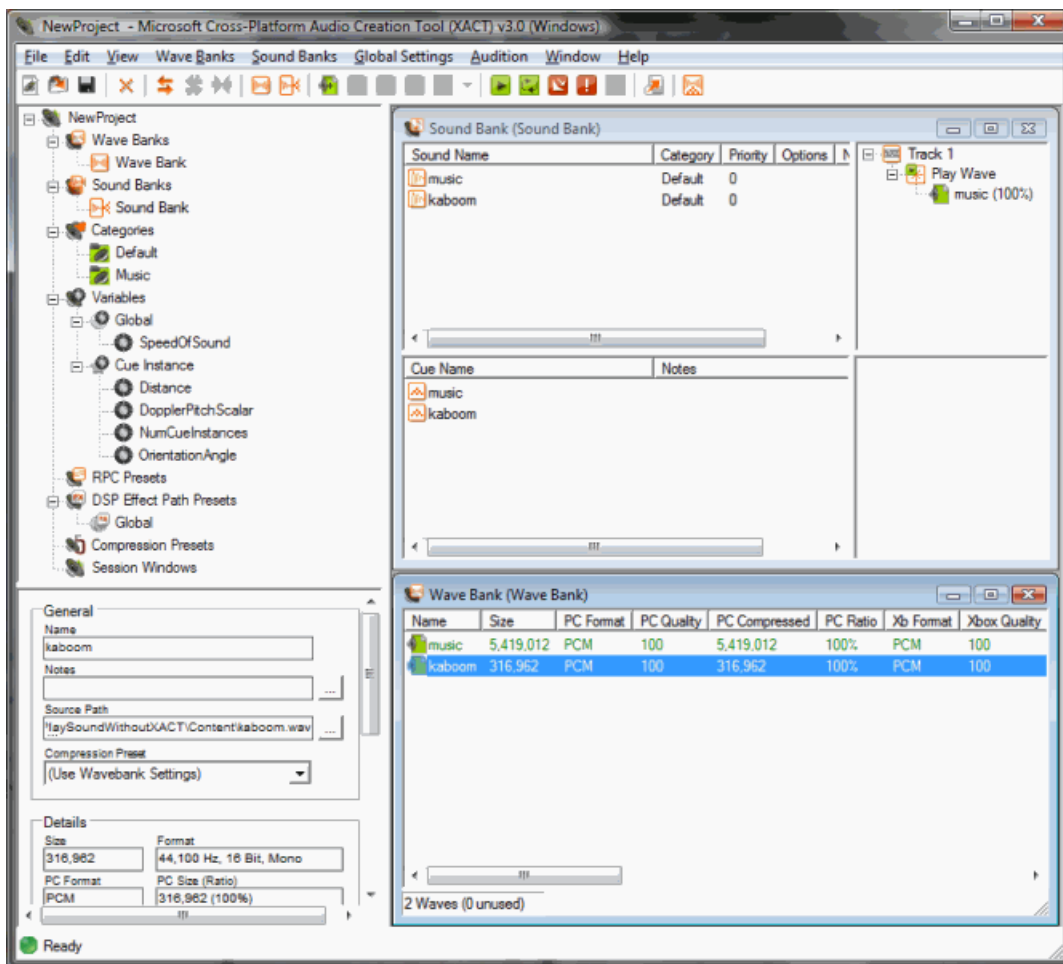

If you successfully added them, they will look similar to the following wave bank window:

Now you need to perform the following step for each wave listed in the wave bank window.

- For each wave listed in the wave bank window, drag the wave from the wave bank window to the sound bank window, and then drop the wave on top of the **Cue Name** panel.

XACT automatically creates a new cue that is linked to a new sound that plays this wave file. It should look similar to the following:

4. If the lower-left corner of the sound bank window does not have any entries, add entries to it by dragging each sound from the upper-left panel of the sound bank to the lower left panel of the sound bank.

This action creates cues that correspond to the sounds.

5. To save the project, click **File**, and then click **Save Project**.

6. Click **File**, and then **Build...** to build your project.

You are now ready to load and play sounds from this project in your game. See [How To: Play a Sound Using XACT](#) for information on how to do this.

Each [Cue](#) instance that you play is unique, even when you play multiple cues with the same name. This enables you to play multiple instances of the same [Cue](#) simultaneously.

Playing a Sound

To insert the desired .xap file into your project

1. With your XNA Game Studio game loaded in Visual Studio, right-click your content icon in the Solution Explorer pane.
2. Click **Add**, click **New Folder**, and then name the new folder "Audio."
3. Move your XACT project file (.xap) and .wav file or files into the new "Audio" file created in the previous step.

The new folder will exist in the Content folder, under your game project folder.

4. Again, with your XNA Game Studio game loaded in Visual Studio, right-click the Audio file the Solution Explorer pane.
5. Click **Add**, and then click **Existing Item**.
6. Select the .xap file from the Audio folder.

The .xap file is then inserted into your project. By default, it is processed by the content pipeline, and built wave and sound banks are accessed automatically when the game is built.

7. Edit your game code.

When following these steps and using the above code, be sure your file names match those given in the example.

To play the sound

1. When your game starts, create a new [AudioEngine](#).
2. Pass in the name of the XACT global settings file output by the XACT project file.
Make sure the name includes an .xgs extension.
3. For each wave bank in your XACT project, create a new [WaveBank](#), and then pass in the audio engine and the name of the XACT wave bank file output by the XACT project file.
Make sure the name includes an .xwb extension.
4. For each sound bank in your XACT project, create a new [SoundBank](#), and then pass in the audio engine and the name of the XACT sound bank file output by the XACT project file.
Make sure the name includes an .xsb extension.
5. During game update, call the [Update](#) method of the [AudioEngine](#) to allow the audio engine to process audio data.
6. Call the [PlayCue](#) method from your [SoundBank](#), and then pass in the name of the cue you wish to play.

How To: Specify Background Music Using XACT

Demonstrates how to specify sound (.WAV) files as background music. Specifying background music enables the XNA Framework to override the background music with the user's music choice, without interrupting other game sounds such as sound effects. This is accomplished by setting the sound bank *category* to *music* in XACT.

Note

Streaming allows for the .WAV file to be gradually read from the disk rather than loaded into memory all at once. Background music files may be larger than files containing other game sounds; therefore, typically they are streamed. In XACT, you need to create and use a streaming [WaveBank](#) to stream background music. To learn about streaming, see [How To: Stream a Sound Using XACT](#).

Specifying Background Music in Your Game

This procedure assumes you have already created an XACT project.

To specify background music in your game

1. To open the XACT project, choose the **File** menu, and then click **Open Project**.
2. Browse to your project location, and click **Open**.

The project will load.

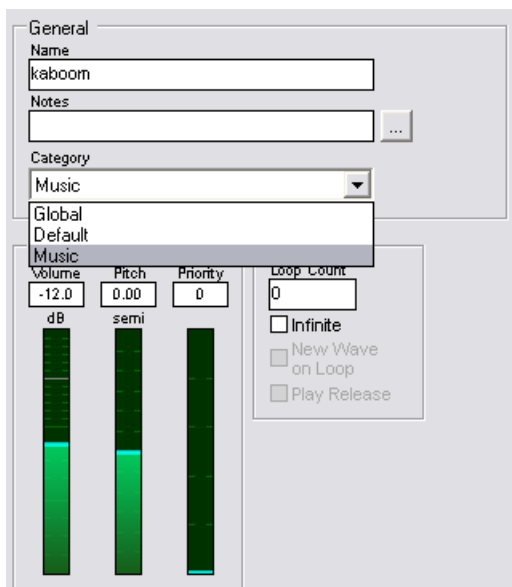

3. Double-click the sound bank that contains the background music.

This highlights the sound bank in the left navigation tree, and displays the sound bank properties pane.

4. Click the sound you wish to designate as background music.

This displays the properties pane, and then shows the category options for the sound.

5. Select **music** in the **category** drop down box, and save the project.

Playing, Pausing, or Stopping a Sound

To play, pause, or stop a sound

1. Create an [AudioEngine](#), [WaveBank](#), and [SoundBank](#) at game start.
2. During game update, call the [Update](#) method of the [AudioEngine](#) to enable the audio engine to process audio data.
3. Retrieve a cue you want to play by calling [SoundBank.GetCue](#), and then store the returned cue value.
4. To play a cue, pause a cue, or stop a cue, call these methods: To play the cue, call [Cue.Play](#); to pause the cue, call [Cue.Pause](#); and to stop the cue entirely, call [Cue.Stop](#).

How To: Change Sound Volume Levels Using XACT

Demonstrates how to initialize the audio engine and how to use categories to change the playback volume of a group of sounds.

Categories control the sound volume levels for groups of sounds in XACT. These categories are collections that can hold one or more references to cues. Global variables linked to runtime parameter controls (RPC) within the XACT project control the individual cue volumes. This topic explains how to use categories to control the volume of groups of sounds.

For more information about using global variables and RPCs, see [XACT Variables](#) and [XACT Runtime Parameter Controls](#). For more information on creating categories within your XACT project, see [Making XACT Categories](#). To see how XACT automatically adjusts the volume based on distance, see [How To: Apply Attenuation and Doppler 3D Audio Effects](#).

Changing Sound Volume Levels

To change sound volume levels

1. Create an [AudioEngine](#), [WaveBank](#) and [SoundBank](#) at game start.
2. During game update, call the [Update](#) method of the [AudioEngine](#) to allow the audio engine to process audio data.
3. To retrieve a category of sounds whose volume you want to change, call [AudioEngine.GetCategory](#), and then pass in the name of the category you created in the XACT project.

4. Call [AudioCategory.SetVolume](#) on the retrieved category.

5. Specify the desired volume.

Typically, your preferred volume will be between 0.0f (silence) and 1.0f (full volume, as authored).

6. To make the volume louder than designed, pass in values greater than 1.0f.

For example, a volume of 2.0f adds +6 dB to the authored level.

Latency

In this context, *latency* is the amount of time that a device takes to retrieve waves from memory and subsequently play the sound. If latency is substantial, it can cause delays in audio playback, or possibly it can interrupt game sounds altogether.

Why Stream?

A wave bank may be designated as *in-memory*, which means all of the waves are loaded from the storage medium into game memory. Otherwise, a wave bank may be designated as *streaming*, which means that waves remain stored on disk. When a wave bank is designated as streaming, the sound information is delivered to the game through in-memory buffers. This is useful for sounds that are too large or too long to completely load into working memory. Streaming allows a game developer to effectively use large amounts of audio data without using too much memory.

When to Stream

Most often it is better to store wave banks in-memory. When waves are in-memory, the playback of the sound always occurs without latency. However, in cases when the sounds are too large to load into memory, a streaming wave bank may be a better choice. For example, this could be the case with background music that is much longer than other game sounds, such as short sound effects.

Creating a Streaming Wave Bank

Using XACT

The process for creating the streaming wave bank in XACT is the same as the process described in [How To: Add a Sound File to Your Game Using XACT](#), with the exception of one step. When creating the new wave bank, select the *streaming* option in the dialog box.

In Code

You can create a streaming wave bank by using the [WaveBank \(AudioEngine, String, Int32, Int16\)](#) constructor that requires two streaming-related parameters: *offset* and *packet size*. An offset of zero will start the stream at the beginning of the wave file. Packet size determines how much memory a streaming wave bank uses for buffering. A smaller packet size will result in smaller amounts of data streaming through the buffer at any given time. A larger packet size indicates a larger amount of data moving through the buffer. Ideally, a game developer will specify a packet size that uses the least amount of memory, while at the same time allows for uninterrupted sounds during game play.

Note

Before you execute code to play any sounds, you must call the [Update](#) method of the [AudioEngine](#) that was used to create the streaming wave bank. Calling the **Update** method prepares the streaming wave bank for use. If you try to use the wave bank before you call the Update method, an **InvalidOperation** exception will be thrown.

How To: Apply Basic 3D Positional Effects to a Cue

Demonstrates how to apply 3D positioning effects to cues.

The XNA Framework audio system contains support for 3D audio positioning effects. It uses the [AudioEmitter](#) and [AudioListener](#) classes, and the [Cue.Apply3D](#) method. The effects simulate 3D positioning for sound by adjusting speaker mix for cues that use the 3D values.

Note that speaker mix is the only effect that will be automatically applied using this method. Attenuation and Doppler-shift pitch modification effects must be applied via creation of runtime parameter controls (RPC) in the Microsoft Cross-Platform Audio Creation Tool (XACT). See [How To: Apply Attenuation and Doppler 3D Audio Effects](#) and [Apply3D](#) for more information.

The Complete Sample

The following example uses a circular rotation around a stationary [AudioListener](#) to emphasize the 3D effect.

Applying Basic 3D Positional Effects to a Cue

To retrieve and play a cue in 3D

1. Create an XACT project and add it to a new XNA Game Studio project as described in [How To: Add a Sound File to Your Game Using XACT](#).
The project should contain at least one cue.
2. In code, create an [AudioEngine](#), [WaveBank](#), and [SoundBank](#) at game start.
3. Create an [AudioEmitter](#), an [AudioListener](#), and a [Vector3](#) to store the 3D position of the sound entity.
4. In the [Game.Initialize](#) method, load the [AudioEngine](#), [WaveBank](#), and [SoundBank](#).
5. Call [SoundBank.GetCue](#) to retrieve the [Cue](#) you want to play in 3D.
6. Call [Cue.Apply3D](#) on the cue you retrieved in the previous step.
7. Call [Cue.Play](#) to begin playback of the cue.

Note that you must have called [Apply3D](#) on the cue first. Otherwise, the next call to [Apply3D](#) will throw an exception.

To process audio data

1. During game update, call the [Update](#) method of the [AudioEngine](#) to enable the audio engine to process audio data.
2. Set the [Vector3](#) to the position from which you want the sound to come.
3. Set the [AudioEmitter.Position](#) property to this vector.
4. As an option, set the [Vector3](#) to the position where you want the listener of the 3D sound to be, and then set the [AudioListener.Position](#) property to this vector.
5. Call [Cue.Apply3D](#) on the cue object you retrieved previously, passing in the [AudioEmitter](#), which is an [AudioListener](#).

Note

Calling the [Cue.Apply3D](#) method automatically sets the speaker mix for any sound played by this cue to a value calculated by the difference in [Position](#) values between *listener* and *emitter*. In preparation for the mix, the sound is converted to monoaural. Any stereo information in the sound is discarded.

How To: Apply Attenuation and Doppler 3D Audio Effects

Demonstrates how to apply attenuation and Doppler 3D positioning effects in code.

Introduction

This topic builds on [How To: Apply Basic 3D Positional Effects to a Cue](#), which discusses the steps required to add 3D audio to your game. This topic introduces concepts such as XACT projects, the audio engine, cues, and emitter and listener positions.

3D game audio typically implements at least three effects: speaker positioning, volume attenuation over distance, and Doppler pitch shifting. The basic 3D audio how-to discusses speaker positioning. This topic explains how to add attenuation and Doppler effects to 3D audio.

At design time, the sound designer defines the attenuation and Doppler effects and applies them to specific sounds. The designer uses XACT Runtime Parameter Controls (RPC) to specify the relationships between game information, exposed as XACT variables, and resulting sound effects. To determine final attenuation and Doppler effects at run time, the XACT engine combines the designer's effects with calculations based on position and velocity of the audio source and listener.

Sound designers can add attenuation without requiring any additional code changes by the developer (assuming that the game already sets the emitter and listener positions). However, Doppler effect requires that XACT know the velocity of the emitter and listener. Therefore, the game must set the [AudioEmitter.Velocity](#) and [AudioListener.Velocity](#) properties.

Media Overview

Describes how the [Microsoft.Xna.Framework.Media](#) namespace provides support for browsing or searching media items in XNA Game Studio. Media is a general term referring to all media on the local system.

Discovery and Enumeration

A game can query strongly-typed media collections for songs, artists, albums, playlist, genres, pictures, and picture albums using the [Microsoft.Xna.Framework.Media](#) namespace. See [How To: Show Pictures](#) for an example. Items in the media library can also be searched based on metadata such as artist name, album name, or musical genre.

Songs as Background Music

Access to the media library, combined with the ability to use playlists, allows games to create interesting background scores that can change with game play. Songs can be played directly from the media library, or imported using the content pipeline.

Pictures as Textures

Games can obtain and use textures from pictures within a media library.

Video Playback

Games can now add videos to their projects using the content pipeline, and display those videos on screen. These videos can be displayed as cutscenes or loading graphics, or as part of an object in 3D space.

To add a video to a project, use the steps outlined in "How To Load Content," and select a WMV file to import. The video content processor that comes with XNA Game Studio has a few limitations:

1. Videos with Digital Rights Management enabled cannot be used.
2. The video must be encoded to the WMV-9 "Main" profile using the VC-1 standard.
3. The video must be encoded with a constant bit rate (CBR).
4. There must be an audio track in the video.
5. The audio accompanying the video must be Windows Media Audio (WMA) encoded, with a single-pass CBR format.
6. XNA Game Studio supports the following maximum bit rates:

Profile	Level	Maximum Bit Rate	Representative Resolutions by Frame Rate
Main	Low	2 Mbps	320 × 240 @ 24 Hz (QVGA)
	Medium	10 Mbps	720 × 480 @ 30 Hz (480p) 720 × 576 @ 25 Hz (576p)
	High	20 Mbps	1280 × 720 @ 30 Hz (720p)

A video must have an audio track or it will fail to load. If it fails to load, this message appears: "Video file is invalid. Please make sure that the video is not DRM protected and is a valid single-pass CBR encoded video file."

Once a video is loaded, games can create a new [VideoPlayer](#) object to play, pause, and resume the video. Once the video has started playing, the game can call the [GetTexture](#) method to get a [Texture2D](#) containing the current frame of video. That texture can be used by [SpriteBatch.Draw](#) or rendered by an Effect as part of an object in 3D space.

Playing Video

To play a video

Add a video to the game project using the steps outlined in [How To: Load Content](#).

1. In [LoadContent](#), load the video using the [ContentManager](#).
2. Create a new instance of the [VideoPlayer](#).

C#

```
Video video;
VideoPlayer player;
Texture2D videoTexture;
protected override void LoadContent()
{
    // Create a new SpriteBatch, which can be used to draw textures.
    spriteBatch = new SpriteBatch(GraphicsDevice);
    video = Content.Load<Video>("video");
    player = new VideoPlayer();
}
```

3. In the [Update](#) method, play the video. Set [IsLooped](#) to **true** if you want the video to repeat.

C#

```
protected override void Update(GameTime gameTime)
{
    ...
    if (player.State == MediaState.Stopped)
    {
        player.IsLooped = true;
        player.Play(video);
    }
    ...
    base.Update(gameTime);
}
```

4. In [Draw](#), if the [VideoPlayer](#) is not stopped, call [GetTexture](#) to get a copy of the latest frame of video.
5. Create a [Rectangle](#) defining where on-screen the video will appear.
6. If the texture is not **null**, draw it onscreen using [SpriteBatch.Draw](#).

C#

```
protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    // Only call GetTexture if a video is playing or paused
    if (player.State != MediaState.Stopped)
        videoTexture = player.GetTexture();
}
```

```
// Drawing to the rectangle will stretch the
// video to fill the screen
Rectangle screen = new Rectangle(GraphicsDevice.Viewport.X,
    GraphicsDevice.Viewport.Y,
    GraphicsDevice.Viewport.Width,
    GraphicsDevice.Viewport.Height);

// Draw the video, if we have a texture to draw.
if (videoTexture != null)
{
    spriteBatch.Begin();
    spriteBatch.Draw(videoTexture, screen, Color.White);
    spriteBatch.End();
}

base.Draw(gameTime);
}
```

Playing Video

To play a video

1. Create a quad (or other 3D surface) on which to display the video.

This sample uses the Quad class from [How To: Draw a Textured Quad](#).

2. Create a View and Projection matrix for viewing the quad.

C#

```
Quad quad;
Matrix View, Projection;
protected override void Initialize()
{
    // Create a scene, including a quad and a view matrix looking at it
    quad = new Quad(Vector3.Zero, Vector3.Backward, Vector3.Up, 1, 1);
    View = Matrix.CreateLookAt(new Vector3(0, 0, 2),
        Vector3.Zero, Vector3.Up);
    Projection = Matrix.CreatePerspectiveFieldOfView(
        MathHelper.PiOver4, 4.0f / 3.0f, 1, 500);

    base.Initialize();
}
```

3. Add a video to the game project using the steps outlined in [How To: Load Content](#).
4. In [LoadContent](#), use the [ContentManager](#) to load the video.
5. Create a new instance of the [VideoPlayer](#).

Set [IsLooped](#) to **true** if you want the video to repeat.

6. Set up your [Effect](#) for drawing.

In this case, we use [BasicEffect](#), enabling default lighting and a texture.

C#

```
BasicEffect quadEffect;
Video video;
VideoPlayer player;
Matrix World;
VertexDeclaration quadVertexDecl;
protected override void LoadContent()
{
    // Load a video, and initialize a player
    video = Content.Load<Video>("video");
    player = new VideoPlayer();
    player.IsLooped = true;

    // Setup our BasicEffect for drawing the quad
    World = Matrix.CreateScale((float)video.Width, (float)video.Height, 1, 1);
}
```

```

quadEffect = new BasicEffect(graphics.GraphicsDevice, null);
quadEffect.EnableDefaultLighting();
quadEffect.World = World;
quadEffect.View = View;
quadEffect.Projection = Projection;
quadEffect.TextureEnabled = true;

// Create a vertex declaration so we can call
// DrawUserIndexedPrimitives later
quadVertexDecl = new VertexDeclaration(GraphicsDevice,
    VertexPositionNormalTexture.VertexElements);
}

```

7. In the `Update` method, play the video.

C#

```

protected override void Update(GameTime gameTime)
{
    ...
    // Play the video if it isn't already.
    if (player.State != MediaState.Playing)
        player.Play(video);

    base.Update(gameTime);
}

```

8. In `Draw`, if the `VideoPlayer` is not stopped, call `GetTexture` to get a copy of the latest frame of video, and link it to your effect.

9. Draw the 3D object using your effect.

C#

```

protected override void Draw(GameTime gameTime)
{
    GraphicsDevice.Clear(Color.CornflowerBlue);

    // If the video is playing, get the current frame
    // as a texture. (Calling GetTexture on a stopped
    // player results in an exception)
    if (player.State == MediaState.Playing)
        quadEffect.Texture = player.GetTexture();

    // Draw the quad
    GraphicsDevice.VertexDeclaration = quadVertexDecl;
    quadEffect.Begin();
    foreach (EffectPass pass in quadEffect.CurrentTechnique.Passes)
    {
        pass.Begin();

        GraphicsDevice.DrawUserIndexedPrimitives
            <VertexPositionNormalTexture>(
                PrimitiveType.TriangleList,
                quad.Vertices, 0, 4,
                quad.Indexes, 0, 2);

        pass.End();
    }
    quadEffect.End();
}

```

```
    base.Draw(gameTime);  
}
```

Storage Overview

The XNA Framework provides a set of classes in the [Microsoft.Xna.Framework.Storage](#) namespace that are used to read and write files from user storage and title storage, including player saves or title data.

- [Storage Devices](#)
- [Storage Locations](#)

Storage Devices

When you are programming with the XNA Framework, you read files from two general locations:

- Title storage, where the game executable and support files (shaders, meshes, textures, and so on) are located.
- User storage, the space a player provides for game data (such as saves) that is either locked to a particular profile or available to all players.

To access title storage, the XNA Framework provides the [StorageContainer](#) class, whose [TitleLocation](#) property contains a path to the location of the title itself. Title support files can be loaded based on this location.

To access user storage, the XNA Framework provides the [Guide](#) class, which contains the [BeginShowStorageDeviceSelector](#) method. This method brings up a dialog box on Xbox 360 where the user selects a storage device (memory unit or hard drive). This method works asynchronously, notifying the caller with an [IAsyncResult](#) or a callback method when the user has chosen a device. For more information, see [How To: Get a StorageDevice Asynchronously](#).

The [StorageContainer](#) instance provided by [OpenContainer](#) provides access to the selected device. Use **System.IO** objects, such as the [File](#) object, to open, copy, rename, or delete files, using [StorageContainer.Path](#) to determine the location of the files on the device.

Changes to the files within a [StorageContainer](#) on Xbox 360 do not take effect until the [StorageContainer](#) is disposed. For this reason, only one [StorageContainer](#) can be open on the same device for the same profile. Before opening a [StorageContainer](#) on a device, make sure that all previous [StorageContainer](#) objects opened for that profile have been disposed. To dispose a [StorageContainer](#), call [Dispose](#).

Storage Locations

Currently, the title location on a PC is the folder where the executable resides when it is run. Use the [TitleLocation](#) property to access the path.

User storage is in the My Documents folder of the user who is currently logged in, in the **SavedGames** folder. A subfolder is created for each game according to the **titleName** passed to the [OpenContainer](#) method. When no [PlayerIndex](#) is specified, content is saved in the **AllPlayers** folder. When a [PlayerIndex](#) is specified, the content is saved in the **Player1**, **Player2**, **Player3**, or **Player4** folder, depending on which [PlayerIndex](#) was passed to [BeginShowStorageDeviceSelector](#).

Creating a File

To create a save game file in title storage

1. Call the [Guide.BeginShowStorageDeviceSelector](#) method to get a device index indicating which device the user prefers.
2. Open a [StorageContainer](#) on the device, and then pass the name of your title.
3. Call [Path.Combine](#) to merge the container path with the name of the file to be created.
4. Call [File.Exists](#) to confirm that the file is not already present.
5. Call [File.Create](#) with the file name of the file to create.

[File.Create](#) returns a [FileStream](#) object that you can use to add data to the file.

6. Call [Close](#) to close the file after you have populated it with data.
7. Call [StorageContainer](#) to commit the changes to the device.

C#

```
private static void DoCreate(StorageDevice device)
{
    // Open a storage container.
    StorageContainer container =
        device.OpenContainer("StorageDemo");

    // Add the container path to our file name.
    string filename = Path.Combine(container.Path, "demobinary.sav");

    // Create a new file.
    if (!File.Exists(filename))
    {
        FileStream file = File.Create(filename);
        file.Close();
    }
    // Dispose the container, to commit the data.
    container.Dispose();
}
```

Opening a File

To open a save game file in title storage

1. Call the [Guide.BeginShowStorageDeviceSelector](#) method to get a device index indicating which device the user prefers.
2. Open a [StorageContainer](#) on the device, and then pass the name of your title.
3. Call [Path.Combine](#) to merge the container path with the name of the file to be opened.
4. Call [File.Open](#) with the file name of the file to open.

[File.Open](#) returns a [FileStream](#) object that you can use to add data to the file.

5. Call [Close](#) to close the file after you have read it.
6. Dispose the [StorageContainer](#) after closing the file.

C#

```
private static void DoOpen(StorageDevice device)
{
    // Open a storage container.
    StorageContainer container =
        device.OpenContainer("StorageDemo");

    // Add the container path to our file name.
    string filename = Path.Combine(container.Path, "demobinary.sav");

    FileStream file = File.Open(filename, FileMode.Open);
    file.Close();

    // Dispose the container.
    container.Dispose();
}

Copying a File

To copy a save game file in title storage

1. Call the [Guide.BeginShowStorageDeviceSelector](#) method to get a device index indicating which device the user prefers.
2. Open a [StorageContainer](#) on the device, and then pass the name of your title.
3. Call [Path.Combine](#) to merge the container path with the name of the source and destination files.
4. Call [File.Copy](#) with the file name of the file to copy, and the name of the new copy to be created.

You may also specify whether to overwrite existing files.

5. Dispose the [StorageContainer](#) to commit the changes to the device.

C#

```
private static void DoCopy(StorageDevice device)
{
    // Open a storage container.
    StorageContainer container =
        device.OpenContainer("StorageDemo");

    // Add the container path to our file name.
    string filename = Path.Combine(container.Path, "demobinary.sav");
    string copyfilename = Path.Combine(container.Path, "copybinary.sav");

    File.Copy(filename, copyfilename, true);

    // Dispose the container, to commit the change.

3. Call [Path.Combine](#) to merge the container path with the name of the source and destination files.
4. Call [File.Exists](#) to confirm that the destination file does not exist.
5. Call [File.Move](#) with the name of the file to rename, and the new name of the file.
6. Dispose the [StorageContainer](#) to commit the changes to the device.

C#

```

How To: Serialize Data

Demonstrates how to use the [XmlSerializer](#) class to write data in a custom class to a saved game, and how to load the data from the file.

The Complete Sample

The code in the topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download StorageDemo_Sample.zip.](#)

Serializing Data

To define save game data

1. Define a new class or structure.

The size of this class will determine the size of your saved game files, so try to keep the class small. Do not reference other objects from this class unless you want to serialize them as well.

2. Add the `Serializable` attribute to the class.

C#

```
[Serializable]
public struct SaveGameData
{
    public string PlayerName;
    public Vector2 AvatarPosition;
    public int Level;
    public int Score;
}
```

To serialize data to a save game file

1. Create a [StorageContainer](#) to access the specified device.
2. Use [Path.Combine](#) to create a new string specifying the full path to the save game file.
3. Open a [FileStream](#) object on the file using the [File.Open](#) method from the `System.IO` namespace.

Specifying **FileMode.Create** tells [Open](#) to create the save game if it doesn't exist. If it does, the file will be truncated to zero bytes.

4. Create an [XmlSerializer](#) object, passing the type of the structure that defines your save game data.
5. Call [Serialize](#), and then pass the [FileStream](#) and the data to serialize.

The [XmlSerializer](#) will turn the data in the structure into XML and use the [FileStream](#) to write the data into the file.

6. Close the [FileStream](#).
7. Dispose the [StorageContainer](#) to commit the changes to the device.

C#

```
private static void DoSaveGame(StorageDevice device)
{
    // Create the data to save.
    SaveGameData data = new SaveGameData();
    data.PlayerName = "Hiro";
    data.AvatarPosition = new Vector2(360, 360);
    data.Level = 11;
    data.Score = 4200;

    // Open a storage container.
    StorageContainer container =
        device.OpenContainer("StorageDemo");
}
```

```
// Get the path of the save game.
string filename = Path.Combine(container.Path, "savegame.sav");

// Open the file, creating it if necessary.
FileStream stream = File.Open(filename, FileMode.Create);

// Convert the object to XML data and put it in the stream.
XmlSerializer serializer = new XmlSerializer(typeof(SaveGameData));
serializer.Serialize(stream, data);

// Close the file.
stream.Close();

// Dispose the container, to commit changes.
container.Dispose();
}
```

To read serialized data from a save game file

1. Create a [StorageContainer](#) to access the specified device.
2. Use [Path.Combine](#) to create a new string specifying the full path to the save game file.
3. Call [File.Exists](#) to determine if the save game exists.
4. Open a [FileStream](#) object on the file using the [File.Open](#) method from the System.IO namespace.
5. Create an [XmlSerializer](#) object, and then pass the type of the structure that defines your save game data.
6. Call [Deserialize](#), and then pass the [FileStream](#) object.

[Deserialize](#) returns a copy of the save game structure populated with the data from the save game file. (You will have to cast the return value from Object to your type.)

7. Close the [FileStream](#).
8. Dispose the [StorageContainer](#).

How To: Get a StorageDevice Asynchronously

Getting a StorageDevice Asynchronously

To get a StorageDevice asynchronously using IsCompleted

1. In your [Game](#) constructor, add a new [GamerServicesComponent](#) to your [Components](#) collection.
2. Create a variable to track when a request for a [StorageDevice](#) is pending. In this case, declare **GameSaveRequested**.

When the user needs to access the [StorageDevice](#) for the first time (for example, to save a game), call [Guide.BeginShowStorageDeviceSelector](#), specifying which player has requested the save.

3. Check [Guide.IsVisible](#) first to make sure the Guide is not already being displayed.

Calling [Guide.BeginShowStorageDeviceSelector](#) when the Guide is visible results in a [GuideAlreadyVisibleException](#). [Guide.BeginShowStorageDeviceSelector](#) returns an [IAsyncResult](#) interface that is used to determine when the asynchronous request is finished.

4. Set your tracking variable to indicate a request is pending.
5. When a request is pending, check [IAsyncResult.IsCompleted](#) periodically to determine when the user selected the storage device.
6. When [IsCompleted](#) is **true**, call [Guide.EndShowStorageDeviceSelector](#), passing the [IAsyncResult](#) provided by [Guide.BeginShowStorageDeviceSelector](#).

The return value is the selected storage device.

7. Use [IsConnected](#) to ensure that a valid device was chosen (if the user declines to select a device, or the device is removed, [IsConnected](#) will be **false**).
8. If the [StorageDevice](#) is connected, use it to load or save data.
9. Reset your tracking variable.

C#

```
public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";

    this.Components.Add(new GamerServicesComponent(this));
}
IAsyncResult result;
Object stateobj;
bool GameSaveRequested = false;
GamePadState currentState;

protected override void Update(GameTime gameTime)
{
    GamePadState previousState = currentState;
    currentState = GamePad.GetState(PlayerIndex.One);
    // Allows the default game to exit on Xbox 360 and Windows
    if (currentState.Buttons.Back == ButtonState.Pressed)
```

```

        this.Exit();

    if ((currentState.Buttons.A == ButtonState.Pressed) &&
        (previousState.Buttons.A == ButtonState.Released))
    {
        // Set the request flag
        if ((!Guide.IsVisible) && (GameSaveRequested == false))
        {
            GameSaveRequested = true;
            result = Guide.BeginShowStorageDeviceSelector(PlayerIndex.One,
                null, null);
        }
    }
    // If a save is pending, save as soon as the
    // storage device is chosen
    if ((GameSaveRequested) && (result.IsCompleted))
    {
        StorageDevice device = Guide.EndShowStorageDeviceSelector(result);
        if (device != null && device.IsConnected)
        {
            DoSaveGame(device);
        }
        // Reset the request flag
        GameSaveRequested = false;
    }
    base.Update(gameTime);
}

```

To get a StorageDevice asynchronously using an AsyncCallback

1. In your `Game` constructor, add a new `GamerServicesComponent` to your `Components` collection.
2. Create an `AsyncCallback` object that represents the method that will be called when the player chooses a device. That function must take an `IAsyncResult` as a parameter, and return **void**.
3. When the user needs to access the `StorageDevice` for the first time (for example, to save a game), call `Guide.BeginShowStorageDeviceSelector`, specifying which player has requested the save, and your `AsyncCallback` object. You may optionally pass a tracking object to identify the request (or **null**).
4. Check `Guide.IsVisible` first to make sure the guide is not already being displayed.
5. Call `Guide.BeginShowStorageDeviceSelector` when the guide is visible results in a `GuideAlreadyVisibleException`.
6. In your callback method, call `Guide.EndShowStorageDeviceSelector`, passing the same `IAsyncResult` that was passed into the callback method. The return value is the selected storage device.
7. Use `IsConnected` to ensure that a valid device was chosen (if the user declines to select a device, or the device is removed, `IsConnected` will be **false**).
8. If the `StorageDevice` is connected, use it to load or save data.

C#

```

public Game1()
{
    graphics = new GraphicsDeviceManager(this);
    Content.RootDirectory = "Content";

    this.Components.Add(new GamerServicesComponent(this));
}

```

```

IAsyncResult result;
Object stateobj;
bool GameSaveRequested = false;
GamePadState currentState;

protected override void Update(GameTime gameTime)
{
    GamePadState previousState = currentState;
    currentState = GamePad.GetState(PlayerIndex.One);
    // Allows the default game to exit on Xbox 360 and Windows
    if (currentState.Buttons.Back == ButtonState.Pressed)
        this.Exit();

    if ((currentState.Buttons.B == ButtonState.Pressed) &&
        (previousState.Buttons.B == ButtonState.Released))
    {
        if (!Guide.IsVisible)
        {
            // Reset the device
            device = null;
            stateobj = (Object)"GetDevice for Player One";
            Guide.BeginShowStorageDeviceSelector(
                PlayerIndex.One, this.GetDevice, stateobj);
        }
    }
    base.Update(gameTime);
}

StorageDevice device;
void GetDevice(IAsyncResult result)
{
    device = Guide.EndShowStorageDeviceSelector(result);
    if (device != null && device.IsConnected)
    {
        DoSaveGame(device);

}

Gamer Services Overview

The [GamerServices namespace](#) provides functionality available from Xbox LIVE to XNA Framework developers. This includes the capability to retrieve player preferences for local accounts, use gamer Avatars, and to display various LIVE Guide user interface screens programmatically.

Important

Games for Windows - LIVE is not available to finished games. This functionality is not included in the redistributable version of the XNA Framework. A game that attempts to use these components without XNA Game Studio installed will result in a [GamerServicesNotAvailableException](#).

- [Initialization of Gamer Services](#)
- [Player Sign-In](#)
- [Gamer Avatar](#)
- [Player Profile Information](#)
- [Guide User Interface](#)

Initialization of Gamer Services

Users must explicitly initialize the gamer services subsystem before they can use any gamer services or networking API calls. Most games will use the [GamerServicesComponent](#), a game component that takes care of the process of initializing and pumping the gamer services system. This component will pass through the graphics device and window handle automatically. It calls [Update](#) to pump the gamer services pump at regular intervals. To take advantage of this component, most games simply need to add one line to the [Game](#) constructor:

C#

```
Components.Add(new GamerServicesComponent(this));
```

Initializing the gamer services system can be a slow operation, and it has user-visible consequences. For example, the game may display the "Player Signed In" notification when the gamer services system is initialized. This happens when a local profile is set to sign in automatically, and, as a result, trigger a system update. Because of this, if a game is going to use these services, it is desirable to initialize everything in the game startup code in the constructor.

Programs that do not use the XNA Framework application model or component infrastructure can use [GamerServicesDispatcher](#). In this case, you must also call the [GamerServicesDispatcher.Initialize](#) and [GamerServicesDispatcher.Update](#) methods directly. Under these conditions, you should initialize the [GamerServicesDispatcher](#) once at startup, and call [GamerServicesDispatcher.Update](#) at every frame.

The [GamerServicesDispatcher.Update](#) method enables the XNA Framework to raise events for notifications such as sign-in status changes and game invites when it is safe to raise the events.

Player Sign-In

For standard game clients with a user interface, the Guide user interface automatically displays the appropriate user interface when a player presses either the HOME key on the keyboard or the **Guide** button on the Xbox 360 controller, allowing players to sign in. Before a player signs in, you can also choose to manually display the sign-in user interface using the [Guide.ShowSignIn](#) function.

When a [SignedInGamer](#) signs in, the [SignedInGamer.SignedIn](#) event occurs. You can get the list of signed-in players at any time using the static property [Gamer.SignedInGamers](#).

Gamer Avatar

Avatars are three-dimensional animated characters that represent the gamer in a versatile, personalized, engaging manner. Gamer services implements support for displaying and animating a gamer's avatar using standard effects and animations. In addition, access to the metadata of an avatar (such as hierarchy information and textures) allows developers to implement custom rendering and animating of a gamer's avatar.

Note

Avatar support is only available for Xbox 360 applications.

Avatars are used in a variety of ways on the Xbox 360 console: as a gamerpic and integrated into the friends list display, the Xbox Guide, and the dashboard. Also, game titles can use avatars in-game to represent various game players and to provide unique spectators, cut scene actors, crowd members, or game characters.

For more information on implementing avatar support in your application, see [Avatars](#).

Player Profile Information

The player profile information that is accessible using the [Gamer.GetProfile](#) method returns information such as the gamer picture, motto, and gamerzone. Specifically, the gamer profile provides the following information about a gamer:

- [Gamerscore](#)
- [Gamerzone](#)
- [Gamer picture](#)
- [Region](#)
- [Motto](#)
- [Reputation](#)
- [Number of achievements](#)
- [Number of titles played](#)

You may use [SignedInGamer.GameDefaults](#) to retrieve a local gamer's preferred settings, such as:

- [Controller sensitivity](#)
- [Game difficulty](#)
- [Primary](#) and [secondary](#) colors
- Action movement preferences such as [auto-aim](#), [auto-center](#), and [y-axis inversion](#)
- Preferred [racing camera angle](#), [accelerator](#), [brake](#), and [transmission](#)

Using [SignedInGamer.Privileges](#), you can see if the player is allowed to:

- [Communicate using voice, text, or messaging.](#)
- [Join online multiplayer sessions.](#)
- [View profiles.](#)

You can also view whether a gamer is [LIVE-enabled](#) or a [guest](#).

Privileges will be enforced by the framework. A player can never create an online session if his or her multiplayer privilege is not enabled. We provide programmatic access to these settings so that games may check to see if anything is forbidden. In such a case, the relevant menu options are grayed out—this keeps the user from selecting a forbidden option and getting an exception or error when trying to call the forbidden method.

Guide User Interface

The XNA Framework exposes a property, [Guide.IsVisible](#), which checks to see if the Guide user interface is active. The Guide runs independently alongside games. The player can view the Guide at any time by pressing the HOME key on the keyboard or the **Guide** button on the controller.

Many of the Guide calls are blocking. The XNA Framework uses the standard .NET async pattern to expose asynchronous versions of all the Guide methods. Blocking versions of the Guide methods automatically pump the graphics device while the UI is active. They call [GraphicsDevice.Present](#) at regular intervals with an empty (black) backbuffer. Games should have the asynchronous versions of the methods if it is desirable to continue rendering behind the Guide. The existing storage device UI has been changed to match the new design.

Programming with Avatars

Discusses the support for avatars in XNA Game Studio applications targeting the Xbox 360 console. Avatar support includes retrieving existing gamer avatars or creating new ones, and rendering and animating avatars using built-in support.

Overview

Avatars provide other ways of placing the player in your game. With avatars, you can render and animate the avatar within the game, or you can generate one or more random avatars to use as a crowd backdrop or as additional characters in the game.

You must meet the following requirements before using avatars in your game:

- The game targets the Xbox 360 platform.

Note

Code related to avatars can be present in a Windows game, but all methods will return default values and nothing will render to the screen. This is by design.

- Gamer services must be initiated. For more information, see the Initialization of Gamer Services section in [Gamer Services Overview](#).

The avatar of a signed-in gamer is stored in the [Avatar](#) property. Create one or more random avatars using the [CreateRandom](#) method. This method creates an [AvatarDescription](#) object, initialized with random data. You can then render this avatar with a call to [Draw](#).

XNA Game Studio provides avatar rendering with the [AvatarRenderer](#) class, and animation with the [AvatarAnimation](#) class. The renderer uses basic lighting and shading effects. You can invoke the renderer with a single call to [AvatarRenderer.Draw](#). This method also uses an animation to indicate the avatar currently is being loaded. This is automatically used by the renderer until loading is completed. Once the avatar is displayed, idle animations cycle randomly unless you specify a specific animation from the standard list. For a complete list, see [AvatarAnimationPreset](#). The **AvatarRenderer** class contains properties related to the lighting and rendering of the avatar. These properties include the directional light color and direction, the transformation matrices, and others. For a full listing of these properties, see [AvatarRenderer Properties](#).

How To: Use Gamertags and Gamer Pictures

Demonstrates how to retrieve gamertags and pictures using a technique that can be applied to retrieve other gamer profile information.

Using Gamertags and Gamer Pictures

To retrieve the gamertag and profile picture of a player in a game

- Use [Gamer.GetProfile](#) to retrieve the profile information for any player in the game.

Note that this method will complete quickly when you use it with a locally signed-in profile. However, this method can take some time if you call it on a remote gamer instance. In the remote case, you might use the non-blocking alternative [Gamer.BeginGetProfile](#).

The [GamerProfile](#) returned by [Gamer.GetProfile](#) also contains such information as the motto, gamerscore, and more.

If the gamer is a [SignedInGamer](#), you can retrieve the local player's preferred settings for gameplay using the [SignedInGamer.GameDefaults](#) property. You can also retrieve the local player's privileges using [SignedInGamer.Privileges](#). Unlike [Gamer.GetProfile](#), which can be slow for remote players, the properties of a [SignedInGamer](#) return instantly.

C#

```
foreach (NetworkGamer gamer in session.AllGamers)
{
    string text = gamer.Gamertag;
    GamerProfile gamerProfile = gamer.GetProfile();
    Texture2D picture = gamerProfile.GamerPicture;
}
```

How To: Add Presence Information

To set presence information for a player, use the [SignedInGamer.Presence](#) property, which is a reference to a [GamerPresence](#) object. **GamerPresence** has two properties that are used to set presence information:

- [PresenceMode](#), which is set to one of the values of [GamerPresenceMode](#).

GamerPresenceMode contains values that represent strings describing what the player is doing in your game. For a full description of each, see the **GamerPresenceMode** reference topic.

- [PresenceValue](#), which is an integer that provides a numeric value used with some of the presence modes such as **Stage**, **Level**, and **Score**.

To set presence information for a player

Set [SignedInGamer.Presence.PresenceMode](#) with one of the values of [GamerPresenceMode](#), as shown:

C#

```
foreach (SignedInGamer signedInGamer in
    SignedInGamer.SignedInGamers)
{
    signedInGamer.Presence.PresenceMode =
        GamerPresenceMode.InCombat;
}
```

Note

Some values will also require [SignedInGamer.Presence.PresenceValue](#) to be set, as described previously.

Note

A game title will not be displayed in a player's presence information on the Xbox LIVE service until that game passes peer review. Once a game passes peer review, the presence information for a player shows three things: a confirmation the player is playing an Xbox LIVE Indie Game, the game's title, and the presence information set by [SignedInGamer.Presence](#). For example:

```
Xbox LIVE Indie Game
My Game Title
Fighting the Boss
```

While a game is in development, but before the game passes peer review, the presence information indicates the developer is using the XNA Creators Club, as shown:

```
XNA Creators Club

Fighting the Boss
```

How To: Add Support for Game Invitations

The XNA Framework [player match](#) multiplayer network session type enables players to invite friends to play a game online over Xbox LIVE. Games of this type are able to host other players when the session is joinable, when there are open slots, and when game invitations are enabled.

Gamers can send game invitations from the Xbox LIVE friends list or by using the [Guide.ShowGameInvite](#) method. Game Invitations can also be sent to members of a gamer's LIVE Party by using [LocalNetworkGamer.SendPartyInvites](#). For more information about LIVE Parties, see [How To: Add LIVE Party Support](#).

The [NetworkSession.InviteAccepted](#) event receives the notification of an accepted game invitation. For this reason, titles *must* register for the [InviteAccepted](#) event to send game invitations.

Gamers can accept game invitations from the message center or from the friends list. A gamer can also ask to join an existing game session without an invitation by selecting **Join Session In Progress** from the friends list or from the game lobby. Either of these actions will cause an [InviteAccepted](#) event to be sent to the title.

Important

If your title does not register for the [InviteAccepted](#) event, its sessions will always show up as non-joinable.

To register for the [InviteAccepted](#) event

- Register an event handler for the [NetworkSession.InviteAccepted](#) event when your game starts.

You can use the game [constructor](#) or the [Game.Initialize](#) method to register this event.

C#

```
NetworkSession.InviteAccepted +=
    new EventHandler<InviteAcceptedEventArgs>(
        NetworkSession_InviteAccepted);
```

Once the [InviteAccepted](#) event has been registered, the registered event handler will be called when the event is received. This happens either when a game invitation has been accepted or a player has requested to join a session in progress.

To respond to the [InviteAccepted](#) event

- In the handler registered for [InviteAccepted](#), check whether the invitation is for a pre-existing local session by examining [IsCurrentSession](#). If it is not for the current local session, call [NetworkSession.JoinInvited](#) to allow the gamer to join the remote session. If another local gamer has already joined the session, call [NetworkSession.AddLocalGamer](#) to add additional gamers to the session.

C#

```
void NetworkSession_InviteAccepted(object sender,
    InviteAcceptedEventArgs e)
{
    // if this is from a session that other local gamers are already in
    if (e.IsCurrentSession)
    {
        // and that sessions is still running...
        if (session != null)
            session.AddLocalGamer(e.Gamer); // add the additional gamer
    }
    else // else the invite is to a different session
    {
        if (session != null)
        {
            session.Dispose();
            session = null;
        }
        session = NetworkSession.JoinInvited(maxLocalGamers);
    }
}
```

```
}
```

Note

If an invitation is pending already because the game started in response to a cross-title invite, the method to handle the game invitation event will be called as soon as you subscribe to the event. Because of this, it is important to initialize everything upon which the event handler depends *before* it is registered.

When a game is able to host other gamers, the **Send Game Invite** option button automatically appears in the Xbox LIVE friends list. Because a gamer can send invitations at any point in the game by pressing the **Guide** button and navigating to the friends list, typically you won't need to write additional code to display the game invitation screen.

However, there may be situations when you'd like to bring up the game invitation UI yourself as a result of player actions in the game. In this case, you can use the [Guide.ShowGameInvite](#) method in your title's code to bring up the UI directly.

To display the game invitation user interface

- Call [Guide.ShowGameInvite](#) to show the game invitation UI.

You can do this from any point in your code, but be sure that the title already is registered to receive the [InviteAccepted](#) event as described above.

C#

```
if (IsButtonPressed(GamePadButton.Y) && !Guide.IsVisible)
{
    Guide.ShowGameInvite(PlayerIndex.One, null);
}
```

Invitations to Games that Have Not Been Installed

When a player accepts an invitation for an Xbox LIVE Indie Game that is not already installed on his or her console, the invited player will be taken to the game offer. The offer enables the invited player to download the game and accept the invitation to start the game.

For Creator's Club games still waiting to pass peer review and for which no game offer exists, a game invitation will still be sent over the Xbox LIVE service to the other player. If the game is not installed, the invited player will be prompted with a message indicating that he or she can get the game from the game creator.

How To: Add LIVE Party Support

LIVE Party gives groups of gamers additional ways to connect, chat, and play together. The XNA Framework supports LIVE Party through the [Guide](#), [LocalNetworkGamer](#), and [SignedInGamer](#) classes. This topic shows you how to use these classes to add LIVE Party support to your game title.

Note

Currently, the only platform that supports LIVE Party is the Xbox 360. Other platforms do not support LIVE Party functionality, even though the platform may support LIVE otherwise.

Showing the LIVE Party Screens

The Guide provides two screens related to LIVE Party: the Party screen and Party Sessions screen.

The Party screen serves as the main interface to LIVE Party functionality for a given player. It allows a player to do the following:

- View all the members of the current party.
- Manage the party (if the player is the party organizer).
- Send party invitations to other party members.

The Party Sessions screen allows a player to see all party members who are in a joinable session in the same game. It allows the player to join any of these sessions.

To show the Guide's LIVE Party screen

- Call [Guide.ShowParty](#) with the [PlayerIndex](#) of the player for which the Party Sessions screen will be shown.

C#

```
// Show the party screen for the player on the first controller.
Guide.ShowParty(PlayerIndex.One);
```

To show the Guide's LIVE Party Sessions screen

- Call [Guide.ShowPartySessions](#) with the [PlayerIndex](#) of the player for which the Party Sessions screen will be shown.

C#

```
// Show the party sessions screen for the player on the first controller.
Guide.ShowPartySessions(PlayerIndex.One);
```

Sending a Game Invitation to Party Members

For party members not yet in the game, the player can use the [LocalNetworkGamer](#) class to send them an invitation to the current game session.

To send a game invitation to all party members not in the current game session

- Call [LocalNetworkGamer.SendPartyInvites](#) for the gamer for whom invitations will be sent.

C#

```
// Send invitations to all members of each local network gamer's LIVE party.
foreach(LocalNetworkGamer gamer in NetworkSession.LocalGamers)
{
    gamer.SendPartyInvites();
}
```

Note

When a gamer responds to a game invitation, the person who sent the invitation gets the [NetworkSession.InviteAccepted](#) event. For more information, see [How To: Add Support for Game Invitations](#)

Retrieving the Number of Party Members for a Gamer

You can use the gamer's [SignedInGamer](#) class to determine the number of party members in a gamer party.

To get the number of party members for a player.

- Read the value of [SignedInGamer.PartySize](#).

Note

[PartySize](#) is read-only. It cannot be used to set the party size.

C#

```
// get the party size for the first signed-in gamer.
if(Gamer.SignedInGamers(0).PartySize > 0)
{
    // The player is a member of a LIVE party!
    ...
}
```

How To: Initialize and Update the Gamer Services Dispatcher

Describes how an application would use the [GamerServicesDispatcher](#) instead of the [GamerServicesComponent](#) for cases in which a program may not be using the XNA Framework application model or component infrastructure.

Automatically Updating the Gamer Services Dispatcher

The XNA Framework provides a [GamerServicesComponent](#). This is a game component that automatically takes care of initializing and updating the gamer services dispatcher. To make use of this component, XNA Framework games need to add only one line of code to the [Game](#) constructor.

To automatically update the gamer services dispatcher

- To make use of this component, add this line of code to the [Game](#) constructor:

C#

```
Components.Add(new GamerServicesComponent(this));
```

Manually Updating the Gamer Services System

In some cases a program might not use the XNA Framework application model or component infrastructure. For this application, it is possible to call the [GamerServicesDispatcher](#) directly.

To manually initialize and update the gamer services system

- Once, in the startup code for the application, call [GamerServicesDispatcher.Initialize](#) to initialize the gamer services subsystem.

C#

```
protected override void Initialize()
{
    GamerServicesDispatcher.WindowHandle = Window.Handle;

    GamerServicesDispatcher.Initialize(Services);

    base.Initialize();
}
```

- Call [GamerServicesDispatcher.Update](#) once every frame to update the gamer services system.

C#

```
protected override void Update(GameTime gameTime)
{
    GamerServicesDispatcher.Update();
    base.Update(gameTime);
}
```

How To: Detect or Simulate Trial Mode and Present a Marketplace Offer

Demonstrates how to detect and simulate trial mode for the purpose of testing the display of a Marketplace offer that will allow a player to purchase your game.

Note

It is not necessary to write special code to ensure that a Marketplace offer is available to players of Xbox LIVE Indie Games. By default, trial mode games that have been released will present a Marketplace offer to the player when the gameplay time limit expires. However, you might want to write special code in your game to present a Marketplace offer, or control other areas of gameplay when a game is in trial mode.

To simulate trial mode

The XNA Framework provides a property, [Guide.SimulateTrialMode](#), that allows developers to test the behaviors of a game under trial mode conditions. When games are in trial mode, a developer might choose to limit the capabilities of the game.

- In this example, [Guide.SimulateTrialMode](#) is set to **true** for the purpose of later testing a marketplace offer that is presented if the game is in trial mode. This property is usually set in the game [constructor](#), and must be set before the first call to [Game.Update](#).

C#

```
Guide.SimulateTrialMode = true;
```

To detect when a game is in trial mode

- Check whether [Guide.IsTrialMode](#) is **true**.
- In this example, if this condition is met, call [Guide.ShowMarketplace](#) to present an offer to purchase the full version of the game.

C#

```
if (Guide.IsTrialMode)
{
    Guide.ShowMarketplace(signedInGamer.PlayerIndex);
}
```

How To: Render and Animate an Avatar Using AvatarRenderer.

Demonstrates how to render and animate a gamer's avatar using the [AvatarRenderer](#) class and a standard animation.

Note

Avatar-related APIs are exposed on Windows to ease cross-platform development between Windows and the Xbox 360. All avatar-related methods return default values, and rendering methods do not draw anything to the screen. This is by design.

The Complete Sample

The code in this topic shows you the technique. You can download a complete code sample for this topic, including full source code and any additional supporting files required by the sample.

[Download AnimatedAvatar_Sample.zip](#).

To Render a Random Model with a Standard Animation

1. Initialize the gamer services dispatcher for your application.

C#

```
Components.Add(new GamerServicesComponent(this));
```

For more information, see [How To: Initialize and Update the Gamer Services Dispatcher](#).

2. Declare three new members in your main game class to store the various objects needed to render and animate the random avatar.

C#

```
AvatarDescription avatarDesc;
AvatarRenderer avatarRenderer;
AvatarAnimation avatarAnimation;
```

3. Create and initialize the avatar data to a random set with a call to [CreateRandom](#). Use the [Initialize](#) method of your [Game](#) class, after the existing call to [Initialize](#).

C#

```
avatarDesc = AvatarDescription.CreateRandom();
```

4. Create a new avatar renderer for the recently-created random avatar, with the standard loading effect. Use the [Initialize](#) method of your [Game](#) class.

C#

```
avatarRenderer = new AvatarRenderer(avatarDesc, true);
```

5. Create a new [AvatarAnimation](#) object, and load any standard animation from the list supported by [AvatarAnimationPreset](#). Use the [Initialize](#) method of your [Game](#) class.

For this example, because the avatar gender is unknown at the time of rendering, use the gender-neutral clap animation.

Note

Gender-specific animations work with any avatar, but each was designed with the proportions of that gender in mind. This prevents the avatar model from clipping through itself during the animation cycle.

C#

```
avatarAnimation = new AvatarAnimation(AvatarAnimationPreset.Clap);
```

6. Initialize the avatar's transformational matrices (world, projection, and view), using the [World](#), [Projection](#), and [View](#) properties of the `avatar` object. Use the [Initialize](#) method of your [Game](#) class.

C#

```
avatarRenderer.World =  
    Matrix.CreateRotationY(MathHelper.ToRadians(180.0f));  
avatarRenderer.Projection =  
    Matrix.CreatePerspectiveFieldOfView(MathHelper.ToRadians(45.0f),  
    GraphicsDevice.Viewport.AspectRatio, .01f, 200.0f);  
avatarRenderer.View =  
    Matrix.CreateLookAt(new Vector3(0, 1, 3), new Vector3(0, 1, 0),  
    Vector3.Up);
```

Note

The values used in this example are for demonstration purposes only. Although they provide a good location and orientation for the camera (in terms of this sample), your application will require different values, which are determined by your application's needs.

7. Make any necessary modifications to the current values of the avatar's ambient light and directional light properties, using the similarly-named properties of the `avatar` object (for example, `AvatarRenderer.AmbientLightColor`).
8. Update the current animation of the avatar.

The recommended place for this code is within the `Update` method of your application.

C#

```
if (avatarRenderer.IsLoaded)  
{  
    avatarAnimation.Update(gameTime.ElapsedGameTime, true);  
}
```

9. In the `Draw` method of your game, render the avatar by calling `Draw`.

C#

```
avatarRenderer.Draw(avatarAnimation.BoneTransforms,  
    avatarAnimation.Expression);
```

When you render the avatar, keep in mind that various parts of the avatar model can be transparent (for example, glasses). Any transparent parts are rendered with the depth buffer disabled. Therefore, first render all opaque objects in the scene, except the avatar. Then render the avatar and any other transparent objects, sorted by depth (from back to front).

In addition, avatar rendering ignores the current state of the `RenderState.FillMode` property. It is always treated as if `FillMode.Solid` is the current value.

Getting Started With Networked Games

Important

Games for Windows - LIVE is not available to finished games. This functionality is not included in the redistributable version of the XNA Framework. A game that attempts to use these components without XNA Game Studio installed will result in a [GamerServicesNotAvailableException](#).

Dependency on Gamer Services

XNA Framework games must explicitly initialize the *gamer services* system before networking methods are called. Gamer services allows your game to receive notifications such as sign-in status changes, game invitations and other messages from Xbox LIVE, and it gives your game access to the Guide. The Guide provides a user interface allowing players to sign in to Xbox LIVE, view messages or game invitations, and use Xbox LIVE user interface elements such as the on-screen keyboard during a game.

Most games use [GamerServicesComponent](#), a game component that wraps the [GamerServicesDispatcher](#) object and takes care of sending and receiving messages from Xbox LIVE. This component also passes in the graphics device and window handle to allow rendering of the Guide, and it calls [GamerServicesDispatcher.Update](#) at regular intervals. To use this component, most games only need to add one line to the [Game](#) constructor:

C#

```
Components.Add(new GamerServicesComponent(this));
```

For more information on Gamer Services, see [Gamer Services Overview](#).

XNA Creators Club and Xbox LIVE Membership Requirements

There are two types of online multiplayer games available when you create a networked game with XNA Game Studio: system link game sessions and LIVE sessions. These two forms of online multiplayer gaming describe whether the multiplayer gaming session is on the local area network (system link games), or if the gaming session is advertised and found through the LIVE service. With system link games, you can search the local area network to find the gaming sessions. With LIVE sessions, you can use the LIVE service to find available game sessions. Use the *searchProperties* argument of [NetworkSession.Find](#) to specify the parameters used to search for an available game session—a game session that uses either system or the LIVE service.

Developing and testing a networked game requires at least two machines, but you only need one Xbox 360 console and one Creators Club membership to test network code for the Xbox 360. This is because XNA Framework supports cross-platform system links so developers can run one instance of a game on an Xbox 360, and a second on a Windows-based computer. This functionality helps creators debug their titles without having to purchase a second console. It is also possible for more than one Windows-based development computer to connect several machines in a system link session without any memberships required.

Memberships are required for a player on a Windows-based computer and an Xbox 360 console in a network session, depending on the session type that has been created.

	Xbox 360 console	Windows-based development computer	Zune
Run an XNA Framework Game	LIVE Silver membership + Premium XNA Creators Club membership	No memberships required	No memberships required

Caution

XNA Framework components that interact with Games for Windows - LIVE require an XNA Creators Club membership. If for any reason a LIVE profile without a Creators Club membership is set to auto sign in to a Windows-based computer, the game will be unable to connect to the LIVE service. Furthermore, the XNA Framework gamer services components, including the Guide, will be unavailable. To disable auto sign in for a LIVE profile on a Windows-based computer, disconnect from the network, launch an XNA Framework game, and then open the Guide.

Hardware Requirements

It is not possible to run multiple simultaneous instances of a networked game on a single development computer.

When you launch to multiple machines for network testing, we recommend that you load multiple copies of your solution into separate Visual Studio instances, one per machine.

For a system link game, you can use any one of the following hardware configurations to test a networked game:

- *One development computer and one Xbox 360 console* (running one instance of the game on a Windows-based computer and one on Xbox 360). The creator needs one LIVE Silver and one Creators Club membership to run code on the Xbox 360.
- *One development computer and one client computer* (running one instance of the game on each Windows-based computer). Creators cannot run two networked XNA Framework games at the same time on the same computer. Creators need a second machine to run a second game instance for testing purposes. No LIVE memberships or Creators Club memberships are required for this scenario.
- *One development computer and two Xbox 360 consoles* (running one instance of the game on each Xbox 360). Here a creator deploys and debugs the game on two Xbox 360s. The creator needs at least two LIVE Silver memberships and two Creators Club memberships (one pair for each Xbox 360) for this scenario.
- *One development computer and two Zune devices* (running one instance of the game on each Zune). Here a creator deploys and debugs the game on two Zune devices. The creator needs no additional memberships for this scenario. Note that Zune only supports system link networking and does not support cross-platform networking or internet connectivity.

If a creator wants to use LIVE to connect to gaming machines over the Internet as opposed to using system link to connect gaming machines over a local subnet, you may use any one of the following hardware configurations:

- *One development computer and one Xbox 360 console* (running one instance of the game on the development computer and one on the Xbox 360). The creator needs two LIVE Gold memberships and two Creators Club memberships (one pair for each machine) for this scenario.
- *One development computer and one client computer* (running one instance of the game on each computer). The creator needs two LIVE Gold memberships and two Creators Club memberships (one pair for each machine).
- *One development computer and two Xbox 360 consoles* (running one instance of the game on each Xbox 360 console). The creator needs two LIVE Gold memberships and two Creators Club memberships (one set for each machine).

Network Session Management

Any matchmaking scenario involves the creation of a network session. Network sessions give XNA Framework games access to profile data on all the gamers in a potential game.

- [Session Updates](#)
- [Matchmaking](#)
- [Session Types](#)
- [Finding Sessions](#)
- [Session Management](#)

Session Updates

The [NetworkSession](#) class has a single [Update](#) method that must be called once per frame. This update call performs the following actions:

- Sends the network packets.
- Changes the session state, such as which players are in the session and which player is talking currently.
- Raises the managed events for any significant state changes.
- Returns the incoming packet data.

This explicit update call allows the framework to synchronize the session so that packet-received and state-change events will never be raised asynchronously with the rest of the game code. This allows developers to program against the network session object without any threading concerns.

Session updates are kept separate from the gamer services system pumping for two reasons:

- To clarify when session events will be raised.
- To allow developers the option to update the session from a background worker thread, which allows these developers the option to run this in parallel with the main game update.

Matchmaking

To play a networked game with other people, the game needs a way to publish an instance of the game for others to discover the instance and join the game. This matchmaking and peer discovery mechanism is available through the [NetworkSession.Find](#) and [NetworkSession.BeginFind](#) methods, which return a collection of [AvailableNetworkSession](#) instances. You may examine the properties of each [AvailableNetworkSession](#), and pass a suitable [AvailableNetworkSession](#) to [Join](#) to join the session.

Players

The [NetworkSession](#) object exposes a collection of player instances, along with [events](#) indicating when players join or leave the session. There are properties for querying which player is the host ([NetworkSession.Host](#)), and for determining which players are local players signed on to the same machine and physically located together ([NetworkGamer.IsLocal](#)).

Friends

The XNA Framework exposes basic functionality for programmatic friends list access:

- Query the contents of the friends list using [SignedInGamer.GetFriends](#), obtaining gamertags and presence information using the methods and properties available from a [FriendGamer](#).
- Query whether another player is a friend using [SignedInGamer.IsFriend](#).

Local Sign-In

When you first create a session, a game must specify the maximum number of local players that it supports (1, 2, 3, or 4). The framework will automatically add up to this number of profiles to the session, and keep this up to date if the sign-in state changes. If there are more signed-in profiles than the game wants, only the lower-numbered profiles will be added to the session. If extra players sign after the session is created the players will not be added. If the host player signs off, the session will either be torn down or a host migration will take place depending on whether the [NetworkSession.AllowHostMigration](#) option is enabled.

Session Types

The XNA Framework supports four kinds of sessions:

- Local
- System link
- Xbox LIVE unranked session
- LIVE ranked session

The same matchmaking API is used for both LIVE and system link session types. The session type must be specified when creating or searching for sessions, and only sessions of an identical type will be returned by the query.

Local sessions are interesting for games that want to build both networking and local split-screen multiplayer on top of the same infrastructure. This allows this type of game to implement both online and offline game modes using the same framework session interfaces.

Finding Sessions

The XNA Framework provides a single fixed matchmaking query in the form of a [NetworkSessionProperties](#) collection that represents the desired session to match. This collection is passed to the [NetworkSession.Find](#) and [NetworkSession.BeginFind](#) static methods. These methods return an [AvailableNetworkSessionCollection](#) containing a maximum of 25 [AvailableNetworkSession](#) objects, which in turn contain the following data about each session:

- [Gamertag of the host](#).
- [Number of players in the network session](#).
- Number of free [public](#) and [private](#) slots. On Windows- and Xbox 360-based games, the supported range is between 2 and 31. On the Zune platform, the supported range is between 2 and 8.
- [Quality of service](#) information. This information is filled in over time, so search results will be returned initially without quality of service data, that will then become available at a later time.

Session Management

One important task in writing a networked game is managing the session, or instance, of the game. The events on the [NetworkSession](#) object allow you to be aware of the following:

- A player connects or disconnects using [GamerJoined](#) and [GamerLeft](#)
- The game has changed state between lobby, gameplay, and post-gameplay modes using [GameStarted](#), [GameEnded](#), and [SessionEnded](#)
- The network machine hosting the session changes using [HostChanged](#)

Lobby Transitions

The XNA Framework keeps track of whether the session is in the lobby or actually playing the game. It enables events to notify titles when the state changes. While in the lobby, each player can use [IsReady](#) to signal that he or she is ready to move from the lobby and into the game. The host can check [IsEveryoneReady](#) to see if all the players are ready to begin the game.

Each network session can use [AllowJoinInProgress](#) to specify whether the game supports join-in-progress. This is used in conjunction with the lobby versus play state to automatically update the session joinability status on the matchmaking servers.

Reliable Packet Delivery

Reliable TCP sockets generally are considered unsuitable for game networking, for a variety of reasons. Most of the reasons have to do with how the sockets handle congestion and how they prioritize in-order delivery over timeliness. Most games use UDP sockets, which means they send the vast bulk of their gameplay data unreliably. Reliable delivery is still necessary for some subsets of the data, however. To improve reliability, the XNA Framework provides a reliable delivery mechanism on top of UDP.

The XNA Framework [SendData](#) and [ReceiveData](#) methods are built over a reliable UDP packet layer. This packet layer provides optional ordering and/or delivery guarantees, plus automatic packet coalescence (if several packets are sent in rapid succession) and splitting (if the payload is too big for a single UDP wire packet) to make efficient use of the underlying UDP channel.

Fundamentally, this is a peer-to-peer architecture with reliable connections from each machine to all other machines. However, this does not place any limitation on what topologies the game can use for its own network traffic. Client-server, peer-to-peer, or any kind of hybrid architecture can benefit from the reliable UDP protocol supported by the XNA Framework.

Packet Delivery Options and Network Performance

There are five packet delivery options available through the [SendDataOptions](#) parameter that is passed to any call to [SendData](#):

- Unreliable, out-of-order ([SendDataOptions.None](#))
- Unreliable, in-order ([SendDataOptions.InOrder](#))
- Reliable, out-of-order ([SendDataOptions.Reliable](#))
- Reliable, in-order ([SendDataOptions.ReliableInOrder](#))
- Chat data ([SendDataOptions.Chat](#))

If a reliable sequential message sent using [SendDataOptions.ReliableInOrder](#) is dropped, later sequential messages cannot be delivered until the message is resent and received. In effect, this stalls the channel. If you use this option to send more messages, you are going to see real-world bottlenecks. If the receiver does not call [ReceiveData](#) quickly enough or just stops altogether, the queue of messages to resend fills up.

Unreliable sequential messages sent using [SendDataOptions.InOrder](#) may have gaps in the sequence, but they will never go backward or stall because of previous non-reliable sequential messages. Unreliably sent data will not be resent. This is good for information that is updated frequently, information such as player position. Newer information will be available by the time the sender attempts to resend the data. For all game data that is sent regardless of the delivery option, always be sure to send the minimum amount of data necessary to communicate the information. This can be done by sending only changes in the game state rather than the entire game state.

For best performance in a network game, minimize the use of reliable and in-order packet delivery. In general, reliable packet delivery should only be used for data critical for your game to function properly, as it consumes bandwidth resending packets as necessary.

[SendDataOptions.Chat](#) can be included independently of any other flags, and has two effects. First, any in-order chat sends are only guaranteed to be ordered with regard to other chat sends. There is no guarantee of ordering between non-chat and chat sends. Second, data within a chat send is not encrypted between the sender and receiver.

Network Topologies and Host Migration

Although the XNA Framework specifies one machine as the host of a session, this does not imply anything about the network topology used to route the actual gameplay. The host is responsible for the following:

- Owning the session description on the Xbox LIVE servers
- Updating multiplayer session properties as the game state changes
- Controlling when to transition between the lobby and play states
- Removing players from the session (peers cannot directly remove other peers – only the host can do this)

Games are free to choose any network topology for their gameplay data:

- Peer-to-peer
- Client-server, where the host doubles as the server
- Client-server, using one of the other session members as the server
- Any other hybrid approach

The host and server are often the same, but they are not required to be. The host has significance to the LIVE service, while the server relates purely to gameplay. The host is chosen by the XNA Framework. The host will be the machine that creates the session. However, the host may change if there is a host migration. The game architecture determines which server is chosen. The host is an important part of XNA Framework gamer services, but the concept of a server only exists inside the game code. There are no types or properties relating to servers in the framework itself. Games need not have any server at all if they are using a pure peer-to-peer architecture.

Hosts and Peers

One of the gaming machines is designated the host for a LIVE multiplayer session. The other gaming machines are peers. The concept of host or peer is independent of the network topology chosen for the game. That is, the concept of host does not necessarily imply that the console is the network host, or even that a client-host topology is in use, even though many titles align the two concepts.

The XNA Framework automatically handles host migration. When a host leaves, the run time will automatically elect a new host. It then raises an event to inform the game of the change. Support for host migration is optional. It is disabled by default.

Note that the XNA Framework automatically migrates the host, but not the server. The game is still responsible for migrating the simulation state. This is often trivial for peer-to-peer titles, but can be more challenging for client-server architectures. If the host quits the game gracefully through a menu selection, the game code could explicitly transfer the server simulation state before actually leaving the session. However, this is very difficult to do, particularly for the more general case of forced exits such as a hardware reboot.

Latency Simulation and Bandwidth Usage

To debug and test a networked game, you need to create at least two peers and have them communicate. There are several ways to create multiple peers, including running multiple instances across equal numbers of computers or a mix of computers and Xbox 360 consoles. Most development will take place on a local area network (LAN) where network throughput and quality is not an issue. Networked games that run across the Internet, however, will need to handle a number of issues such as lower bandwidth availability, non-reliable delivery of messages, and firewall and proxy support.

To help developers test networked games over a subnet where you will typically see much lower levels of latency and packet loss than can be expected, the XNA Framework includes a latency and packet loss simulator. This simulator requires no special hardware, extra network cards, or unusual Windows network configurations. You can use the latency simulation capabilities to test techniques, such as client-side prediction, that you might use in your game design.

You can use [NetworkSession.SimulatedLatency](#) to set the desired latency, and you can use [NetworkSession.SimulatedPacketLoss](#) to set a desired packet loss percentage.

The network simulation respects the [SendDataOptions.Reliable](#) and [SendDataOptions.InOrder](#) flags. Packets that are sent reliably will never be discarded, no matter how high [SimulatedPacketLoss](#) is set. Packets sent without [SendDataOptions.InOrder](#) will be delayed by a random value from a bell curve centered on the current [SimulatedLatency](#) setting, which has the effect of reordering packets in addition to delaying them. Packets that use [SendDataOptions.InOrder](#) will be delayed without any reordering.

For a game to play well over the Internet, it is recommended that you design it to handle up to 0.1 (10%) packet loss, and give it 200 milliseconds of latency.

The XNA Framework also includes performance metrics with the [NetworkSession.BytesPerSecondSent](#) and [NetworkSession.BytesPerSecondReceived](#) so games can easily measure upstream and downstream bandwidth usage.

Voice Support

Voice data is automatically transmitted and replayed without any title effort whatsoever. The [GamerPrivileges.AllowCommunication](#) property enables you to see which players are allowed to send voice data. The [LocalNetworkGamer.EnableSendVoice](#) method allows a game to programmatically specify which players can talk. Titles can use this to implement team chat or proximity voice. The XNA Framework does not expose direct program access to the voice data stream.

There are three Boolean properties exposed to query the voice status of another player:

- Do they have voice access? [NetworkGamer.HasVoice](#)
- Are they currently talking? [NetworkGamer.IsTalking](#)
- Are they muted? [NetworkGamer.IsMutedByLocalUser](#)

These properties allow games to display voice-related information in the user interface. One example would be flashing the name of the player who is currently talking.

How To: Create a Network Session

- [Conducting a Network Session](#)

A network session is made up of the players in the game and an optional set of attributes to aid in describing the type of session that is being created. The attributes that are used to describe an available multiplayer session are known as session properties. These session properties are created by you to describe this particular type of multiplayer session for your particular game. They might contain descriptions of details such as a whether this game is a timed session or capture-the-flag session.

Note

Creating a [NetworkSessionProperties](#) collection to describe your session is optional. You can also pass in **null** when creating a new network session.

The [NetworkSessionProperties](#) supports up to eight integer values that describe the session. Because these values are integers, we will create a set of enums in this example to describe these integer values and their placement in the [NetworkSessionProperties](#).

C#

```
enum SessionProperty{ GameMode, SkillLevel, ScoreToWin }

enum GameMode{ Practice, Timed, CaptureTheFlag }

enum SkillLevel{ Beginner, Intermediate, Advanced }
```

Conducting a Network Session

To describe session properties

1. Create a new [NetworkSessionProperties](#).
2. Set the values to the custom session properties.

C#

```
NetworkSessionProperties sessionProperties =
    new NetworkSessionProperties();

sessionProperties[(int)SessionProperty.GameMode]
    = (int)GameMode.Practice;
sessionProperties[(int)SessionProperty.SkillLevel]
    = (int)SkillLevel.Beginner;
sessionProperties[(int)SessionProperty.ScoreToWin]
    = 100;
```

You can create many different types of sessions. One is a local session, which is used for split-screen gaming and requires no network traffic. Another is a system link session, which connects multiple gaming machines over a local subnet. Finally, there is an Xbox LIVE multiplayer session, which takes place over the Internet. In this example, we will create a system link game.

Note

The gaming machine that creates the session is called the host. It owns the multiplayer session. The host does not imply a game server or authority. There are no network topologies implied, such as client-server, peer-to-peer, or hybrid. The network topology will be determined by your implementation of your game.

C#

```
NetworkSession session;

int maximumGamers = 8;
int privateGamerSlots = 2;
int maximumLocalPlayers = 1;
```

```
// Create the session
session = NetworkSession.Create(
    NetworkSessionType.SystemLink,
    maximumLocalPlayers, maximumGamers, privateGamerSlots,
    sessionProperties );
```

To enable host migration and join-in-progress functionality

- Set the [AllowJoinInProgress](#) and [AllowHostMigration](#) properties to values appropriate for your game.

C#

```
session.AllowHostMigration = true;
session.AllowJoinInProgress = true;
```

To subscribe to session events

- Subscribe to any session events in which your game has an interest.

Multiplayer sessions have events that occur when the game transitions from lobby to gameplay ([GameStarted](#) and [GameEnded](#)), when players join and leave ([GamerJoined](#) and [GamerLeft](#)), when the host changes ([HostChanged](#)), and when the session ends ([SessionEnded](#)).

C#

```
session.GamerJoined +=
    new EventHandler<GamerJoinedEventArgs>(session_GamerJoined);
session.GamerLeft +=
    new EventHandler<GamerLeftEventArgs>(session_GamerLeft);
session.GameStarted +=
    new EventHandler<GameStartedEventArgs>(session_GameStarted);
session.GameEnded +=
    new EventHandler<GameEndedEventArgs>(session_GameEnded);
session.SessionEnded +=
    new EventHandler<NetworkSessionEndedEventArgs>(
        session_SessionEnded);
```

To end the session

- If you are a host ending the session purposefully and the conditions for ending the session have been met, call [NetworkSession.EndGame](#).

In this example, when the host presses the ESC key or **Back** button indicating that the player wants to exit the game, the host checks to see whether there are players still in the game. If not, the host ends the session.

C#

```
// Check for exit.
if ( IsButtonPressed(GamePadButton.B ) ||
    IsButtonPressed( GamePadButton.Back ) )
{
    if (session != null)
    {
        if (session.AllGamers.Count == 1)
        {
            session.EndGame();
            session.Update();
        }
    }
}
```

The end of a game is controlled by the [NetworkSession.EndGame](#) method. At the end of a game, you might choose to move back to the lobby or to end the session. Players in the game can subscribe to the [NetworkSession.GameEnded](#) and

[NetworkSession.SessionEnded](#) events.

[How To: Find and Join a Network Session](#)

How To: Find and Join a Network Session

Describes how to find and join a network session.

The [NetworkSessionProperties](#) collection used to create a session with specific properties can also be used to search for sessions with particular properties. Because these values are integers, we will create a set of enumerations in this example to describe these integer values and their placement in the [NetworkSessionProperties](#) collection.

Note

Setting session properties to use as search parameters is an optional step. You may also pass in an empty [NetworkSessionProperties](#) to [NetworkSession.Find](#) or [NetworkSession.BeginFind](#) to view all available sessions regardless of property settings.

C#

```
enum SessionProperty{ GameMode, SkillLevel, ScoreToWin }

enum GameMode{ Practice, Timed, CaptureTheFlag }

enum SkillLevel{ Beginner, Intermediate, Advanced }
```

Joining a Network Session

To set the search parameters

1. Create a [NetworkSessionProperties](#) collection.
2. Set the values to the desired search parameters.

C#

```
NetworkSessionProperties searchProperties =
    new NetworkSessionProperties();
searchProperties[(int)SessionProperty.GameMode] =
    (int)GameMode.Practice;
searchProperties[(int)SessionProperty.SkillLevel] =
    (int)SkillLevel.Beginner;
```

To find an available network session

1. Create an [AvailableNetworkSessionCollection](#) to hold the search results.

C#

```
AvailableNetworkSessionCollection availableSessions;
```

2. Use [NetworkSession.Find](#) to retrieve the list of available sessions.
3. Specify the type of session in which you are interested, the number of local players that wish to join, and any session properties that should be matched when searching.

Note that the *searchProperties* argument is optional. You may pass in **null** to match any available session regardless of the session properties settings for that session.

C#

```
int maximumLocalPlayers = 1;
availableSessions = NetworkSession.Find(
    NetworkSessionType.SystemLink, maximumLocalPlayers,
    searchProperties);
```

Note

This search may also be performed asynchronously using [NetworkSession.BeginFind](#) and [NetworkSession.EndFind](#).

Once you have a list of available sessions, you can examine the session to determine if you would like to join a particular session. In this example, we will print some information about the available session for the player to examine.

C#

```
int sessionIndex = 0;
AvailableNetworkSession availableSession =
    availableSessions[sessionIndex];

string HostGamerTag = availableSession.HostGamertag;
int GamersInSession = availableSession.CurrentGamerCount;
int OpenPrivateGamerSlots =
    availableSession.OpenPrivateGamerSlots;
int OpenPublicGamerSlots =
    availableSession.OpenPublicGamerSlots;
string sessionInformation =
    "Session available from gamertag " + HostGamerTag +
    "\n" + GamersInSession +
    " players already in this session. \n" +
    +OpenPrivateGamerSlots +
    " open private player slots available. \n" +
    +OpenPublicGamerSlots + " public player slots available.";

spriteBatch.DrawString(spriteFont, sessionInformation,
    new Vector2(100, y), color);
```

To join an available multiplayer session

1. Create a [NetworkSession](#).

C#

```
NetworkSession session;
```

2. Join the [AvailableNetworkSession](#) using [NetworkSession.Join](#).

C#

```
session = NetworkSession.Join(
    availableSessions[selectedSessionIndex]);
```

3. After joining a [NetworkSession](#), subscribe to any session events that the peer might be interested in.

C#

```
session.GamerJoined +=
    new EventHandler<GamerJoinedEventArgs>(session_GamerJoined);
session.GamerLeft +=
    new EventHandler<GamerLeftEventArgs>(session_GamerLeft);
session.GameStarted +=
    new EventHandler<GameStartedEventArgs>(session_GameStarted);
session.GameEnded +=
    new EventHandler<GameEndedEventArgs>(session_GameEnded);
session.SessionEnded +=
    new EventHandler<NetworkSessionEndedEventArgs>(
    session_SessionEnded);
```

[Network Session Management](#)

Tasks

[How To: Create a Network Session](#)

How To: Manage Players Joining and Leaving the Game

Manages the data associated with a player by subscribing to events that occur when players are joining or leaving a game.

A [NetworkSession](#) contains several properties that list the players who have joined a session. The collection of all gamers in a session is described by the property [NetworkSession.AllGamers](#). This information is guaranteed to be the same on all game machines in a session. Within this list, the gamers might be local (playing on the same game machine through split-screen play) or remote (playing on a different game machine). The property [NetworkSession.LocalGamers](#) provides a list of all local players playing from a local game machine. The [NetworkSession.RemoteGamers](#) property provides a list of all players not playing on the local game machine.

To respond to players joining or leaving the game, you may subscribe to the [NetworkSession.GamerJoined](#) and [NetworkSession.GamerLeft](#) events with and create custom event handlers.

Subscribing to Gamer Events

To subscribe to gamer events

1. After creating or joining a session, subscribe to the events that are associated with players joining or leaving the game.

C#

```
session.GamerJoined +=
    new EventHandler<GamerJoinedEventArgs>(session_GamerJoined);
session.GamerLeft +=
    new EventHandler<GamerLeftEventArgs>(session_GamerLeft);
```

2. Create the [GamerJoined](#) event handler.

Note that the [GamerJoinedEventArgs](#) object contains a [Gamer](#) property. You can use it to read information about a specific player, or to associate information with a specific player. You can use the [Gamer.Tag](#) property to associate player data with the player.

C#

```
void session_GamerJoined(object sender, GamerJoinedEventArgs e)
{
    // Associate a tank object with this gamer.
    e.Gamer.Tag =
        new Tank(Content, GraphicsDevice.PresentationParameters);
}
```

3. Create the [GamerLeft](#) event handler.

C#

```
void session_GamerLeft(object sender, GamerLeftEventArgs e)
{
    Tank tank = e.Gamer.Tag as Tank;

    tank.LeaveGame();
}
```

Note

If the host player leaves the session calling [Game.Exit](#), this forces a host re-election. The host is automatically migrated to another player. If you are using a network topology other than peer-to-peer, such as a client-server or hybrid topology, and your host is also a server in the game, it will be necessary to migrate game state to the new game server when the host is migrated. Players in the game can use the [HostChanged](#) event to respond to host migration.

How To: Manage Player Movement Between Lobby and Gameplay Modes

Describes the properties and events associated with a multiplayer session that allow a game to move between lobby and gameplay modes. It identifies the game's current mode.

Managing Player Movement Between Modes

To manage player movement between lobby and gameplay modes

1. Hook up the session state change events.

The [NetworkSession.GameStarted](#) event indicates that all players have moved from the lobby to gameplay. The [NetworkSession.GameEnded](#) event occurs when the players move from gameplay back to the lobby. [NetworkSession.SessionEnded](#) occurs when the session is over, and all players move from the lobby of a session back to find another available session.

C#

```
session.GameStarted +=
    new EventHandler<GameStartedEventArgs>(session_GameStarted);
session.GameEnded +=
    new EventHandler<GameEndedEventArgs>(session_GameEnded);
session.SessionEnded +=
    new EventHandler<NetworkSessionEndedEventArgs>(
    session_SessionEnded);
```

2. Use [NetworkGamer.IsReady](#) to signal that a player is ready to move from the lobby to the game.

C#

```
// Signal I'm ready to play!
if (IsButtonPressed(GamePadButton.A))
{
    foreach (LocalNetworkGamer gamer in session.LocalGamers)
        gamer.IsReady = true;
}
```

3. On the host gaming machine, check [NetworkSession.IsEveryoneReady](#) to see if all players are ready.
4. If this is **true**, call [NetworkSession.StartGame](#) to change the game state from the lobby to gameplay mode.

C#

```
// The host checks if everyone is ready,
// and moves to game play if true.
if (session.IsHost)
{
    if (session.IsEveryoneReady)
    {
        session.StartGame();
        foreach (SignedInGamer signedInGamer in
            SignedInGamer.SignedInGamers)
        {
            signedInGamer.Presence.PresenceMode =
                GamerPresenceMode.InCombat;
        }
    }
}
```

5. In the [NetworkSession.GameStarted](#) event handler, make preparations for the game to begin.

In this example, the game object states are reset for the new game.

C#

```
void session_GameStarted(object sender, GameStartedEventArgs e)
{
    /// Reset everything when we are starting a new game.
    NetworkSession session = (NetworkSession)sender;

    for (int i = 0; i < session.AllGamers.Count; i++)
    {
        Tank tank = session.AllGamers[i].Tag as Tank;
        tank.Reset(i);
    }
}
```

6. In the [NetworkSession.GameEnded](#) event handler, make preparations to return the players to the lobby, such as recording the high score.

C#

```
void session_GameEnded(object sender, GameEndedEventArgs e)
{
    ReturnToLobby();
}
```

7. In the [NetworkSession.SessionEnded](#) event handler, return to the game title screen.

Note that before the session ends, the session can move between lobby and gameplay states as many times as the player wants. To retrieve the session state at any time, you can check the [NetworkSession.SessionState](#) property.

C#

```
void session_SessionEnded(object sender, NetworkSessionEndedEventArgs e)
{
    ReturnToTitleScreen();
}
```

How To: Join an In-Progress Game

Describes how to enable the [AllowJoinInProgress](#) property to make an in-progress game available to peers searching for available sessions.

Joining an In-Progress Game

To join an in-progress game

1. After creating a [NetworkSession](#), set [AllowJoinInProgress](#) to **true**.

C#

```
int maximumGamers = 8;
int privateGamerSlots = 2;
int maximumLocalPlayers = 1;

// Create the session
session = NetworkSession.Create(
    NetworkSessionType.SystemLink,
    maximumLocalPlayers, maximumGamers, privateGamerSlots,
    sessionProperties );

session.AllowJoinInProgress = true;
```

In the [NetworkSession.GamerJoined](#) event handler, the gamer may be a player who joined an in-progress game.

2. Associate any data necessary to enable a gamer to join while the game is in-progress.

C#

```
void session_GamerJoined(object sender, GamerJoinedEventArgs e)
{
    // Associate a tank object with this gamer.
    e.Gamer.Tag =
        new Tank(Content, GraphicsDevice.PresentationParameters);
}
```

Note

Network sessions of type [NetworkSessionType.Ranked](#) cannot be made join-in-progress, due to the competitive nature of ranked sessions.

How To: Send Data

Describes the options available for sending data to all clients or to a specific player.

Sending Data

To send data to all peers

1. Create a [PacketWriter](#) to use in writing the data.

The [PacketWriter](#) is a helper for efficiently formatting outgoing network packets. A multiplayer game can create a single [PacketWriter](#) instance at startup, and reuse it any time the players want to send a packet.

C#

```
PacketWriter packetWriter = new PacketWriter();
```

Each [LocalNetworkGamer](#) playing on the same game machine might send data. At this point, players can loop through the [LocalGamers](#) collection.

2. To send a packet, call the various overloads of the [PacketWriter.Write](#) method to store data into the writer, and then pass the [PacketWriter](#) to [SendData](#).

Note that it is also possible to send data to a specific player by specifying the player in the call to [SendData](#).

Sending the packet will automatically clear the [PacketWriter](#). It can then be reused to write different data for another packet. Although it is not used in this example, the [PacketWriter](#) supports offsets through the [Position](#) property.

In the call to [SendData](#), be careful to specify a [SendDataOptions](#) value for *options* that is appropriate for the type of data being sent. Not all game data needs to be sent reliably. Sending excessive data using [SendDataOptions.ReliableInOrder](#) can cause the client to lag as it waits for data to be delivered in order.

C#

```
foreach (LocalNetworkGamer gamer in session.LocalGamers)
{
    // Get the tank associated with this player.
    Tank myTank = gamer.Tag as Tank;
    // Write the data.
    packetWriter.Write(myTank.Position);
    packetWriter.Write(myTank.TankRotation);
    packetWriter.Write(myTank.TurretRotation);
    packetWriter.Write(myTank.IsFiring);
    packetWriter.Write(myTank.Health);

    // Send it to everyone.
    gamer.SendData(packetWriter, SendDataOptions.None);
}
```

How To: Receive Data

Describes how the local players on a gaming machine receive data from the other players in a networked game.

Receiving Data

To receive data

1. Create a [PacketReader](#) to assist in reading the incoming network data.

A [PacketReader](#) is a helper for efficiently reading incoming network packets. A multiplayer game can create a single [PacketReader](#) instance at startup. It can reuse it any time the players want to read a packet.

C#

```
PacketReader packetReader = new PacketReader();
```

Each [LocalNetworkGamer](#) playing on the same game machine might receive data. At this point, players can loop through the [LocalGamers](#) collection.

2. To read a packet, pass the [PacketReader](#) to [ReceiveData](#), and then use the various [PacketReader.Read](#) methods to extract data from the reader.

C#

```
foreach (LocalNetworkGamer gamer in session.LocalGamers)
{
    // Keep reading while packets are available.
    while (gamer.IsDataAvailable)
    {
        NetworkGamer sender;

        // Read a single packet.
        gamer.ReceiveData(packetReader, out sender);

        if (!sender.IsLocal)
        {
            // Get the tank associated with this packet.
            Tank remoteTank = sender.Tag as Tank;

            // Read the data and apply it to the tank.
            remoteTank.Position = packetReader.ReadVector2();
            remoteTank.TankRotation = packetReader.ReadSingle();
            remoteTank.TurretRotation = packetReader.ReadSingle();
            remoteTank.IsFiring = packetReader.ReadBoolean();
            remoteTank.Health = packetReader.ReadInt32();
        }
    }
}
```

How To: Write Games for Less Capable Hardware

Demonstrates how to write games for a variety of computer configurations. Specifically, this topic addresses ways to write a game so it will work on high-end hardware, yet continue to give adequate performance when the game is run on a computer that is less capable.

Computers with different graphics cards and CPUs give different levels of performance. Writing game code that prepares for and adapts to slower and less capable hardware will allow games to have a larger audience.

Hardware Specific Degradation

Pixel Shader Support

When possible, take advantage of high-end hardware, but do not rely on it. For example, it is a good idea to create and use shaders to take advantage of higher-end hardware if it will benefit the game. But it is also a good idea to create alternative shaders that give acceptable effects and performance on lower-end hardware.

The following code sample tests the current graphics adapter. If the current graphics adapter does not support at least pixel shader version 2.0, a 1.1 version pixel shader is used instead.

C#

```
ContentManager content = new ContentManager(Services);
Effect effect;

// Check the graphics device used by the game for the
// necessary shader support.
GraphicsDeviceCapabilities caps =
    GraphicsDevice.GraphicsDeviceCapabilities;

if (caps.MaxPixelShaderProfile < ShaderProfile.PS_2_0)
{
    // Select a 1.1 version pixel shader if the computer has a
    // graphics adapter that cannot support 2.0 shaders.
    effect = content.Load<Effect>("PixelShader1_1");
}
else
{
    // Graphics adapter supports 2.0 version pixel shaders.
    effect = content.Load<Effect>("PixelShader2_0");
}
```

Single vs. Multiple CPUs

If a computer has multiple CPUs, some work can be offloaded to the other CPUs. The following code sample shows how to determine the number of available CPUs in the computer. If the game takes advantage of multiple CPUs, but does not require them, this code sample describes where to place code for single-processor computers and multi-processor computers.

C#

```
// Scale appropriately for the number of processors on this computer

if (Environment.ProcessorCount == 1)
{
    // Perform tasks specific to single processor systems.
}
else
{
    // Perform tasks specific to multi-processor systems.
}
```

Performance-Specific Degradation

You can measure performance levels by the number of times the [Update](#) method is called each second. Once the update rate falls below a certain level (the default is 60 times per second) [GameTime.IsRunningSlowly](#) will be set to **true**.

This code sample shows where to place code that should be skipped if the game's performance falls below 60 frames per second.

C#

```
// Perform the following only if the game is running
// at 60 frames per second or faster

if (gameTime.IsRunningSlowly == false)
{
    // Perform time consuming update or draw here.
}
```

If 60 frames per second is not ideal for the game, you can change the default by altering [TargetElapsedTime](#). To have [IsRunningSlowly](#) become **true** when the game slows to less than 30 frames per second, include this in the program's initialization code.

C#

```
// Alert the program when the frame rate falls below 30 frames per second.

TargetElapsedTime = new TimeSpan(10000000L / 30L);
```

To test for a different frame rate, change the 30 of the 30L to the frames-per-second desired (for example, 45L for 45 frames per second, or 100L for 100 frames per second).

Xbox 360 Programming Considerations

Summarizes a few of the issues that XNA Framework programmers should consider when creating Xbox 360 games.

Graphics Considerations

The most important graphics consideration for programming for the Xbox 360 console is the wide variety of televisions that the Xbox 360 system supports. The Xbox 360 system supports both HDTV and normal television sets, at multiple resolutions (480p, 720p, 1080i, and 1080p), and multiple aspect ratios (4:3, 16:9, and 16:10). The console will automatically scale the output of a game to the resolution of the owner's display, and if the game is using a widescreen aspect ratio, the console automatically adds "black bars" (letterboxing) if the owner's display is not widescreen.

However, there are still two things XNA Framework programmers should consider when programming for the Xbox 360: the title safe region, and aspect ratios.

Title Safe Region

On standard tube televisions, the display area of the television is normally not a perfect rectangle. In fact, a significant amount of the display may not be visible on a CRT tube. In television, the inner 80–90 percent of the picture is considered the "title safe" region. Any graphics displayed outside of this region on a standard television may be obscured or distorted.

[How To: Draw a Sprite](#) demonstrates how to calculate the title safe region for the current display using the [Viewport](#) on the current [GraphicsDevice](#).

Programmers should ensure that any critical information (score, number of lives, ammo, and so on) is displayed within the title safe region, while drawing the background or a 3D scene across the entire display. Critical text should be displayed within the inner 80 percent of the screen. Programmers should also ensure that any text displayed on-screen is large enough to be legible on a standard television.

Aspect Ratio

If the aspect ratio of the back buffer is widescreen and the aspect ratio of the owner's display is not, the Xbox 360 will add black bars at the top of the display so that the entire back buffer is on screen. To avoid letterboxing, developers must program their games to use both standard and widescreen aspect ratios, and adjust their display to the default aspect ratio offered by the Xbox 360. For this reason, a single widescreen back buffer on Xbox games is recommended.

To detect the console display setting, you can use the [DisplayMode](#) property on the [GraphicsDevice](#). This will be valid during or after your game's [Initialize](#) method. Some common display modes are listed here.

Xbox Display Setting	DisplayMode Width and Height
AV (Composite)	640×480
480p (Normal)	640×480
480p (Widescreen)	640×480
720p (Widescreen)	1280×720
1080i/1080p (Widescreen)	1920×1080

Multisampling

4×AA multisampling is provided for free by the Xbox 360, so using 4×AA multisampling is recommended. Developers should be aware that this will often activate predicated tiling.

Shader Versions

Shaders compiled for Xbox 360 will be compiled as Shader 3.0 shaders regardless of the version specified in the effect file. Shaders written for 1.1 may exhibit errors on Xbox 360 if they depended on clamping behavior in 1.1 that is not present in 3.0.

Multiple Render Targets

Render targets function similarly on both Xbox 360 and Windows. By default, the content of a render target is always cleared when the render target is resolved unless [persistence](#) was specified during construction of the render target. Developers can avoid problems by rendering fully to each render target before using a new render target, and by rendering their final scene after all the other render targets have been resolved.

TextureUsage Flags

[TextureUsage](#) flag settings other than [TextureUsage.Tiled](#) and [TextureUsage.Linear](#) have no effect on Xbox 360. You will still get exceptions in Xbox 360 games if you specify [TextureUsage](#) settings that are not valid on Windows. It is recommended that you use [TextureUsage.None](#) on Xbox 360 and Windows whenever possible.

⚠ Caution

The [Texture.FromFile](#) method is only available when programming for Windows.

Dynamic Vertex Buffer Usage

Xbox 360 does not support dynamic vertex buffers that use the Overwrite/Discard semantic. This affects calls to [DrawPrimitives](#). For this reason, when rendering dynamic geometry, [DrawUserPrimitives](#) is recommended at all times on both Xbox 360 and Windows. (The performance disadvantages of [DrawUserPrimitives](#), though previously a factor on Windows, are largely obsolete in newer video drivers.)

Also for performance reasons, *static* geometry should always be rendered using vertex buffers and [DrawPrimitives](#).

For more information, see [Dynamic Vertex Buffers in XNA](#).

Input Considerations

The Xbox 360 supports three input devices: the game controller, the Xbox LIVE Vision camera, and an optional USB keyboard. Mice are not supported, and most Xbox 360 users will not have a keyboard connected to their console. The XNA Framework does not support the Vision camera. Games for the Xbox 360 should be programmed so that they will accept all critical input from the gamepad.

Audio Considerations

XACT audio wave banks, sound banks, and settings files are platform-specific. The XNA Framework Content Pipeline will automatically process XACT project files (.xap) into the correct platform type if the project file is added to Solution Explorer. If you are building the XACT project manually, ensure you are using the correct built files for your platform type when you load the built files into your game. Failure to use the correct platform-specific files will result in an error.

Storage Considerations

Accessing a player's storage on Xbox 360 (to let them save a game, for example) requires displaying the Storage Device Guide, where the user can choose between the hard drive or memory units. The best way to do this is to use the [BeginShowStorageDeviceSelector](#) method, as demonstrated in [How To: Get a StorageDevice Asynchronously](#). The largest space available on a memory unit is 52 MB, so any saved games must not exceed that size.

The maximum size of an XNA Framework project on an Xbox 360 console is 2 GB, so the entire game, including support files (level data, sound, and so on) must not exceed that size.

Source Code Considerations

Xbox 360 projects define an XBOX symbol for use with conditional compilation directives such as **#if**. You can use this to maintain source code that acts differently on Windows and Xbox 360 if that source is shared between projects. [How To: Draw a Sprite](#) shows an example of conditional compilation where the available screen space is calculated differently for Xbox 360 and Windows.

Xbox 360 Surface Formats

In the XNA Framework, all two-dimensional (2D) images are represented by a range of memory called a surface. Within a surface, each element holds a color value representing a small section of the image, called a pixel. An image's detail level is defined by both the number of pixels needed to represent the image, and the number of bits needed for the image's color spectrum. For example, an image that is 800 pixels wide by 600 pixels high with 32 bits of color for each pixel (written as $800 \times 600 \times 32$) is more detailed than an image that is 640 pixels wide by 480 pixels tall with 16 bits of color for each pixel (written as $640 \times 480 \times 16$). Likewise, the more detailed image requires a larger surface to store the data. For an $800 \times 600 \times 32$ image, the surface's array dimensions are 800×600 , and each element holds a 32-bit value to represent its color.

All surfaces have a size and store a specific number of bits that represent color. The bits that represent color are separated into individual color elements: red, green, and blue. All color elements are defined by the [SurfaceFormat](#) enumerated type. A color format is broken down into the number of bytes reserved for each color. For example, a 16-bit color format is defined as [SurfaceFormat.BGR565](#), where 5 bits are reserved for red (R), 6 bits for green (G), and 5 bits for blue (B).

On any platform, you can obtain the available render target platforms and depth-stencil formats by using the [GraphicsAdapter.CheckDeviceFormat](#) and [GraphicsAdapter.CheckDepthStencilMatch](#) methods

Render Target Formats

The following render target formats are supported on the Xbox 360 platform.

- [SurfaceFormat.Single](#)
- [SurfaceFormat.Vector2](#)
- [SurfaceFormat.HalfVector2](#)
- [SurfaceFormat.HalfVector4](#)
- [SurfaceFormat.Color](#)
- [SurfaceFormat.Bgr32](#)
- [SurfaceFormat.Rgba32](#)
- [SurfaceFormat.Rgb32](#)
- [SurfaceFormat.Bgra1010102](#)
- [SurfaceFormat.Rgba1010102](#)
- [SurfaceFormat.NormalizedAlpha1010102](#)

Both $2 \times$ and $4 \times$ multisampling are supported. On resolve, the GPU can downsample multisampled render targets, and it can format conversion. However, multisample downsampling is limited to blendable target formats.

Render targets must be padded to certain dimensions based on the multisample mode. The padding required for 32-bits-per-pixel formats is 80×16 for $1 \times$ antialiasing, 80×8 for $2 \times$ antialiasing, and 40×8 for $4 \times$ antialiasing.

Depth-Stencil Formats

The following depth-stencil formats are supported on the Xbox 360 platform.

- [DepthFormat.Depth24](#)
- [DepthFormat.Depth24Stencil8](#)
- [DepthFormat.Depth24Stencil8Single](#)

Unsupported Surface Formats

The following surface formats are not supported on the Xbox 360 platform for any [ResourceType](#), including textures:

- [SurfaceFormat.Bgr24](#)
- [SurfaceFormat.Bgra2338](#)
- [SurfaceFormat.Bgr233](#)
- [SurfaceFormat.NormalizedByte2Computed](#)
- [SurfaceFormat.LuminanceAlpha8](#)
- [SurfaceFormat.Palette8](#)

Predicated Tiling

Describes predicated tiling in Xbox 360 development.

The Xbox 360 has 10 MB (10×1024×1024) of fast embedded dynamic RAM (EDRAM) that is dedicated for use as the back buffer, depth stencil buffer, and other render targets. Depending on the size and format of the render targets and the antialiasing level, it may not be possible to fit all targets in EDRAM at once. For example, 10 MB of EDRAM is enough to hold two 1280×720 32-bit surfaces with no multisample antialiasing (MSAA) or two 640×480 4× MSAA 32-bit surfaces. However, a 1280×720 2× MSAA 32-bits-per-pixel render target is 7,372,800 bytes. Combined with a 32-bit Z/stencil buffer of the same dimensions, it becomes apparent that 10 MB might not be sufficient.

Predicated tiling allows rendering to larger surfaces than can fit into EDRAM at any one time. In predicated tiling, the screen space is broken up into tiles (rectangles). The following figure shows the screen space broken into two tiles.

In predicated tiling, the commands issued in the **Draw** method are recorded before execution. The recorded commands, such as **DrawPrimitives** calls, are then executed for each tile, predicated based on whether the rendered primitives intersect the tile. In the preceding figure, both the triangle primitives would be rendered in **Tile 0**. Once the primitives for a tile are fully rendered, the tile is then resolved into the texture that is used for the front buffer. Each successive tile is handled the same way and is resolved into the same texture.

Triggering Predicated Tiling

Predicated tiling occurs automatically for Xbox 360 games created with XNA Game Studio when the size and format of the render targets exceed the console's available EDRAM. In predicated tiling, the size of the render targets and the depth-stencil are no longer limited by EDRAM memory, although each individual tile has to fit into EDRAM.

Once predicated tiling has been triggered, all rendering commands in **Draw** are accumulated and played back for each tile in separate passes. An adjusted window offset and clip rectangle are used to render only those portions that intersect with the specified screen-space tile rectangle. Drawing is done only when the primitive drawing call is known to be visible on the given tile. This is determined by using hardware screen-space extent queries, which compute if the geometry lies within the tile. All rendering is then completed using the render target and depth stencil surface that are currently set.

Restrictions Encountered After Predicated Tiling Has Been Triggered

A few restrictions apply when predicated tiling has been triggered.

Resources that are referenced in the command buffer cannot be modified by the CPU, because the command buffer has to be played back more than once to accomplish the tiling. It is okay for the GPU to modify resources and then reuse them in the same pass, because the GPU can appropriately recreate the memory on every pass.

Specifically, in the **Draw** method of an Xbox 360 game, vertex buffers, index buffers, and textures should not be written to using **SetData** during the **Draw** method. This condition may lead to graphics corruption or crashes. For vertex buffers, this issue can be avoided by using [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#) as the preferred alternative to [VertexBuffer.SetData](#) for dynamic vertex generation.

Data from an occlusion query (specifically, a call to [IsComplete](#)) on Xbox 360 is not available from within the tiling bracket. Access this data by switching to a different render target or end the frame. This condition does not apply to games targeting the Windows platform.

HLSL Input Semantics (Xbox 360)

Describes the high-level shader language (HLSL) input semantics available when developing games for Xbox 360.

Vertex Shader Input Semantics

One special vertex shader input semantic is available in HLSL for the Xbox 360: INDEX. Any kind of shader can use the INDEX input semantic. It enables you to retrieve vertex.

For more details, see [Vertex Fetching in HLSL](#).

Pixel Shader Input Semantics

To support point sprites, a specific pixel shader input semantic is available in HLSL: SPRITETEXCOORD. This semantic is required to read the sprite texture coordinates in a point sprite pixel shader.

The following HLSL code demonstrates a pixel shader that can be used with SPRITETEXCOORD to render point sprites.

```
sampler2D s;  
float4 main( float2 t : SPRITETEXCOORD ) : COLOR  
{  
    return tex2D( s, t );  
}
```

HLSL Attributes (Xbox 360)

High-level shader language (HLSL) attributes are compiler hints that you can apply in your Xbox 360 shader code.

The HLSL compiler uses attributes to generate microcode in the manner specified by the attributes. HLSL attributes give the compiler more information about how to compile your shaders.

Use HLSL attributes to generate optimized microcode from HLSL source. For example, you can use HLSL attributes to control how branching statements are compiled into microcode, controlling the type microcode branching instructions that will be emitted. Using HLSL attributes, you can optimize your code and sometimes control the amount of microcode emitted.

HLSL attributes for Xbox 360 are similar to DirectX 10 HLSL attributes for Microsoft Windows.

Attribute Categories

High-level shader language (HLSL) attributes for Xbox 360 are compiler hints that influence how microcode is generated from HLSL. Using the attributes, you can optimize how microcode is emitted and tune the shader performance.

The high-level shader language attributes consist of the following categories.

- [Branching Statement Attributes](#)
- [Looping Statement Attributes](#)
- [Function Attributes](#)
- [Miscellaneous Attributes](#)

Branching Statement Attributes

HLSL supports the following attributes that modify the microcode output of branching statements. These attributes affect only **if** statements.

- [branch](#)
- [flatten](#)
- [ifAll](#)
- [ifAny](#)
- [predicate](#)
- [predicateBlock](#)

Looping Statement Attributes

HLSL supports the following attributes that modify the microcode output of looping statements. Use these attributes to affect **for**, **while**, and **do-while** statements.

- [unroll](#)
- [loop](#)

Function Attributes

HLSL supports the following attributes that modify the microcode output related to functions. Use these attributes to affect either how functions are called or how microcode is generated throughout the scope of a function.

- [call](#)
- [maxExports](#)
- [maxTempReg](#)
- [reduceTempRegUsage](#)
- [smpreg](#)

Miscellaneous Attributes

HLSL supports the following attributes to isolate areas of HLSL code for optimization and mark certain input parameters as unused.

- [isolate](#)
- [maxInstructionCount](#)
- [noExpressionOptimizations](#)
- [removeUnusedInputs](#)
- [unused](#)

Attribute Syntax

High level shader language (HLSL) attributes use the following syntax.

```
[AttributeName [ (Parameter) ] ]
```

Apply HLSL attributes by specifying the attribute name between opening and closing brackets.

Some attributes accept parameters, while others do not. Parameters are passed between opening and closing parentheses similar to the way C function parameters are passed. If the attribute does not accept a parameter, you do not have to supply the parentheses.

Different HLSL attributes modify different statement types. To modify a statement, place the attribute in front of a statement type that is compatible with the particular attribute you are using. HLSL attributes can modify the following types of statements.

- Branching statements.
- Loop statements.
- Functions.
- Function parameters.
- Output parameters.
- Arbitrary statements, functions, or scopes delineated by brackets.
- Entire shaders.

Applying HLSL Attributes

The following code example demonstrates how to apply an attribute. This example applies the `call` attribute to an HLSL function. Using the `call` attribute, you can specify that a function should not be inlined.

```
[call]
float4 MyFunction()
{
// ...
}
```

The HLSL compiler provides warnings that help you properly apply attributes. The HLSL compiler displays a warning in the following cases.

- An attribute is unrecognized.
- An attribute is applied to an incompatible statement.
- An attribute cannot be respected in the current context.

Contains reference information about high-level shader language (HLSL) attributes. The following HLSL attributes are implemented.

Attribute	Description
branch	Performs branching.
call	Prevents inlining of a function.
flatten	Performs branching.
ifAll	Executes the conditional part of an if statement when the condition is true for all threads on which the current shader is running.
ifAny	Executes the conditional part of an if statement when the condition is true for any thread on which the current shader is running.
isolate	Optimizes the specified HLSL code independently of the surrounding code.
loop	Gives preference to flow control constructs.
maxexports	Specifies the maximum number of export instructions that will execute along any path from the entry point to an exit.
maxInstructionCount	Sets the maximum number of instructions available to a shader.
maxtempreg	Restricts temporary register usage to the number of registers specified. Generates a compiler error if unsuccessful.
noExpressionOptimizations	Avoids optimization of expressions.
predicate	Performs branching by using predication.
predicateBlock	Performs branching by using predicated exec blocks.
reduceTempRegUsage	Restricts temporary register usage to the number of registers specified. Generates a compiler warning if unsuccessful.
removeUnusedInputs	Removes unused interpolator inputs from pixel shaders.
sampreg	Sets the ranges of pixel and vertex sampler registers used by the compiler.
unroll	Avoids flow control constructs.
unused	Suppresses warnings about unused shader parameters.

Parameters

None

Scope

Applies to **if** statements.

call (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Prevents inlining of a function.

Syntax

```
[call]
```

Parameters

None

Scope

Applies to function definitions and function calls.

Remarks

By default, all user-defined HLSL functions are inlined by the HLSL compiler on Xbox 360. Use the **call** attribute to turn off inlining and decrease the amount of microcode emitted by the HLSL compiler.

You can use the **call** attribute to control inlining either when the function is defined or when a function is called.

- If applied to a function definition, the function will not be inlined anywhere.
- If applied to a function call, the function will not be inlined during the current call, but might be inlined elsewhere.

Examples

The following HLSL code snippet demonstrates how to apply the **call** attribute.

```
// This function will not be inlined.
[call]
float4 ComputePosition1 ()
{
    ...
}

// This function will be inlined wherever possible.
float4 ComputePosition2 ()
{
    ...
}

float4 main () : POSITION
{
    // ComputePosition1 will not be inlined.
    // ComputePosition2 will be inlined at this specific call site.
    float4 pos = ComputePosition1() + ComputePosition2();

    // ComputePosition2 will not be inlined at this specific call site.
    [call]
    return pos + ComputePosition2();
}

Parameters

None.

Scope

Applies to **if** statements.

ifAll (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Executes the conditional part of an **if** statement when the condition is true for all threads on which the current shader is running.

Syntax

```
[ifAll]
```

Parameters

None.

Scope

Applies to **if** statements.

Remarks

Apply the **ifAll** attribute to **if** statements to make a dynamic branch behave more like a static branch. This causes all threads to branch together. The **ifAll** attribute executes conditional statements only if the condition is true on all threads.

On static branches, the **ifAll** attribute is similar to the [branch](#) attribute. However, the **ifAll** attribute does not permit optimizations that need to invert the original branch condition.

On dynamic branches, the **ifAll** attribute differs from the [branch](#) attribute. When you apply the [branch](#) attribute to a dynamic **if** statement, the conditional statements are predicated. They are skipped only if no thread needs to execute the code. The [branch](#) attribute allows each thread to execute different instructions for an **if** statement. The **ifAll** attribute forces every thread to execute the same instructions.

Note that you cannot apply the **ifAll** attribute to a nested dynamic branch.

Examples

The following HLSL code snippet shows how to apply the **ifAll** attribute.

```
float x = tex2D( sampler, coord );
float result = g_value1;

[ifAll]
if (x > 0)
{
    result = g_value2;
}
```

ifAny (HLSL)

Note

Executes the conditional part of an **if** statement when the condition is true for any thread on which the current shader is running.

Syntax

```
[ifAny]
```

Parameters

None.

Scope

Applies to **if** statements.

Remarks

Apply the **ifAny** attribute to **if** statements to make a dynamic branch behave more like a static branch. This causes all threads to branch together. The **ifAny** attribute executes conditional statements if the condition is true on any thread.

On static branches, the **ifAny** attribute is similar to the [branch](#) attribute. However, the **ifAny** attribute does not permit optimizations that need to invert the original branch condition.

On dynamic branches, the **ifAny** attribute differs from the [branch](#) attribute. When you apply the [branch](#) attribute to a dynamic **if** statement, the conditional statements are predicated. They are skipped only if no thread needs to execute the code. The [branch](#) attribute allows each thread to execute different instructions for an **if** statement. The **ifAny** attribute forces every thread to execute the same instructions.

Note that you cannot apply the **ifAny** attribute to a nested dynamic branch.

Examples

The following HLSL code snippet shows how to apply the **ifAny** attribute.

```
float x = tex2D( sampler, coord );
float result = g_value1;
[ifAny]
if (x > 0)
{

isolate (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Optimizes the specified HLSL code independently of the surrounding code.

Syntax

```
[isolate]
```

Parameters

None.

Scope

Applies to output parameter declarations, functions, structures, or any scope.

Remarks

You can apply the **isolate** attribute in the following ways.

- When the attribute is applied to an output parameter declaration, any code related to computation of the output is optimized independently of the rest of the function.
- When the attribute is applied to a scope, microcode in the scope is optimized independently of the surrounding code. Isolated scopes are ordered with respect to each other. Isolated scopes can be nested. The inner scope is optimized independently of the outer scope.
- When the attribute is applied to a function, the function can be inlined, but the inlined code will not be merged with code at the call site.
- When the attribute is applied to a structure that is returned by a shader, the function has the same effect as applying it to an output parameter.

The **isolate** attribute is useful for multipass shaders that need a floating-point output of two different shaders to be equivalent bitwise. The generated microcode of the two shaders might not be identical bit-for-bit, but both shaders should compute bit-for-bit identical results.

When you work with multipass shaders, the source code affected by the **isolate** attribute must be identical to guarantee identical microcode. Subtle differences in the HLSL can cause the **isolate** attribute to emit different microcode. Sometimes the emitted microcode has the same instructions, but it might have different [swizzle](#) values, or it might have different combinations of the same vector computations. Differences in HLSL can also affect the order in which optimizations occur.

Example

The following HLSL code snippet shows how to apply the **isolate** attribute.

```
// Apply the attribute to a declaration.
void main ([isolate] out float4 pos : POSITION)
{
    pos = ComputePosition();
}

// These two fetches are always generated in the order specified in the
// HLSL.
[isolate]
{
    tex1 = tex3D( coord1 );
}

[isolate]
{
    tex2 = tex3D( coord2 );
}

// The HLSL compiler can swap these two fetches, but the compiler cannot
// insert other instructions between them.
```

```
[isolate]
{
    tex1 = tex3D( coord1 );
    tex2 = tex3D( coord2 );
}
```

Gives preference to flow control constructs.

Syntax

```
[loop]
```

Parameters

None.

Scope

Applies to **for**, **while**, and **do-while** statements.

Examples

The following HLSL code snippet shows how to apply the **loop** attribute.

```
float value = 0;

[loop]

maxexports (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Specifies the maximum number of export instructions that will execute along any path from the entry point to an exit.

Syntax

```
[maxexports(n)]
```

Parameters

n

Integer that represents the maximum number of export instructions.

Scope

Applies to functions. The **maxexports** attribute is ignored on any function except the shader entry point that is currently being compiled.

Examples

The following HLSL code snippet shows how to apply the **maxexports** attribute.

```
row_major float4x4 a;  
float4 b;  
row_major float4x4 c;  
float4 d;  
  
[maxexports(2)]  
void main ( out float4 pos : POSITION,  
            out float4 coord : TEXCOORD ) {  
  
    pos = mul( a, b );  
    coord = mul( c, d );  
}
```

Without the call to the **maxexports** attribute, each **mul** HLSL intrinsic yields four microcode instructions.

With the call to the **maxexports** attribute, the HLSL compiler adds extra **mov** instructions to reduce the number of export instructions to two.

maxInstructionCount (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Sets the maximum number of instructions available to a shader.

Syntax

```
[maxInstructionCount(n)]
```

Parameters

n

Integer that represents the maximum number of instructions. The *n* parameter must be a value between 256 and 3839.

Scope

Applies to an entire shader.

Remarks

The Xbox 360 GPU contains an instruction store of 4096 microcode instructions that Direct3D allocates between vertex and pixel shaders. By default, Direct3D allocates 2047 instructions on the GPU to vertex shaders and 2048 instructions on the GPU to pixel shaders. (One instruction at index 0 is reserved.) By default, the HLSL compiler accommodates these requirements by emitting shaders that do not exceed 2048 instructions.

Use the **maxInstructionCount** attribute to increase or decrease the limit to the number of instructions that can be emitted by the HLSL compiler. Note that this attribute does not change the number of instructions allocated to shaders on the GPU.

The number of instructions that can be emitted by the HLSL compiler should not be greater than the number of instructions available on the GPU. This situation produces an error.

maxtempreg (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Restricts temporary register usage to the number of registers specified. Generates a compiler error if unsuccessful.

Syntax

```
[maxtempreg(n)]
```

Parameters

n

Integer that represents the maximum number of temporary registers.

Scope

Applies to functions. The **maxtempreg** attribute is ignored on any function except the shader entry point that is currently being compiled. The parameter also applies to any function that is compiled for this entry point, whether the function is inlined or not.

Remarks

If the HLSL compiler is unable to restrict temporary registers to the number specified by the **maxtempreg** attribute, the compiler reports an error and fails to compile the shader.

Note that the [reduceTempRegUsage](#) attribute also restricts temporary register usage. However, the [reduceTempRegUsage](#) attribute reports a warning and then does compile the shader by using the number of temporary registers as close as possible to the number specified.

Examples

The following HLSL code snippet shows how to apply the **maxtempreg** attribute and the [reduceTempRegUsage](#) attribute. This example specifies that the compiler never allocate more than 32 registers for temporary usage. Instead, the compiler should try to stay as close to 12 registers as possible. If the compiler exceeds an allocation of 12 registers, it displays a warning. However, if the compiler exceeds 32 registers, it displays an error and fails to compile the shader.

```

noExpressionOptimizations (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Avoids optimization of expressions.

Syntax

```
[noExpressionOptimizations]
```

Parameters

None.

Scope

Applies to statements, functions, or any scope.

Remarks

The **noExpressionOptimizations** attribute instructs the compiler not to optimize expressions. The resulting microcode assembly is kept as close to the original HLSL as possible.

In general, do not apply the **noExpressionOptimizations** attribute. Use it only to disable optimizations that are causing problems in your code.

In some situations, the compiler must perform expression optimization even if you apply the **noExpressionOptimizations** attribute. For example, the compiler must optimize expressions during sampler array indexing.

Also, the compiler may need to optimize expressions within the scope of the attribute when neighboring code is optimized. To avoid this situation, apply the **noExpressionOptimizations** attribute to the shader entry point.

The **noExpressionOptimizations** attribute cannot be nested. This attribute implies the [isolate](#) attribute.

Remarks

Use the **predicateBlock** attribute with the [flatten](#) attribute to specify exactly how to flatten a branch.

reduceTempRegUsage (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Restricts temporary register usage to the number of registers specified. Generates a compiler warning if unsuccessful.

Syntax

```
[reduceTempRegUsage(n)]
```

Parameters

n

Integer that represents the maximum number of temporary registers.

Scope

Applies to functions. The **reduceTempRegUsage** attribute is ignored on any function except the shader entry point that is currently being compiled.

Remarks

If the HLSL compiler is unable to restrict temporary registers to the number specified by the **reduceTempRegUsage** attribute, the HLSL compiler reports a warning and then compiles by using the number of temporary registers as close as possible to the number specified.

Note that the [maxtempreg](#) attribute also restricts temporary register usage. However, the [maxtempreg](#) attribute reports an error and fails to compile if it is unable to restrict temporary registers to the number specified.

Examples

The following HLSL code snippet demonstrates how to apply the **reduceTempRegUsage** attribute and the [maxtempreg](#) attribute. This example specifies that the compiler should never allocate more than 32 registers for temporary usage, but should try to stay as close to 12 registers as possible. If the compiler exceeds an allocation of 12 registers, it displays a warning. However, if the compiler exceeds 32 registers, it displays an error and fails to compile the shader.

```
[maxtempreg(32) ]
[reduceTempRegUsage(12) ]
float4 main ( float4 in )
{
    // ...
}
```

removeUnusedInputs (HLSL)

Removes unused interpolator inputs from pixel shaders.

Syntax

```
[removeUnusedInputs]
```

Parameters

None.

Scope

Applies to an entire pixel shader.

Remarks

Apply the **removeUnusedInputs** attribute to a pixel shader entry point. This automatically removes unused interpolator inputs.

Without the **removeUnusedInputs** attribute, the HLSL compiler declares all interpolator inputs in the microcode, whether they are used or not. If interpolator inputs are not used, and the [unused](#) attribute is not applied to them, the compiler displays a warning.

The **removeUnusedInputs** attribute can sometimes improve performance for shaders that are interpolant-bound. Removing unused interpolants allows the shader to spend less time in the interpolant calculation phase.

The **removeUnusedInputs** attribute is sometimes disadvantageous, because it can cause vertex shader outputs and pixel shader inputs to be mismatched. If the two are mismatched, the shaders are patched, which can decrease performance.

sampreg (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Sets the ranges of pixel sampler and vertex sampler registers used by the compiler.

Syntax

```
[sampreg(n,m)]
```

Parameters

n

Starting vertex sampler register.

m

Starting pixel sampler register.

Scope

Applies to functions. The **sampreg** attribute is ignored on any function except the shader entry point that is currently being compiled. The parameters also apply to any function that is compiled for this entry point, whether the function is inlined or not.

unroll (360 HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Avoids flow-control constructs.

Syntax

```
[unroll(MaxIterationCount)]
```

Parameters

MaxIterationCount

An integer that represents the iteration count. The *MaxIterationCount* parameter is optional. If it is omitted, the HLSL compiler automatically determines the iteration count.

Scope

Applies to **for**, **while**, and **do-while** statements.

Remarks

The iteration count can be any arbitrary expression and is handled much like inline microcode options. For example, the iteration count can be a function parameter. The HLSL compiler automatically inlines the function to resolve the parameter to a constant.

Examples

The following HLSL code snippet shows how to apply the **unroll** attribute.

```
float value = 0;
[unroll(3)]
while( value <= 5 )
{
    value ++;
}
```

unused (HLSL)

Note

This HLSL attribute is available only when developing for the Xbox 360.

Suppresses warnings about unused shader parameters.

Syntax

```
[unused]
```

Parameters

None.

Scope

Applies to function parameters.

Remarks

The **unused** attribute is useful for shaders that use preprocessors, where the same vertex shader is used with different pixel shaders. In this case, a pixel shader may not use some of the inputs.

Examples

The following HLSL code snippet shows how to apply the **unused** attribute.

```
float4 main ( float4 coord0 : TEXCOORD0,  
[unused] float4 coord1 : TEXCOORD1 ) : COLOR  
{  
    #ifdef SHADER_2  
        return coord0 + coord1;

Zune Programming

The following topics discuss programming for the Zune platform, and provide information about Zune hardware capabilities.

In This Section

[Zune Programming Considerations](#)

Describes general programming issues to consider when creating Zune games.

[Zune HD Input Overview](#)

Provides an overview of the touch screen and accelerometer input features for the Zune HD device.

[Zune Button Mapping](#)

Describes how various Zune buttons map to the buttons on a standard Xbox 360 gamepad.

Provides an overview of networked Zune games.

[How To: Build a Simple Networked Game on Zune](#)

Demonstrates networking functionality on Zune.

Zune Programming Considerations

Describes general programming issues to consider when creating Zune games.

Graphics

When programming for Zune, these graphics considerations are the most important:

- Zune supports 2D graphics only.
- Zune has a fixed 240x320 display size.

Zune Display Surface

The Zune device has a fixed display size of 240x320 pixels. The display can be used in either portrait or landscape orientation.

Zune games use the full 240x320 resolution of the Zune display. The entire display surface is available for text, and for critical game information such as score, number of lives, ammo, and so on. Games can draw the background texture across the entire display.

On Zune, games don't need to perform calculation of a title safe region. However, code that performs this calculation within a `#if XBOX` conditional directive (in order to limit the calculation to the Xbox 360) will continue to function correctly. See [How To: Draw a Sprite](#) for an example.

Zune supports only one aspect ratio, 4:3 (or 3:4, when held vertically). Neither the XNA Framework nor the Zune device performs any aspect ratio conversion or letterboxing.

3D Graphics

The Zune device supports 2D graphics only. It does not support 3D graphics or 3D acceleration, including 3D primitives, 3D textures, index and vertex buffers, shaders, effects, and multisampling. Zune does not implement classes that provide 3D functionality, including the following: [Texture3D](#), [IndexBuffer](#), [Model](#), [BasicEffect](#), [PixelShader](#), [ClipPlane](#), [DepthStencilBuffer](#), [Effect](#), and [SamplerState](#).

The documentation for each type and member in the XNA framework identifies supported platforms.

ResourceUsage Flags

[TextureUsage](#) flag settings other than [TextureUsage.None](#) have no effect on Zune. The XNA Framework will still raise exceptions for invalid combinations of [TextureUsage](#) flags and other texture settings (such as format and number of mipmap levels). Use [TextureUsage.None](#) for Windows, Xbox 360, and Zune platforms, whenever possible.

Input

For input, the Zune device has two buttons and either a control pad or a Zune Pad. These inputs map to controller input, retrieved with the [GamePad.GetState](#) method. For more information on specific mappings and programmatically detecting user input, see [Zune Button Mapping](#).

Note

APIs related to input devices not available on Zune, such as [Mouse](#) and [Keyboard](#), can be accessed in code running on a Zune device. The **X** and **Y** values in [MouseState](#) returned on Zune will always be zero. Similarly, checking for keys pressed using [Keyboard](#) on Zune will always return keys in an unpressed state. Also, you should not expect an exception when you access the mouse, keyboard, or other unexpected input devices on Zune.

Media and Audio

Zune audio uses the new [SoundEffect](#) and [SoundEffectInstance](#) classes for sound effects, including playing .mp3 and .wma files. Zune games use the new [Microsoft.Xna.Framework.Media](#) namespace and classes for playing songs on the Zune device and for viewing pictures in the media library. To create a rich media experience, games use the capabilities of the **Media** namespace to incorporate media from the device library directly into gameplay.

Zune does not use XACT audio wave banks or sound banks.

Storage

To get a storage device and then create containers and files on that device, Zune games use the [BeginShowStorageDeviceSelector](#) method, just as Xbox 360 games do. On Zune, this call immediately returns the [StorageDevice](#) object. [How To: Get a StorageDevice Asynchronously](#) demonstrates this process.

The maximum size of an XNA Framework project on a Zune device is 2 GB. This means the entire game, including support files such as level data, sound, and so on, must not exceed that size.

The maximum memory usage of an XNA Framework game on a Zune device is 16 MB. This means that memory usage and content loaded by the game (graphics, sound, levels, and so on) should not exceed 16 MB.

Source Code

Zune projects define a ZUNE symbol for use with conditional compilation directives such as **#if**. You can use conditional compilation to maintain source code that is shared between projects, but has different behaviors for Windows, Xbox 360, or Zune. [How To: Draw a Sprite](#) gives you an example of conditional compilation where the available screen space is calculated differently for Xbox 360 than for Windows and Zune. (See [#if \(C# Reference\)](#) and [C# Preprocessor Directives](#) for more information on conditional compilation and C# preprocessor directives.)

XNA Game Studio and Your Zune

Exiting a Game

When an XNA Framework game exits on the Zune, the Zune device reboots. This behavior is by design (and is also desirable—it ensures that game and runtime resources are completely cleaned up after a game exits).

Holding down the Back button for 2 seconds will force the currently executing game to exit, regardless of the game's normal exit semantics.

Rebooting Your Zune

If your Zune device becomes unresponsive or is not operating as expected, you may want to reboot it.

To restart the Zune device

1. Set the **Hold** switch to the unlocked position.

Note

To make sure that the **Hold** switch is in the unlocked position, you may have to move the switch first to the locked position, and then to the unlocked position. This ensures the switch is fully in the unlocked position.

2. Press and hold the **Back** button as you press the top portion ('**Up**') on the **Zune Pad**.
3. Release both buttons when the Zune device begins to restart.

Typically, the device will restart 2-3 seconds after you begin holding both buttons down.

For additional Zune device information, visit www.zune.net.

Zune HD Input Overview

Provides an overview of the touch screen and accelerometer input features for the Zune HD device.

XNA Game Studio provides support for developing applications that use input gathered from the built-in touch screen and accelerometer of the Zune HD device. For an example of touch screen and accelerometer programming, see [Platformer: Adding Touch Support](#).

Touch Screen

The touch screen of the Zune HD device can detect multiple touches and the pressure of each touch. The touch screen can track up to four separate touch locations at the same time. Each location tracks values such as screen location, pressure of the touch, and the state of the touch (such as pressed or released). These touch locations and their information is stored in a [TouchCollection](#) structure.

The following tables demonstrate common scenarios of touch interactions with the device, and the resulting values of the touch location collection.

The easiest case is when the screen is not touched. The value of the [Count](#) property is zero, and the [TouchCollection](#) object has no additional information.

The following table is generated when a finger taps the screen:

Frame	Touch Collection ([item1], [item2], ...)
0	(([Id = 1, State = Pressed])
1	(([Id = 1, State = Released])
2	N/A

The following table is generated when a finger touches the screen, moves across the screen, and then is lifted:

Frame	Touch Collection ([item1], [item2], ...)
0	(([Id = 1, State = Pressed])
1	(([Id = 1, State = Moved])
2	(([Id = 1, State = Moved])
...	(([Id = 1, State = Moved])
n	(([Id = 1, State = Released])
n+1	N/A

The following table is generated when two fingers simultaneously touch the screen, move across the screen, and then each finger is lifted individually:

Frame	Touch Collection ([item1], [item2], ...)
0	(([Id = 1, State = Pressed], [Id = 2, State = Pressed])
1	(([Id = 1, State = Moved], [Id = 2, State = Moved])
2	(([Id = 1, State = Moved], [Id = 2, State = Moved])
3	(([Id = 1, State = Released], [Id = 2, State = Moved])
4	(([Id = 2, State = Moved])
5	(([Id = 2, State = Released])
6	N/A

Basic Usage Code for the Touch Screen API

The following code sample calls the `DrawStroke` method whenever a stroke gesture is detected:

C#

```
// Process touch locations.
foreach (TouchLocation location in curTouches)
{
    switch (location.State)
    {
        case TouchLocationState.Pressed:
            //Start tracking a particular touch location
            //In this example, you start the stroke from a special
            //area of the screen.
```

```

        if (castingArea.Contains((int)(location.Position.X),
            (int)(location.Position.Y)))
        {
            magicSpellStrokeId = location.Id;
        }
        break;
    case TouchLocationState.Moved:
        TouchLocation prevLoc;
        if (location.TryGetPreviousLocation(out prevLoc))
            DrawStroke(prevLoc.Position, location.Position);
        break;
    case TouchLocationState.Released:
        if (strokeBeginning)
        {
            if (location.Id == magicSpellStrokeId)
                magicSpellStrokeId = -1;
            curStr = waitingStr;
        }
        break;
    }
}

```

Tip

In the sample above, the ID of a specific touch location is stored by the `magicSpellStrokeId` variable. If this variable is declared at a higher level, it becomes very easy to track that touch location over multiple frames. This is because a touch location never changes its ID, but its index in the touch collection can change.

For more information about using the touch screen API in your application, see [Platformer: Adding Touch Support](#).

Accelerometer

The Zune HD device has a built-in accelerometer that detects acceleration along three axes: x, y, and z. This mirrors the right-handed coordinate system used by the XNA framework:

- Positive x-axis pointing to the right.
- Positive y-axis pointing upwards.
- Positive z-axis pointing out from the front of the device (towards the observer).

This acceleration, measured as G-force (g), ranges from -1 to 1 for each axis.

For example, when the device is held upright, aligned along the y axis, the acceleration value is (0, -1, 0). The x- and z-axes values are zero because the device isn't moving along those lines, and the y-axis value is -1 due to the effect of Earth's gravity, relative to the device. Therefore, to achieve an acceleration value of (0, 0, 0), the device would have to be dropping along the y-axis at a rate of 1 g. This cancels the omnipresent effect of the Earth's gravity.

You can use this acceleration vector (for example, (0, -1, 0)) to determine the current tilt of the device with simple trigonometry. For example, when the device is tilted 45 degrees around the z-axis (towards the right), the acceleration vector is (0.5, -0.5, 0). Using this value, the z-axis rotation can be computed using the rotation matrix returned by the [GetRotation](#) method and the following formula: `float zRot = (float)Math.Atan2(-rotationMatrix.Right.Y, rotationMatrix.Right.X);`. The result is -.8 radians (or -45 degrees).

You can use this approach for the remaining axes. The resultant code is as follows:

C#

```

Matrix rotation = acc1State.GetRotation();
float xrot =
    (float)Math.Atan2(rotation.Forward.Y, rotation.Forward.Z);
float yrot = (float)Math.Atan2(rotation.Up.X, rotation.Up.Z);
float zrot = (float)Math.Atan2(-rotation.Right.Y, rotation.Right.X);

```

Note

Since the Zune HD device does not have a gyroscope sensor, this tilt computation is not always accurate. For example, the tilt angle changes when you hold the device in the same orientation and move the device along a directional axis.

Basic Usage Code for the Accelerometer API

The following code is a simple example of using accelerometer data to alter a screen position. Tilting the device causes the position to shift in the direction the device is tilted:

C#

```
// Get touch state.  
acclState = Accelerometer.GetState();  
//Update position based on the tilt of the device  
position.X += acclState.Acceleration.X * 10.0f;
```

For more information about using the accelerometer API in your application, see [Platformer: Adding Touch Support](#).

Zune Button Mapping

Describes how various Zune buttons map to the buttons on a standard Xbox 360 gamepad.

Input

For input, the Zune device has two buttons and either a device control pad (version 1.0) or a Zune Pad (version 2.0). These inputs map to controller input, retrieved with the [GamePad.GetState](#) method.

Back and Play/Pause Buttons

The **Back** button maps to [GamePadState.Buttons.Back](#), and the **Play/pause** button maps to [GamePadState.Buttons.B](#).

Device Control Pad (version 1.0)

The control pad provides input for presses (or 'clicks') on the pad.

Directional presses on the control pad map to the [GamePadState.DPad](#) directions: up, down, left, and right, or to a combination of two of those directions. Pressing straight down in the middle of the control pad maps to [GamePadState.Buttons.A](#).

Zune Pad

In addition to the behavior described in the previous sections, touch or motion over the Zune Pad is also reported as left thumbstick position in the [GamePadState.ThumbSticks.Left](#) property. Finally, clicking anywhere on the Zune Pad maps to [GamePadState.Buttons.LeftShoulder](#).

Zune Performance

Provides detailed information about performance on different Zune hardware.

Screen Refresh Rates

	Refresh Rate	Screen Resolution
Zune 30	60 Hertz	240 x 320
Zune 4, 8, or 80	30 Hertz	240 x 320

Developers may notice performance differences between the Zune 30, and the Zune 4, 8, and 80. While the hardware of the two devices is similar, screen refresh rates are more frequent on the Zune 30. In terms of actual performance, however, the difference between the Zune 30, on the one hand, and the Zune 4, 8, and 80, on the other, is nearly imperceptible.

The screen resolution on all devices is exactly the same: 240 x 320. On Zune 30, the screen refreshes at 60 Hertz or 60 times a second. On Zune 4, 8, and 80, the screen refreshes at 30 Hertz or 30 times a second. The less-frequent refresh rate saves battery life on the Zune 4, 8, and 80. Prolonging battery life is a major benefit for users.

Internally, the XNA Framework is optimized to save Zune battery life. A call to [Game.Draw Method](#) is not worthwhile unless the screen can refresh. For example, if the screen can only draw a sprite 30 times in one second, it would waste processing power and battery life to draw the game screen 45 times in one second. Update will still be called as much as possible regardless of the screen refresh.

Code that calculates frames per second (FPS) in a Draw loop will show close to 60 FPS on a Zune 30. That same code will show close to 30 FPS on a Zune 80. This difference provides savings in battery life, a critical performance metric on a mobile device.

Battery Life

Processors in all versions of the Zune device are similar enough to be considered virtually identical. However, the processor in the Zune 4, 8, and 80 runs at 399 MHz, and the processor in the Zune 30 runs at 524 MHz. This difference gives the new series of Zune devices more battery life.

Zune Networking Overview

Provides an overview of networked Zune games.

Networking for Zune is designed to be consistent with Xbox 360 and Windows. The general structure of a networked game on Zune will be similar to a networked game on Xbox 360 or Windows.

Zune Networking APIs

Two XNA namespaces support Zune networking. The [Microsoft.Xna.Framework.Net](#) namespace provides actual networking functionality. For example, it supports APIs for network creation and network related events. The [Microsoft.Xna.Framework.GamerServices](#) namespace provides access to the [Guide](#) class.

Most APIs under the [Microsoft.Xna.Framework.Net](#) namespace are supported on Zune. Some APIs in the [Microsoft.Xna.Framework.GamerServices](#) namespace are not supported. Zune networking capabilities are not based on Xbox LIVE. There is limited [Guide](#) class functionality on Zune, and Xbox LIVE IDs are not accessible in networked games on Zune.

Using the Guide Class on Zune

These [Guide](#) members are supported on Zune:

- [BeginShowStorageDeviceSelector](#)
- [EndShowStorageDeviceSelector](#)
- [Guide.IsScreenSaverEnabled](#)
- [Guide.IsVisible](#)

Use the [Guide](#) class to access local storage through the [BeginShowStorageDeviceSelector](#) and [EndShowStorageDeviceSelector](#) methods. Use the [Guide.IsVisible](#) property to check for the existence of guide functionality in code. This property is always **false** on Zune.

See the [Networking](#) section for detailed information and additional networking examples.

Note

See the *Supported Platforms* section on individual reference pages to check for Zune support. If Zune is not on the supported platforms list, the API is not supported. If listed, there is support for the API.

Zune Networking Specifics

- Eight is the maximum number of Zune devices that can simultaneously share and play in one game. This is less than the maximum on Xbox 360 and Windows.
- Networking APIs on Zune do not support Internet connectivity.
- Network types supported on Zune are [NetworkSessionType.SystemLink](#) and [NetworkSessionType.Local](#). When you create a network with either [Create](#) or [BeginCreate](#), you must use one of these network types.
- A networked Zune game can only be played on Zune devices. Players on a nearby Xbox 360 or Windows machine cannot join a game.

Events and Game Design

Zune networking features give developers tools to build creative and unique games. However, creating a networked game requires extra decisions. For example, will the game support just one player? Will the game allow other players to join mid-game? What happens when gamers leave the game in the middle of play? Answers to these questions will dictate how to build the basic game structure. Use the following events to build a game design.

Event Name	Description
GameEnded	Game moves from gameplay to the lobby
GamerJoined	New player joins a multiplayer session
GamerLeft	Player leaves the multiplayer session
GameStarted	Game moves from the lobby into actual gameplay
HostChanged	Session host has changed
SessionEnded	Multiplayer session ends

Troubleshooting

Make sure wireless is turned on when testing networked Zune games. If wireless is turned on, you will see a symbol above the battery icon in the bottom left corner of the display.

When the device is rebooted with wireless turned on, you may have to wait for wireless to return. The symbol above the battery icon needs to reappear before you try wireless after a reboot.

Zune Wireless Icon

To turn on wireless on Zune

1. Click the **settings** menu.
2. Under **settings**, click the **wireless** menu.
3. Turn wireless on by clicking **wireless: off**. If the menu says **wireless: on**, then wireless is already turned on.

How To: Build a Simple Networked Game on Zune

Demonstrates networking functionality on Zune.

This example builds on the code shown in [Your First Game: Microsoft XNA Game Studio in 2D](#). The code from that sample is expanded to include some basic game play and simple networking. The following sections show you how to transform the simple example code into a networked game on Zune:

- [The Complete Sample](#)
- [Adding Networking Objects](#)
- [Creating or Joining an Existing Networked Game](#)
- [Reading and Writing Network Packets](#)
- [Using Network Events](#)
- [Encapsulating Code](#)

Note

Not all APIs are available on Zune. See the *Supported Platforms* section on individual reference pages to check for Zune support. If Zune is not on the supported platforms list, the API is not supported. If listed, there is support for the API.

Network connections between Zunes do not form instantaneously. When running this example, either creating or joining a network session will take a few moments.

The Complete Sample

The code in this tutorial illustrates the technique described in the text. A complete code sample for this tutorial is available for you to download, including full source code and any additional supporting files required by the sample.

[Download NetworkSimpleGame_Sample.zip](#).

Adding Networking Objects

First, add necessary networking objects to the game class that derives from [Game](#).

C#

```
// networking objects
NetworkSession networkSession;
PacketWriter packetWriter = new PacketWriter();
PacketReader packetReader = new PacketReader();
```

Add a [GamerServicesComponent](#) `GamerServicesComponent` in the game constructor.

C#

```
Components.Add(new GamerServicesComponent(this));
```

Creating or Joining an Existing Networked Game

Two types of networks are supported on Zune, [NetworkSessionType.SystemLink](#) and [NetworkSessionType.Local](#). This example creates a [NetworkSessionType.SystemLink](#) network using the [Create](#) method. This example game allows players to join in the middle of game play, and it allows for a maximum of eight players.

C#

```
networkSession =
    NetworkSession.Create(NetworkSessionType.SystemLink,
        maxLocalGamers, maxGamers);
HookNetworkSessionEvents();
```

Reading and Writing Network Packets

This method updates the server on the status of the game. The code sends the number of gamers in the game, the enemy

location, and the location of each player sprite. Notice the order that the data is sent, and that the data is read back in reverse order in the method that executes on the clients.

C#

```
// send a packet that first indicates how many
// players it has data for
packetWriter.Write(networkSession.AllGamers.Count);

// send a packet that has position of enemy on server
packetWriter.Write(enemyPos);
packetWriter.Write(enemySpeed);

// send to all gamers in network
foreach (NetworkGamer gamer in networkSession.AllGamers)
{
    // look up this player
    Rodent r = gamer.Tag as Rodent;

    // write state of mouserat to the output network packet
    packetWriter.Write(r.Position);
    packetWriter.Write(r.Dead);
}

// send the combined data for all players to everyone in the session
LocalNetworkGamer server = (LocalNetworkGamer)networkSession.Host;
server.SendData(packetWriter, SendDataOptions.InOrder);
```

This method updates a local game based on data from the server. Again, note the order of data received.

C#

```
// Keep reading as long as incoming packets are available.
while (gamer.IsDataAvailable)
{
    NetworkGamer sender;

    // Read a single packet from the network.
    gamer.ReceiveData(packetReader, out sender);

    // If a player has recently joined or left, it is possible the
    // server might have sent information about a different number
    // of players than the client currently knows about. If so,
    // we will be unable to match up which data refers to which
    // player. The solution is just to ignore the packet for now:
    // this situation will resolve itself as soon as the client
    // gets the join/leave notification.
    if (networkSession.AllGamers.Count != packetReader.ReadInt32())
        continue;

    // read the position of the enemy
    enemyPos = packetReader.ReadVector2();
    enemySpeed = packetReader.ReadVector2();

    // next read the position of all current network gamers
    foreach (NetworkGamer remoteGamer in networkSession.AllGamers)
    {
        Rodent r = remoteGamer.Tag as Rodent;
        r.Position = packetReader.ReadVector2();
        r.Dead = packetReader.ReadBoolean();
    }
}
```

In this example, the sprite added to the game in [Your First Game: Microsoft XNA Game Studio in 2D](#) still moves around the screen without interruption from user input. The addition of networked play allows for each player to control one sprite. This method updates the position of the local gamer based on inputs and sends out update packets including the new local player position.

C#

```
int MaxX = graphics.GraphicsDevice.Viewport.Width - r.Width;
int MinX = 0;
int MaxY = graphics.GraphicsDevice.Viewport.Height - r.Height;
int MinY = 0;

// check pad input
if (IsPressed(Buttons.DPadRight))
{
    if (!(r.PositionX > MaxX))
    {
        r.PositionX += 1.2f; // move mouserat right
    }
}
else if (IsPressed(Buttons.DPadLeft))
{
    if (!(r.PositionX < MinX))
    {
        r.PositionX -= 1.2f; // move mouserat left
    }
}
else if (IsPressed(Buttons.DPadUp))
{
    if (!(r.PositionY < MinY))
    {
        r.PositionY -= 1.2f; // move mouserat up
    }
}
else if (IsPressed(Buttons.DPadDown))
{
    if (!(r.PositionY > MaxY))
    {
        r.PositionY += 1.2f; // move mouserat down
    }
}

// check for collison with the enemy cat, update dead property
CheckIfEaten(r);

// if not the server, send this update info to
// all other network gamers
if (!networkSession.IsHost)
{
    // write updated position and life status to network packet
    packetWriter.Write(r.Position);
    packetWriter.Write(r.Dead);

    // send to server
    gamer.SendData(packetWriter, SendDataOptions.InOrder,
        networkSession.Host);
}
```

This method updates the position of other players.

C#

```
// Keep reading as long as incoming packets are available.
while (gamer.IsDataAvailable)
{
    NetworkGamer sender;

    // Read a single packet from the network.
    gamer.ReceiveData(packetReader, out sender);

    if (!sender.IsLocal)
    {
        Rodent r = sender.Tag as Rodent;
```

```

        r.Position = packetReader.ReadVector2();
        r.Dead = packetReader.ReadBoolean();
    }
}

```

Using Network Events

This method hooks up event handlers. It is called when you create the network.

C#

```

void HookNetworkSessionEvents()
{
    networkSession.GamerJoined += GamerJoinedEventHandler;
    networkSession.SessionEnded += SessionEndedEventHandler;
}

```

These are the event handler methods.

C#

```

void GamerJoinedEventHandler(object sender, GamerJoinedEventArgs e)
{
    // new gamer, add new rodent player object
    e.Gamer.Tag = new Rodent(this);
    Components.Add(e.Gamer.Tag as Rodent);
}

```

C#

```

void SessionEndedEventHandler(object sender,
    NetworkSessionEndedEventArgs e)
{
    DrawMenuMessage("Network Session Has Ended.");
    networkSession.Dispose();
    networkSession = null;
}

```

Encapsulating Code

The original simple game example contained all functionality within one class. Encapsulating logic and data for the added sprite into in new class adds organization. Each game instance in a networked play can use the new class. The new class is derived from [DrawableGameComponent](#).

C#

```

class Rodent : Microsoft.Xna.Framework.DrawableGameComponent
{
    Texture2D rodentTexture;    // alive texture
    Texture2D deadRodentTexture; // dead texture
    SpriteBatch spriteBatch;   // spritebatch for drawing sprites
                                // to the screen

    bool dead;                 // is this rodent dead or alive
    Vector2 rodentPos;         // rodent position

    # region properties

    public bool Dead
    {
        get
        {
            return dead;
        }
        set
        {
            dead = value;
        }
    }
}

```

```

    }
}

public Vector2 Position
{
    get
    {
        return rodentPos;
    }
    set
    {
        rodentPos = value;
    }
}

public float PositionX
{
    get
    {
        return rodentPos.X;
    }
    set
    {
        rodentPos.X = value;
    }
}

public float PositionY
{
    get
    {
        return rodentPos.Y;
    }
    set
    {
        rodentPos.Y = value;
    }
}

public int Width
{
    get
    {
        return this.rodentTexture.Width;
    }
}

public int Height
{
    get
    {
        return this.rodentTexture.Height;
    }
}

#endregion

public Rodent(Game game)
    : base(game)
{
    dead = false;
    rodentPos = new Vector2(204.0f, 287.0f);
}

public override void Initialize()
{
    base.Initialize();
}

```

```

protected override void LoadContent()
{
    spriteBatch = new SpriteBatch(GraphicsDevice);
    rodentTexture = Game.Content.Load<Texture2D>("mouserat");
    deadRodentTexture = Game.Content.Load<Texture2D>("deadmouserat");

    base.LoadContent();
}

protected override void UnloadContent()
{
    base.UnloadContent();
}

public override void Draw(GameTime gameTime)
{
    spriteBatch.Begin(SpriteBlendMode.AlphaBlend);
    if (dead)
    {
        spriteBatch.Draw(deadRodentTexture, rodentPos, Color.White);
    }
    else
    {
        spriteBatch.Draw(rodentTexture, rodentPos, Color.White);
    }
    spriteBatch.End();

    base.Draw(gameTime);
}
}

.NET Compact Framework for Xbox 360

The XNA Framework includes the .NET Compact Framework for Xbox 360, which is a version of the .NET Compact Framework designed specifically for the Xbox 360 video game and entertainment system. The .NET Compact Framework for Xbox 360 implements a subset of the .NET Compact Framework, and has been optimized to take advantage of and expose the power of the Xbox 360. XNA Game Studio projects that target Windows-based game machines have access to the full .NET Framework, while projects that target Xbox 360 use the .NET Compact Framework for Xbox 360.

This section provides information on developing XNA Game Studio applications using the C# language and the .NET Compact Framework for Xbox 360.

Namespaces and Classes Supported by the .NET Compact Framework for Xbox 360

The .NET Compact Framework for Xbox 360 implements a subset of the namespaces, types, and members available in the .NET Compact Framework. This topic discusses that subset and explains how to determine support for specific classes or members.

Determining Supported Namespaces, Types, and Members

The following methods help you determine the specific types and members that are supported by the .NET Compact Framework for Xbox 360.

- The online MSDN [.NET Framework Class Library](#) documentation has been updated to show the types and members that are supported on the Xbox 360. Version information in those topics indicates XNA Framework support. Also, in the member summary pages, members supported on Xbox 360 display the 'Supported by XNA Framework' icon  after the .NET Compact Framework icon .
- The [Namespaces, Types, and Members](#) topic lists the namespaces, types, and members that are supported by the .NET Compact Framework for Xbox 360.

While working within an Xbox 360 project, the following methods of determining supported types and methods are available.

- IntelliSense will show only types and members that are available to Xbox 360 projects. For information about IntelliSense, see [Using IntelliSense](#).
- You will receive compiler errors when you use unsupported types or members within an Xbox 360 project.

For code portability, you may want to use only types and members supported by the .NET Compact Framework for Xbox 360, even though XNA Game Studio projects for Windows have access to the entire .NET Framework. Doing so will make it easier to create single-source applications that compile and run on both Windows and Xbox 360.

Unsupported Classes

The following sections discuss a few of the classes that are not supported by the .NET Compact Framework for Xbox 360.

To determine the full set of namespaces, types, and members that are supported by the .NET Compact Framework for Xbox 360, see [Determining Supported Namespace, Types, and Members](#), preceding.

To see additional members available only in the .NET Compact Framework for Xbox 360, see [Additions to the .NET Compact Framework for Xbox 360](#)

Note

The .NET Compact Framework is itself a subset of the full .NET Framework. Those differences are not described here, but you can find information in [Differences with the .NET Framework](#).

User Interface Classes

The .NET Compact Framework for Xbox 360 does not include the [System.Windows.Forms](#) namespace or any of its classes. User interface elements in an XNA game are composed of 2D or 3D graphics (or both), created using classes in the [Microsoft.Xna.Framework.Graphics Namespace](#) namespace.

Games typically have menus and other user interface elements that are unique and customized to the game, rather than standardized versions that wouldn't adequately express the game's unique feel and flow.

Web and Network Classes

The .NET Compact Framework for Xbox 360 does not include the [System.Web](#) namespace. It supports only a small subset of the [System.Net](#) namespace. See [Determining Supported Namespace, Types, and Members](#), preceding, for information on determining that subset.

Games developed for Xbox 360 using XNA Game Studio can use the functionality provided in the [Microsoft.Xna.Framework.Net](#) namespace to create system link or Xbox LIVE multiplayer games.

- EventWaitHandle.EventWaitHandle
- [EventWaitHandle Methods]
- EventWaitHandle.Close
- EventWaitHandle.Finalize
- EventWaitHandle.Reset
- EventWaitHandle.Set
- EventWaitHandle.WaitOne

System.Threading.Interlocked class

- [Interlocked Methods]
- Interlocked.CompareExchange
- Interlocked.Decrement
- Interlocked.Exchange
- Interlocked.Increment

System.Threading.ManualResetEvent class

- ManualResetEvent.ManualResetEvent

System.Threading.Monitor class

- [Monitor Methods]
- Monitor.Enter
- Monitor.Exit
- Monitor.TryEnter

System.Threading.Mutex class

- Mutex.Mutex
- [Mutex Methods]
- Mutex.Close
- Mutex.ReleaseMutex
- Mutex.WaitOne

System.Threading.Thread class

- Thread.Thread
- [Thread Methods]
- Thread.Abort

IXmlLineInfo.LineNumber

IXmlLineInfo.LinePosition

System.Xml.IXmlNamespaceResolver interface

[IXmlNamespaceResolver Methods]

IXmlNamespaceResolver.GetNamespacesInScope

IXmlNamespaceResolver.LookupNamespace

IXmlNamespaceResolver.LookupPrefix

System.Xml.NameTable class

NameTable.NameTable

[NameTable Methods]

NameTable.Add

NameTable.Get

System.Xml.NewLineHandling enumeration

System.Xml.ReadState enumeration

System.Xml.ValidationType enumeration

System.Xml.WhitespaceHandling enumeration

System.Xml.WriteState enumeration

System.Xml.XmlAttribute class

XmlAttribute.XmlAttribute

[XmlAttribute Methods]

XmlAttribute.AppendChild

XmlAttribute.CloneNode

XmlAttribute.InsertAfter

XmlAttribute.InsertBefore

XmlAttribute.PrependChild

XmlAttribute.RemoveChild

XmlAttribute.ReplaceChild

XmlAttribute.WriteContentTo

XmlAttribute.WriteTo

[XmlAttribute Properties]

Additions to the .NET Compact Framework for Xbox 360

The .NET Compact Framework for Xbox 360 implements a subset of the .NET Compact Framework, and adds the following namespaces, types, or members.

New Methods

SetProcessorAffinity Method

Currently, the .NET Compact Framework for Xbox 360 adds just one more method. It belongs to the [System.Threading.Thread](#) class.

The [SetProcessorAffinity](#) method sets the processor or hardware thread on which a software thread will execute (the thread's *processor affinity*). The Xbox 360 has six hardware threads (two on each of three cores). Four of these can be used by applications. [SetProcessorAffinity](#) has the following signature:

C#

```
public void SetProcessorAffinity (  
    params int[] cpus  
)
```

[System.Threading.Thread.SetProcessorAffinity Method](#)

Thread.SetProcessorAffinity Method

Sets the processor affinity for a managed thread. Processor affinity determines the processors on which a thread runs.

Namespace: System.Threading

Assembly: mscorlib (in mscorlib.dll)

Syntax

C#

```
public void SetProcessorAffinity (
    params int[] cpus
)
```

Parameters

cpus

An array of identifiers that specify the hardware threads on which the managed thread is permitted to run.

For Xbox 360, only a single hardware thread can be specified—the *cpus* array should contain only one element. The hardware thread number must be in the range 0 through 5.

XNA Game Studio games should not use hardware threads 0 or 2; see [Remarks](#) below.

Exceptions

Exception type	Condition
InvalidOperationException	Either an invalid value was passed to the method or the thread attempting the change was different from the target thread.

Remarks

Each of the three CPU cores on the Xbox 360 has two hardware threads; the hardware thread number selects a specific hardware thread on a specific core. Hardware threads 0 and 1 are the hardware threads on core 0; 2 and 3 are the hardware threads on core 1; and 4 and 5 are the hardware threads on core 2.

Hardware Thread Number	Core
0 or 1	0
2 or 3	1
4 or 5	2

Xbox 360 software threads are associated with, and run on, only a single hardware thread at a time. The hardware thread on which a thread runs (the thread's *processor affinity*) must be set to a single hardware thread, but can be subsequently changed by calling **SetProcessorAffinity** with a different hardware thread number. When a thread is created, it is initially assigned to the current hardware thread (that is, the hardware thread on which the current thread is running).

For Xbox 360 threads, you cannot clear the thread's processor affinity by passing an empty array as the *cpus* parameter. An Xbox 360 thread will always be associated with one hardware thread.

XNA Game Studio games should not use hardware threads 0 or 2, which are reserved for the XNA Framework. The following table identifies Xbox 360 hardware thread usage.

Hardware Thread	Available
0	No, reserved for XNA Framework.
1	Yes
2	No, reserved for XNA Framework.
3	Yes
4	Yes
5	Yes

To determine the number of hardware threads supported by the hardware, use [System.Environment.ProcessorCount](#).

This method should not be used with threads created by the [ThreadPool](#) or [Timer](#) classes. It should only be called from the thread whose affinity is being changed.

Thread Pools in the .NET Compact Framework for Xbox 360

A *thread pool* is a collection of threads that can be used to perform background tasks, thus freeing the primary application thread to perform other tasks asynchronously. The .NET Compact Framework for Xbox 360 supports thread pools and portions of the [System.Threading.ThreadPool](#) class. Thread pools on the Xbox 360 are slightly different than those on the .NET Framework or .NET Compact Framework.

Xbox 360 Thread Pools

The Xbox 360 CPU has six hardware threads (two on each of three cores). Each one is capable of independently executing a software thread. These hardware threads execute independently. However, the two hardware threads executing on a single core do share some resources, such as the vector unit and L1 cache.

The thread pool distributes the threads it creates evenly among four available hardware threads (two are reserved for system use). The thread pool does not try to determine the activity level of the processors before assigning threads, nor does it try to load-balance existing threads. Once a thread is assigned to a hardware thread, the thread pool will not assign that thread to a different hardware thread.

Maximum Number of Threads

The default maximum number of threads in an Xbox 360 thread pool is 256. When a new task is queued with [ThreadPool.QueueUserWorkItem](#), the thread pool first tries to assign the task to an available thread in the pool. If all threads in the thread pool are busy performing tasks, the thread pool will create a new thread to handle the task, up to the maximum number of threads set for the pool. If no threads are available and the maximum number of threads have already been created, the task is queued until a thread in the pool becomes available.

To specify the maximum number of threads for the pool, use [ThreadPool.SetMaxThreads](#). If the threads in a thread pool do not require much processing time and are cycling their tasks quickly, it may be more efficient to lower the maximum number of threads for the pool (from its default of 256). Doing so reduces the amount of context switching that occurs when a large number of ready threads are being scheduled alternately for execution on the available processors.

Using Threading

Thread pools provide an easy and efficient mechanism of scheduling asynchronous background tasks. To achieve finer control of the number, type, scheduling, and processor affinity of your application's threads, use the [System.Threading.Thread](#) class directly. You can use threads created with the [Thread](#) class instead of, or together with, thread pools.

For more information on using threading and thread pools in the .NET Framework, see [Threading](#) and [How To: Use a Thread Pool](#).

Note

The online MSDN .NET Framework documentation has been updated to show the types and members of the [System.Threading](#) namespace that are supported on the Xbox 360. Also see [Namespaces and Classes Supported by the .NET Compact Framework for Xbox 360](#) for information on determining all of the types and members supported by the .NET Compact Framework for Xbox 360.

Language, Locales, and Cultures in the .NET Compact Framework for Xbox 360

Language and locale support on the Xbox 360 video game and entertainment system differs from that provided by managed culture objects in .NET. The Xbox 360 console language and locale are set by the user, and are independent of each other. For example, the console may be using the German language, but be located in Greece.

Managed culture objects (such as [CultureInfo](#)), however, are based on both language and region, where the region is dependent on the language. For example, the German language has only five valid culture regions: Austria, Germany, Liechtenstein, Luxembourg, and Switzerland.

In the .NET Compact Framework for Xbox 360, the [CultureInfo](#) returned for [CurrentCulture](#) and [CurrentUICulture](#) is based primarily on the console's current language, *not* its locale. Only if the locale matches one of a subset of regions for the current language will the locale secondarily affect the returned culture.

For example, if the console's language is German, the culture returned by [CurrentCulture](#) will be:

- 'de-AT' (German - Austria) if the console's locale is Austria,
- 'de-CH' (German - Switzerland) if the console's locale is Switzerland, and
- 'de-DE' (German - Germany) for all other locales, including locales that are valid for German (Germany, Liechtenstein, and Luxembourg) and those that are not (Greece, Korea, and India, for example).

Due to these differences, it is important to use static [CultureInfo](#) objects (rather than those returned by [CurrentCulture](#)) when displaying data from [RegionInfo](#) objects or non-Gregorian calendars. If you do not use static [CultureInfo](#) objects, note that locale mapping differences may produce unexpected or undesirable results. For example:

- If the console language is set to Traditional Chinese, and the locale is set to China, [CurrentCulture](#) and [CurrentUICulture](#) return the culture 'zh-TW' (Chinese - Taiwan).
- If the console language is set to Simplified Chinese, and the locale is set to Taiwan, [CurrentCulture](#) and [CurrentUICulture](#) return the culture 'zh-CN' (Chinese - China).

Important

Whether it is Traditional Chinese or Simplified Chinese, the console language, not the locale, determines the returned culture.

XNA developers must also be aware of locale mapping differences that can affect application development when they develop for Xbox 360 instead of Windows-based game machines. For example, the behavior of many managed functions, such as [ToUpper](#), can vary based on the value of [CurrentCulture](#) and [CurrentUICulture](#).

The following table shows the culture returned by [CurrentCulture](#) and [CurrentUICulture](#) based on the console's language and locale setting. A default culture is returned when the console's locale doesn't match a region supported for the console's language.

Console Language	Console Locale	Culture
Chinese (Simplified)	China	zh-CN (Chinese - China)
	Singapore	zh-SG (Chinese - Singapore)
	(all others)	zh-CN (Chinese - China)
Chinese (Traditional)	Hong Kong SAR	zh-HK (Chinese - Hong Kong SAR)
	Taiwan	zh-TW (Chinese - Taiwan)
	(all others)	zh-TW (Chinese - Taiwan)
English	Australia	en-AU (English - Australia)
	Canada	en-CA (English - Canada)
	Great Britain	en-GB (English - Great Britain)
	Ireland	en-IE (English - Ireland)
	New Zealand	en-NZ (English - New Zealand)
	South Africa	en-ZA (English - South Africa)

XNA Framework Remote Performance Monitor for Xbox 360

The XNA Framework Remote Performance Monitor for Xbox 360 is a performance analysis tool that provides run-time performance data for XNA Game Studio applications. You can monitor the data while you run the application. Also, you can use the Windows Performance Monitor (PerfMon.exe) to view the data.

How To: Monitor Performance at Run Time

Describes performance monitoring with the XNA Framework Remote Performance Monitor for Xbox 360.

The XNA Framework Remote Performance Monitor for Xbox 360 is a performance analysis tool included with the XNA Framework. This tool provides a user interface that lets you view performance data at application run time. When you start your application from Remote Performance Monitor, the tool will read statistical data for the XNA Framework performance counters directly from the common language runtime (CLR).

You can also view XNA Framework performance counters using the Windows desktop tool, PerfMon.exe. Using Remote Performance Monitor in combination with PerfMon.exe gives you a live, graphical view of the performance counter data generated by the CLR.

With the Remote Performance Monitor you can:

- View performance counter data while you run an application.
- View performance counter data in a graphical format in PerfMon.exe while you run an application.
- View garbage collector heap dumps. For more information, see [How To: Generate a Garbage Collector Heap Dump](#).
- View .stat files.

For a list of the available performance counters, see [Performance Counters in the XNA Framework](#).

Using XNA Framework Remote Performance Monitor for Xbox 360

Note

Before you use Remote Performance Monitor, you must configure your Xbox 360 console to communicate with XNA Game Studio on your desktop computer. See [Configuring XNA Game Studio and Your Xbox 360 Console](#).

To run an application from Remote Performance Monitor

1. On the Xbox 360 console, start **XNA Game Studio Connect**, and then select **Launch**.
2. On your desktop computer, start **All Programs | Microsoft XNA Game Studio 3.1 | Tools | XNA Framework Remote Performance Monitor for Xbox 360**.
3. Click the **Launch Application** icon, which is the green arrow on the toolbar.
4. In the **Device** list, click the Xbox device to which you are connected.
5. In the **Application** text box, enter the game's name.

The name is set in **Project | Properties | Application | Assembly Information | Title**. This is the name of the game displayed in **XNA Game Studio Connect**.

6. In the **Arguments** text box, enter any command-line arguments for the application.
7. Verify that the application is not currently running on the device, and that the XNA Game Studio Connect screen is visible.
8. Click **OK**.

Remote Performance Monitor starts the application and displays performance data.

To use PerfMon.exe with Remote Performance Monitor

1. On your desktop computer, start **All Programs | Microsoft XNA Game Studio 3.1 | Tools | XNA Framework Remote Performance Monitor for Xbox 360**.

Caution

If you are using this tool under Windows Vista, you must run the tool with administrator privileges.

2. From the **Options** menu, click **Publish to Perfmon**.
3. Start an application from Remote Performance Monitor using the previous procedure.
4. Start PerfMon.exe.

This file is located in \Windows\System32.

5. In the left pane of PerfMon.exe, click **Performance Monitor** if it is not already selected.
6. Right-click in the right pane of PerfMon.exe, and then click **Add Counters**.
7. From the **Performance Object** list box, select a counter group name (or expand the group and select a single counter) that you want to graph in PerfMon.exe.

The group names correspond to the categories that appear when you view statistical data in Remote Performance Monitor. For example, the garbage collection group is called "Xbox 360 GC" in PerfMon.exe.

8. Click **Add**.

To save performance data

1. Start an application from Remote Performance Monitor.
2. Start PerfMon.exe, and then graph performance data.
3. From the Performance Monitor graph window, right-click and select **Save Settings As...**
4. Type a name for the file, and specify the folder in which to save the file.

The file will be saved with a .htm extension. Use Internet Explorer or Remote Performance Monitor to open and view the generated .htm file.

Performance Counters in the XNA Framework

The XNA Framework contains a set of predefined performance counters for analyzing the types of load your application has on the XNA Framework. The counters are not extensible.

You can generate performance statistics about your application at run time. See [How To: Monitor Performance at Run Time](#) for the procedure.

The performance counters are useful for understanding the impact of garbage collection and just-in-time (JIT) compilation on application performance. From these statistics, you can determine where optimizations should occur.

The statistics file lists performance counters with the following columns.

Column	Description
Total	Summation of occurrences
Last Datum	The last piece of information
N	The number of occurrences
Mean	The intermediate between other values
Min	The minimum value
Max	The maximum value

XNA Framework Counters

Performance counters fall into the following categories.

- [Loader](#)
- [Generics](#)
- [Locks and threads](#)
- [Garbage collection](#)
- [JIT compilation](#)
- [Exceptions](#)

Loader Counters

The following counters pertain to the portion of the common language runtime (CLR) that is responsible for resolving and loading components that are referenced by your application, such as assemblies and classes.

Name	Description
Total Program Run Time (ms)	The elapsed time, in milliseconds, from CLR invocation.
App Domains Created	The number of application domains created in the application's process.
App Domains Unloaded	The number of application domains that have been unloaded during the run time of the application.
Assemblies Loaded	The number of assemblies that have been loaded across all application domains for the application.
Classes Loaded	The number of classes that have been loaded across all application domains during the run time of the application.
Methods Loaded	The total number of methods loaded across all application domains during the run time of the application.

Generics Counters

The generics counters are loader counters that are specific to the generics feature of the XNA Framework. The CLR uses generics internally. Consequently, you might see values in these counters even if your application does not use generics explicitly.

Name	Description
Closed Types Loaded	The count of unique generic types that have been loaded across all application domains. A <i>closed type</i> is a generic class that has been bound with a specific data type. For example, an instance of <code>MyGeneric<Type<Int32></code> is a closed type.

Closed Types Loaded per Definition	<p>The maximum number of unique generic types created for a given definition across all application domains.</p> <p>For example, if an application instantiates <code>MyGenericType<Int32></code>, <code>MyGenericType<String></code>, and <code>MyGenericType<Single></code>, the number of closed types loaded for the <code>MyGenericType<T></code> definition is three (3).</p> <p>A large number (several hundred or more) in the Max column can indicate working-set pressure in terms of JIT-compiled code and CLR data structures.</p>
Open Types Loaded	<p>The count of open generic types created across all application domains.</p> <p>An <i>open type</i> is a generic class that has been loaded, but has not been bound with a specific data type. Open types are typically created only in reflection scenarios.</p> <p>For example, loading an instance of <code>MyGenericType<T></code> by using reflection will increment the Open Types Loaded counter. When the type has been bound, such as in <code>MyGenericType<Single></code>, it becomes a closed type and the Closed Types Loaded counter is incremented. The XNA Framework CLR uses reflection internally and can be the source of the open types. For example, Xml serialization and Web services use reflection internally.</p>
Closed Methods Loaded	<p>The count of unique generic methods that have been loaded across all application domains.</p> <p>A <i>closed method</i> is a generic method that has been bound with a specific data type. The type that contains the method may or may not be a generic type. For example, an instance of <code>MyType.ProcessData<Int32>()</code> is a closed method.</p>
Closed Methods Loaded per Definition	<p>The maximum number of unique generic methods created for a given definition across all application domains.</p> <p>This counter is similar to the Closed Types Loaded per Definition counter. Using the following instances of <code>MyType.ProcessData<Int32>()</code>, <code>MyType.ProcessData<String>()</code>, and <code>MyType.ProcessData<Single>()</code> will create three closed methods for the <code>MyType.ProcessData<T>()</code> definition.</p>
Open Methods Loaded	<p>The count of open generic methods created across all application domains. Open methods are typically created only in reflection scenarios. An <i>open method</i> is a generic method that has been loaded, but is not bound to a specific type.</p> <p>The XNA Framework runtime uses reflection internally and can be the source of the open methods.</p>

Locks and Threads Counters

The following counters pertain to threading, locks, timers, and thread pools. These counters can help identify threading-related performance issues by providing data on thread, timer, and lock usage during the run time of your application.

Name	Description
Threads in Thread Pool	<p>The number of threads currently in the thread pool.</p> <p>This counter counts the threads that are started by using the System.Threading.ThreadPool.QueueUserWorkItem method. This counter does <i>not</i> include threads that are started by using the System.Threading.Thread.Start method.</p>
Pending Timers	The number of timers currently queued.
Scheduled Timers	The number of timers that are currently running or scheduled to run.
Timers Delayed by Thread Pool Limit	The number of timers that have been delayed by the thread pool limit.
Work Items Queued	The number of work items queued to the thread pool.
Uncontested Monitor.Enter Calls	Number of calls made to the System.Threading.Monitor.Enter method that were not contested.
Contested Monitor.Enter Calls	<p>Number of calls made to Monitor.Enter that were contested.</p> <p>In multi-threaded applications, if <i>Thread1</i> is holding a lock and <i>Thread2</i> needs to access code that is guarded by the lock, the Contested Monitor.Enter Calls counter is incremented.</p>

Garbage Collection Counters

The following counters pertain to garbage collection operations.

Name	Description
Peak Bytes Allocated (native + managed)	The maximum number of bytes in use by the CLR, including both native and managed memory.
Managed Objects Allocated	The count of objects allocated by the garbage collector.
Unused Managed Objects Allocated	The count of objects allocated that were never used.
Managed Bytes Allocated	The count of bytes allocated by the garbage collector.
Unused Managed Bytes Allocated	The count of bytes allocated that were never used.
Managed String Objects Allocated	The number of managed string objects allocated by the garbage collector.
Bytes of String Objects Allocated	The count of bytes of string objects allocated by the garbage collector.
Garbage Collections (GC)	The number of times the garbage collector has run.
Bytes Collected by GC	The count of bytes collected by the garbage collector.
Managed Bytes in Use After GC	The number of bytes allocated to live objects after the last garbage collection.
Total Bytes in Use After GC	The number of bytes of memory, native and managed, in use after the last garbage collection.
GC Compactions	The number of times the garbage collector has compacted the heap.
Code Pitchings	The number of times the garbage collector has discarded JIT-compiled code.
Calls to GC.Collect	The number of times the application has called the System.GC.Collect method.
GC Latency Time (ms)	The total time, in milliseconds, that the garbage collector has taken to collect objects and compact the heap. The latency time of the garbage collector includes the time to collect managed objects that are no longer in scope and the compaction time, if necessary, of the GC Heap.
Pinned Objects	The count of pinned objects encountered while performing a garbage collection. <i>Pinned objects</i> are objects whose locations in memory cannot change. For example, a memory buffer that is being used to communicate between managed and unmanaged code is a pinned object. Pinned objects cannot be moved by the garbage collector during heap compaction.
Objects Moved by Compactor	The count of objects moved by the garbage collector during a compaction.
Objects Not Moved by Compactor	The count of the objects that were not moved by the garbage collector during a compaction. Objects might not be moved for a number of reasons. Some objects cannot be moved, but these objects are rare. Other objects are not moved because they are in a portion of the heap that does not need to be compacted.
Objects Finalized	The count of objects for which a finalizer has been run.
Boxed Value Types	The number of value types that have been boxed.

JIT Counters

The following counters pertain to JIT compiler operations.

Name	Description
Native Bytes Compiled JIT	The count of bytes of native code generated by the JIT compiler.
Methods Compiled JIT	The count of methods generated by the JIT compiler.
Bytes Pitched	The count of bytes of native code generated by the JIT compiler that has been discarded.
Methods Pitched	The count of methods generated by the JIT compiler that have been discarded. Unless your application was moved to the background during its run time, any positive value for the Methods Pitched counter indicates that the application ran under memory pressure.
Method Pitch Latency Time (ms)	The total time, in milliseconds, spent discarding methods generated by the JIT compiler.

Exceptions Counters

The following counters pertain to exceptions.

Name	Description
Exceptions Thrown	The count of managed exceptions that have been thrown. Because throwing an exception consumes significant resources, tracking the number of exceptions thrown by your application can help identify potential design issues.

How To: Generate a Garbage Collector Heap Dump

Explains how to generate a heap dump using the XNA Framework Remote Performance Monitor for Xbox 360.

Introduction

To help diagnose memory leaks related to objects that are kept alive inappropriately, the XNA Framework includes a remote heap dump utility. The heap dump utility is integrated with Remote Performance Monitor. Because of this, you can view the heap dump while you are running the monitor.

XNA Framework applications can experience memory leaks, although the garbage collector mitigates this issue by releasing objects that are no longer referenced.

The garbage collector walks the application roots to identify storage locations for objects on the managed heap that are no longer needed. The term *object root* refers to the object's associated application root, such as a global or static object pointer. The garbage collector will not release any object that is kept alive by a root, even if the application does not need the object any longer. For example, an object might be rooted by a static variable. Because static variables live for the life of the process, unless they are explicitly set to **null**, the objects they reference will be kept alive as long as the process is alive.

Viewing the heap dump provides the following information about the heap.

- Garbage collector heap statistics
- Root of each object in the heap
- Object references for each object in the heap

This topic describes how to view, save, open, and compare heap dumps.

Generating a Garbage Collector Heap Dump

To view a heap dump

1. Start Remote Performance Monitor.
2. Attach it to a process.

For more information, see [How To: Monitor Performance at Run Time](#).

3. In the **Live Counters window**, click **View GC Heap**.

This generates a heap dump in Remote Performance Monitor. The main view of the heap provides general statistics, a tree view of each object and its root, and a table that contains the number of instances of each type together with its cumulative size. By default, only types that are defined by the application are shown in the view. No .NET Compact Framework class library types are shown in the view.

4. Select the check boxes that correspond to the specific types that you want to see in the heap view.
5. Click **Refresh Tree** to update the view.

You can use this updated view to determine the root that keeps a particular object instance alive.

6. If you want to view object references for an object in the heap, either right-click the object and click **View Object References**, or on the **File** menu, click **View Object References**.

The object references appear in a new window.

To save a heap dump

- Save the current heap dump when you close the view of the current heap dump and you are prompted to save.

To open a previously saved heap dump

1. Start Remote Performance Monitor.
2. On the **File** menu, click **Open GC log**, and select a previously saved heap dump file.

To compare heap dumps

1. Start Remote Performance Monitor.

2. In the **Live Counters** window, click **View GC Heap** multiple times to generate heap dumps for comparison.

You can also open previously saved heap dumps to include in the comparison.

3. On the **View** menu, click **Compare Heap**.

This generates a table view of all heaps that are currently open. Each column represents a heap, with the oldest heap appearing first and the most recent heap appearing last. Each row in the column displays the number of instances of the specified type contained in the heap. If this number differs from the previous heap, the difference is shown in parentheses. For example, an entry of 152 (+90) indicates that the specified object had 90 more instances than it had in the previous heap.

[Heap Dump File Information](#)

Heap Dump File Information

Introduction

Garbage collector heap dump files are text files that include information for every object present in the garbage collector heap at the time the dump is generated. The XNA Framework Remote Performance Monitor for Xbox 360 creates the heap dumps. For more information about generating heap dumps, see [How To: Generate a Garbage Collector Heap Dump](#).

Heap Dump File Records

Each line in the heap dump text file contains one record. The five types of records in the file are as follows.

- AppDomain record – identifies the application domain to which the dump file applies.
- Type record – describes a type that is present in the heap.
- Object record – describes an instance of a type that is present in the heap.
- Root record – describes a root instance.
- End AppDomain record – marks the end of the dump file.

Each record contains several elements separated by spaces. The first element in each line indicates the record type. The following example shows a section of a dump file.

 Note
This example is intended to show the format of the file, and may not be semantically accurate.

```
a 2 bubblecs.exe 763f9d2
t 2 System.RuntimeType
o 7c79f 2 64
t 1 System.NullReferenceException
o 7cb42 2 64
o 1ce004 1 18
t 3 System.OutOfMemoryException
o 1ce056 1d 118 1ce11f 1ce14c 1ce079 1ce113 1ce116 1ce267 1ce26a 1ce26d
r 22c81b 5 0
o 22c81e 1b 24
r 22c81e 5 0
o 22c823 1b 28
r 22c823 5 0
c bubblecs.exe 763fbef
```

AppDomain Record

An AppDomain record marks the beginning of a file section that pertains to a particular application domain. All the type, object, and root information for the garbage collector heap for that application domain is included in this section of the file. All AppDomain records close with a corresponding End AppDomain record.

The AppDomain record has four elements.

- Letter "a" – identifies the record as an AppDomain record.
- Version number – number used to track the file format of the dump file. For example, in the .NET Compact Framework version 2.0 Service Pack 2, this number is always "2".
- AppDomain name – name of the application domain used to generate the heap dump file. This is typically the name of the executable that ran in the application domain.
- Time stamp – time that the log data was generated. This value shows the number of milliseconds, represented as a hex value, since the device booted.

The following example shows an AppDomain record.

```
a 2 HH3.exe 763f9d2
```

Type Record

Type records identify types in the garbage collector heap. Each Type record contains three elements.

- Letter "t" – identifies the record as a Type record.

- Type ID – unique numeric identifier for the type. This identifier ties object instances to their types. (See the description of Object records in the next section.)

Note

The type ID is not guaranteed to be unique across dump files. For example, the identifier for the "CorporateContacts" type in the following example is not guaranteed to be "a1" in a different dump that is taken from the same application at a different point in time.

- Type name – fully qualified name of the type.

The following example shows a Type record.

```
t a1 com.PBSG.WATS.HH3.Biz.Entity.CorporateContacts
```

Object Record

Object records describe specific instances of types in the garbage collector heap. Object records have a variable number of elements.

The first four elements are required, and are as follows.

- Letter "o" – identifies the record as an Object record.
- Object ID – unique numeric identifier for the object.

Note

Object identifiers are not guaranteed to be unique across dump files. Because object identifiers can change in different dumps of the same heap, it is not possible to develop tools that identify trends across dump files.

- Type ID – identifier for the type of the object.
- Object size – size, in bytes, of the object instance.

In addition to the four required elements, Object records may have a variable number of the following element.

- Referenced object IDs – identifies other objects that the object references.

The Type record that corresponds to a particular Object record is not guaranteed to precede the Object record in the dump file.

The following example shows an Object record with three referenced object IDs.

```
o 1ce056 1d 118 1ce11f 1ce14c 1ce079
```

Root Record

Root records identify garbage collector roots.

Each Root record contains four required elements.

- Letter "r" – identifies the record as a root record.
- Object ID – identifier of the root object.
- Root descriptor – explains why the object instance is classified as a root.

The following table shows the possible values for the descriptor.

Val	Definition
0	The object instance is rooted internally by the .NET Compact Framework. For example, this includes object instances for application domains, assemblies, exceptions, and so forth.
1	The object instance is a local variable.
2	The object instance is on the finalizer queue waiting for its finalizer to run. After the finalizer runs, the object will be collected during the next garbage collection.
3	A garbage collector handle (that is, a GCHandle) exists that refers to the object instance.
4	The object instance is a static variable.
5	The object instance is a root that is specific to the garbage collection implementation in the .NET Compact Framework. For example, this includes interned strings and class descriptions.

- Root flag – flags that provide more information about the root.

The following table shows the possible flags.

Flag	Definition
0	Normal root. This value is applied to the root if none of the other flags apply.
1	The root is pinned. A root can be pinned for the following reasons. <ul style="list-style-type: none">• It refers to managed objects that are passed to native code through platform invoke.• It is referenced by a GCHandle that is created with a GCHandleType of Pinned.• A pointer in unsafe code points to the object.• A value type field within the object is referenced directly by a method argument.
2	A GCHandle whose GCHandleType is Weak refers to the object.
4	The object is pointed to by a pointer in unsafe code or is referenced by a value type field inside another object.

If the root descriptor is static (4), the root record will have an additional element.

- Root container – identifier of the type that contains the static variable.

The following example shows a root record with an additional root container element.

```
r b2753 4 0 13c
```

End AppDomain Record

End AppDomain records close the section that is initiated by a corresponding AppDomain record.

End AppDomain records have three elements.

- Letter "c" – identifies the record as an End AppDomain record.
- Application name – name of the application from which the dump file was generated. This name matches the name in the AppDomain record at the beginning of the file.
- Time stamp – time that the log data was completed. This value shows the number of milliseconds, represented as a hex value, since the device booted.

The following example shows an End AppDomain record.

```
c HH3.exe 763fbef
```

Introduction

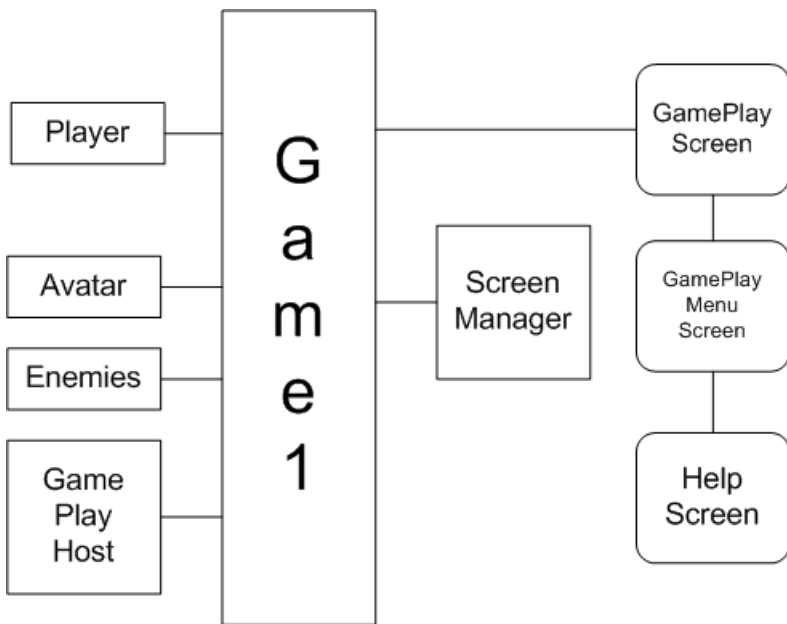

This article is the first in a series that examines how to construct a complete game using the XNA Framework. In this series, we will touch on not just graphics, but networking, input, storage, audio, and other key topics for making a fully functional game. Along the way we will show you how to implement features that go beyond gameplay – supporting multiple controller configurations, in-game volume controls, network presence, and other best practices that will make your games appear more polished and professional.

In this game, two players are represented by red and green ships in the bottom half of the screen. Vaguely insectoid enemy ships fly down from the top of the screen, and the player gains points for shooting them. A collision between an enemy and a player will destroy them both. When a player accumulates enough points, a green insectoid ship called a "seeker" will fly directly toward the player's ship until killed. If the player kills the seeker, the player can grab the lifepod the seeker ejects to gain an extra life. Below is a screenshot from the Xbox 360 version:

This version of the game is coded as a prototype. It can help us examine gameplay issues before we do the hard work of handling sound, multiple inputs, networking, etc. There are three main screens: the `GamePlayScreen`, which handles the actual gameplay, the `GamePlayMenu` which implements a popup menu over the `GamePlayScreen`, and a `HelpScreen` available from the menu.

`Game1` hosts the `GamePlayScreen`, along with helper objects: the `ScreenManager` to manage screens, the `Player` class to manage players, the `Avatar` and `Enemies` classes to handle onscreen ships, and the `GamePlayHost` to determine hits, misses, deaths, and other important events in the game.

Game State Management

The first problem to tackle when you develop your game is how to manage game state. When you play a game, you spend a lot of time in specific screens. You might go from the main menu into a network lobby, to a battle screen, and back to the network lobby, and then perhaps to an options screen, or a help screen. These screens all use art assets, and all use system memory. Some screens may need to occupy memory at the same time. For example, if the user pauses the game to change the controller configuration, you don't want to push the game screen out of system memory. Even though these screens share data, they can all be written as separate classes, and you can develop and test them individually.

To manage our screens, this sample uses code from the [Game State Management sample](#) available for free on the Creator's Club Online Web site. The Game State Management sample defines a base class called `GameScreen`, and a `ScreenManager` game component. The `ScreenManager` component keeps track of which screens are active, and the top-to-bottom order of screens.

Just like the `Game` class, the `GameScreen` class defines an `Initialize`, `LoadContent`, `Update`, and `Draw` method, and the `ScreenManager` calls these methods as a screen is loaded and displayed by the game. (`Initialize` is a new addition for this sample). Unlike the `Game` class, the `GameScreen` class defines a new method, `HandleInput`, that the `ScreenManager` will call on the topmost screen. `HandleInput` takes an instance of `InputState` as a parameter. `InputState` is a small helper class that tracks the `GamePadState` and `KeyboardState` from the last two frames. It contains some helper functions to find new button or key presses.

GamePlayScreen

In this sample, the first screen we use is the `GamePlayScreen`. The `GamePlayScreen` has two main responsibilities: draw the game, and process the input into discrete commands. Those commands are then passed back to the game. The `GamePlayScreen` doesn't act on the input directly. It doesn't hold any of the logic used for enemy AI, detecting collisions, moving the player, and so on. This is handled by the **Game** object itself, and the helper objects it uses. In essence, the `GamePlayScreen` acts like a network client, sending messages out and drawing the screen based on the current data. This is very intentional, because later on it just might be a network client. Structuring the relationship between the `GamePlayScreen` and the **Game1** object in this way gives us a preview of what our network traffic will look like when we enable network play later on.

How does `GamePlayScreen` process input? Let's take a look.

Handling Player Input

From `GamePlayScreen.cs`:

```

public override void HandleInput(InputState input)
{
    playerOneInput = ProcessPlayer(game.Main, input);

    if (game.Guest.IsPlaying)
        playerTwoInput = ProcessPlayer(game.Guest, input);

    base.HandleInput(input);
}
  
```

```

}

private static NeutralInput ProcessPlayer(Player player,
    InputState input)
{
    NeutralInput state;
    state.Fire = false;
    Vector2 stick = Vector2.Zero;
    GamePadState gpState =
        input.CurrentGamePadStates[(int)player.Controller];

    // Get gamepad state
    stick = gpState.ThumbSticks.Left;
    state.Fire = (gpState.Triggers.Right > 0);

    state.StickMovement = stick;
    return state;
}

```

The goal of `HandleInput` is to fill out a `NeutralInput` structure for each player. There are a lot of different controller configurations that could move the ship – two thumbsticks, a dpad, keyboard arrow keys, a mouse, and so on. There are also a lot of buttons on the controller or keyboard you might use to fire the ship's guns. `NeutralInput` is a structure – defined just for this game – that records the result of the input, without knowing which keys and sticks were used. Once we have the `NeutralInput` structures filled out, we leave `HandleInput`. Later on during update, this input structure is examined and real commands are issued (how far did the ship move? Did the ship fire?).

From `GamePlayScreen.cs`:

```

public void ProcessInput(int player, float totalGameSeconds,
    float elapsedGameSeconds, NeutralInput input)
{
    if (input.StickMovement.X > 0)
        accumMove.X += Move(input.StickMovement.X, elapsedGameSeconds);
    if (input.StickMovement.X < 0)
        accumMove.X -= Move(-input.StickMovement.X, elapsedGameSeconds);
    if (input.StickMovement.Y > 0)
        accumMove.Y -= Move(input.StickMovement.Y, elapsedGameSeconds);
    if (input.StickMovement.Y < 0)
        accumMove.Y += Move(-input.StickMovement.Y, elapsedGameSeconds);

    TryMove(player);

    if (input.Fire == true)
    {
        TryFire((byte)player, totalGameSeconds);
    }
}

```

Processing the input is also pretty straightforward. We gather the movement for each cardinal direction, and add it to an accumulator value. `TryMove` will move the ship when the accumulated movement is greater than half a pixel. This keeps us from sending movement commands for movements that won't actually change the ship's position on screen. This will save you a little network bandwidth later. `TryFire` lets the player fire when enough time has passed between shots.

From `GamePlayScreen.cs`:

```

private void TryMove(int player)
{
    if (accumMove.Length() > .5)
    {
        // Find out how far we are allowed to move
        Vector2 move = game.ships[player].VerifyMove(accumMove);

        // Send our movement event to Game1
    }
}

```

```

        Vector2 pos = game.ships[player].position + move;
        game.ShipMove((byte)player, pos);

        // Zero out accumulated input
        accumMove = Vector2.Zero;
    }
}

private void TryFire(byte player, float totalGameSeconds)
{
    if (game.ships[player].status != ObjectStatus.Active)
        return;

    // if the time between the last shot and the current
    // time is less than 1/ROF, don't fire
    if (game.ships[player].VerifyFire(totalGameSeconds))
    {
        game.ShipFire(player, totalGameSeconds);
    }
}

```

`TryMove` notifies the **Game1** object when the ship has moved by calling the `ShipMove` method. `TryFire` calls `ShipFire` in the same way. These are our notifications from the client to the "server" that the user has done something important. But it's up to `Game1` to decide whether to update the ship.

Drawing the game

The other major responsibility of `GamePlayScreen` is to draw the game in progress. This means drawing good guys, bad guys, bullets, explosions, and a scoreboard. To do that, it needs access to the position data for the player ship, enemy ships, and bullets. This data is stored in the **Game1** object, in an **Enemies** object and two **Ship** objects (one for each player). It also needs to load copies of the sprite graphics. This is handled in `LoadContent`:

From `GamePlayScreen.cs`:

```

Texture2D bullet;
Texture2D ship;
Vector2 bulletorigin;
Vector2 shiporigin;
Texture2D villain;
Vector2 villainOrigin;
Texture2D gameover;
Vector2 gameoverOrigin;
SpriteFont arcade;

public override void LoadContent()
{
    bullet = game.Content.Load<Texture2D>("Photon");
    ship = game.Content.Load<Texture2D>("Playership");
    shiporigin = new Vector2(ship.Width / 2, ship.Height / 2);
    bulletorigin = new Vector2(bullet.Width / 2, bullet.Height / 2);

    villain = game.Content.Load<Texture2D>("Villain");
    villainOrigin = new Vector2(villain.Width / 2, villain.Height / 2);

    gameover = game.Content.Load<Texture2D>("gameover");
    gameoverOrigin =
        new Vector2(gameover.Width / 2, gameover.Height / 2);

    arcade = game.Content.Load<SpriteFont>("Arcade");
    Explosion.Texture = game.Content.Load<Texture2D>("Explosion");

    base.LoadContent();
}

```

For convenience, we separate each part of the drawing process into separate methods. Note that the raw data for drawing comes from the `Game1` class.

From `GamePlayScreen.cs`:

```
public override void Draw(GameTime gameTime)
{
    base.Draw(gameTime);

    // Draw each player
    DrawPlayer(game.ships[0], game.TotalGameSeconds);
    DrawPlayer(game.ships[1], game.TotalGameSeconds);

    // Draw the enemies
    DrawEnemies(game.TotalGameSeconds);

    // Draw each player's bullets
    DrawBullets(game.ships[0].bullets, game.TotalGameSeconds);
    DrawBullets(game.ships[1].bullets, game.TotalGameSeconds);

    // Draw the score
    DrawUI();

    // If the game is over, draw a special graphic
    DrawGameOver();
}
```

First up is our hero, the player's ship. To draw the ship, we borrow an initialized `SpriteBatch` from the `ScreenManager`, and then call `Begin`. If you're not familiar with `SpriteBatch`, it's a class that renders textures as on-screen sprites. It does this by creating quads (two-dimensional squares) in 3D space and applying the texture to the quad. Rotating the quad rotates the sprite; stretching the quad stretches the sprite, and so on. `SpriteBatch` draws the sprites all at once (hence "batch") in between `Begin` and `End` calls. `Begin` specifies what kind of rendering to use, and how to handle batches of sprites. We specify `SpriteBlendMode.AlphaBlend` to turn on alpha blending, and `SpriteSortMode.Deferred` indicates that we want to wait until `End` is called to draw all the sprites.

From `GamePlayScreen.cs`:

```
private void DrawPlayer(Avatar state, double totalGameSeconds)
{
    // Initialize our own SpriteBatch. We want default Alpha blending,
    // and the render states set by SpriteBatch to be reset
    // when End() is called.
    SpriteBatch batch = this.ScreenManager.SpriteBatch;
    batch.Begin(SpriteBlendMode.AlphaBlend, SpriteSortMode.Deferred,
        SaveStateMode.SaveState);

    switch (state.status)
    {
    case ObjectStatus.Inactive:
        break; // Draw nothing
    case ObjectStatus.Active:
        // Draws our avatar at the current position with no tinting
        batch.Draw(ship, state.position, null, state.color, 0,
            shiporigin, 1.0f, SpriteEffects.None, 0.5f);
        break;
    case ObjectStatus.Dying:
        Explosion.Draw(batch, state.position, 0, totalGameSeconds,
            state.deathTimeTotalSeconds,
            state.deathTimeTotalSeconds + Avatar.RespawnTime);
        break;
    case ObjectStatus.Immune://blink 5 times per second
        if (((int)(totalGameSeconds * 10) % 2) == 0)
            batch.Draw(ship, state.position, null, Color.Silver, 0,
                shiporigin, 1.0f, SpriteEffects.None, 0.5f);
        break;
    default:

```

```

        break;
    }
    batch.End();
}

```

With an active [SpriteBatch](#), we draw the appropriate graphic depending on what state the player is in. If the player is `Active`, we draw the ship with the normal color. If the player is `Dying`, we use the `Explosion` class to draw an explosion at the player's location. After they explode, the players become `Immune` to damage as they respawn. In this case we draw the ship in silver and blink the image as a cue that they won't be immune for very long, and they should move to a safe place.

Drawing the bullets is much the same process, with one difference. When a bullet is fired, we record the X and Y coordinate of the new bullet in a `Vector3`, and the time the bullet was fired becomes the Z coordinate. From then on, we do not update the X and Y coordinate of the bullet. Instead, we use the fact that all bullets fly at a constant speed to calculate the current location of the bullet, as in the following code:

From `GamePlayHost.cs`:

```

public static float bulletSpeed = 300;
public static Vector2 FindBulletPosition(Vector3 bullet,
    double totalGameSeconds)
{
    Vector2 pos = Vector2.Zero;
    pos.X = bullet.X;
    pos.Y =
        bullet.Y - (bulletSpeed * ((float)totalGameSeconds - bullet.Z));
    return pos;
}

```

To draw the bullets, we call `FindBulletPosition` for each bullet. If we find a bullet position that is actually offscreen, we remove the bullet from the list:

From `GamePlayScreen.cs`:

```

private void DrawBullets(List<Vector3> bullets, double TotalGameSeconds)
{
    SpriteBatch batch = this.ScreenManager.SpriteBatch;
    batch.Begin();
    Vector2 pos;
    for (int i = 0; i < bullets.Count; i++)
    {
        pos = GamePlayHost.FindBulletPosition(bullets[i],
            TotalGameSeconds);
        if (pos.Y > -10) // bullet is far off the top of the screen
        {
            batch.Draw(bullet, pos, null, Color.White, 0,
                bullet.Origin, 1.0f, SpriteEffects.None, 0.6f);
        }
        else
        {
            // Since we are iterating each bullet anyway, now is a
            // good time to remove bullets that go offscreen.
            bullets.RemoveAt(i);
        }
    }
    batch.End();
}

```

Drawing enemies is a little more complicated. Just like the bullets, we don't actually store the current position of the enemies. But the enemies don't move in a straight line – they swoop around the screen. For that reason, this sample uses the XNA

Framework [Curve](#) class to store one curve for the Y axis of the enemy, and one curve for the X axis. As time elapses, the enemy moves along each curve until eventually the enemy disappears offscreen. Then we reset the position on the curve back to the beginning and start again. So in order to draw each enemy, we need to determine the new position of each enemy. That's done with the following method of the `Enemies` class (the `EnemyInfo` class holds the proper curve for a given type of enemy):

From Enemies.cs:

```
public static Vector2 GetPosition(float position, EnemyInfo info)
{
    Vector2 pos = Vector2.Zero;
    pos.Y = info.YCurve.Evaluate(position) * info.ScreenBounds.Height;
    pos.X = info.XCurve.Evaluate(position) * info.ScreenBounds.Width;
    return pos;
}
```

Once we have the position of an enemy, we just have to draw the position (if the enemy is alive), or draw an explosion if the enemy is dying. Seekers do not use curves – they each have an X and Y position just like the players.

From GameplayScreen.cs:

```
private void DrawEnemies(float TotalGameSeconds)
{
    SpriteBatch batch = this.ScreenManager.SpriteBatch;
    batch.Begin();
    // Draw first enemy type
    foreach (EnemyState enemy in game.enemies.waves)
    {
        Vector2 pos = Enemies.GetPosition(TotalGameSeconds, enemy);
        if (enemy.status == ObjectStatus.Active)
        {
            batch.Draw(villain, pos, null, Color.White, 0,
                villainOrigin, 1.0f, SpriteEffects.None, .6f);
        }
        else if (enemy.status == ObjectStatus.Dying)
        {
            // I'm exploding!
            Explosion.Draw(batch, pos, enemy.deathTimeTotalSeconds,
                TotalGameSeconds,
                enemy.deathTimeTotalSeconds,
                enemy.deathTimeTotalSeconds + 1.5);
        }
    }
    // Draw seekers, if any
    foreach (SeekerState seeker in game.enemies.seekers)
    {
        if (seeker.status == ObjectStatus.Active)
        {
            batch.Draw(villain, seeker.position, null, Color.LightGreen,
                seeker.angle, villainOrigin, 1.0f,
                SpriteEffects.None, .6f);
        }
        else if (seeker.status == ObjectStatus.Dying)
        {
            // Draw the powerup
            batch.Draw(villain, seeker.position, null, Color.White,
                seeker.angle, villainOrigin, 0.5f,
                SpriteEffects.None, .6f);

            // Draw the explosion
            Explosion.Draw(batch, seeker.position,
                seeker.deathTimeTotalSeconds, TotalGameSeconds,
                seeker.deathTimeTotalSeconds,
                seeker.deathTimeTotalSeconds + .5);
        }
    }
    batch.End();
}
```

```
}
```

Our last major task for the `GamePlayScreen`, then, is drawing the score. First, we construct a multi-line string for each player, giving the score, name, and how many lives remain for each player. Then we use a `SpriteBatch` with the `DrawString` method (instead of the `Draw` method we've been using for sprites). `DrawString` takes a given string and draws the letters from a given `SpriteFont`. We loaded the `SpriteFont`, named `arcade`, in `LoadContent`. We use the `MeasureString` method to make sure that we will have enough room to print the second player's gamertag.

From `GamePlayScreen.cs`:

```
private void DrawUI()
{
    string P2Text = (game.ships[1].Player.IsPlaying) ? "2P " +
        game.ships[1].score.ToString("000000") :
        "2P Press Start";
    P2Text += "\n\r" + game.ships[1].Player.Name;
    P2Text += "\n\r" + game.ships[1].lives.ToString() + " lives";

    string P1Text = "1P " + game.ships[0].score.ToString("000000");

    P1Text += "\n\r" + game.ships[0].Player.Name;
    P1Text += "\n\r" + game.ships[0].lives.ToString() + " lives";

    Vector2 Pos = new Vector2(uiBounds.X, uiBounds.Y+10);

    SpriteBatch batch = this.ScreenManager.SpriteBatch;
    batch.Begin(SpriteBlendMode.AlphaBlend, SpriteSortMode.Deferred,
        SaveStateMode.SaveState);
    batch.DrawString(arcade, P1Text, Pos, Color.Pink);

    // Gamertags can be 15 characters
    int gamertagwidth =
        (int)(arcade.MeasureString("123456789012345").X);
    Pos.X = uiBounds.Right - gamertagwidth;

    batch.DrawString(arcade, P2Text, Pos, Color.Pink);
    batch.End();
}
```

GamePlayHost

Now that we can draw the game, let's take a look at the brains of the game: `GamePlayHost`. The gameplay logic is sequestered into a separate object for a couple reasons, but mainly because in a network game, only the host actually needs it. Let's begin by taking a look at the `Update` method for `GamePlayHost`:

From `GamePlayHost.cs`:

```
public void Update(GameTime gameTime)
{
    if (!bActive)
        return;

    SpawnWaves(Game.TotalGameSeconds);

    HandleCollisions(Game.ships[0], 0,
        Game.enemies, Game.TotalGameSeconds);
    HandleCollisions(Game.ships[1], 1,
        Game.enemies, Game.TotalGameSeconds);

    SpawnSeekers();

    for (int j = 0; j < Game.enemies.seekers.Length; j++)
    {
        UpdateSeeker(Game.TotalGameSeconds,
```

```

        (float)gameTime.ElapsedGameTime.TotalSeconds,
        Game.enemies.seekers[j], (byte)j, Game.ships);
    }
}

```

After checking to see if the host is active (and returning early if it's not), we farm out the major logic tasks to other methods. `SpawnWaves` checks to see if it's time to create another wave of enemies. `HandleCollisions` runs once for each player ship on screen, checking the player's position and the player's bullets against the currently active enemies. Lastly, "Seekers" are a special type of enemy that chase the player, and so `GamePlayHost` determines when they get created, and how they move.

From `GamePlayHost.cs`:

```

private void SpawnWaves(double TotalGameSeconds)
{
    // If it's time for a new wave and no enemies are
    // left from the last wave
    if ((Game.enemies.ActiveEnemies == 0) &&
        (TotalGameSeconds >= NextWaveEarliestSeconds))
    {
        // If the wave was killed in one pass, both players get a bonus
        if (bKillAllInOnePass)
        {
            //Game.state.Players[0].score += 1000;
            Game.IncreaseScore(0, 1000);

            // PlayerTwo doesn't get a bonus if they're not playing
            if (Game.ships[1].status != ObjectStatus.Inactive)
                Game.IncreaseScore(1, 1000);
        }

        // Spawn the next wave
        Game.SpawnNextWave((float) TotalGameSeconds);

        // Reset our booleans
        bLastWaveBasic = !bLastWaveBasic;
        bKillAllInOnePass = true;

        // Reset the wave timer
        NextWaveEarliestSeconds = (float)TotalGameSeconds + 2.0f;
    }
    else if (TotalGameSeconds >= NextWaveEarliestSeconds)
    {
        NextWaveEarliestSeconds = (float)TotalGameSeconds + 2.0f;
        bKillAllInOnePass = false;
    }
}

```

The most important thing to note about `SpawnWaves` is that it doesn't actually create the new enemies. `Game.SpawnNextWave` does that. `GamePlayHost.SpawnWaves` just determines if it's the proper time to do so. `Game.SpawnNextWave` creates new enemies because in this sample `Game1` owns all the data. In later versions, `Game1` will spawn new waves in response to a network message from the host.

The second thing to note is that `SpawnWaves` decides if players get a bonus for clearing the wave in one try, and uses methods on `Game` to increase their score.

In a game like this, or any game that involves shooting, you're going to be spending a lot of CPU time detecting collisions. Detecting collisions between all the objects in your world can be a laborious process. For example, if you have bullets in your game that hit objects, you have to check the position of each bullet to the location of each object a bullet might hit. As the number of objects and bullets grows, the CPU time spent detecting collisions goes up geometrically.

Fortunately, there a lot of tricks you can use. We won't detail them all here, but they all involve reducing the number of objects to be tested, or dividing them into batches. In this case, the number of objects doesn't grow too much. We know the maximum number of enemies, of players, and bullets. Therefore, we compare each player to the data set for the enemies. Comparing two sets of objects to see if any collide (in this case, bullets and enemies) usually involves two nested loops. Inside the inner loop,

you test one object against another:

From GameplayHost.cs:

```
public void HandleCollisions(Avatar player, byte playerId,
    Enemies enemies, float totalGameSeconds)
{
    // Skip a lot of processing if the player isn't playing
    if (player.status == ObjectStatus.Inactive)
        return;

    for (int j = 0; j < enemies.waves.Length; j++)
    {
        if (enemies.waves[j].status == ObjectStatus.Active)
        {
            Vector2 enemyPos = Enemies.GetPosition(totalGameSeconds,
                enemies.waves[j]);
            for (int i = 0; i < player.bullets.Count; i++)
            {
                {
                    // Did player kill the enemy?
                    if (DetectCollision(player.bullets[i],
                        enemyPos, totalGameSeconds))
                    {
                        player.bullets.RemoveAt(i);
                        Game.EnemyKilled((byte)j, (byte)playerId);
                    }
                }
            }
            // Did the player crash into the enemy?
            if (DetectCrash(player, enemyPos,
                Enemies.GetInfoForType(enemies.waves[j].type)))
            {
                Game.EnemyKilled((byte)j, (byte)playerId);
                DestroyPlayer((byte)playerId);
            }
        }
    }
}
```

If the player is playing, we start with the list of enemies, determining the position of each one, then checking each of our player bullets to see if this enemy was hit. We then to check to make sure that the player didn't crash into the enemy, either. If a bullet hits an enemy, we inform the **Game1** object of the results of the collision. If a player hits the enemy, we inform the **Game1** object of the (slightly different) results.

The second half of `HandleCollisions` repeats this process for each Seeker type enemy onscreen (if any):

From GameplayHost.cs:

```
for (int k = 0; k < enemies.seekers.Length; k++)
{
    if (enemies.seekers[k].status == ObjectStatus.Active)
    {
        for (int l = 0; l < player.bullets.Count; l++)
        {
            // Did player kill seeker?
            if (DetectCollision(player.bullets[l],
                enemies.seekers[k].position, totalGameSeconds))
            {
                Game.SeekerDestroyed((byte)k);
                player.bullets.RemoveAt(l);
            }
        }
    }
    // Did the player crash into the seeker?
    if (DetectCrash(player, enemies.seekers[k].position,
        Enemies.GetInfoForType(EnemyType.Seeker)))
```

```

    {
        // The seeker is live, crash the player
        if (enemies.seekers[k].status == ObjectStatus.Active)
        {
            Game.SeekerCrashed((byte)k);
            DestroyPlayer((byte)playerId);
        }
        // The seeker is a popup, reward the player
        else if (enemies.seekers[k].status == ObjectStatus.Dying)
        {
            Game.IncreaseLife(playerId);
            Game.SeekerCrashed((byte)k);
        }
    }
}
}
}

```

You may have noticed the `DetectCrash` and `DetectCollision` method calls in the code above. These two helpers functions do the real work of determining if a player or a bullet has hit an enemy. To see if a bullet collides with an enemy, we treat the bullet as a point and the enemy as a rough circle. Testing if a point is within a circle is pretty straightforward:

From `GamePlayHost.cs`:

```

public static bool DetectCollision(Vector3 bullet, Vector2 enemy,
    double totalGameSeconds)
{
    Vector2 pos =
        GamePlayHost.FindBulletPosition(bullet, totalGameSeconds);
    if (Vector2.Distance(pos, enemy) < 30)
        return true;

    return false;
}

```

To see if a player collides with an enemy, we treat each object as a rough circle. Then to see if the two circles touch, we add the radius of each circle together, and compare that with the real distance between the center of each circle:

From `GamePlayHost.cs`:

```

public static bool DetectCrash(Avatar player, Vector2 enemy,
    EnemyInfo enemyType)
{
    if (player.status == ObjectStatus.Active)
    {
        float distance = Vector2.Distance(player.position, enemy);
        return (distance < Avatar.CrashRadius + enemyType.CrashRadius);
    }
    return false;
}

```

Game1

Our **Game1** object plays a critical role in this sample. It's responsible for all the gameplay data in the sample, and with few exceptions only the **Game1** object changes the basic state data of the game. It's also in charge of the game's players, hardware configuration, hosting components like the `ScreenManager`, and provides the heartbeat of the game through the `Update` and `Draw` methods. In later versions it will host other managers, like the `NetworkManager`, `InputManager`, and `AudioManager`, as well as controlling network traffic.

Managing Game Data

To signal a change in the state data for the game, `Game1` exposes a series of small methods. We've encountered some of these methods already, like `ShipMove`, `ShipFire`, and `SpawnNextWave`. This state data is kept in three variables, `Game1.enemies`, `Game1.ships`, and `Game1.TotalGameSeconds`. The `Enemies` class keeps track of both enemy waves and the Seekers, and the `Ship` class handles the on-screen players. (A separate class, `Player`, keeps track of the players whether they are currently playing a game or not – specifically, who is signed in to which controller). Here we see an example of how the **Game** object handles data:

From `Game1.cs`:

```
public void SpawnNextWave(float totalGameSeconds)
{
    enemies.SpawnNextWave(totalGameSeconds);
}

public void ShipMove(byte player, Vector2 pos)
{
    ships[player].position = pos;
}

public void ShipFire(byte player, float totalGameSeconds)
{
    ships[player].bullets.Add(new Vector3(ships[player].position,
        totalGameSeconds));
}
```

Managing Players

A robust game has to be able to keep track of players as independent entities, regardless of whether they are playing over the network, or using a local controller (and regardless of which controller they're using). For this reason, we use the `Player` class to keep track of our player information. For now we just track their local controller port, name, and play status (`IsPlaying`). There are two **Player** objects in **Game1 – Main**, and **Guest**. In this sample, the **Main** player controls the menus and becomes **Player One** during any gameplay; the **Guest** player is the second controller and becomes **Player Two**.

We initialize the **Main** player during `Game1.Initialize`. After that, we check during `Update` to see if the **Guest** player has joined the game:

From `Game1.cs`:

```
// Check for Player Two pressing Start, and initialize them.
if (GamePad.GetState(PlayerIndex.Two).IsButtonDown(
    Buttons.Start) && !Guest.IsPlaying)
{
    InitializeGuest(PlayerIndex.Two);
}
```

Menu

Menus are a critical (if boring) component of games. Most games will have more than one, even multiple layers of menus to track. This sample uses two classes to encapsulate the menu. The first class, `MenuComponent`, is a reusable component that will display a list of menu choices and keep track of which item is currently selected. The `MenuComponent` is designed to be hosted by a `GameScreen` that represents the entire menu. In this sample, that `GameScreen` is called `GamePlayMenu`, and is called up by the `GamePlayScreen` when the Main player presses **Start**. The `GamePlayMenu` initializes the `MenuComponent` with a list of menu options along with the current viewport. `GamePlayMenu` also handles the `MenuSelected` and `MenuCanceled` events, which are raised when the user presses the **A** or **B** button:

From `GamePlayScreen.cs`:

```
MenuComponent menu;
...
public override void Initialize()
{
    menu = new MenuComponent(this.ScreenManager.Game,
        this.ScreenManager.Font, this.ScreenManager.SpriteBatch);
}
```

```

menu.AddText("Resume");
menu.AddText(" Help");
menu.AddText("Restart");
menu.AddText(" Quit");
menu.MenuOptionSelected +=
    new MenuEventHandler(menu_MenuOptionSelected);
menu.MenuCanceled += new MenuEventHandler(menu_MenuCanceled);
menu.Initialize();
Viewport view = this.ScreenManager.GraphicsDevice.Viewport;
menu.CenterMenu(view);

TransitionPosition = 0.5f;
base.Initialize();
}

```

To allow the `MenuComponent` to handle input itself we added a `HandleInput` method that uses an `InputState` parameter, just like `GameScreen` objects do. `GamePlayMenu` calls `MenuComponent.HandleInput` during its own `HandleInput`:

From `GamePlayScreen.cs`:

```

public override void HandleInput(InputState input)
{
    menu.HandleInput(input);
    base.HandleInput(input);
}

```

`GamePlayScreen` monitors user input during `Update`, looking for the user to press the **Start** button:

From `GamePlayScreen.cs`:

```

// If the user activates the menu...
if ((GamePad.GetState(game.Main.Controller).Buttons.Start ==
    ButtonState.Pressed) && !bPaused)
{
    this.ScreenManager.AddScreen(menu);
    // Use this to keep from adding more than one menu to the stack
    bPaused = game.BeginPause();
    return;
}

```

That sets in motion a chain of events where we add the `GamePlayMenu` screen to the stack. `GamePlayMenu` displays the `MenuComponent`, which pops up the menu list supplied during `Initialize`.

We also pause the game, and set a Boolean. The Boolean we use is very important. Because we are detecting when the **Start** button is held down, we know for certain that our routine would be called more than once as the **Start** button is pressed down from frame to frame. Whenever you're detecting a button press, you can be quite sure that button will not be down for only one frame. You can wait until the button is released before taking any action, and we do so in other circumstances. However, when it comes to pausing the game, we want the game to appear responsive and not wait for the player to let go of the **Start** button. So in this case we don't wait for the button to be released, and we use the Boolean instead.

Once displayed, the `GamePlayMenu` screen dims the screen, and the `MenuComponent` displays four choices, including an option for Help.

HelpScreen

A **Help** screen is another item that's important for a successful game. Even if your controls are intuitive, and it's clear what the obstacles are and how to overcome them, you can be sure that someone in your audience might be confused or otherwise need a nudge in the right direction. (What if they've never played this type of game before? Or any game?). Even a simple Help screen can go a long way toward satisfying those customers. This sample provides a very simple Help screen that is available from the menu.

Miscellaneous Graphics

The sample project has a file named `Graphics.cs` that contains miscellaneous graphics-related classes.

Background Screen

This game features a background starfield with floating clouds of dust. This theme will be reused for most of our future screens, so we've created the `BackgroundScreen` class to serve as a base class for screens featuring a starfield.

`BackgroundScreen` uses two instances of the `ScrollingBackground` class, each running a full-screen graphic at different speeds.

`BackgroundScreen` also contains a couple of useful utility functions. One, `GetTitleSafeArea`, is designed to calculate the current title safe area. The title safe area is the part of the screen (especially on a standard definition television) that is guaranteed to be visible by the user. Screens should take care to display important graphics and text within this area. The title safe area is typically considered to be the inner 90 percent of the total area.

The other utility function is `DrawBorder`, which draws a colored border around a given rectangle. This is used by many screens in the game to provide either a practical or aesthetic effect. The border is constructed by drawing a single corner graphic in the corners – properly rotated – and using rectangular scaling with `SpriteBatch.Draw` to stretch a single border graphic between the corners.

Explosion

Creating a realistic explosion is hard. Very hard. Nice explosions can add a lot to a game, however (assuming your game has things that explode). Most explosions in games are a multi-frame graphic that shows the explosion begin, expand, and then fade out. In this sense explosions are just another type of animation. There are other ways to render explosions, such as particle systems, especially in 3D. But it's hard to top a real explosion captured digitally and replayed as an animation.

The `Explosion` class takes one frame of an explosion graphic, and use `SpriteBatch` functionality to make it expand, brighten, and then fade away. How large and how bright the explosion becomes is determined by when the explosion starts, when it ends, and the current time. By manipulating one texture we can create the illusion of an animation with a little less overhead than having a string of images that represent an animation.

To create the illusion, we change three parts of the animation: the size, the brightness, and the alpha value. To change the size, we simply create a scale parameter that starts at 60 percent of the original graphic's size, and increases from there:

From `Graphics.cs`:

```
double duration = endSeconds - startSeconds;
double time = totalSeconds - startSeconds;

// The explosion gets bigger as time goes on
float scale = (float) ((time / duration)*.5f) + .6f;
```

Duration represents how long the explosion will last, and time is how long the explosion has already been active. While the explosion is growing, it also gets brighter:

From `Graphics.cs`:

```
// The explosion gets brighter as time goes on
float intensity = (float) (time / duration) * .5f;
Vector4 colorval = new Vector4(0.75f + intensity);
```

The original intensity of the explosion is 75 percent and gets brighter as time goes on. So the explosion starts darker than normal and then grows to full intensity. We accomplish this effect by passing RGB values that are less than 1 as the color parameter of `SpriteBatch.Draw`. This darkens the texture being drawn. In this case, we create a `Vector4` where the X, Y, and Z properties will hold our R, G, and B values.

Part of the color parameter of `SpriteBatch.Draw` is an alpha value. This part of the color determines how transparent the image should be. An alpha value of 0 is fully transparent (i.e. invisible), and 1 is fully opaque. The `Explosion` class uses a modified sine wave to create a smooth increase and decrease in transparency, so the explosion fades in and out. This alpha value is encoded as the W value of the `Vector4` we used to store the RGB values.

From `Graphics.cs`:

```
// The explosion also fades in and out
colorval.W = (float)Math.Sin((time / duration) * MathHelper.Pi)+.2f;
```

Finally, we take the [Vector4](#) and convert it to a Color, where the XYZW values become RGBA values. Then we draw the explosion:

From Graphics.cs:

```
// The intensity and fade determines our tint color
Color color = new Color(colorval);

// Draw the texture with the appropriate scale and tint
batch.Draw(texture, pos, null, color, rotation, origin, scale,
    SpriteEffects.None, 0.5f);
```

Coming up Next

In [Part 2](#) of this series, we'll explore how to move this prototype game into a full-fledged arcade game by adding more screens, audio support, more sophisticated controller and gamer profile handling, and support for gamer presence on Xbox LIVE.

Introduction

In this series, we will touch on not just graphics, but networking, input, storage, audio, and other key topics for making a fully functional game. Along the way, we will show you how to implement features that go beyond gameplay—features such as supporting multiple controller configurations, in-game volume controls, network presence, and other best practices that will make your games appear more polished and professional.

In our second installment, we take the basic game from Part 1, and add audio support, controller support, some Xbox LIVE support, a main menu screen, an options screen, and a start screen. So by the time we are done, the code will look something like this:

We're also adding a main menu screen, an options screen, and a start screen. The options screen and Help screen both exit back to the screen that created them, and the main menu can exit back to the start screen, like so:

AudioManager

To add audio to the sample, we created the `AudioManager`. Like the `ScreenManager`, this is a component that we load and add to the game's `Components` collection. Instead of handling `GameScreens`, however, this component keeps track of our current sounds, and exposes methods we can use to play specific sounds, pause sounds, and set volume levels.

To play audio, the `AudioManager` uses the new `Song` and `SoundEffect` classes. A `SoundEffect` is loaded from the content manager, and encapsulates a wave (WAV) file. For each `SoundEffect`, you have the option of creating a `SoundEffectInstance` for managing the sound after it begins to play. If you choose to use a `SoundEffectInstance`, you must call `SoundEffect.CreateInstance` before you call `SoundEffectInstance.Play`. The `AudioManager` declares a private variable for each `SoundEffect` it uses, and a separate `SoundEffectInstance` for each of the sounds that play continuously. A song can be loaded from the content manager or from the user's existing media library, and the `MediaPlayer` class allows us to play a specific song.

From `AudioManager.cs`:

```

private SoundEffect Shot;
private SoundEffect Explosion;

private Song Music;
private SoundEffect Seeker; // Looped
private SoundEffectInstance SeekerInstance;

```

`AudioManager` is declared as a `DrawableGameComponent`. Even though it never draws, this gives us an overridable `LoadContent` method for loading our sounds:

From `AudioManager.cs`:

```

protected override void LoadContent()
{
    Music = Game.Content.Load<Song>("Menu_Loop");
    MediaPlayer.Volume = MusicVolume;
    MediaPlayer.IsRepeating = true;

    Seeker = Game.Content.Load<SoundEffect>("engine_2");

    // We call CreateInstance to get a permanent handle
    // on the seeker sound, and set it's pitch, volume,
    // and looping accordingly.
    SeekerInstance = Seeker.CreateInstance();
    SeekerInstance.Volume = FXVolume;
    SeekerInstance.Pitch = 0.75f;
    SeekerInstance.IsLooped = true;

    Shot = Game.Content.Load<SoundEffect>("tx0_fire1");
    Explosion = Game.Content.Load<SoundEffect>("explosion1");

    base.LoadContent();
}

```

The `Music` [Song](#) represents the background music, a short sample that plays in a continuous loop. The `Seeker` [SoundEffect](#) represents the sound of the seeker's engine. In our `LoadContent`, we create a [SoundEffectInstance](#) for the `Seeker` sound. Because we want the sound to be continuous when it is played, we set the `IsLooped` property as soon as we get an instance.

Even for a short-lived [SoundEffect](#), it can be useful to hold on to the [SoundEffectInstance](#) returned by `CreateInstance`. We need to have the [SoundEffectInstance](#) if we want to pause and resume the sound. For this game, we want the audio manager to be able to pause all sounds, and resume them. To that end, the `AudioManager` has a queue to hold [SoundEffectInstances](#), and the `AddSound` method that creates a [SoundEffectInstance](#) for a specific [SoundEffect](#), and adds the [SoundEffectInstance](#) to the queue.

From `AudioManager.cs`:

```
private Queue<SoundEffectInstance> Sounds;
private void AddSound(SoundEffect sound, float volume, float pitch)
{
    SoundEffectInstance handle = sound.CreateInstance();
    handle.Volume = volume;
    handle.Pitch = pitch;
    handle.Play();
    Sounds.Enqueue(handle);
}
public void PlayShot()
{
    if (!bPaused)
        AddSound(Shot, 1.0f, 0.5f);
}
```

The methods used to play [SoundEffects](#), like `PlayShot`, all call `AddSound` if the audio is not paused. This adds the [SoundEffectInstance](#) to the queue. During `Update`, the `AudioManager` checks the first sound of the queue. If the sound has expired, it removes it from the queue. This keeps the queue size manageable.

To play music, we use the `Play` method on [MediaPlayer](#).

From `AudioManager.cs`:

```
public void PlayMusic()
{
    MediaPlayer.Play(Music);
}
```

The most useful function for the audio manager is the ability to pause all sounds currently being played. This is why we put each [SoundEffectInstance](#) into a queue. When the audio is paused, we iterate over the queue and pause all the sounds being played. We also pause the `Seeker` sound. To pause everything, including music, we call [MediaPlayer.Pause](#) along with `PauseSounds`.

From `AudioManager.cs`:

```
public void PauseSounds()
{
    bPaused = true;
    SeekerInstance.Pause();
    foreach (SoundEffectInstance item in Sounds)
    {
        if (item.State == SoundState.Playing)
            item.Pause();
    }
}
public void PauseAll()
{
    PauseSounds();
}
```

```
    MediaPlayer.Pause();
}
```

To resume playback, the game calls `ResumeAll`, which iterates over the queue again, resuming any sounds in the `Paused` state. It also calls `Resume` for the `Seeker` instance. If the seeker sound was stopped when `Pause` was called, then the `SeekerInstance` state will be `Stopped` and not `Paused`. Therefore, the seeker sound will not resume playing. To see pause and resume in action, press **Start** during normal gameplay—a popup menu will appear, during which time all sounds are paused. Select **Resume** on the menu to resume the game, and any paused sounds will continue playing.

For a polished game, you probably need to add some kind of sound management tools to pause and resume certain sounds while not pausing others. The `AudioManager` is not a general purpose solution for this problem, but it does illustrate one approach you can take, particularly if you use the `SoundEffect` class. Ultimately, how you manage audio is up to you, the developer.

Input Manager

To manage our controllers for this sample, we created the `InputManager`. The input manager is not responsible for reporting gamepad buttons, triggers, or thumbstick status to the game. That is still handled by the `ScreenManager`, which uses the `InputState` class. The input manager is responsible for just about everything else related to controllers, including vibrating controllers and detecting disconnected controllers.

The first major controller-related task in the game is detecting which controller the main player is using. You may recall this game keeps track of two players with the `Player` class: the `Main` player, who controls the menus and is considered player one, and the `Guest` player, who controls player two.

Most games detect the primary player by presenting a title screen, and asking one of the players to press **Start**. Whoever presses **Start** is designated as player one! Pretty simple. This is the approach we take in our game. The start screen is the first screen displayed by the game. In every frame, the `StartScreen` calls an `InputManager` method, `CheckPlayerOneStart`, to see if anybody has pressed **Start**. Once one of the players presses **Start**, the screen calls `Game1.InitializeMain`, and then exits. `CheckPlayerOneStart` returns the `PlayerIndex` of the player who pressed **Start**, which is passed to `Game1.InitializeMain`.

From `InputManager.cs`:

```
public static bool CheckPlayerOneStart(out PlayerIndex playerOne)
{
    playerOne = PlayerIndex.One;
    if (IsSupported(
        GamePad.GetCapabilities(PlayerIndex.One).GamePadType) &&
        (GamePad.GetState(PlayerIndex.One).Buttons.Start
        == ButtonState.Pressed))
    {
        playerOne = PlayerIndex.One;
        return true;
    }
    if (IsSupported(
        GamePad.GetCapabilities(PlayerIndex.Two).GamePadType) &&
        (GamePad.GetState(PlayerIndex.Two).Buttons.Start
        == ButtonState.Pressed))
    {
        playerOne = PlayerIndex.Two;
        return true;
    }
    if (IsSupported(
        GamePad.GetCapabilities(PlayerIndex.Three).GamePadType) &&
        (GamePad.GetState(PlayerIndex.Three).Buttons.Start
        == ButtonState.Pressed))
    {
        playerOne = PlayerIndex.Three;
        return true;
    }
    if (IsSupported(
        GamePad.GetCapabilities(PlayerIndex.Four).GamePadType) &&
        (GamePad.GetState(PlayerIndex.Four).Buttons.Start
        == ButtonState.Pressed))
    {
        playerOne = PlayerIndex.Four;
    }
}
```

```

        return true;
    }
    return false;
}

```

`CheckPlayerOneStart` relies on a helper function, `IsSupported`, which is defined by the `InputManager`. The `IsSupported` method allows us to define which controllers the game considers valid, and by omission which controllers it should ignore. For example, our game supports a gamepad, an arcade stick, and a flight stick. By extension, we will not support guitars or drums, or `BigButton` controllers. If any of those controllers presses **Start**, we will ignore their inputs.

From `InputManager.cs`:

```

private static bool IsSupported(GamePadType type)
{
    return ((type == GamePadType.GamePad) ||
           (type == GamePadType.ArcadeStick) ||
           (type == GamePadType.FlightStick));
}

```

The second major controller-related task in the game is detecting when the `Main` player's controller is disconnected. That's the first thing the `InputManager` looks for during its `Update` cycle:

From `InputManager.cs`:

```

// Detect disconnected controller
if ((!GamePad.GetState(game.Main.Controller).IsConnected) &&
    (cdScreen == null))
{
    // Display Screen to wait for reconnect
    cdScreen = new ControllerDisconnectScreen(game.Main.Controller);
    game.screenManager.AddScreen(cdScreen);
}

```

The way the input manager handles a disconnected controller is to put a new `GameScreen` – `ControllerDisconnectScreen` – in front of the other screens. This has the effect of interrupting the previous screen. The other screens can detect during `Update` that they are not on top by checking the `coveredByOtherScreen` parameter, and act accordingly. Meanwhile the `ControllerDisconnectScreen` remains on top, displaying an error message, until the user reconnects the controller.

After checking the `Main` controller, the input manager embarks upon its third major task—handling controller vibration. Controller vibration can be a very tricky case because different vibrations are often being exerted at the same time. To accommodate this, `InputManager` defines a `ControllerEvent`, which adds vibration to a particular controller for a specific period of time:

From `InputManager.cs`:

```

public struct ControllerEvent
{
    public int finalFrame;
    public PlayerIndex player;
    public float leftMotor;
    public float rightMotor;
}

```

A method on the `InputManager` called `AddVibration` creates these events on demand and stores them in a **List** object.

From `InputManager.cs`:

```

private int currentFrame = 0;
private List<ControllerEvent> Vibrations;
...
private void AddVibration(PlayerIndex player, int frames,
    float leftMotor, float rightMotor)
{
    ControllerEvent vibe;
    vibe.finalFrame = currentFrame+frames;
    vibe.leftMotor = leftMotor;
    vibe.rightMotor = rightMotor;
    vibe.player = player;
    Vibrations.Add(vibe);
}

```

Finally, during `Update`, the list is combed for obsolete entries, and then each event is tallied for each controller. The input manager then calls the [SetVibration](#) method using the new totals.

From InputManager.cs:

```

if (!bPaused)
{
    currentFrame++;

    Vector2 pOne = Vector2.Zero;
    ...
    // Clear the list of expired events;
    for (int i = 0; i < Vibrations.Count; i++)
    {
        // Add up all the vibrations for each player
        if (Vibrations[i].finalFrame < currentFrame)
            Vibrations.RemoveAt(i);
        else
        {
            switch (Vibrations[i].player)
            {
                case PlayerIndex.One:
                    pOne.X += Vibrations[i].leftMotor;
                    pOne.Y += Vibrations[i].rightMotor;
                    break;
                ...
            }
        }
        // Play the vibrations for each player
        GamePad.SetVibration(PlayerIndex.One, pOne.X, pOne.Y);
        ...
    }
}

```

The `InputManager` also provides a way to pause the vibration, using the `BeginPause/EndPause` pattern common to this program:

From InputManager.cs:

```

private bool bPaused = false;
...
public void BeginPause()
{
    bPaused = true;
    if (GamePad.GetState(game.Main.Controller).IsConnected)
    {
        GamePad.SetVibration(game.Main.Controller, 0, 0);
    }
    if (GamePad.GetState(game.Guest.Controller).IsConnected)

```

```

    {
        GamePad.SetVibration(game.Guest.Controller, 0, 0);
    }
}
...
public void EndPause()
{
    bPaused = false;
}

```

Setting Options

Once the input and audio systems in your game are in place, it's a good idea to think about player options for input and audio. Input options typically include different controller configurations, while audio options normally come down to volume levels for different types of sound. In our sample, we include two controller configurations, and two sound levels. The two controller configurations differ in which thumbstick is used for movement. This is one of the options gamers can specify in their gamertag for cross-game preferences, and so the chance to honor that preference is important. The sound levels apply to sound and music levels.

To model the different options available, we create the `OptionsState` struct:

From OptionsScreen.cs:

```

public enum InputMode
{
    Normal,
    Southpaw,
}
public struct OptionsState
{
    public InputMode PlayerOne;
    public InputMode PlayerTwo;
    public float FXLevel;
    public float MusicLevel;
}

```

The options are stored as a read-only property and a private member on `Game1` called `Options` and `options`, respectively. The first time we run into this structure is when we try to populate it, in a function called `LoadOptions`. `LoadOptions` is called twice—once during `Game1`'s `Initialize` to set sensible defaults, and again when the main player is set for the game. `LoadOptions` deals with two scenarios: if no player is signed in, it looks in the title location for any previously set options; if there is a player signed in, it looks for a valid storage container and loads options from there. If there's nothing to load, it sets some sensible defaults. `LoadOptions` is called twice: once during `Initialize`, resulting in a load from the title container or from sensible defaults, and again when a player presses **Start** on the start screen.

From Game1.cs:

```

public void LoadOptions()
{
    // If we know what the player One storage device is, we call
    // FinishLoadOptions directly. If not, we need to prompt for it,
    // after which the Guide will call FinishLoadOptions for us.
    if ((Main.Device == null) || (!Main.Device.IsConnected))
        Guide.BeginShowStorageDeviceSelector(Main.Controller,
            FinishLoadOptions, null);
    else
        FinishLoadOptions(null);
}
public void FinishLoadOptions(IAsyncResult ar)
{
    // If ar is null, assume we have a device already
    if (ar != null)
        Main.Device = Guide.EndShowStorageDeviceSelector(ar);
}

```

```

// In case the user didn't supply a valid storage device, check
// the title location
string path = Path.Combine(StorageContainer.TitleLocation,
    "options.xml");

// If they did, open a container
StorageContainer container = null;
if (Main.Device != null)
{
    container = Main.Device.OpenContainer("TopdownShooter");
    path = Path.Combine(container.Path, "options.xml");
}

if (File.Exists(path))
{
    XmlSerializer serializer = new XmlSerializer(typeof(OptionsState));
    FileStream file = File.OpenRead(path);
    options = (OptionsState)serializer.Deserialize(file);
    file.Close();
}
else // If there's no options to find, set sensible defaults
{
    options = new OptionsState();
    options.FXLevel = 0.7f;
    options.MusicLevel = 0.6f;
    options.PlayerOne = InputMode.Normal;
    options.PlayerTwo = InputMode.Normal;
}

// Dispose the container if we opened one:
if (container != null)
    container.Dispose();

// Set the audio manager with the options we just loaded
audio.SetOptions(options.FXLevel, options.MusicLevel);
}

```

This is our first foray into the [Microsoft.Xna.Framework.Storage](#) namespace. Because we need to call [Guide.BeginShowStorageDeviceSelector](#) and that's an asynchronous function, the function is broken into pieces: `LoadOptions` and `FinishLoadOptions`. [BeginShowStorageDeviceSelector](#) will call this function for us when it completes, if we don't end up calling it directly. `FinishLoadOptions` builds a path based on whether we have a `StorageDevice` defined for us (meaning the player chose a device instead of cancelling the dialog), and then loads a serialized version of `OptionsState` from a file named `options.xml`.

In some cases, there won't be options to load, so this is where we encode our default settings and return those. Regardless of where the options come from, we immediately apply them.

When calling a [Guide](#) function like [BeginShowStorageDeviceSelector](#), it's important to consider what your game will do if the user cancels the dialog instead of choosing what you expect the user to choose. Presenting the same dialog again will probably result in another cancellation, so it's good to either have a backup plan (in this case, we look in the title container, or load defaults) or be prepared to quit whatever process required information from the user. We also double-check that the last device specified is still there when we try to access it, and prompt to replace it if it's gone. If they're using a memory unit, this has the beneficial side effect of reminding them to re-insert it.

After a player uses the `OptionsScreen` to change the options, it calls `SetOptions`, which acts as a mirror image to `LoadOptions`:

From Game1.cs:

```

public void SetOptions(OptionsState state)
{
    this.options = state;

    // Reassign gamer preferences
    Main.Options = state.PlayerOne;
    Guest.Options = state.PlayerTwo;

    // Change audio levels

```

```

audio.SetOptions(state.FXLevel, state.MusicLevel);

// If we know what the player One storage device is, we call
// FinishSetOptions directly. If not, we need to prompt for it,
// after which it will call FinishSetOptions for us.
if ((Main.Device == null) || (!Main.Device.IsConnected))
    Guide.BeginShowStorageDeviceSelector(Main.Controller,
        FinishSetOptions, null);
else
    FinishSetOptions(null);
}
private void FinishSetOptions(IAsyncResult ar)
{
    // If ar is null, assume we have a device already
    if (ar != null)
        Main.Device = Guide.EndShowStorageDeviceSelector(ar);

    // In case the user prompted did not supply a valid storage device, save
    // options to title storage.
    string path = Path.Combine(StorageContainer.TitleLocation, "options.xml");
    StorageContainer container = null;
    // If they did supply a valid storage device, save options in a container
    if (Main.Device != null)
    {
        container = Main.Device.OpenContainer("TopdownShooter");
        path = Path.Combine(container.Path, "options.xml");
    }

    XmlSerializer serializer = new XmlSerializer(typeof(OptionsState));

    FileStream file = File.Open(path, FileMode.Create);
    serializer.Serialize(file, this.options);
    file.Close();
    if (container != null)
        container.Dispose();
}

```

Networking

Even though this version of our sample is a single-player game, there are a few useful things you can do with networking. For our sample, we use LIVE to set **Presence Information**, which is one of a few pre-defined strings that show up as the player's online status—for example, **At Menu**, **Local CoOp**, and so on. To accommodate setting presence strings, we made a few additions to the `Player` class:

From Player.cs:

```

GamerPresenceMode previousMode;
public void BeginPause()
{
    if (SignedInGamer != null)
    {
        previousMode = this.SignedInGamer.Presence.PresenceMode;
        this.SignedInGamer.Presence.PresenceMode = GamerPresenceMode.Paused;
    }
}
public void EndPause()
{
    if (SignedInGamer != null)
        this.SignedInGamer.Presence.PresenceMode = previousMode;
}
public GamerPresenceMode SetPresence(GamerPresenceMode mode)
{
    if (SignedInGamer != null)
    {
        GamerPresenceMode retval = this.SignedInGamer.Presence.PresenceMode;
        this.SignedInGamer.Presence.PresenceMode = mode;
        return retval;
    }
}

```

```

        return GamerPresenceMode.None;
    }
    public int SetPresenceValue(int value)
    {
        if (SignedInGamer != null)
        {
            int retval = this.SignedInGamer.Presence.PresenceValue;
            this.SignedInGamer.Presence.PresenceValue = value;
            return retval;
        }
        return 0;
    }
}

```

BeginPause and EndPause are both called by Game1 to swap the PresenceMode to "Paused" and back. SetPresence is called by Game1 during Update based on the PresenceMode property of the topmost game screen:

From Game1.cs:

```

// Which type of screen is on top?
GamerPresenceMode mode =
    this.screenManager.GetScreens()[0].PresenceMode;
Main.SetPresence(mode);
Guest.SetPresence(mode);

```

PresenceMode is a new property we added to GameScreen for this project. Because the PresenceMode largely depends on what screen the player is currently using, it made sense to let the screens dictate the mode.

From GameScreen.cs:

```

public GamerPresenceMode PresenceMode
{
    get { return presenceMode; }
    protected set { presenceMode = value; }
}

GamerPresenceMode presenceMode = GamerPresenceMode.None;

```

The GameplayScreen uses [GamerPresenceMode.Score](#), which requires a presence value to indicate the score. That score is set separately by the Avatar class by using its Update method. The Avatar class has a Player property that gives it access to the SetPresenceValue method:

From Avatar.cs:

```

// Set presence info for Player
Player.SetPresenceValue(score);

```

This means that while GameplayScreen is active, users on Xbox LIVE who look at the player's online status will see their current score!

The Start Screen

Three new main screens have been added to this example in order to provide more options and create a normal Xbox experience. The first screen is the start screen. The start screen is the title screen that most games present after the developer and publisher logos. Players are asked to press the **Start** button, and when they do the screen transitions to the main menu. Thus, the attractive title screen serves the purpose of identifying the controller being used by the main player.

The `StartScreen` class is based on the `BackgroundScreen` class, so it will display the starfield common to the rest of the game. On top of the starfield, the `StartScreen` has a fairly simple `Draw` routine that draws the title of the game with a flashing **Press Start** message beneath it. The `StartScreen` checks every `Update` to see if anyone has pressed start (using the `InputManager`'s `CheckPlayerOneStart` method). If one of the controllers does press **Start**, it sets an exiting flag and calls `TrySignIn` on `Game1`:

From `Game1.cs`:

```
public void TrySignIn(ScreenFinished handler)
{
    // Prompt for sign in if nobody is signed in
    if (SignedInGamer.SignedInGamers.Count == 0)
    {
        SignInScreen screen = new SignInScreen(1, true);
        screen.ScreenFinished += handler;
        screenManager.AddScreen(screen);
    }
    else
        handler();
}
```

`TrySignIn` creates a popup screen, `SignInScreen`, that calls [Guide.ShowSignIn](#) and remains up as long as the guide is present.

The SignIn Screen

The sign-in screen is a brief screen that calls [Guide.ShowSignIn](#) to prompt a user to sign in. This screen will remain on top as long as the guide is showing, then invoke a callback function (if one was supplied) and exit. Most of the logic in `SignInScreen` happens in `Update`:

From `NetworkManager.cs`:

```
bool GuideShown = false;
public override void Update(GameTime gameTime, bool otherScreenHasFocus,
    bool coveredByOtherScreen)
{
    // If we haven't activated the guide yet,
    // and it's not up for another purpose, activate it now
    if ((!GuideShown) && (!Guide.IsVisible))
    {
        Guide.ShowSignIn(paneCount, onlineOnly);
        GuideShown = true;
    }
}
```

```

else if ((GuideShown) && (Guide.IsVisible))
{
    // If the guide is up, do nothing
}
// Screen must have been shown and closed
else if (!Guide.IsVisible)
{
    // Activate our callback function and exit
    if (ScreenFinished != null)
        ScreenFinished();
    ExitScreen();
}
base.Update(gameTime, otherScreenHasFocus, coveredByOtherScreen);
}

```

The Menu Screen

After presenting the start screen and prompting for sign-in, the game presents the main menu screen, to which the user will return until he or she quits the game. The `MenuScreen` is based on the `BackgroundScreen` class, and uses the same menu component featured in the first sample. In this case the `MenuScreen` provides two strings for each menu item, and the `MenuComponent` is smart enough to display the second string for the item that is currently selected. As you can see from the code where the `MenuComponent` is initialized, the main menu provides four options: **Local Game**, **Options**, **Help**, and **Quit**:

From `MenuScreen.cs`:

```

menu = new MenuComponent(this.ScreenManager.Game,
    this.ScreenManager.Font);

//Initialize Main Menu
menu.Initialize();

menu.AddText("  Local Game",
    " - Up to two players on this console");
menu.AddText("    Options",
    " - Change volume levels or controller configuration");
menu.AddText("      Help",
    " - How to play");
menu.AddText("    Quit",
    " - Return to Arcade");
menu.uiBounds = menu.GetExtents();
menu.uiBounds.Offset(uiBounds.X, titleBounds.Bottom + 60);
menu.SelectedColor = Color.LightBlue;
menu.MenuOptionSelected += new MenuEventHandler(menu_MenuOptionSelected);
menu.MenuCanceled += new MenuEventHandler(menu_MenuCancelled);

```

When the main player selects a menu item, the `MenuScreen` takes action. This occurs in the event handler for the `MenuComponent`:

From `MenuScreen.cs`:

```
void menu_MenuOptionSelected(int selection)
{
    switch (selection)
    {
        case 0: // Local Game
            ExitScreen();
            ((Game1)this.ScreenManager.Game).BeginSinglePlayer();
            break;
        case 1: // Options
            ((Game1)this.ScreenManager.Game).DisplayOptions();
            break;
        case 2: // Help
            ScreenManager.AddScreen(new HelpScreen());
            break;
        case 3: // Quit
            this.ScreenManager.Game.Exit();
            break;
        default:
            break;
    }
}
```

The `MenuScreen` remains resident in memory as other screens are spawned on top of it. As they call `ExitScreen`, `MenuScreen` becomes the topmost screen and takes over input processing.

The Options Screen

With the addition of sound and controller options, we need to create a way for users to change these options. So we've created a very simple screen called `OptionsScreen`. The options screen is available from the main menu, and from the popup menu provided by `GamePlayScreen` during a game. The screen is exactly the same in each case.

The options screen divides the display in half. In the top half, a drawing of the Xbox controller is shown, with a legend indicating either the Normal or Southpaw button arrangements. Which legend is displayed depends on the controller layout of the main player. As the menu selection changes between the `Main` and `Guest` player's controller configuration, the legend changes to match. If either configuration is changed, the legend changes to match as well. The legends themselves are just static graphics that overlay the controller graphic.

In your own game, it is a very good idea to display a graphic with a picture of the controller (or more than one) accompanied by a legend showing which buttons and controls are used, and for what purpose. If your game uses triggers and shoulder buttons, you may even want to show two graphics, so the second can highlight those controls. Stock images of the controller are available on the [XNA Creator's Club](#) Web site. As mentioned previously, this game also provides two controller configurations, to allow us to respect the `MoveWithRightThumbstick` preference that can be found on the [SignedInGamer's](#)

[GameDefaults](#) property.

Below the controller options are two more options for music and sound volume levels. These options use the `SliderComponent` class, a small [DrawableGameComponent](#) that displays a series of lightened and darkened bars indicating a numeric value. The `SliderArea` property is a rectangle indicating the drawable area for the component. `SliderUnits` sets the total number of bars to display, and `SliderSetting` is the number of those that are lighted. `SetColor` and `UnsetColor` determine the lighted and unlighted color, respectively.

From OptionsScreen.cs:

```
musicSlider = new SliderComponent(this.ScreenManager.Game,
    this.ScreenManager.SpriteBatch);
musicSlider.Initialize();
tempExtent = menu.GetExtent(3);
musicSlider.SliderArea = new Rectangle(menu.uiBounds.Right + 20,
    tempExtent.Top + 4, 120, tempExtent.Height - 10);
musicSlider.SliderUnits = 10;
musicSlider.SliderSetting =
    (int)(state.MusicLevel*musicSlider.SliderUnits);
musicSlider.SetColor = Color.Cyan;
musicSlider.UnsetColor = Color.DodgerBlue;
```

For this screen, the `MenuComponent` does not handle all its own input. Instead, we use the `HandleInput` method on the screen itself to process input based on the current selection. During `HandleInput`, we check the current selection, and call a specific handler method for each menu item to process input as it sees fit:

From OptionsScreen.cs:

```
public override void HandleInput(InputState input)
{
    // If they press Back or B, exit
    if (input.IsNewButtonPress(Buttons.Back) ||
        input.IsNewButtonPress(Buttons.B))
        ExitScreen();

    musicSlider.UnsetColor = menu.UnselectedColor;
    volumeSlider.UnsetColor = menu.UnselectedColor;
    switch (menu.Selection)
    {
        case 0:
            HandlePlayerOne(input, Game.Main.Controller);
            break;
        case 1:
            HandlePlayerTwo(input, Game.Main.Controller);
            break;
        case 2:
            HandleFXAudio(input, Game.Main.Controller);
            volumeSlider.UnsetColor = menu.SelectedColor;
            break;
        case 3:
            HandleMusic(input, Game.Main.Controller);
            musicSlider.UnsetColor = menu.SelectedColor;
            break;
        default:
            break;
    }

    // Let the menu handle input regarding selection change
    // and the A/B/Back buttons:
    menu.HandleInput(input);

    base.HandleInput(input);
}
```

The `MenuComponent`'s `Update` method still handles changes to the selection, and will raise the `MenuOptionSelected` event if the player presses the **A** button. If that happens, `OptionsScreen` only responds if the current selection is **Save and Exit**:

From `OptionsScreen.cs`:

```
void menu_MenuOptionSelected(int selection)
{
    if (menu.Selection == 4) // Save and Exit
    {
        ExitScreen();
        Game.SetOptions(state);
    }
}
```

This is also where we tell `Game1` what the new options are, as we exit.

Changes to `GamePlayScreen`

You may remember that our prototype `GamePlayScreen` had a popup menu allowing people to exit, restart, and so on. Because we now have a main menu, we want users who exit the game to go back to the main menu, not exit the game. We also want to give them access to the `HelpScreen` and the `OptionsScreen` from within the game. That means modifying `GamePlayMenu` with some new menu options in the `Initialize` function:

From `GamePlayScreen.cs`:

```
public override void Initialize()
{
    menu = new MenuComponent(this.ScreenManager.Game, this.ScreenManager.Font,
        this.ScreenManager.SpriteBatch);
    menu.AddText("Resume");
    menu.AddText("Help");
    menu.AddText("Options");
    menu.AddText("Restart");
    menu.AddText("Quit to Main Menu");
    menu.MenuOptionSelected += new MenuEventHandler(menu_MenuOptionSelected);
    menu.MenuCanceled += new MenuEventHandler(menu_MenuCanceled);
    menu.Initialize();
    Viewport view = this.ScreenManager.GraphicsDevice.Viewport;
    menu.CenterMenu(view);

    TransitionPosition = 0.5f;
    base.Initialize();
}
```

Because we have new menu options, the callback function that responds to the menu has to be updated, too:

From `GamePlayScreen.cs`:

```
void menu_MenuOptionSelected(int selection)
{
    switch (selection)
    {
        case 0: // Resume
            break;
        case 1: // Help
            ScreenManager.AddScreen(new HelpScreen());
            break;
        case 2: // Options
            game.DisplayOptions();
            break;
        case 3: // Restart
            game.Restart();
            break;
    }
}
```

```

        case 4: // Quit
            QuitToMenu();
            break;
        default:
            break;
    }
}

```

Adding new screens for Game1

Now that we have the new screens, we have to integrate them into `Game1`. When `Game1` has finished initialization, it loads the `StartScreen` before exiting `Initialize`:

From `Game1.cs`:

```

// Bring up the Start screen
screenManager.AddScreen(new StartScreen(this));

```

`StartScreen` loads `MenuScreen` itself before it exits, but `StartScreen` will also call `Game1.InitializeMain` to setup the `Main` player with the information that we can gather from his or her profile:

From `Game1.cs`:

```

public void InitializeMain(PlayerIndex index)
{
    if (!Main.IsPlaying)
    {
        SignedInGamer gamer = NetworkManager.FindGamer(index);
        if (gamer == null) // No signed in gamer on this controller
            Main.InitLocal(index, "Player One", InputMode.Normal);
        else
        {
            Main.InitFromGamer(gamer);
            LoadOptions();
        }
    }
}

```

If the network manager can find a gamer associated with that controller, we initialize `Main` with the gamer's information, and load options from the player's container.

After the main menu is active, it will load screens or exit with no interaction with `Game1` until it tries to start a game. To start a game, it calls `BeginSinglePlayer`:

From `Game1.cs`:

```

public void BeginSinglePlayer()
{
    Reset();

    // Get our players and ships setup properly
    ships[0].Activate(Main);
    ships[1].Player = Guest;
    bStateReady = true;

    host.StartGame();
    playScreen = new GameplayScreen(this);
    screenManager.AddScreen(playScreen);
}

```

At this point, `Game1` leaps into action. It assigns players to ships, it starts the `GamePlayHost`, and it launches the `GamePlayScreen` itself.

Integrating the new components into `Game1`

Once the game is underway, some of the gameplay events are modified to play sounds and vibrations. For example, when the ship fires, there's a sound and a controller vibration associated with it:

From `Game1.cs`:

```
public void ShipFire(byte player, float totalGameSeconds)
{
    ships[player].bullets.Add(new Vector3(ships[player].position,
        totalGameSeconds));
    audio.PlayShot();

    input.PlayShot(player);
}
```

To get this functionality, of course, we have to add these components to the `Game1` constructor:

From `Game1.cs`:

```
// This gives us access to the guide
Components.Add(new GamerServicesComponent(this));

// This component handles audio playback
audio = new AudioManager(this);
Components.Add(audio);

// This component keeps track of controllers for us
input = new InputManager(this);
Components.Add(input);
```

Conclusion

Now that we've added support for Xbox gamers, multiple controller types, sound and input options, we've taken our prototype game to a more professional level using the XNA Framework. This project follows many of the best practices for Xbox LIVE Indie Games, and will hopefully guide you to making polished and successful Indie Games of your own using the XNA Framework!

Figure 1. The Complete FuelCell Game

The purpose of this multipart topic is to educate you about various strategies and challenges encountered during the development of a simple 3D game. The FuelCell diary focuses on developing a basic 3D game with a simple goal: collecting objects scattered randomly around a playing field, which is also populated with randomly-placed barriers. The components of FuelCell are deliberately limited to provide a clear picture of the structure and scope of the game.

Game development is hard – especially 3D game development. XNA Game Studio was developed specifically to make game development easier and, hopefully, more enjoyable. Unlike the solid content found in the [Programming Guide](#) and [Getting Started with XNA Game Studio](#) sections, the purpose of this diary is to provide a continuous discussion of the work required for developing a simple 3D game using XNA Game Studio. In addition to articles focused on implementing a specific technique, this diary also contains material on initial game design and how game design drives future development of that game. Also, since game development is not all candy and roses, the diary also focuses on problems encountered during development and how they were overcome.

FuelCell is designed around a central concept: a basic gameplay mechanism that is easily extensible. The initial version, discussed in the following topics, draws a random playfield of barriers and collectable objects. The player, controlling a vehicle that can be driven around the playing field, searches for a collection of fuel cells. Due to the modularity of the game design, future versions could easily add additional effects and game features.

The primary components of FuelCell (camera, avatar control, and collision detection) use existing topics found in the [Programming Guide](#). This diary ties together these disparate concepts into a complete (albeit, simple) 3D game.

Each step in the series contains a list of important topics that are covered in the body of the topic and a link to the completed sample code of that step.

The Purpose Behind Game Design

Before every good game, there was game design. Notice that part about "good games"? A common pitfall for game developers is that they might have great ideas in mind, but the translation to the screen turns out to be impossible. It's hard not to lose heart when the developer must focus on developing basic game and code structure before displaying the defense of a planet against hordes of 3D alien enemies. Game design can seem boring and needless when compared to getting the developer's vision onto the monitor.

Unfortunately, a poor game design can lead to the situation where a person sits down with the latest demo, plays it for ten minutes, and gets lost or frustrated.

Like computer games, books are another example of a product that requires a careful design. Every good book has a "hook" line: an opening sentence that immediately piques the reader's curiosity or interest. If the reader finishes the first page (or even the first paragraph) and does not have at least one story-related question rattling around in the brain, that reader probably will not finish the book.

Game design is a technique that creates the "hook" for the player. Your purpose is to capture the gamer's attention in the first couple of minutes. Otherwise, the player may walk away. A good set of game features enrolls your audience into the game's story. It convinces a player to finish the game. However, a good opening is not enough. You must have equally good content that continues to engage or challenge the gamer.

With that in mind, in addition to a good opening, games typically benefit from the following features:

- A clear and achievable goal. But what about the cries of outrage from the 80's arcade crowd: "And what was the achievable goal of <insert favorite 80's arcade game here>?! There was no goal – you died no matter how good you were!" Okay, they may have a point there, but times have changed. Today's games no longer require a constant flow of quarters to survive; they require a consistent paycheck (or a consenting adult with a consistent paycheck).
- Replayability. This can range from a randomly-generated dungeon level or treasure pile to an ending that depends on the actions of the player. It can be argued that replayability is not a requirement of a good game, but it helps to lengthen the span of interest in a game, and it provides more entertainment for the player without the need for extra content or expansion packs.
- One or more obstacles to overcome. No one wants a game where the player just wanders over to the end level boss, it falls dead at your feet, and the end credits roll. A little challenge (or a lot) is necessary to keep the player engaged. This can be, and usually is, the main content of a game. Common challenges include collecting special items, defeating enemies to reach a specific place in the game, or solving a complex puzzle using simple in-game items collected (or taken by force) earlier.

If a game provides at least these features, it is probably a game worth playing at least once. This is the part where game design comes into play. When you design your game, keep these features in mind. Providing content for these features is difficult, but worth the effort when it all comes together.

FuelCell Features

To illustrate this point, the game design for FuelCell focused on fulfilling these three criteria:

Game Feature	FuelCell Feature

Client	Collect 12 fuel cells (green canisters of goo) before time runs out. Fuel cells are collected using a player-controlled model (the fuel carrier). The game is won when the player collects all fuel cells and time remains. The game is lost if less than 12 fuel cells are found and time runs out.
Goal	
Requirements	The playing field is a basic, level grid with fuel cells scattered at random. In addition, a large amount of barriers are also scattered about the playing field. These barriers are opaque and (eventually) cannot be driven through. The replayability comes from the random placement of the fuel cells and barriers for each new game.
Challenges	The fuel carrier always starts in the middle of the field, but the fuel cells and barriers are scattered randomly. There are enough barriers to prevent the player from initially seeing all available fuel cells. The barriers have two purposes: slowing the player down and obscuring some of the fuel cells at all times. In some cases, a fair bit of hunting is required by the player to retrieve all fuel cells. In later versions of the game, existing factors could easily be tweaked to increase the difficulty and introduce new sub-goals (such as a power-up allowing a clearer view or a faster vehicle).

With the FuelCell feature set explained, let's move on to the actual coding of the game. The next [step](#) focuses on a critical part of any 3D game – the camera.

Overview

One of the largest hurdles a game developer faces when moving from 2D to 3D is that third 'D': depth. In the 2D world, game objects (called sprites) have two dimensions and are positioned using literal screen coordinates. There is a concept of depth, but this is used only to determine if a sprite is partially or fully obscured by another.

In a 3D game, what you see on your screen is a projection of a 3D environment onto a 2D surface (that is, your screen). This translation of 3D space into 2D space is accomplished using transformation matrices. Specifically, we refer to these three matrices as world, view, and projection matrices. Transformation is just a fancy word for changing the value of a coordinate by multiplication. Using these matrices, the XNA Framework transforms the coordinates of a 3D model to a set of new coordinate values (through rotation, scaling, or translation) used by the projection matrix. In a separate but related step, a view matrix simulates a viewpoint (often called the camera) in the same 3D space as the model; it looks in a certain direction. With these two matrices, a third matrix is brought into the "picture" to perform a final transformation into 2D screen coordinates. This creates a realistic 2D picture of the 3D scene on your computer screen.

Earlier, we mentioned a camera. Even though this isn't a real camera, it fulfills the same role in the 3D game. This camera observes the 3D world and renders whatever it sees into a 2D representation. This representation appears on the computer screen. In a game, the camera class usually is implemented as a stand-alone class. It is one of two varieties: a first-person camera (used in this game and first-person shooters) and a third person camera (often used in RPGs or platform games). First-person cameras are great for games that focus on a single player or are trying to immerse the player in the game world. Third-person cameras are better suited to viewing a large playing field or controlling numerous entities in the game. For this step, you will implement a first-person camera using code from [How To: Make a First-Person Camera](#).

We use a first-person camera because the player controls a small vehicle that can move around and collect fuel cells. The difficulty of the game is finding these items before time runs out. It's difficult because the playing field has opaque barriers randomly scattered across it. Since we use a first-person camera, the player must drive around to view previously-hidden areas.

In addition to the camera code, you will also use code from [How To: Render a Model](#) to display the 3D playing field model, which is a simple two-tone grid floating in space.

Objects in the Game

3D game development is all about position and the relation to other objects in the local coordinate system (that is, the game world). In addition to position, a 3D object usually has an associated model. Because this is a 3D game, the model has three dimensions. This means it can be viewed from all angles and has volume. In addition to these two properties, the 3D object should have a bounding sphere. The bounding sphere is a theoretical sphere that encapsulates the model volume. It is used for detecting collisions in the game world with other 3D objects. You can ignore this for now, but it becomes critical later in the development process.

A class is the obvious solution for storing and tracking all these variables. However, before we can add this class, you need to first create a new project for the FuelCell game.

- Open XNA Game Studio and create a Windows Game 3.1 project called FuelCell.

- In this project, create a new class called `GameObject`.

The `GameObject` class will contain all those properties mentioned earlier and a constructor that sets the various properties to known values. The file containing this new class only has a few references by default (located at the top). To grant easy access to the XNA Framework assemblies, you'll need to add some XNA-specific ones. At the top of the file, add the following references:

C#

```
using Microsoft.Xna.Framework;
using Microsoft.Xna.Framework.Content;
using Microsoft.Xna.Framework.Graphics;
using Microsoft.Xna.Framework.Input;
```

These new references make it possible to use the short form of reference for XNA Framework-specific classes. For instance, instead of declaring a variable of type `Vector2` by specifying `Microsoft.Xna.Framework.Vector2`, we can use `Vector2` instead. That will save a lot of typing during the development of `FuelCell`!

You're ready to modify the default class declaration to better fit your needs. Replace the existing `GameObject` class declaration with the following:

C#

```
class GameObject
{
    public Model Model { get; set; }
    public Vector3 Position { get; set; }
    public bool IsActive { get; set; }
    public BoundingBox BoundingBox { get; set; }

    public GameObject()
    {
        Model = null;
        Position = Vector3.Zero;
        IsActive = false;
        BoundingBox = new BoundingBox();
    }
}
```

This new version now tracks the position, model, and bounding sphere of an object in the game using auto-implemented properties. The constructor is simple, and it initializes each property to a reasonable value – either **null** or `Vector3.Zero`.

The Camera

The `GameObject.cs` file will also contain the camera class declaration, which is taken from the [How To: Make a First-Person Camera](#) topic. As mentioned earlier, the main purpose behind this developer diary is to demonstrate how you (or any developer) can use various How To articles as stepping stones when developing an XNA Framework game. For this first usage, this concept is clearly illustrated by not changing any of the variable names or classes, whenever possible. This may cause a bit of confusion or head-scratching when you come across variable names like `_avatarHeadOffset` and `avatarYaw`, but it serves to tie the source How To more closely to the actual game code. This creates the ability to easily determine where the source code of a How To ends up in a typical game project by searching for the variable name used in the How To.

For example, in this step, some of the property names match the names used in the original sample code: `_avatarHeadOffset` is the camera's distance above the playing field and `_targetOffset` is the offset from the target. In this case, it is a fixed distance in front of the fuel carrier vehicle. These values are used when calculating the camera position from the current position of the fuel carrier vehicle (for example, `position`) in the world coordinate system.

The camera class is similar in structure to the `GraphicObject` class. It has a set of properties and a method. In this case, it is `Update`. For this game, the camera acts like a rigid chase camera. It follows behind, and slightly above, the actual vehicle and points in the same direction as the vehicle at all times.

All right, enough talk – let's start developing!

Add the following code after the existing `GameObject` class declaration:

C#

```
class Camera
```

```

{
    public Vector3 AvatarHeadOffset { get; set; }
    public Vector3 TargetOffset { get; set; }
    public Matrix ViewMatrix { get; set; }
    public Matrix ProjectionMatrix { get; set; }

    public Camera()
    {
        AvatarHeadOffset = new Vector3(0, 7, -15);
        TargetOffset = new Vector3(0, 5, 0);
        ViewMatrix = Matrix.Identity;
        ProjectionMatrix = Matrix.Identity;
    }

    public void Update(float avatarYaw, Vector3 position, float aspectRatio)
    {
        Matrix rotationMatrix = Matrix.CreateRotationY(avatarYaw);

        Vector3 transformedheadOffset =
            Vector3.Transform(AvatarHeadOffset, rotationMatrix);
        Vector3 transformedReference =
            Vector3.Transform(TargetOffset, rotationMatrix);

        Vector3 cameraPosition = position + transformedheadOffset;
        Vector3 cameraTarget = position + transformedReference;

        //Calculate the camera's view and projection
        //matrices based on current values.
        ViewMatrix =
            Matrix.CreateLookAt(cameraPosition, cameraTarget, Vector3.Up);
        ProjectionMatrix =
            Matrix.CreatePerspectiveFieldOfView(
                MathHelper.ToRadians(GameConstants.ViewAngle), aspectRatio,
                GameConstants.NearClip, GameConstants.FarClip);
    }
}

```

This is the camera class declaration. The major difference between this declaration and its appearance in the original How To is that the camera's functionality has been internalized into a class. This means that previously global variables that tracked camera position, the transformation matrices, and other properties are now stored within the class. These properties can be divided into two parts: offset variables and transform matrices. The offset variables (`AvatarHeadOffset` and `TargetOffset`) force the camera to a specific position behind and above the vehicle's current position. Hence, the name chase camera.

Researching Transformation Matrices

The transformation matrices are used to rotate, move, or scale objects in a world coordinate system and then (along with the view matrix) to a perspective 2D coordinate system: your screen. The theory and application of this concept involves a truckload of math. However, you can read more about these concepts in other areas of the XNA Game Studio documentation:

- [Math Overview](#)
- Step 4 (of [Tutorial 1: Displaying a 3D Model on the Screen](#)) discusses the usage of all three matrices.
- [Viewports and Frustums](#)

The `Update` method is where the main math for updating the camera takes place. This function takes the current rotation of the vehicle and creates a transformation matrix, which in turn is used to transform the camera's offset values. These values are then added to the current vehicle position, creating a point, in the world coordinate system, where the camera "sits." The final step generates the view and perspective matrices, used when rendering the 3D game world view onto your 2D monitor screen.

Game Constants

Did you notice that some of the method arguments were from a `GameConstants` class? Let's create this class and then I'll explain its purpose.

- Add a new class to the project, called `GameConstants`.
- Since you will also be using XNA Framework references in this file, add the following references to the beginning of the

file:

C#

```
using Microsoft.Xna.Framework;  
using Microsoft.Xna.Framework.Content;  
using Microsoft.Xna.Framework.Graphics;  
using Microsoft.Xna.Framework.Input;
```

- Now add the following to the `GameConstants` class declaration:

C#

```
//camera constants  
public const float NearClip = 1.0f;  
public const float FarClip = 1000.0f;  
public const float ViewAngle = 45.0f;
```

You'll use this class to gather common game variables into a single location. You can then easily and quickly alter the value of any game constant and have the new value affect the entire game, or at least those areas where the game constant was used. At this point, you have three candidates for game constants: the near and far clipping planes of the camera and the angle of view used by the camera. The camera's clipping planes determine the distance (in world coordinates) when objects approaching the screen or receding from it are no longer drawn.

It's a good idea to give them informative names so another person, looking at the code, easily understands their purpose.

Okay, that wraps up the camera class and constants implementation. Let's move on to the visually appealing stuff: drawing stuff on the screen!

Getting a Grip

Up until now, the new code has focused on setting up a viewpoint in the game world and added some additional infrastructure that is used by the game and various components. Game assets, in the form of models, are a large part of any 3D game. Even though this is a simple game, `FuelCell` includes many different types of game assets: models that represent game objects, textures that clothe the models, and a font to display game information such as the current score and goal status. For this step, let's add a very basic model and get it on the screen so we can begin to understand how our game world will look.

Every project template created by XNA Game Studio has a sub-project called `Content`. This project must contain all your game assets. Although it isn't required, it's a good idea to organize this content project such that similar assets are in the same folder. A common organization uses several folders: `Models`, `Textures`, `Fonts`, and `Audio`. These folders cover the main parts of a game. Let's add a `Models` folder, and a model, to our game.

⚠Caution

This diary assumes you are using the game assets located in the `FuelCell` sample file downloaded earlier. These assets have been sized in relation to each other so that none are too small or too large. You can use other models, but their scale (the size in the world coordinate system) might be radically different from the `FuelCell` models. This can cause a model to be rendered as a massive or miniscule object in the game world. In some cases, the camera (due to its position) might not be able to see the model at all. Therefore, it is recommended that you use the included `FuelCell` models when following these steps. After gaining some experience working with the camera class and rendering a 3D scene, you can experiment by adding your own models.

- Select the **Content** folder icon and select **New Folder** from the context menu.
- Name this new folder `Models`.
- Select the **Models** folder icon and from the context menu, select **Add** and then **Existing Item...**
- Navigate to the folder containing the downloaded game assets and add the `ground.x` model.

You now have a working camera object, and a ground model, in your project. In the next step, you will add code declaring and initializing both these objects and use them to render a nice terrain in the game world. For the remainder of this step, you will be working exclusively in the `Game1.cs` file, which is the main file of an XNA Framework game.

- Open the `Game1.cs` file using Solution Explorer.
- Add the following code, after the existing declaration of the `graphics` member of `Game1`:

C#

```
GameObject ground;  
Camera gameCamera;
```

- In the existing `Initialize` method, initialize both game objects (using their default constructors) by adding the following code:

C#

```
ground = new GameObject();  
gameCamera = new Camera();
```

- Next, add the following code to the existing `LoadContent` method:

C#

```
ground.Model = Content.Load<Model>("Models/ground");
```

You've added code declaring and initializing your camera class and the terrain model. To see all this work on the screen, you must update the existing `Draw` method to render the terrain. This is also a good time to add code that updates, during each frame, the camera's position and orientation. Currently, this update code does nothing because the fuel carrier (the user-controlled avatar vehicle) isn't in the game yet. However, when the vehicle is added in a later step, the camera automatically updates, chasing the vehicle around as the player tries to find hidden fuel cells.

Opening Your "Eye"

Updating the camera occurs in the aptly-named `Update` method. At this time, the information passed to the `Camera.Update` method is faked because there is no vehicle to focus on. Specifically, the position and rotation for the camera are zeroed out. This means the camera is centered slightly above the terrain model and aligned with the z-axis. This is the axis that represents the depth of the game world. Once you add the vehicle, the `Camera.Update` method will be passed the position and rotation of the vehicle, instead of zeros.

This modification is very simple because you already implemented the `Camera.Update` method. Now, you just need to call it at the proper time and pass some valid values.

- Add the following code to the `Update` method of the `Game1.cs` file:

C#

```
float rotation = 0.0f;  
Vector3 position = Vector3.Zero;  
gameCamera.Update(rotation, position,  
    GraphicsDevice.Viewport.AspectRatio);
```

The final step modifies the existing `Draw` method.

- Modify the body of the `Draw` method of the `Game1.cs` file to match the following:

C#

```
graphics.GraphicsDevice.Clear(Color.Black);  
  
DrawTerrain(ground.Model);
```

This code calls the non-existent `DrawTerrain` method. The method uses the approach detailed in [How To: Render a Model](#) to render the terrain. Let's add that method now.

- Add the following method after the `Draw` method:

C#

```
private void DrawTerrain(Model model)  
{
```

```
foreach (ModelMesh mesh in model.Meshes)
{
    foreach (BasicEffect effect in mesh.Effects)
    {
        effect.EnableDefaultLighting();
        effect.PreferPerPixelLighting = true;
        effect.World = Matrix.Identity;

        // Use the matrices provided by the game camera
        effect.View = gameCamera.ViewMatrix;
        effect.Projection = gameCamera.ProjectionMatrix;
    }
    mesh.Draw();
}
}
```

The `DrawTerrain` method uses a rendering technique commonly used by XNA Framework games – iterative draw calls on child meshes of the parent model. In this rather simple case, the ground model only has one mesh. But for more complex models, this approach is required to properly render the model on the screen. The calls to [EnableDefaultLighting](#) and [PreferPerPixelLighting](#) highlight the power of the XNA Framework because you'll get standard 3-source lighting and smoother model lighting for free, creating some great results with little work!

Go ahead and compile and build your project. You should be hovering over a gray and light-blue terrain under a black sky. It doesn't look like much now, but the next [part](#) adds the rest of the 3D models and displays them on the screen.

FuelCell: Casting Call

Discusses the implementation of the remaining game elements, such as barriers, fuel cells, and an avatar model.

The Complete Sample

The code in this tutorial illustrates the technique described in the text. A complete code sample for this tutorial is available for you to download, including full source code and any additional supporting files required by the sample.

[Download FuelCell_3_Sample.zip.](#)

Note

You must download the above sample code in order to access the 3D models used in this tutorial step.

Supporting Cast

It's time to add the remaining models: the fuel cells and the fuel carrier. They represent the various barriers encountered in the game.

The fuel cell model (fuelcell.x) is a simple canister-like object with a single texture (fuelcell.png). Typically, you only need to add the model file and not the texture. The texture file is automatically used when the Content Pipeline processes the model file. The barrier models are similar to the fuel cell model. They each have a specific model and a single texture. Since the game has three barrier types, we will be adding three different models (cube10uR/cylinder10uR/pyramid10uR.x) and a set of textures (BarrierBlue/BarrierPurple/BarrierRed.png). Unlike the fuel cell model, the barrier textures are simple and can be used with any barrier model.

Note

The rather unique model names are the result of keeping the scale relatively uniform among all models. The naming convention begins with the model name and then the radius, measured in the units of the 3D modeling application used. Therefore, pyramid10uR is the name of the pyramid model whose radius is 10 units in length.

- Right-click the **Models** directory icon of the Content project.
- Click **Add** and then **New Item....**
- Navigate to the Models sub-directory of the downloaded source, and add the following files:
 - fuelcell.x and fuelcell.png
 - fuelcarrier.x and carriertextures.png
 - cube10uR.x, cylinder10uR.x, and pyramid10uR.x
 - BarrierBlue.png, BarrierPurple.png, and BarrierRed.png
- From Solution Explorer, select all .png files in the Models sub-directory.
- Right-click and select **Exclude From Project**.

This prevents the textures from being processed twice.

Implementing the FuelCell Class

Model implementation is similar to what you did in the last step. You'll add some member variables to store the models, load them with the `LoadContent` method, initialize them (placement, etc.), and then render them on the playing field.

First, the fuel cell class. After the `GameObject` class, add the following `FuelCell` class.

C#

```
class FuelCell : GameObject
{
    public bool Retrieved { get; set; }

    public FuelCell()
        : base()
    {
        Retrieved = false;
    }
}
```

```

public void LoadContent(ContentManager content, string modelName)
{
    Model = content.Load<Model>(modelName);
    Position = Vector3.Down;
}
}

```

Compared to the `GameObject` base class, it contains a new member (`Retrieved`). This is a flag used by the game to determine if the fuel cell has been retrieved. The constructor uses the base constructor, setting `Retrieved` to **false**. You'll use this flag later to optimize your drawing code. If it has been found, it no longer needs to be drawn. The `LoadContent` loads the specified model and then sets the Y-component of the `Position` member to -1. That value is used as an indicator that the fuel cell has not been initialized.

This next bit of code declares a `Draw` method that takes a view and projection matrix and draws the fuel cell. There are two important aspects of this new code: the first is related to optimization and the second is related to future proofing. In terms of optimization, notice the check on the value of the `Retrieved` member. This is the optimization we discussed previously. If the fuel cell has been retrieved by the player, there is no need to draw the fuel cell. This may seem like a minor thing, but changes like this add up over the course of your game's development.

The second is a bit more complicated, but is required for correctly rendering most 3D models: bone transforms. Nearly every 3D model is comprised of a collection of bones. Basically, a model bone is a matrix representing the position of a mesh relative to other bones in the 3D model. An excellent description of model bones can be found [here](#).

For our purposes, it's sufficient to know that a 3D model has a set of these matrices. To position them properly (and, in more complex cases, to animate them), you'll need to incorporate these transform matrices into the code that draws the fuel cell. You can accomplish this easily by copying the bone transforms of the model being drawn into a temporary set of matrices (using [CopyAbsoluteBoneTransformsTo](#)). Then you apply the proper transform matrix to the world matrix before you draw the current sub-mesh of the model. In the code you will add, this is done in the innermost nested **foreach** loop by multiplying the world matrix by the proper transform matrix.

You're probably wondering why this code is called future proofing. Ironically, the code related to applying bone transforms to the 3D model being rendered is unnecessary for `FuelCell`! One of the design rules used for `FuelCell` was to keep everything as simple as possible. This resulted in the rudimentary (and unmoving) models in the game. Each model has a set of bones, but these bones are always rendered statically and cannot be animated. However, this code is necessary to properly render any minimally complex model or one that has movable parts (like a tank rolling across a terrain map). This code makes it easier to be reused in future games without having to remember all this bone transform business. Now, when you copy the code into another 3D game, it just works. Even if the model is very complex!

Now that you understand the code better, add the following code to the `FuelCell` class.

C#

```

public void Draw(Matrix view, Matrix projection)
{
    Matrix[] transforms = new Matrix[Model.Bones.Count];
    Model.CopyAbsoluteBoneTransformsTo(transforms);
    Matrix translateMatrix = Matrix.CreateTranslation(Position);
    Matrix worldMatrix = translateMatrix;

    if (!Retrieved)
    {
        foreach (ModelMesh mesh in Model.Meshes)
        {
            foreach (BasicEffect effect in mesh.Effects)
            {
                effect.World =
                    worldMatrix * transforms[mesh.ParentBone.Index];
                effect.View = view;
                effect.Projection = projection;

                effect.EnableDefaultLighting();
                effect.PreferPerPixelLighting = true;
            }
            mesh.Draw();
        }
    }
}

```

```
}
```

- You'll need to automatically scale the fuel cell model by selecting the newly-added model from Solution Explorer, and, on the property page of the model asset, setting the **Scale** property to .03. The **Scale** property is found by expanding the **Processor** field.

One of the cool features of XNA Game Studio (specifically, the content pipeline) are [processor parameters](#). You can change common values for a processor by changing the related property of a selected game asset using the **Properties** window. If you didn't use this feature, you would need to use a scaling matrix to shrink the fuel cell model before rendering it on the screen.

Did you notice the [Matrix](#) declarations at the beginning of the [Draw](#) function? You need to transform the world coordinates of our object (in this case, the fuel cell) based on the fuel cell's position in the game. If the translation matrix wasn't used before drawing the fuel cell, it would always be in the center of the playing field.

That completes the implementation of the fuel class. Next stop, the barrier class.

Implementing the Barrier Class

The `Barrier` class implements the geometrical barriers that are randomly scattered across the playing field. They are an important part of the game because they provide a new experience for every game (since they are placed randomly) and they provide a challenge to the player who is trying to find fuel cells (also randomly placed) before time runs out. In a later step, when collision detection is added, these barriers become impassable and must be driven around.

- Automatically scale the barrier models by selecting each barrier model from Solution Explorer and setting the **Scale** property to .3, located on the property page of the model asset. The **Scale** property is found by expanding the **Processor** field.

In `GameObject.cs`, add the following class declaration after the `FuelCell` class declaration:

C#

```
class Barrier : GameObject
{
    public string BarrierType { get; set; }

    public Barrier()
        : base()
    {
        BarrierType = null;
    }

    public void LoadContent(ContentManager content, string modelName)
    {
        Model = content.Load<Model>(modelName);
        BarrierType = modelName;
        Position = Vector3.Down;
    }
}
```

The `Barrier` class has a new member (`BarrierType`) that stores, oddly enough, the barrier type. In the `FuelCell` game, there are three possible barrier types: cubes, cylinders, and pyramids. Similar to the `FuelCell` class, the `LoadContent` method is overridden that loads the specified model, stores the barrier type, and sets the Y-component of the `Position` member to -1 (indicating that the barrier is not placed).

Since barrier objects behave in a similar fashion to fuel cells (that is, they stay in one place and do nothing), we'll use the same drawing code with one change. Add the following `Draw` method to the `Barrier` class:

C#

```
public void Draw(Matrix view, Matrix projection)
{
    Matrix[] transforms = new Matrix[Model.Bones.Count];
    Model.CopyAbsoluteBoneTransformsTo(transforms);
    Matrix translateMatrix = Matrix.CreateTranslation(Position);
    Matrix worldMatrix = translateMatrix;

    foreach (ModelMesh mesh in Model.Meshes)
```

```

    {
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.World =
                worldMatrix * transforms[mesh.ParentBone.Index];
            effect.View = view;
            effect.Projection = projection;

            effect.EnableDefaultLighting();
            effect.PreferPerPixelLighting = true;
        }
        mesh.Draw();
    }
}

```

Unlike fuel cells, barriers can't be retrieved and are always visible. Therefore, there is no need to determine if a barrier should be drawn; it is always drawn. This is reflected in the code.

Implementing the Fuel Carrier

In game development terms, the fuel carrier is the avatar of the player. It is the object that represents the player in the game world and is controlled by the player. The `FuelCarrier` class starts out very simple but, in later steps, you'll add more features like user control and collision detection. For now, it has a few basic methods that load the model and render it on the playing field.

The process for implementing the fuel carrier class is similar to the `FuelCell` and `Barrier` class implementations.

- Automatically scale the fuel carrier model by selecting it from Solution Explorer and setting the **Scale** property to .1, located on the property page of the model asset. The **Scale** property is found by expanding the **Processor** field.
- After the `Barrier` class declaration, add the `FuelCarrier` class declaration:

C#

```

class FuelCarrier : GameObject
{
    public float ForwardDirection { get; set; }
    public int MaxRange { get; set; }

    public FuelCarrier()
        : base()
    {
        ForwardDirection = 0.0f;
        MaxRange = GameConstants.MaxRange;
    }

    public void LoadContent(ContentManager content, string modelName)
    {
        Model = content.Load<Model>(modelName);
    }
}

```

- Implement the `Draw` method by adding the following code to the `FuelCarrier` class declaration:

C#

```

public void Draw(Matrix view, Matrix projection)
{
    Matrix[] transforms = new Matrix[Model.Bones.Count];
    Model.CopyAbsoluteBoneTransformsTo(transforms);
    Matrix worldMatrix = Matrix.Identity;
    Matrix rotationYMatrix = Matrix.CreateRotationY(ForwardDirection);
    Matrix translateMatrix = Matrix.CreateTranslation(Position);
}

```

```

worldMatrix = rotationYMatrix * translateMatrix;

foreach (ModelMesh mesh in Model.Meshes)
{
    foreach (BasicEffect effect in mesh.Effects)
    {
        effect.World =
            worldMatrix * transforms[mesh.ParentBone.Index]; ;
        effect.View = view;
        effect.Projection = projection;

        effect.EnableDefaultLighting();
        effect.PreferPerPixelLighting = true;
    }
    mesh.Draw();
}
}

```

This `Draw` method differs from the fuel cell and barrier `Draw` methods in one important aspect: the calculation of a rotation matrix. In the future, the fuel carrier is controlled by the player. This means that the fuel carrier's orientation is always changing as the player races around collecting fuel cells. You have to account for this in the rendering code so that any changes by the player (such as turning left or right) are reflected in the game world. If fuel carrier orientation is not taken into account, you would have some very weird behavior for your game! At this point, you will add the support for this, but it won't be used until the next step: [FuelCell: What's My Motivation](#).

- Add the fuel carrier constants to the end of the `GameConstants` class, located in `GameConstants.cs`:

C#

```

//ship constants
public const float Velocity = 0.75f;
public const float TurnSpeed = 0.025f;
public const int MaxRange = 98;

```

As usual, the `FuelCarrier` data members are specific to the class. In this case, there is an orientation property, storing the current direction (in radians) that the fuel carrier is facing. This property is also used by the camera class to orientate along the same vector. The `MaxRange` member is used later to prevent the fuel carrier from driving off the playing field. This is something that would completely break the game play illusion.

As mentioned earlier, the methods are similar to the implementation code for the fuel cell and barrier classes. However, in the next part, you will add code that allows the player to drive the fuel carrier around the playing field. In fact, the fuel carrier has the singular honor of being the only moving part in the game!

Setting the Stage

It's time to shift our focus back to the main game class, `Game1.cs`. You're going to add member variables representing the new game objects you added: the fuel carrier, fuel cell, and various barriers. At this stage, we'll display a fuel cell, three barriers (each of a different type), and the fuel carrier on the playing field. Later in the development cycle, you'll add code that randomly generates and places the fuel cells and barriers.

However, before you start modifying this file, rename it `FuelCellGame.cs`. This follows the naming format of the other project files.

- In `FuelCellGame.cs`, after the declaration of the camera and ground variables, add the following code:

C#

```

Random random;
FuelCarrier fuelCarrier;
FuelCell[] fuelCells;
Barrier[] barriers;

```

- After the initialization of the camera and ground variables (located in the `Initialize` method), add the following code:

C#

```
//Initialize and place fuel cell
fuelCells = new FuelCell[1];
fuelCells[0] = new FuelCell();
fuelCells[0].LoadContent(Content, "Models/fuelcell");
fuelCells[0].Position = new Vector3(0, 0, 15);

//Initialize and place barriers
barriers = new Barrier[3];

barriers[0] = new Barrier();
barriers[0].LoadContent(Content, "Models/cube10uR");
barriers[0].Position = new Vector3(0, 0, 30);
barriers[1] = new Barrier();
barriers[1].LoadContent(Content, "Models/cylinder10uR");
barriers[1].Position = new Vector3(15, 0, 30);
barriers[2] = new Barrier();
barriers[2].LoadContent(Content, "Models/pyramid10uR");
barriers[2].Position = new Vector3(-15, 0, 30);

//Initialize and place fuel carrier
fuelCarrier = new FuelCarrier();
fuelCarrier.LoadContent(Content, "Models/fuelcarrier");
```

This code initializes all our new models and places them in front of the camera. The fuel cell is in the front row and the barriers are in a line behind it.

- Modify the existing `Draw` method by adding the following code after the `DrawTerrain` call:

C#

```
fuelCells[0].Draw(gameCamera.ViewMatrix,
    gameCamera.ProjectionMatrix);
foreach (Barrier barrier in barriers)
    barrier.Draw(gameCamera.ViewMatrix,
        gameCamera.ProjectionMatrix);
fuelCarrier.Draw(gameCamera.ViewMatrix,
    gameCamera.ProjectionMatrix);
```

Build and run the project and you will now see, in addition to the playing field, several cool things on the screen. You see some barriers, with a fuel cell slightly behind them, and a funny blue ovoid in the foreground. That is actually the fuel carrier. It's a (very) simple model, but it suits the purpose of the game. The next [step](#) implements user control of the game avatar.

Overview

The goal for this part is the implementation of a control schema for the fuel carrier. With this schema, the player can use either the keyboard (A or D for left/right rotation and W and S for forward/backward movement) or a standard gamepad (using the left thumbstick for rotation and forward/backward movement). In addition, we'll check the `_maxRange` data member against the current position, and only allow movement that keeps the player on the playing field. This prevents the player from driving off the playing field.

GamePad States

In order to control the fuel carrier, you need input from a keyboard or gamepad. There are two approaches to getting input from the player: single-state and two-state. In a single-state approach, input is determined from a single snapshot of the controller, taken during execution of the `Update` method. Any actions that need to be taken by the game are initiated, thus enabling game play to move forward. This approach is demonstrated by [How To: Detect Whether a Controller Button Is Pressed](#).

However, when discrete input is required, the single-state approach doesn't solve the problem. For instance, suppose a game is designed to fire one bullet for every press of a key or button. If you use the single-state approach, multiple bullets are fired per key or button press. This happens because human reflexes are slower than the standard update cycle of the game. Even a very quick player is going to have a key or button pressed for at least a few update cycles (unless the game uses a fixed-step approach). In order to fire a single bullet every time a key or button is pressed, you must look for a current state where a specific key or button is released and a previous state where that same key or button was pressed. This condition is only satisfied at the instant when the key or button transitions from pressed to released.

Hence, the two-state approach: tracking the current state of the controller *and* the previous state of the controller. This allows the game to determine single occurrences of player action, such as a key or button press. With this approach, it doesn't matter how slow (or fast) the player's reflexes are. The input is only valid at that moment when the previous and current input states match the criteria determined by the input code. This approach is demonstrated by [How To: Detect Whether a Controller Button Has Been Pressed This Frame](#) and [How To: Detect Whether a Key Is Pressed](#).

It turns out that if you do any amount of XNA Game Studio game development, you often run into this controller update issue. The two-state approach is the best solution in most situations, and it is easy to implement. That same code also fulfills the needs of a single-state approach. In terms of keyboard and gamepad controls, FuelCell uses a two-state approach, but with a twist. The support for two-state input checking is in the code but FuelCell needs only check for current key and thumbstick states. Therefore, there is no need to check for a discrete event.

This code is an example of "future-proofing." If you were to add the capability to blow up a barrier with a missile, you would already have the necessary code to use the two-state approach.

Implementation begins in the FuelCellGame.cs file. Add the following code after the declaration of the `graphics` data member:

C#

```
KeyboardState lastKeyboardState = new KeyboardState();
```

```
KeyboardState currentKeyboardState = new KeyboardState();
GamePadState lastGamePadState = new GamePadState();
GamePadState currentGamePadState = new GamePadState();
```

Now, in the existing `Update` method, initialize the variables at the beginning of the method:

C#

```
lastKeyboardState = currentKeyboardState;
currentKeyboardState = Keyboard.GetState();
lastGamePadState = currentGamePadState;
currentGamePadState = GamePad.GetState(PlayerIndex.One);
```

You can now use either set of variables to determine exactly when a key or button is pressed or just use `currentGamePadState` if you only need the current position of the thumbstick. Your next step is to use this input to update the position and direction of the fuel carrier.

Updating the Fuel Carrier

Currently, the `FuelCarrier` class doesn't have a method for updating its position and heading. You'll add that method now and modify the main `Update` method to call it.

Staying within the `FuelCellGame.Update` function, replace this code:

C#

```
float rotation = 0.0f;
Vector3 position = Vector3.Zero;
gameCamera.Update(rotation, position,
    GraphicsDevice.Viewport.AspectRatio);
```

with the following:

C#

```
fuelCarrier.Update(currentGamePadState,
    currentKeyboardState, barriers);
float aspectRatio = graphics.GraphicsDevice.Viewport.AspectRatio;
gameCamera.Update(fuelCarrier.ForwardDirection,
    fuelCarrier.Position, aspectRatio);
```

The only difference is a call to the new update method, `FuelCarrier.Update`. This method takes as input the current keyboard and gamepad states and the `barriers` array. The method determines if the ship can move based on the current input and barrier locations. Ignore the `barriers` parameter for now; it is used in a later step. At this point, the function only prevents the vehicle from driving off the playing field. If an attempt is made to go over the playing field edge, the input is ignored.

Replace the code that checks for a Back button press with the following:

C#

```
// Allows the game to exit
if ((currentKeyboardState.IsKeyDown(Keys.Escape)) ||
    (currentGamePadState.Buttons.Back == ButtonState.Pressed))
    this.Exit();
```

The game now checks for both keyboard (ESC key) and gamepad input (Back button) when the player wishes to exit the game.

In the `GameObject.cs` file, locate your `FuelCarrier` class, and add the new update method:

C#

```
public void Update(GamePadState gamepadState,
    KeyboardState keyboardState, Barrier[] barriers)
{
    Vector3 futurePosition = Position;
    float turnAmount = 0;

    if (keyboardState.IsKeyDown(Keys.A))
```

```

    {
        turnAmount = 1;
    }
    else if(keyboardState.IsKeyDown(Keys.D))
    {
        turnAmount = -1;
    }
    else if(gamepadState.ThumbSticks.Left.X != 0)
    {
        turnAmount = -gamepadState.ThumbSticks.Left.X;
    }
    ForwardDirection += turnAmount * GameConstants.TurnSpeed;
    Matrix orientationMatrix = Matrix.CreateRotationY(ForwardDirection);

    Vector3 movement = Vector3.Zero;
    if (keyboardState.IsKeyDown(Keys.W))
    {
        movement.Z = 1;
    }
    else if(keyboardState.IsKeyDown(Keys.S))
    {
        movement.Z = -1;
    }
    else if (gamepadState.ThumbSticks.Left.Y != 0)
    {
        movement.Z = gamepadState.ThumbSticks.Left.Y;
    }

    Vector3 speed = Vector3.Transform(movement, orientationMatrix);
    speed *= GameConstants.Velocity;
    futurePosition = Position + speed;

    if (ValidateMovement(futurePosition, barriers))
    {
        Position = futurePosition;
    }
}

```

This method is important, so let's go through it in detail. First, the future position is set to the current position and the turn amount is set to 0. The amount of vehicle rotation is calculated, based on the current state of the A and D keys or the X-axis of the left thumbstick, and a rotation matrix is created. This matrix is later used to rotate the vehicle the proper amount in world coordinates. The second chunk of code calculates how far the ship moved in either a forward or backward direction, based on the current state of the W and S keys or the Y-axis of the same thumbstick. This distance is then transformed using the rotational matrix created earlier, and this result is multiplied by a constant velocity (`GameConstants.Velocity`). The final result is then added to the current position, resulting in a projected future position. Finally, this result is passed to a private method called `ValidateMovement`. If it is valid, the `_position` member is updated and control returns to the main `Game1.Update` method.

Programming Tip

You might be wondering why you couldn't just test the current position for validity instead of calculating a future position and testing that. The answer is that if you only tested the current position, it's already too late to prevent illegal movement. When the test is made, the vehicle has already had its position updated. Suppose that new position is illegal (past the edge of a boundary case). This causes further tests to fail, resulting in the vehicle "sticking" to the current position. Obviously, this is not optimal behavior for a player-controlled vehicle.

It is better to check the future position and prevent any illegal moves. This check allows the player to attempt something different (like backing up), and not get stuck because the player *currently* is in a legal position.

The remaining piece is the implementation of the `ValidateMovement` method. Add the following method after the `FuelCarrier.Update` method:

C#

```

private bool ValidateMovement(Vector3 futurePosition,
    Barrier[] barriers)
{

```

```
//Don't allow off-terrain driving
if ((Math.Abs(futurePosition.X) > MaxRange) ||
    (Math.Abs(futurePosition.Z) > MaxRange))
    return false;

return true;
}
```

Currently, this method only checks for the edge of the playing field. Any attempt to drive off the playing field is ignored.

After the usual drill of rebuilding the project and running it, drive the fuel carrier freely around the map. Test out the boundary code by driving to the edge of the playing field. You'll notice that you stop moving until you choose a new direction. The control schema implementation was pretty easy but, [coming up](#), the game really starts to come together... which requires a *lot* of coding!

FuelCell: What's My Line?

Demonstrates a simple, random technique for placing barriers and fuel cells on the playing field.

The main points of this topic are:

- Randomly Populating a Playing Field
- Designing Algorithms to Solve a Specific Problem

The Complete Sample

The code in this tutorial illustrates the technique described in the text. A complete code sample for this tutorial is available for you to download, including full source code and any additional supporting files required by the sample.

Overview

The goal of this topic is the implementation of a good algorithm for placing a set number of barriers and fuel cells randomly throughout the playing field. The valid placement area (on a 100 x 100 unit playing field) is 90 x 90. A barrier centered on this limit does not overhang the playing field. In addition to an outer limit, you need an inner limit. This prevents a situation where the fuel carrier (always placed at the origin of the playing field: 0,0,0) is trapped by barriers. This still wouldn't be a problem at this stage because the game implements no collision detection, but in the finished product it would make for a frustrating game experience. Finally, another limit is used when placing a barrier. This is a minimum distance a new barrier must be from existing barriers. This prevents a collision with an existing barrier.

After testing with different values, 12 fuel cells and 40 barriers produced a challenging field. They are nicely cluttered with a good probability that many fuel cells are initially obscured by one or more barriers. You are encouraged to experiment with these numbers, but be warned that a higher total makes random placement of the barriers more difficult. The game could begin "thrashing," which means it is endlessly generating new random locations (to resolve a collision) only to find the new locations currently occupied.

A good example of unforeseen development problems was the coordinate system of the playing field. Because the playing field origin is at 0, 0, 0, the X and Z axes have both positive *and* negative values. This "automatically" divides the playing field into four quadrants because the sign can be either positive or negative values for the X and Z coordinates (the Y coordinate is clamped to 0). Therefore, randomly generating two positive numbers between the minimum and maximum distances populates only one quarter of the playing field. This is another bad gaming experience!

The solution used by FuelCell is to randomly assign positive and negative values to the randomly generated X and Z coordinates. This decently scatters the barriers around the playing field. However, due to the random nature of coordinate generation and limits imposed by a minimum and maximum, you'll notice that there is a bit of a "corridor" along the X and Z axes.

Pick Two: High Quality, Fast, and Cheap.

You might know (or at least heard) about the trilemma above. You're given three characteristics, but you can only choose two because of their interdependency. Any two of the characteristics negates the possibility of the third. For example, you can have something made cheaply and quickly, but it will be of poor quality.

Trilemmas can also be applied to software algorithms. A cheap, fast algorithm wastes a lot of resources compared to the result. On the other hand, a high quality algorithm that is fast is not cheap in terms of resources (in this case, development man hours).

The algorithm used by FuelCell is a fast, cheap algorithm. It took very little design time, and code, to implement, and it is as fast as other possible algorithms because the problem set is pretty small. However, the quality is very poor. It performs many unnecessary checks, it uses a brute-force approach when placing a new game object, and the randomness of the playing field is compromised in certain aspects (such as the axes corridors).

Initially, during early development of this game, a different algorithm was developed after observing the performance of the simple one used here. This algorithm was designed to prevent clustering and to generate an even spread of game objects throughout the playing field.

The solution was to treat the playing field as four separate 2D grids (or quadrants). This approach prevented the axes from fluctuating as the algorithm moved around the playing field grid. Each quadrant was populated individually using nested for loops: a loop for each axis. In addition, each quadrant was allocated a fourth of the total fuel cells and barriers. Once the buckets emptied, the algorithm moved onto the next quadrant. As the loops incremented, the algorithm automatically walked through each square in the quadrant (like iterating through a 2D array). As it walked through the possible placement areas, a random number was generated. If the random number matched a simple rule, it called another routine to place an object and zero out a weight counter. If there was no match, the algorithm placed nothing, incremented the weight counter, and moved on to the next grid location. If the weight counter reached a certain level, and pieces still remained for placement, it forced a piece placement. This ensured an even distribution throughout the quadrant.

The secondary function triggered when a piece needed to be placed. A random number (representing a percentile) was generated. Forty percent of the time a fuel cell was placed (if fuel cells remained in the quadrant allocation); otherwise, a barrier was placed (if barriers remained in the quadrant allocation). This matched the frequency of fuel cells to barriers and provided a general distribution. If the object being placed was a barrier, another random number determined the barrier type.

Finally, the algorithm verified that all game objects were placed before exiting the quadrant and that some type of object was placed, when required.

The end result was a consistently populated playing field that hardly ever had clusters or axes corridors. However, when this tutorial was written, the algorithm was overkill and introduced needless complexity to the main purpose: designing a 3D game. Therefore, the fast and cheap algorithm was used, making the code easier to understand.

Initializing the Random Number Generator

Since we are going to *randomly* populate the playing field with game objects, an obvious first step is to set up a random number generator. Let's keep it simple and declare a file-level random variable (in FuelCellGame.cs) that can be accessed by any FuelCellGame method.

After the gamepad state declarations, add the following:

C#

```
Random random;
```

Initialize the random number generator in the FuelCellGame constructor:

C#

```
random = new Random();
```

Modifying the LoadContent Method

In [FuelCell: What's My Motivation](#), we added some temporary code that created the FuelCell models on the playing field. You'll remove that code now, and initialize the arrays properly.

Remove the following from the Initialize method:

C#

```

//Initialize and place fuel cell
fuelCells = new FuelCell[1];
fuelCells[0] = new FuelCell();
fuelCells[0].LoadContent(Content, "Models/fuelcell");
fuelCells[0].Position = new Vector3(0, 0, 15);

//Initialize and place barriers
barriers = new Barrier[3];

barriers[0] = new Barrier();
barriers[0].LoadContent(Content, "Models/cube10uR");
barriers[0].Position = new Vector3(0, 0, 30);
barriers[1] = new Barrier();
barriers[1].LoadContent(Content, "Models/cylinder10uR");
barriers[1].Position = new Vector3(15, 0, 30);
barriers[2] = new Barrier();
barriers[2].LoadContent(Content, "Models/pyramid10uR");
barriers[2].Position = new Vector3(-15, 0, 30);

//Initialize and place fuel carrier
fuelCarrier = new FuelCarrier();
fuelCarrier.LoadContent(Content, "Models/fuelcarrier");

```

Add this code to the `LoadContent` method, after the loading of the ground game asset:

C#

```

//Initialize fuel cells
fuelCells = new FuelCell[GameConstants.NumFuelCells];
for (int index = 0; index < fuelCells.Length; index++)
{
    fuelCells[index] = new FuelCell();
    fuelCells[index].LoadContent(Content, "Models/fuelcell");
}

//Initialize barriers
barriers = new Barrier[GameConstants.NumBarriers];
int randomBarrier = random.Next(3);
string barrierName = null;

for (int index = 0; index < barriers.Length; index++)
{
    switch (randomBarrier)
    {
        case 0:
            barrierName = "Models/cube10uR";
            break;
        case 1:
            barrierName = "Models/cylinder10uR";
            break;
        case 2:
            barrierName = "Models/pyramid10uR";
            break;
    }
    barriers[index] = new Barrier();
    barriers[index].LoadContent(Content, barrierName);
    randomBarrier = random.Next(3);
}
PlaceFuelCellsAndBarriers();

//Initialize fuel carrier
fuelCarrier = new FuelCarrier();
fuelCarrier.LoadContent(Content, "Models/fuelcarrier");

```

Let's examine this code before moving on.

The first block initializes the array of fuel cells, loading each with the model for the fuel cell.

Barrier initialization is next. This code is a bit more complicated because there are three available barrier models. This looks like a job for the random number variable! A random number is generated and the corresponding model is loaded into the current barrier element using a **switch**> statement. The rest of the barrier object is initialized and a new random number is generated before moving to the next array element. After barrier initialization, the fuel cells and barriers are placed on the playing field with a call to `PlaceFuelCellsAndBarriers`. We'll discuss this function in detail later.

The final bit of code initializes and loads the model for the fuel carrier.

Fuel Cell and Barrier Initialization, Part 2

Now it is time to take a closer look at the `PlaceFuelCellsAndBarriers` method and its helper method, `GenerateRandomPosition`. Add the following code to the game (after the `LoadContent` method), and then we'll walk through it.

C#

```
private void PlaceFuelCellsAndBarriers()
{
    int min = GameConstants.MinDistance;
    int max = GameConstants.MaxDistance;
    Vector3 tempCenter;

    //place fuel cells
    foreach (FuelCell cell in fuelCells)
    {
        cell.Position = GenerateRandomPosition(min, max);
        tempCenter = cell.BoundingBox.Center;
        tempCenter.X = cell.Position.X;
        tempCenter.Z = cell.Position.Z;
        cell.BoundingBox = new BoundingBox(tempCenter,
            cell.BoundingBox.Width);
        cell.Retrieved = false;
    }

    //place barriers
    foreach (Barrier barrier in barriers)
    {
        barrier.Position = GenerateRandomPosition(min, max);
        tempCenter = barrier.BoundingBox.Center;
        tempCenter.X = barrier.Position.X;
        tempCenter.Z = barrier.Position.Z;
        barrier.BoundingBox = new BoundingBox(tempCenter,
            barrier.BoundingBox.Width);
    }
}

private Vector3 GenerateRandomPosition(int min, int max)
{
    int xValue, zValue;
    do
    {
        xValue = random.Next(min, max);
        zValue = random.Next(min, max);
        if (random.Next(100) % 2 == 0)
            xValue *= -1;
        if (random.Next(100) % 2 == 0)
            zValue *= -1;
    } while (IsOccupied(xValue, zValue));

    return new Vector3(xValue, 0, zValue);
}
```

It's not complicated, but it is also one of the bigger functions in the game. First, a few variables are declared, making the code more reader-friendly. The next part is a **foreach** loop that places the fuel cells. The algorithm is as follows:

1. Generate random values for the X and Z coordinates, verify that the new random location is not already occupied, and

update the fuel cell position with this new position.

Possible values are limited by the minimum and maximum placement values (defined in GameConstants.cs).

2. Initialize the bounding sphere property to the current fuel cell location.
3. Mark the fuel cell as unretrieved.

You follow the same process when you place the barriers.

The `GenerateRandomPosition` helper method makes up the remaining portion of newly added code. This method generates two random numbers. Another random number is generated and, depending on the result of the modulus operation (50% chance of negation), the X coordinate is negated. The same is done for the Z coordinate. The new position is then checked for existing occupants. If occupied, a new position is generated and the loop continues until a vacant location is found.

Let's add the new helper method, `IsOccupied`, to the project next.

Fuel Cell and Barrier Initialization, Part 3

Add this code after the `PlaceFuelCellsAndBarriers` method:

C#

```
private bool IsOccupied(int xValue, int zValue)
{
    foreach (GameObject currentObj in fuelCells)
    {
        if (((int)(MathHelper.Distance(
            xValue, currentObj.Position.X)) < 15) &&
            ((int)(MathHelper.Distance(
            zValue, currentObj.Position.Z)) < 15))
            return true;
    }

    foreach (GameObject currentObj in barriers)
    {
        if (((int)(MathHelper.Distance(
            xValue, currentObj.Position.X)) < 15) &&
            ((int)(MathHelper.Distance(
            zValue, currentObj.Position.Z)) < 15))
            return true;
    }
    return false;
}
```

This method uses the nifty `Distance` method when checking for collision with an existing game object (fuel cell or barrier). As you can see from the code, if the new object is closer than 15 units from an existing object, it is not placed. This can be modified, but keep in mind that the higher the distance, the more the placement method churns. It's that cheap, but fast effect again.

The final change to `FuelCellGame.cs` occurs in the `Draw` method. The new code draws all our wonderful fuel cells and barriers. Modify the contents of the `Draw` method to match the following:

C#

```
graphics.GraphicsDevice.Clear(Color.Black);

DrawTerrain(ground.Model);

foreach (FuelCell fuelCell in fuelCells)
    fuelCell.Draw(gameCamera.ViewMatrix,
        gameCamera.ProjectionMatrix);
foreach (Barrier barrier in barriers)
    barrier.Draw(gameCamera.ViewMatrix,
        gameCamera.ProjectionMatrix);
fuelCarrier.Draw(gameCamera.ViewMatrix,
    gameCamera.ProjectionMatrix);

base.Draw(gameTime);
```

New Game Constants

Before you can build and admire all your hard work, you need to add some constants to the GameConstants.cs file. Add the following code after any existing constants in the `GameConstants` class:

C#

```
//general
public const int MaxRangeTerrain = 98;
public const int NumBarriers = 40;
public const int NumFuelCells = 12;
public const int MinDistance = 10;
public const int MaxDistance = 90;
```

After a successful rebuild of the project, you now have fuel cells to find and barriers to avoid. Go ahead and take a spin around the new digs before moving on to adding a critical game feature: [collision detection](#).

Out of My Way!

Currently, the game is not very challenging (and impossible to win). The player can drive through barriers and fuel cells without retrieving them. The only boundaries are the edges of the playing field, added in Step 4. It's time to implement the main feature of the game: collision detection.

Collision detection is a technique used in nearly all games, whether they are 2D or 3D. It simulates (to varying degrees) the interaction of real world objects. Without collision detection, objects in the game world could be seamlessly rendered within the space of the objects with which they collide. In most cases, this is unacceptable. The player expects to "collide" with objects in the game world and not merge with them. The desired behavior in FuelCell is to allow the player free motion around the playing field as long as he or she avoids the barriers. However, if the player attempts to drive through any part of a barrier, the player's current motion stops. Players must drive around the barriers, as they would in the real world. The behavior for fuel cells is a bit different. When a player "collides" with a fuel cell, the fuel cell object is marked as retrieved and no longer is drawn in the game world. This simulates the retrieval of the fuel cell. In the final step, the game display tracks these retrievals. The game ends when the player retrieves all the fuel cells.

FuelCell's implementation of collision detection is based on the [BoundingSphere](#) class and the following article: [How To: Detect Whether Two Models Collide](#). Collision detection with bounding spheres is a good approach for a variety of reasons:

- Bounding spheres (in addition to [bounding boxes](#) and [frustums](#)) are already available (courtesy of the XNA Framework) for use in your code.
- Bounding spheres do not have to be rotated if the enclosed object is rotated. This is not true when using bounding boxes or frustums. This saves some coding and reduces the complexity of the implementation.
- Bounding spheres are automatically generated for sub-meshes by the XNA Framework. Each mesh has a related bounding sphere, accessible with the [BoundingSphere](#) property of the [ModelMesh](#) object.

It's time to dive back into the code and take advantage of some of these features as we implement the collision detection.

Adding the Bounding Sphere Model

During development, it's incredibly useful to render your bounding spheres along with its related model. This makes debugging the collision detection code much easier when things don't seem to be working properly. FuelCell represents the bounding sphere as a spherical wire-frame model, whose radius is 1 unit. When rendering the bounding sphere of a model, it is easily scaled (using the radius of the model's bounding sphere) and placed by setting the bounding sphere's center to the current position of the model.

For example, if the radius of the bounding sphere of a mesh is 4, the bounding sphere model is scaled by 4, which matches the size of the original bounding sphere.

In order to use this technique, you need to add and initialize a spherical model with a radius of 1 unit. Luckily, the `sphere1uR.x` model is the model you need.

1. Add the `sphere1uR.x` and `White.png` files to the `Models/Content` directory of the FuelCell project.
2. Exclude the `White.png` file from the project.

3. In `FuelCellGame.cs`, declare a member variable (called `boundingSphere`) of type `GameObject`, after the declaration of the game camera.
4. In the existing `Initialize` method, initialize the new variable after initializing the game camera:

C#

```
boundingSphere = new GameObject();
```

5. In the existing `LoadContent` method, load the bounding sphere model after loading of the playing field model:

C#

```
boundingSphere.Model = Content.Load<Model>("Models/sphere1uR");
```

Once the model is loaded, you can use it to render the bounding spheres of your game objects. The only data you'll need to track is the size and position of each object's bounding sphere. For `FuelCell`, there are three types of bounding spheres: fuel carrier, fuel cell, and barrier. You can use the bounding sphere model for each type as long as you scale and position the model before rendering it. For simplicity's sake, the rendering code for a game object and its bounding sphere are kept together. Because the procedure for doing this is the same for both fuel cells and barriers, you will only walk through the fuel cell side of things. After that, we'll discuss the barrier implementation at a higher level.

Calculating the Boundary of the Fuel Cell Model

Do you remember the member variable you added previously to the `GameObject` class, `BoundingSphere`? This is the step that finally makes use of that variable, with the help of a bit of code. The first step involves calculating a decent approximation of the bounding sphere of the game object's model. We'll use the `CreateMerged` method. It's a quick and cheap way to calculate the bounding spheres of simple models. We'll start with the initial bounding sphere and, for every two spheres encountered in the model, we'll merge them. This continues until no more bounding spheres are left.

Note

For single mesh models, like those in `FuelCell`, this approach works perfectly. However, the approach begins to lose accuracy when applied to a complex model. This is why there are entire shelves of books devoted to solving this problem at your local bookstore.

Since we need the bounding sphere values from the model's sub-meshes, a good place for the initial calculation of this variable is in the `LoadContent` of the fuel cell model. Add the following code after any existing code:

C#

```
BoundingSphere = CalculateBoundingSphere();
```

This code makes a call to a helper function (`CalculateBoundingSphere`) that approximates the bounding sphere of the model, returning a new bounding sphere. The result is stored in the `BoundingSphere` variable. The Y-coordinate is set to 0. This causes the upper half of the bounding sphere to project out of the playing field. Since the widest part of the sphere is at the playing field level, it provides a good approximation when testing collision between fuel cells and the fuel carrier.

Add the helper method to the `GameObject` class, after any existing code:

C#

```
protected BoundingSphere CalculateBoundingSphere()
{
    BoundingSphere mergedSphere = new BoundingSphere();
    BoundingSphere[] boundingSpheres;
    int index = 0;
    int meshCount = Model.Meshes.Count;

    boundingSpheres = new BoundingSphere[meshCount];
    foreach (ModelMesh mesh in Model.Meshes)
    {
        boundingSpheres[index++] = mesh.BoundingSphere;
    }

    mergedSphere = boundingSpheres[0];
    if ((Model.Meshes.Count) > 1)
```

```

    {
        index = 1;
        do
        {
            mergedSphere = BoundingSphere.CreateMerged(mergedSphere,
                boundingSpheres[index]);
            index++;
        } while (index < Model.Meshes.Count);
    }
    mergedSphere.Center.Y = 0;
    return mergedSphere;
}

```

At this point, the bounding sphere has an approximate center (clamped to 0 on the Y axis) and radius. Remember the code you added in Step 5 that placed the fuel cells and barriers? After adding the bounding sphere calculation code, the approximated bounding sphere now has the proper coordinates of the related model. In the next step, you'll add code to render both fuel cells and their bounding spheres.

Drawing the Spheres

In the `Draw` function, replace the existing **foreach** loop that draws the fuel cells with the following:

C#

```

foreach (FuelCell fuelCell in fuelCells)
{
    if (!fuelCell.Retrieved)
    {
        fuelCell.Draw(gameCamera.ViewMatrix,
            gameCamera.ProjectionMatrix);
        GraphicsDevice.RenderState.FillMode =
            FillMode.WireFrame;
        fuelCell.DrawBoundingSphere(gameCamera.ViewMatrix,
            gameCamera.ProjectionMatrix, boundingSphere);
        GraphicsDevice.RenderState.FillMode =
            FillMode.Solid;
    }
}

```

What's new about this code? The most important changes are the graphics device state changes and the call to `DrawBoundingSphere`. The state changes are necessary to render the sphere model as a white wireframe model. We did this for two reasons: so the underlying model wouldn't be obscured, and the bounding sphere model would be easily visible. The switch to wireframe rendering is made by setting `RenderState.FillMode Property` to `FillMode.WireFrame`. Once the sphere model is drawn, the fill mode is set back to the default, `FillMode.Solid`. The second change is the call to a new draw function of the `GameObject` class, `DrawBoundingSphere`. Add the following code after the `CalculateBoundingSphere` method:

C#

```

internal void DrawBoundingSphere(Matrix view, Matrix projection,
    GameObject boundingSphereModel)
{
    Matrix scaleMatrix = Matrix.CreateScale(BoundingSphere.Radius);
    Matrix translateMatrix =
        Matrix.CreateTranslation(BoundingSphere.Center);
    Matrix worldMatrix = scaleMatrix * translateMatrix;

    foreach (ModelMesh mesh in boundingSphereModel.Model.Meshes)
    {
        foreach (BasicEffect effect in mesh.Effects)
        {
            effect.World = worldMatrix;
            effect.View = view;
            effect.Projection = projection;
        }
        mesh.Draw();
    }
}

```

Even though the two methods are similar, there are some important differences. First, the bounding sphere model is scaled using the radius of the fuel cell's bounding sphere instead of a constant factor. Second, the nice default lighting is turned off. This makes the model "pop" a bit more amidst the other models rendered with default lighting.

At this point, rebuild the game and start it. You'll notice that the fuel cells now have wireframe spheres surrounding them. You'll also notice that the spheres are pretty bad approximations of the fuel cell's boundaries. We'll get to that eventually. For now, let's add the code that updates and renders the bounding spheres for the fuel carrier and barriers.

Implementing the Remaining Bounding Spheres

First, let's update the barrier-related code since the barriers don't move, which results in less code to write.

- Modify the `LoadContent` method to calculate the initial bounding sphere.
- In the `Draw` method, modify the **foreach** loop (that draws the barriers) to draw the related bounding sphere.

Next up, the fuel carrier. It's the same procedure except for some extra code at the end to handle vehicle movement and fuel cell collision.

- Modify the `LoadContent` method to calculate the initial bounding sphere.
- Modify the `FuelCarrier.Update` method to update the bounding sphere location with the future position of the fuel carrier.
- In the `Draw` method, modify the fuel carrier draw code to also draw the related bounding sphere.

This completes the modifications to draw all the bounding spheres. If you rebuild and run the game, you'll now see lots of wire-frame spheres. But there is still more work (related to fuel carrier collision detection) to make these bounding spheres useful. At this point, the fuel carrier still ignores the fuel cell and barrier bounding spheres. Let's fix this now.

Collision Checking for the Fuel Carrier

There are two collision events that need implementation: collision with a fuel cell and collision with a barrier. If you remember, you already implemented the playing field edge collision code.

Fuel cell collision is important because that it is the only way the player can score points and win the game. You need to add code that checks for collisions between a fuel cell and the fuel carrier. If they collide, you need to mark the fuel cell as retrieved, update the retrieved fuel cells counter, and not draw the fuel cell in the future. This gives the impression that the fuel cell has been picked up by the fuel carrier.

Begin by modifying the `FuelCellGame.Update` method to check for collision between the fuel cell and the fuel carrier. Add the following code after the game camera update:

C#

```
foreach (FuelCell fuelCell in fuelCells)
    fuelCell.Update(fuelCarrier.BoundingSphere);
```

Add the `FuelCell.Update` method, called with the preceding code. Place it after the `Draw` method:

C#

```
internal void Update(BoundingSphere vehicleBoundingSphere)
{
    if (vehicleBoundingSphere.Intersects(this.BoundingSphere))
        this.Retrieved = true;
}
```

This checks for intersection between the bounding spheres of the carrier and the fuel cell. This is the essence of the procedure discussed in [How To: Detect Whether Two Models Collide](#).

Go ahead and remove the now-redundant check (located in `FuelCell.Draw`) to see if the fuel cell is retrieved before drawing. That check is now being made in the `FuelCellGame.Draw` method. This completes the code support for the first collision event.

The second event requires less code because, for the most part, the infrastructure already exists. The existing `ValidateMovement` method will be updated to check for barrier collision in addition to game field boundary collision.

Calculate the future position of the bounding sphere, based on the future position of the fuel carrier. Add the following code to the beginning of the `FuelCarrier.ValidateMovement` method:

C#

```
BoundingBox futureBoundingBox = BoundingBox;  
futureBoundingBox.Center.X = futurePosition.X;  
futureBoundingBox.Center.Z = futurePosition.Z;
```

In the same method, add the following code to the end of the current code but before the last **return** call:

C#

```
//Don't allow driving through a barrier  
if (CheckForBarrierCollision(futureBoundingBox, barriers))  
    return false;
```

Finally, add the new `CheckForBarrierCollision` method:

C#

```
private bool CheckForBarrierCollision(  
    BoundingBox vehicleBoundingBox, Barrier[] barriers)  
{  
    for (int curBarrier = 0; curBarrier < barriers.Length; curBarrier++)  
    {  
        if (vehicleBoundingBox.Intersects(  
            barriers[curBarrier].BoundingBox))  
            return true;  
    }  
    return false;  
}
```

Initial Bounding Sphere Results

Once you rebuild and run `FuelCell`, look at the size of the default bounding spheres. For each object, the bounding sphere is quite large. In some cases, the addition of bounding sphere volumes creates situations where the code prevents the vehicle from passing through barriers that are far enough apart for the vehicle itself. The collision detection, as it stands now, is pretty good considering that this is the result if you do nothing but use the default bounding sphere parameters. However, with a simple modification to the code we can improve the experience of the player. The modification involves applying another scaling factor to the bounding spheres of each game object. This allows realistic interaction between the vehicle and the game world.

The implementation requires scaling factors for each object type. A good place for these is in the `GameConstants.cs` file. Add the following declarations to the end of the `GameConstants` class:

C#

```
//bounding sphere scaling factors  
public const float FuelCarrierBoundingBoxFactor = .8f;  
public const float FuelCellBoundingBoxFactor = .5f;  
public const float BarrierBoundingBoxFactor = .7f;
```

There are factors for the fuel carrier, fuel cells, and barriers.

The second modification is to the `LoadContent` methods of the fuel carrier, fuel cell, and barrier classes. After the bounding sphere is first calculated, the radius is then modified by the appropriate factor. This shrinks the radius of the bounding sphere, creating a tighter fit with the object's visible boundary.

Modify the `FuelCell.LoadContent` method by adding the following code after the bounding sphere calculation:

C#

```
BoundingBox scaledSphere;  
scaledSphere = BoundingBox;  
scaledSphere.Radius *= GameConstants.FuelCellBoundingBoxFactor;  
BoundingBox =  
    new BoundingBox(scaledSphere.Center, scaledSphere.Radius);
```

Modify the `FuelCarrier.LoadContent` method by adding the following code after the bounding sphere calculation:

C#

```
BoundingBox scaledSphere;  
scaledSphere = BoundingBox;  
scaledSphere.Radius *=  
    GameConstants.FuelCarrierBoundingBoxFactor;  
BoundingBox =  
    new BoundingBox(scaledSphere.Center, scaledSphere.Radius);
```

Modify the `Barrier.LoadContent` method by adding the following code after the bounding sphere calculation:

C#

```
BoundingBox scaledSphere;  
scaledSphere = BoundingBox;  
scaledSphere.Radius *= GameConstants.BarrierBoundingBoxFactor;  
BoundingBox =  
    new BoundingBox(scaledSphere.Center, scaledSphere.Radius);
```

Rebuild and run the game. The bounding spheres are noticeably smaller, and they no longer enclose the game models. However, the important area (a band on the ground going around the game object) matches the outline of the model fairly accurately. At this point, the collision detection is good enough for our purposes. However, with a little effort, the placement and size of the bounding spheres could be modified even further to produce more accurate collision detection. Like most things in game development, the more time you spend on a feature, the better it gets (remember that trilemma we discussed earlier?). There's one more step before we can call it done. In the last [step](#), we'll add some new screens (for example, start, win or lose), game state tracking and HUD elements, and a few other items.

Overview of Game State Management

As a game, FuelCell is nearly complete, but we are missing some important features. These features include:

- Game state management
- Start and win/loss screens
- Game status display (such as the current score and time remaining)

Game state management is the management of different states of the game through displaying different screens and/or by logic code added to the existing code. Common states for a basic game include: starting, playing, win/loss, and pause. Each of these states could have one or more related screens, such as an options screen or a gameplay screen.

FuelCell manages three states (starting, playing, won/lost) and three different screens:

- a starting screen with instructions on playing the game
- a gameplay screen displaying the fuel carrier and the playing field—the screen we have been working on from the beginning
- a screen that informs whether the player won or lost, and enables the player to start a new game or exit

The game state management code is confined to the FuelCellGame.cs file (with some constants defined in GameConstants.cs). Heavy modification of the `Update` and `Draw` methods is needed, and additional new code will be added in various areas of the file.

However, before we start that work, remove the code that renders the bounding spheres. It served its purpose and only gets in the way now. In the `Draw` method, comment out (or remove) all code that sets the wire frame rendering mode, and calls the `DrawBoundingSphere` method. Rebuild the game and run it. Without all the wireframe spheres, it looks like a real game.

Note

If this were a real game in development, you would either remove these calls completely or enclose them in `DEBUG` conditionals. In addition, you could remove or conditionalize the code around initializing and loading the bounding sphere model (`BoundingSphere`). However, you still need the remaining code initializing and calculating the bounding spheres for the various game objects. Without it, our collision detection disappears.

For our purposes, a simple commenting out suffices.

Anybody Got the Time?

One of the goals of FuelCell is to collect 12 fuel cells. It's not a very difficult task if the player has all the time in the world. Let's fix that now by adding a time limit to the game. The player starts with a set amount of time. In this case, we'll use 30 seconds. If the player collects all 12 fuel cells before time runs out, the player wins the game. However, if time runs out and there are still fuel cells on the playing field, the player loses. The winning and losing conditions are handled by the game state management code that you'll add later. For now, let's implement the time limit feature.

In `FuelCellGame.cs`, declare three variables (of type `TimeSpan`) for the various times to be tracked. You'll also need a variable for tracking the number of retrieved fuel cells (of type `int`).

C#

```
int retrievedFuelCells;
TimeSpan startTime, roundTimer, roundTime;
```

In the `FuelCellGame` constructor, add initialization code for the starting and round times. This code sets the start and game time variables to 0. Zero indicates the game hasn't started. The round time variable is then set to 30.25 seconds. The .25 seconds is to give enough time to flash 30 on the screen before it begins counting down.

C#

```
roundTime = GameConstants.RoundTime;
```

While you are in here, add the following code to specify a resolution of 853x480. This resolution causes output from any Xbox console to look good, regardless of the widescreen capabilities of the output device.

C#

```
graphics.PreferredBackBufferWidth = 853;
graphics.PreferredBackBufferHeight = 480;
```

In the `Update` method, add code that sets the time variables to their proper values when the player presses the Start button on the gamepad. A good place for this code is after the code that checks for pressing of the Exit button:

```
if (currentGamePadState.Buttons.Start == ButtonState.Pressed)
{
    roundTimer = roundTime;
}
```

This code sets the current and start times to the current total game time, and then calculates the end time. Now that the time is set, you'll need to track the amount of elapsed game time.

Staying in the same method, add the following code after the fuel cell update code:

```
roundTimer -= gameTime.ElapsedGameTime;
```

Gimme a T!

Next, you'll implement a simple HUD that displays the remaining time and the number of retrieved fuel cells during gameplay. We'll accomplish this by using the technique described by [How To: Draw Text](#).

The first item is a spritefont for the screen text. This is a new content type for the game, so add a new directory to the Content directory called `Fonts`, and then add a new `Spritefont` item to that directory called `StatsFont`.

In the `GameConstants.cs` file, add the following strings:

C#

```
public const string StrTimeRemaining = "Time Remaining: ";
public const string StrCellsFound = "Fuel Cells Retrieved: ";
public const string StrGameWon = "Game Won !";
public const string StrGameLost = "Game Lost !";
public const string StrPlayAgain =
    "Press Enter/Start to play again or Esc/Back to quit";
public const string StrInstructions1 =
    "Retrieve all Fuel Cells before time runs out.";
public const string StrInstructions2 =
    "Control ship using keyboard (A, D, W, S) or the left thumbstick.";
```

These strings are used in various screens to display information on how to play, the current time remaining, and other important stuff. You'll also need a sprite batch and a sprite font variable when drawing the game text. Add these in the `FuelCellGame.cs` file after the `random` variable declaration:

C#

```
SpriteBatch spriteBatch;  
SpriteFont statsFont;
```

In the `LoadContent` method, initialize the sprite batch object, and load the new sprite font with the following code:

C#

```
spriteBatch = new SpriteBatch(GraphicsDevice);  
statsFont = Content.Load<SpriteFont>("Fonts/StatsFont");
```

You'll use a single method, called from `Draw`, to draw all the game statistics on the gameplay screen. In the `FuelCellGame.cs` file, add the following method after the `DrawTerrain` method:

C#

```
private void DrawStats()  
{  
    float xOffsetText, yOffsetText;  
    string str1 = GameConstants.StrTimeRemaining;  
    string str2 =  
        GameConstants.StrCellsFound + retrievedFuelCells.ToString() +  
        " of " + GameConstants.NumFuelCells.ToString();  
    Rectangle rectSafeArea;  
  
    str1 += (roundTimer.Seconds).ToString();  
  
    //Calculate str1 position  
    rectSafeArea = GraphicsDevice.Viewport.TitleSafeArea;  
  
    xOffsetText = rectSafeArea.X;  
    yOffsetText = rectSafeArea.Y;  
  
    Vector2 strSize = statsFont.MeasureString(str1);  
    Vector2 strPosition =  
        new Vector2((int)xOffsetText + 10, (int)yOffsetText);  
  
    spriteBatch.Begin();  
    spriteBatch.DrawString(statsFont, str1, strPosition, Color.White);  
    strPosition.Y += strSize.Y;  
    spriteBatch.DrawString(statsFont, str2, strPosition, Color.White);  
    spriteBatch.End();  
  
    //re-enable depth buffer after sprite batch disablement  
    GraphicsDevice.RenderState.DepthBufferEnable = true;  
    GraphicsDevice.RenderState.AlphaBlendEnable = false;  
    GraphicsDevice.RenderState.AlphaTestEnable = false;  
    GraphicsDevice.SamplerStates[0].AddressU = TextureAddressMode.Wrap;  
    GraphicsDevice.SamplerStates[0].AddressV = TextureAddressMode.Wrap;  
}
```

Let's look at this code block more closely as there's a fair bit of code here.

The first part sets up the locations where the game statistic strings are drawn. A major part of this is the retrieval of the title safe area of the viewport. This is later used to properly place the various text strings. A nice feature of the `TitleSafeArea` property is that, depending on the platform, it automatically adjusts the area returned. The area is smaller if the game targets the Xbox 360 platform. Rendering within this area prevents any sprite drawing in areas of the screen that could get cut off by a TV display. The next part composes the strings with the current game info, and then draws them on the gameplay screen. However, the last bit of code deserves more examination.

You must reset certain properties of the graphics device whenever you combine sprite drawing with 3D rendering, as `FuelCell` does. These properties, related to alpha blending and the depth buffer, are set to different values when a sprite batch is used. If the properties are not reset to the default settings, weird rendering issues could suddenly appear in your game. That is why the final code modifies some `RenderState` and `SampleStates` properties of the graphics device.

You'll need to call the `DrawStats` method from the existing `Draw` method. Add the following code after the call to

```
FuelCarrier.Draw.
```

```
DrawStats();
```

After a rebuild, the time and remaining number of fuel cells are displayed in the upper-left corner. Of course, the values are completely wrong, but we'll be fixing those next.

The State of Things

The remaining code you will add implements the game state management of FuelCell. As mentioned previously, one of the main duties of game state management is to determine the correct game screen to display. In addition, game state management can also monitor the player's progress toward his or her goals. For FuelCell, the goals are to retrieve all fuel cells before time runs out. If the player succeeds, we need to display a Game Won screen or, conversely, a Game Lost screen. In addition, we'll display a splash screen on startup of the game containing instructions for starting a new game and playing it.

The state of the game changes depending on player input and events in the game. This makes the `Update` method an ideal place to monitor and control the varying states. In addition, the `Draw` method will be modified to properly reflect the current stage the game is in by drawing the proper screen.

Let's begin by declaring a new enumeration in the FuelCellGame.cs file that lists the different game states being tracked. Add the following code before the `FuelCellGame` class declaration:

C#

```
public enum GameState { Loading, Running, Won, Lost }
```

Now add a variable (of type `GameState`) after the declaration of the `SpriteBatch` and `SpriteFont` variables.

C#

```
GameState currentGameState = GameState.Loading;
```

We're going to implement the game state component in stages, with the first stage being the Loading state. The first part, setting the current game state to Loading, is already done.

Implementing the Loading Game State

Before the player starts a new game of FuelCell, the player will need some basic instructions for controlling the vehicle and the win conditions. We'll deliver these instructions in a splash screen, which will display when the FuelCell application begins. This screen is only displayed when the game state is in the `Loading` stage.

Modify the following code:

```
        if ((lastKeyboardState.IsKeyDown(Keys.Enter) && (lastKeyboardState.IsKeyUp(Keys.Enter))) ||
            currentGamePadState.Buttons.Start == ButtonState.Pressed)
        {
            roundTimer = roundTime;
        }
```

to match the following:

C#

```
if (currentGameState == GameState.Loading)
{
    if ((lastKeyboardState.IsKeyDown(Keys.Enter) &&
        (currentKeyboardState.IsKeyUp(Keys.Enter))) ||
        currentGamePadState.Buttons.Start == ButtonState.Pressed)
    {
        roundTimer = roundTime;
        currentGameState = GameState.Running;
    }
}
```

The modifications now check the game state when the player presses the Enter key or Start button, and advances the game state if the current state is `GameState.Loading`.

Display of the splash screen is handled in the `Draw` method. Since the game state is based on the current value of an enumeration, we'll draw the proper screen based on the current value of `currentGameState`.

In the `Draw` method, replace the existing code between the `Clear` call and the base `Draw` call with the following code:

```
switch (currentGameState)
{
    case GameState.Loading:
        DrawSplashScreen();
        break;
};
```

Before the player starts the game, the only thing displayed should be the splash screen. The helper method, `DrawSplashScreen`, clears the screen to steel blue, and then displays some informational text. Add that method after the existing `DrawTerrain` method:

C#

```
private void DrawSplashScreen()
{
    float xOffsetText, yOffsetText;
    Vector2 viewportSize = new Vector2(GraphicsDevice.Viewport.Width,
        GraphicsDevice.Viewport.Height);
    Vector2 strCenter;

    graphics.GraphicsDevice.Clear(Color.SteelBlue);

    xOffsetText = yOffsetText = 0;
    Vector2 strInstructionsSize =
        statsFont.MeasureString(GameConstants.StrInstructions1);
    Vector2 strPosition;
    strCenter = new Vector2(strInstructionsSize.X / 2,
        strInstructionsSize.Y / 2);

    yOffsetText = (viewportSize.Y / 2 - strCenter.Y);
    xOffsetText = (viewportSize.X / 2 - strCenter.X);
    strPosition = new Vector2((int)xOffsetText, (int)yOffsetText);

    spriteBatch.Begin();
    spriteBatch.DrawString(statsFont, GameConstants.StrInstructions1,
        strPosition, Color.White);

    strInstructionsSize =
        statsFont.MeasureString(GameConstants.StrInstructions2);
    strCenter = new Vector2(strInstructionsSize.X / 2,
        strInstructionsSize.Y / 2);
    yOffsetText =
        (viewportSize.Y / 2 - strCenter.Y) + statsFont.LineSpacing;
    xOffsetText = (viewportSize.X / 2 - strCenter.X);
    strPosition = new Vector2((int)xOffsetText, (int)yOffsetText);

    spriteBatch.DrawString(statsFont, GameConstants.StrInstructions2,
        strPosition, Color.LightGray);
    spriteBatch.End();

    //re-enable depth buffer after sprite batch disablement
    GraphicsDevice.RenderState.DepthBufferEnable = true;
    GraphicsDevice.RenderState.AlphaBlendEnable = false;
    GraphicsDevice.RenderState.AlphaTestEnable = false;
    GraphicsDevice.SamplerStates[0].AddressU = TextureAddressMode.Wrap;
    GraphicsDevice.SamplerStates[0].AddressV = TextureAddressMode.Wrap;
}
```

That completes the splash screen implementation.

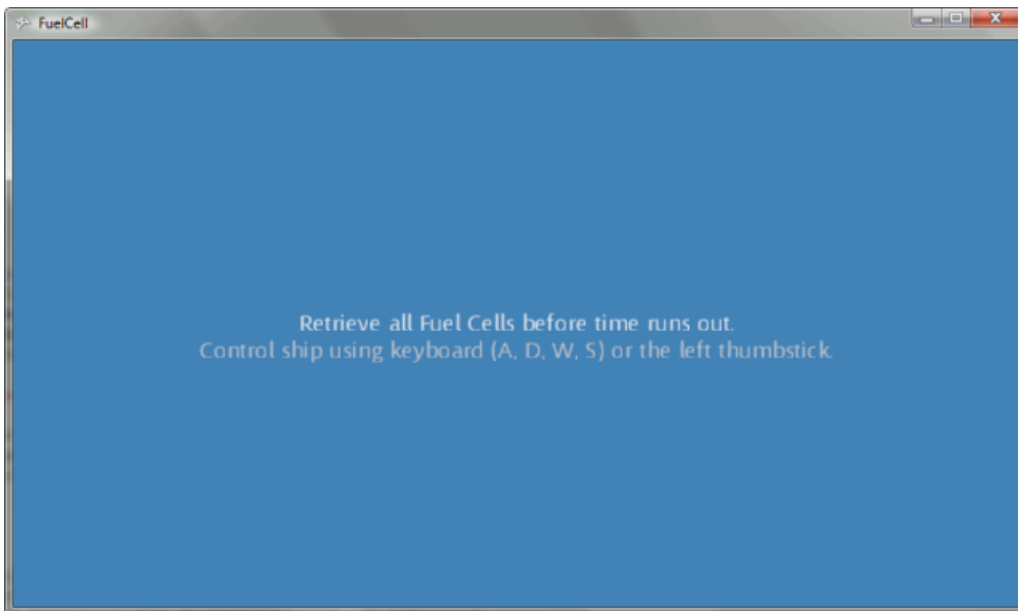

Figure 1. Splash Screen for FuelCell

Implementing the Running (Gameplay) Screen

The next game state you'll implement is the gameplay screen (the screen that you developed in Steps 3-6). This screen is reached after the player presses the Enter key or the Start button from the splash screen. You'll add code to the `Update` and `Draw` methods to draw this screen at the appropriate time.

In the `Update` method, replace the following code:

```
fuelCarrier.Update(currentGamePadState, currentKeyboardState, barriers);
float aspectRatio = graphics.GraphicsDevice.Viewport.AspectRatio;
gameCamera.Update(fuelCarrier.ForwardDirection, fuelCarrier.Position, aspectR
atio);

foreach (FuelCell fuelCell in fuelCells)
fuelCell.Update(fuelCarrier.BoundingBox);
roundTimer -= gameTime.ElapsedGameTime;
```

with the following code:

C#

```
if ((currentGameState == GameState.Running))
{
    fuelCarrier.Update(currentGamePadState,
        currentKeyboardState, barriers);
    gameCamera.Update(fuelCarrier.ForwardDirection,
        fuelCarrier.Position, aspectRatio);
    retrievedFuelCells = 0;
    foreach (FuelCell fuelCell in fuelCells)
    {
        fuelCell.Update(fuelCarrier.BoundingBox);
        if (fuelCell.Retrieved)
        {
            retrievedFuelCells++;
        }
    }
    if (retrievedFuelCells == GameConstants.NumFuelCells)
    {
        currentGameState = GameState.Won;
    }
    roundTimer -= gameTime.ElapsedGameTime;
    if ((roundTimer < TimeSpan.Zero) &&
        (retrievedFuelCells != GameConstants.NumFuelCells))
    {
        currentGameState = GameState.Lost;
    }
}
```

```
}
```

In the `Draw` method, add the following code after the existing game state check:

C#

```
case GameState.Running:  
    DrawGameplayScreen();  
    break;
```

And then, after the `DrawSplashScreen` method, add the following code:

C#

```
private void DrawGameplayScreen()  
{  
    DrawTerrain(ground.Model);  
    foreach (FuelCell fuelCell in fuelCells)  
    {  
        if (!fuelCell.Retrieved)  
        {  
            fuelCell.Draw(gameCamera.ViewMatrix,  
                gameCamera.ProjectionMatrix);  
        }  
    }  
    foreach (Barrier barrier in barriers)  
    {  
        barrier.Draw(gameCamera.ViewMatrix,  
            gameCamera.ProjectionMatrix);  
    }  
  
    fuelCarrier.Draw(gameCamera.ViewMatrix,  
        gameCamera.ProjectionMatrix);  
    DrawStats();  
}
```

At this point, the game displays both the splash and gameplay screens. Only the win/loss screen remains.

Figure 2. Gameplay Screen for FuelCell

Implementing the Game Won/Game Lost Screens

The win/loss screens are similar, differing only in the initial text. From either screen, the player can choose to play another game or exit FuelCell. For this reason, you'll implement both screens using a single function. That function, `DrawWinOrLoss`, accepts a string parameter with the appropriate message.

First, let's modify the `Update` method to check for player input after a game. Add the following code after the check for `GameState.Running`:

C#

```
if ((currentGameState == GameState.Won) ||
    (currentGameState == GameState.Lost))
{
    // Reset the world for a new game
    if ((lastKeyboardState.IsKeyDown(Keys.Enter) &&
        (currentKeyboardState.IsKeyUp(Keys.Enter))) ||
        currentGamePadState.Buttons.Start == ButtonState.Pressed)
        ResetGame(gameTime, aspectRatio);
}
```

There's nothing of note in this code except for the call to the `Reset` method. It "resets" the world, allowing a new game to be played. Let's add that method now.

In `FuelCellGame.cs`, add the following method:

C#

```
private void ResetGame(GameTime gameTime, float aspectRatio)
{
    fuelCarrier.Reset();
    gameCamera.Update(fuelCarrier.ForwardDirection,
        fuelCarrier.Position, aspectRatio);
    InitializeGameField();

    retrievedFuelCells = 0;
    startTime = gameTime.TotalGameTime;
    roundTimer = roundTime;
    currentGameState = GameState.Running;
}
```

In the `GameObject.cs` file, after the `LoadContent` method, add the following method to the `FuelCarrier` class:

C#

```
internal void Reset()
{
    Position = Vector3.Zero;
    ForwardDirection = 0f;
}
```

This returns the fuel carrier to its original position and orientation.

The final code you'll add is `InitializeGameField`. Place this code after the `ResetGame` method (located in `FuelCellGame.cs`):

C#

```
private void InitializeGameField()
{
    //Initialize barriers
    barriers = new Barrier[GameConstants.NumBarriers];
    int randomBarrier = random.Next(3);
    string barrierName = null;

    for (int index = 0; index < GameConstants.NumBarriers; index++)
    {
        switch (randomBarrier)
        {
            case 0:
                barrierName = "Models/cube10uR";
                break;
            case 1:
                barrierName = "Models/cylinder10uR";
                break;
            case 2:
                barrierName = "Models/pyramid10uR";
                break;
        }
    }
}
```

```

    }
    barriers[index] = new Barrier();
    barriers[index].LoadContent(Content, barrierName);
    randomBarrier = random.Next(3);
}
PlaceFuelCellsAndBarriers();
}

```

This method completes the remaining tasks for a new game:

- Generates new positions for all fuel cells and barriers.
- Sets all fuel cells to a non-retrieved state and zeros out the number of retrieved fuel cells.

The final bit of code updates the `Draw` method to draw the winning or losing screen. Add the following code after the check for the Running game state in `Draw`:

C#

```

case GameState.Won:
    DrawWinOrLossScreen(GameConstants.StrGameWon);
    break;
case GameState.Lost:
    DrawWinOrLossScreen(GameConstants.StrGameLost);
    break;

```

Now implement the `DrawWinOrLossScreen` method, after the existing `DrawSplashScreen` method:

C#

```

private void DrawWinOrLossScreen(string gameResult)
{
    float xOffsetText, yOffsetText;
    Vector2 viewportSize = new Vector2(GraphicsDevice.Viewport.Width,
        GraphicsDevice.Viewport.Height);
    Vector2 strCenter;

    xOffsetText = yOffsetText = 0;
    Vector2 strResult = statsFont.MeasureString(gameResult);
    Vector2 strPlayAgainSize =
        statsFont.MeasureString(GameConstants.StrPlayAgain);
    Vector2 strPosition;
    strCenter = new Vector2(strResult.X / 2, strResult.Y / 2);

    yOffsetText = (viewportSize.Y / 2 - strCenter.Y);
    xOffsetText = (viewportSize.X / 2 - strCenter.X);
    strPosition = new Vector2((int)xOffsetText, (int)yOffsetText);

    spriteBatch.Begin();
    spriteBatch.DrawString(statsFont, gameResult,
        strPosition, Color.Red);

    strCenter =
        new Vector2(strPlayAgainSize.X / 2, strPlayAgainSize.Y / 2);
    yOffsetText = (viewportSize.Y / 2 - strCenter.Y) +
        (float)statsFont.LineSpacing;
    xOffsetText = (viewportSize.X / 2 - strCenter.X);
    strPosition = new Vector2((int)xOffsetText, (int)yOffsetText);
    spriteBatch.DrawString(statsFont, GameConstants.StrPlayAgain,
        strPosition, Color.AntiqueWhite);

    spriteBatch.End();

    //re-enable depth buffer after sprite batch disablement
    GraphicsDevice.RenderState.DepthBufferEnable = true;
    GraphicsDevice.RenderState.AlphaBlendEnable = false;
    GraphicsDevice.RenderState.AlphaTestEnable = false;
    GraphicsDevice.SamplerStates[0].AddressU = TextureAddressMode.Wrap;
    GraphicsDevice.SamplerStates[0].AddressV = TextureAddressMode.Wrap;

```

```
}
```

Since the Win and Loss screens differ only in the message, we can cheat a bit and just use the same function, passing in the game result.

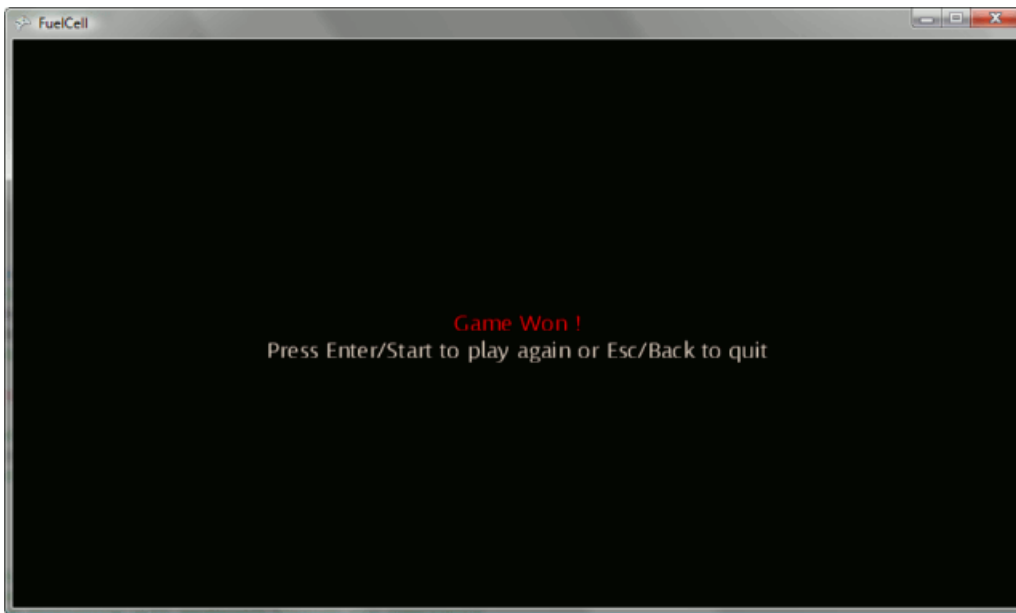

Figure 3. FuelCell Congratulatory Screen

That's a Wrap!

After the (now) traditional rebuild and play session, you can now enjoy the introductory splash screen, a challenging game of retrieve the fuel cells, and (hopefully) a congratulatory winning screen.

At this point, the FuelCell game is complete. Even though you wrote a large amount of code, the possibilities for expansion are endless. For example:

- Multiplayer - invite a competitor and whomever collects the most fuel cells wins!
- Powerups - Add another object, or two, that gives the player a boost of speed for 5 seconds or a "ghost" ability that ignores those pesky barriers!
- Advanced lighting and effects - improve the default lighting with a glow effect or motion blur.
- Sound - add the Whoosh! of fuel carrier acceleration or the Bonk! of barrier collision.

Classes

Name	Description
 BoundingFrustum	Defines a frustum and helps determine whether forms intersect with it.
 Curve	Stores an arbitrary collection of 2D CurveKey points, and provides methods for evaluating features of the curve they define.
 CurveKey	Represents a point in a multi-point curve.
 CurveKeyCollection	Contains the CurveKeys making up a Curve .
 DrawableGameComponent	A game component that is notified when it needs to draw itself.
 FrameworkDispatcher	Implements the Windows-specific portion of a FrameworkDispatcher class.
 Game	Provides basic graphics device initialization, game logic, and rendering code.
 GameComponent	Base class for all XNA Framework game components.
 GameComponentCollection	A collection of game components.
 GameComponentCollectionEventArgs	Arguments used with events from the GameComponentCollection .
 GameServiceContainer	A collection of game services.
 GameTime	Snapshot of the game timing state expressed in values that can be used by variable-step (real time) or fixed-step (game time) games.
 GameWindow	The system window associated with a Game .
 GraphicsDeviceInformation	Holds the settings for creating a graphics device on Windows.
 GraphicsDeviceManager	Handles the configuration and management of the graphics device.
 MathHelper	Contains commonly used precalculated values.
 NoSuitableGraphicsDeviceException	Thrown when no available graphics device fits the given device preferences.
 PowerStatus	Contains system power information, including battery life status and power line status.
 PreparingDeviceSettingsEventArgs	Arguments for the GraphicsDeviceManager.PreparingDeviceSettings event.

Interfaces

Name	Description
 IDrawable	Defines the interface for a drawable game component.
 IGameComponent	Defines an interface for game components.
 IGraphicsDeviceManager	Defines the interface for an object that manages a GraphicsDevice .
 IUpdateable	Defines an interface for a game component that should be updated in Game.Update .

Structures

Name	Description
 BoundingBox	Defines an axis-aligned box-shaped 3D volume.
 BoundingSphere	Defines a sphere.
 Matrix	Defines a matrix.
 Plane	Defines a plane.
 Point	Defines a point in 2D space.
 Quaternion	Defines a four-dimensional vector (x,y,z,w), which is used to efficiently rotate an object about the (x, y, z) vector by the angle theta, where $w = \cos(\text{theta}/2)$.
 Ray	Defines a ray.
 Rectangle	Defines a rectangle.
 Vector2	Defines a vector with two components.
 Vector3	Defines a vector with three components.
 Vector4	Defines a vector with four components.

Enumerations

Name	Description
 BatteryChargeStatus	Indicates battery charge status.
 ContainmentType	Indicates the extent to which bounding volumes intersect or contain one another.
 CurveContinuity	Defines the continuity of CurveKeys on a Curve .
 CurveLoopType	Defines how the value of a Curve will be determined for positions before the first point on the Curve or after the last point on the Curve .
 CurveTangent	Specifies different tangent types to be calculated for CurveKey points in a Curve .
 PlaneIntersectionType	Describes the intersection between a plane and a bounding volume.
 PlayerIndex	Specifies the game controller associated with a player.
 PowerLineStatus	Indicates the status of the system powerline.
 TargetPlatform	Defines the target platform to be used when compiling content.

BoundingBox Structure

Defines an axis-aligned box-shaped 3D volume.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
[TypeConverterAttribute("typeof(Microsoft.Xna.Framework.Design.BoundingBoxConverter)")]  
[SerializableAttribute]  
public struct BoundingBox : IEquatable<BoundingBox>
```

Remarks

The [BoundingBox Structure](#) represents the space occupied by a box. The bounding box class is axis aligned. Each face of the bounding box is perpendicular to the x-axis, the y-axis, or the z-axis.

There are several benefits of using the bounding box for collision detection.

- The bounding box class fits rectangular shapes aligned with the axis very well. Compared to the bounding sphere class, the bounding box class provides a much tighter fit for non-rotated rectangular objects.
- Because the bounding box class is axis aligned, you can make certain assumptions that result in collision checks between bounding boxes being quicker than a bounding box that can be rotated.

There are a few drawbacks of using the bounding box for collision detection.

- Rotating a bounding box causes it to no longer be axis aligned. Because of this, if you rotate a model being bounded, you will need to recreate the bounding box. Doing so can be slow, since all the points in an object are iterated through to get the bounding box. If the model has not changed orientation, you can translate the bounding box instead of recreating it.
- If the model being bounded is not aligned to the axis, the bounding box will have some empty space. The amount of empty space will be greatest when the object is rotated 45 degrees from an axis.
- Empty space in the bounding box can result in false positives when checking for collision.

BoundingBox Members

The following tables list the members exposed by the BoundingBox type.

Public Constructors

	Name	Description
	BoundingBox	Creates an instance of BoundingBox .

Public Fields

	Name	Description
	CornerCount	Specifies the total number of corners (8) in the BoundingBox .
	Max	The maximum point the BoundingBox contains.
	Min	The minimum point the BoundingBox contains.

Public Methods

	Name	Description
	Contains	Overloaded. Tests whether the BoundingBox overlaps another bounding volume.
	CreateFromPoints	Creates the smallest BoundingBox that will contain a group of points.
	CreateFromSphere	Overloaded. Creates the smallest BoundingBox that will contain the specified BoundingSphere .
	CreateMerged	Overloaded. Creates the smallest BoundingBox that contains the two specified BoundingBox instances.
	Equals	Overloaded. Determines whether two instances of BoundingBox are equal.
	GetCorners	Overloaded. Gets an array of points that make up the corners of the BoundingBox .
	GetHashCode	Gets the hash code for this instance.
	GetType	(Inherited from Object .)
	Intersects	Overloaded. Checks whether the current BoundingBox intersects with another bounding volume.
	op_Equality	Determines whether two instances of BoundingBox are equal.
	op_Inequality	Determines whether two instances of BoundingBox are not equal.
	ReferenceEquals	(Inherited from Object .)
	ToString	Returns a String that represents the current BoundingBox .

[Microsoft.Xna.Framework Namespace](#)

BoundingBox.Corners Field

Specifies the total number of corners (8) in the [BoundingBox](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public const int Corners
```

BoundingBox.Max Field

The maximum point the [BoundingBox](#) contains.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public Vector3 Max
```

Remarks The maximum point is the point with components that are greater than or equal to the components of every other point within the [BoundingBox](#). Since a [BoundingBox](#) is axis aligned the maximum point is the upper-right corner of the front face of the [BoundingBox](#) when looking at it from the positive z direction.

BoundingBox.Min Field

The minimum point the [BoundingBox](#) contains.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public Vector3 Min
```

Remarks The minimum point is the point with components that are less than or equal to the components of every other point within the [BoundingBox](#). Since a [BoundingBox](#) is axis aligned the minimum point is the lower-left corner of the back face of the [BoundingBox](#) when looking at it from the positive z direction.

BoundingBox Constructor

Creates an instance of [BoundingBox](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public BoundingBox (  
    Vector3 min,  
    Vector3 max  
)
```

Parameters

min

The minimum point the [BoundingBox](#) includes.

max

The maximum point the [BoundingBox](#) includes.

Remarks

The [BoundingBox Structure](#) represents the space occupied by a box. The bounding box class is axis aligned. Each face of the bounding box is perpendicular to the x-axis, the y-axis, or the z-axis.

There are several benefits of using the bounding box for collision detection.

- The bounding box class fits rectangular shapes aligned with the axis very well. Compared to the bounding sphere class, the bounding box class provides a much tighter fit for non-rotated rectangular objects.
- Because the bounding box class is axis aligned, you can make certain assumptions that result in collision checks between bounding boxes being quicker than a bounding box that can be rotated.

There are a few drawbacks of using the bounding box for collision detection.

- Rotating a bounding box causes it to no longer be axis aligned. Because of this, if you rotate a model being bounded, you will need to recreate the bounding box. Doing so can be slow, since all the points in an object are iterated through to get the bounding box. If the model has not changed orientation, you can translate the bounding box instead of recreating it.
- If the model being bounded is not aligned to the axis, the bounding box will have some empty space. The amount of empty space will be greatest when the object is rotated 45 degrees from an axis.
- Empty space in the bounding box can result in false positives when checking for collision.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static bool op_Inequality (  
    BoundingBox a,  
    BoundingBox b  
)
```

Parameters

a

The object to the left of the inequality operator.

b

The object to the right of the inequality operator.

Return Value

true if *left* is not equal to *right*; **false** otherwise.

BoundingFrustum Class

Defines a frustum and helps determine whether forms intersect with it.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
[TypeConverterAttribute(System.ComponentModel.ExpandableObjectConverter, System, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089)]
[SerializableAttribute]
public class BoundingFrustum : IEquatable<BoundingFrustum>
```

Remarks

A *frustum* in computer graphics is generally a volume of 3D space, defined as the part of a rectangular pyramid that lies between two planes perpendicular to its center line. A frustum is often used to represent what a "camera" sees in your 3D space—for example:

The **BoundingFrustum** class allows you to define a bounding frustum using a combined matrix that is generally the product of a view matrix and a projection matrix.

You can query a **BoundingFrustum** object for any one of its bounding planes, for its corners, and for whether it intersects with a given object. Since objects that don't intersect with your view frustum generally don't need to be rendered, culling them quickly can save you a lot of rendering time.

BoundingFrustum Members

The following tables list the members exposed by the BoundingFrustum type.

Public Constructors

Name	Description
 BoundingFrustum	Creates a new instance of BoundingFrustum .

Public Fields

Name	Description
 CornerCount	Specifies the total number of corners (8) in the BoundingFrustum .

Public Properties

Name	Description
 Bottom	Gets the bottom plane of the BoundingFrustum .
 Far	Gets the far plane of the BoundingFrustum .
 Left	Gets the left plane of the BoundingFrustum .
 Matrix	Gets or sets the Matrix that describes this bounding frustum.
 Near	Gets the near plane of the BoundingFrustum .
 Right	Gets the right plane of the BoundingFrustum .
 Top	Gets the top plane of the BoundingFrustum .

Public Methods

Name	Description
 Contains	Overloaded. Checks whether the current BoundingFrustum contains a specified bounding volume.
 Equals	Overloaded. Determines whether two instances of BoundingFrustum are equal.
 GetCorners	Overloaded. Gets an array of points that make up the corners of the BoundingFrustum .
 GetHashCode	Gets the hash code for this instance.
 GetType	(Inherited from Object .)
 Intersects	Overloaded. Checks whether the current BoundingFrustum intersects a specified volume.
 Op_Equality	Determines whether two instances of BoundingFrustum are equal.
 Op_Inequality	Determines whether two instances of BoundingFrustum are not equal.
 ReferenceEquals	(Inherited from Object .)
 ToString	Returns a String that represents the current BoundingFrustum .

Protected Methods

Name	Description
 Finalize	(Inherited from Object .)
 MemberwiseClone	(Inherited from Object .)

BoundingFrustum Constructor

Creates a new instance of [BoundingFrustum](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public BoundingFrustum (  
    Matrix value  
)
```

Parameters

value

Combined matrix that usually takes view × projection matrix.

Remarks

You can use [BoundingFrustum Class](#) to create a bounding volume that corresponds to the space visible to the camera. You create a bounding frustum from the combined view and projection matrix that the camera is using currently. If the camera moves or rotates, you need to recreate the bounding frustum. The bounding frustum isn't used to determine when two objects collide, but rather when an object is in collision with the volume of space viewable by the camera. Objects that do not intersect and are not contained by the bounding frustum are not visible to the camera and don't need to be drawn. For complex models, this can save the graphics card a lot of work.

BoundingBox Members

The following tables list the members exposed by the BoundingBox type.

Public Constructors

	Name	Description
	BoundingBox	Creates a new instance of BoundingBox .

Public Fields

	Name	Description
	Center	The center point of the sphere.
	Radius	The radius of the sphere.

Public Methods

	Name	Description
	Contains	Overloaded. Checks whether the current BoundingBox contains a specified bounding volume.
 	CreateFromBoundingBox	Overloaded. Creates the smallest BoundingBox that can contain a specified BoundingBox .
 	CreateFromFrustum	Creates the smallest BoundingBox that can contain a specified BoundingFrustum .
 	CreateFromPoints	Creates a BoundingBox that can contain a specified list of points.
 	CreateMerged	Overloaded. Creates a BoundingBox that contains the two specified BoundingBox instances.
	Equals	Overloaded. Determines whether two instances of BoundingBox are equal.
	GetHashCode	Gets the hash code for this instance.
	GetType	(Inherited from Object .)
	Intersects	Overloaded. Checks whether the current BoundingBox intersects another bounding volume.
 	op_Equality	Determines whether two instances of BoundingBox are equal.
 	op_Inequality	Determines whether two instances of BoundingBox are not equal.
	ReferenceEquals	(Inherited from Object .)
	ToString	Returns a String that represents the current BoundingBox .
	Transform	Overloaded. Translates and scales the BoundingBox using a given Matrix .

Protected Methods

	Name	Description
	Finalize	(Inherited from Object .)
	MemberwiseClone	(Inherited from Object .)

```

Parameters

a

The object to the left of the equality operator.

b

The object to the right of the equality operator.

Return Value

true if *left* is equal to *right*; **false** otherwise.

Parameters

matrix

A transformation matrix that might include translation, rotation, or uniform scaling. Note that [BoundingBox.Transform](#) will not return correct results if there are non-uniform scaling, shears, or other unusual transforms in this transformation matrix. This is because there is no way to shear or non-uniformly scale a sphere. Such an operation would cause the sphere to lose its shape as a sphere.

Curve Class

Stores an arbitrary collection of 2D [CurveKey](#) points, and provides methods for evaluating features of the curve they define.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
[TypeConverterAttribute(System.ComponentModel.ExpandableObjectConverter, System, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089)]
[SerializableAttribute]
public class Curve
```

Remarks

The [Curve](#) class describes how two [float](#) values vary with respect to each other even when you cannot easily define their relationship by a formula. Instead, the relationship is defined by an ordered set of value pairs that exemplify it.

You specify a [Curve](#) by adding a sequence of [CurveKey](#) objects to its [Keys](#) collection, each of which must contain at minimum a [Position](#) greater than that of the preceding [CurveKey](#), and a corresponding [Value](#). In practice, the [Position](#) is almost always used to represent a point in time, while the [Value](#) property generally represents a coordinate value corresponding to that point in time.

To represent a time path in two or three dimensions, you can define two or three [Curve](#) objects, each of which corresponds to a different spatial axis. Coordinates of a given time's point on the resulting 2D or 3D curve are calculated very efficiently.

The [Curve.Evaluate](#) method returns a (coordinate) value corresponding to a (time) position that you specify. The position doesn't have to be contained in any of the [CurveKey](#) points, because [Curve](#) interpolates between points depending on the [CurveKey](#) characteristics you have defined.

Not only is [Curve](#) useful for controlling animation and spatial motion, it can also be used anywhere you want to define a response that changes over time. For example, if you are using a button to accelerate a car in your game, you might want to define a complex velocity curve that varies with how long the button is held down to simulate gear shifts.

A [CurveKey](#) point need not always be part of a smoothly varying curve; you can also set a [CurveKey](#) to represent a step or sharp inflection point.

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static bool op_Inequality (  
    CurveKey a,  
    CurveKey b  
)
```

Parameters

a

[CurveKey](#) on the left of the equal sign.

b

[CurveKey](#) on the right of the equal sign.

Return Value

true /> if the [CurveKeys](#) are not equal; **false** otherwise.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public enum CurveLoopType
```

Members

Member name	Description
Constant	The Curve will evaluate to its first key for positions before the first point in the Curve and to the last key for positions after the last point.
Cycle	Positions specified past the ends of the curve will wrap around to the opposite side of the Curve .
CycleOffset	Positions specified past the ends of the curve will wrap around to the opposite side of the Curve . The value will be offset by the difference between the values of the first and last CurveKey multiplied by the number of times the position wraps around. If the position is before the first point in the Curve , the difference will be subtracted from its value; otherwise, the difference will be added.
Linear	Linear interpolation will be performed to determine the value.
Oscillate	Positions specified past the ends of the Curve act as an offset from the same side of the Curve toward the opposite side.

```

Parameters

gameTime

Time passed since the last call to **Draw**.

Remarks

⚠Caution

In the **Draw** method of an Xbox 360 game, vertex buffers, index buffers, and textures should not be written using **SetData** when they are intended to be used for rendering. This condition may lead to graphics corruption or crashes. To avoid this potential issue, use [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#) as the preferred alternative to [VertexBuffer.SetData](#) for dynamic vertex generation.

There is a good reason why you should use [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#). In cases where the size of the back buffer and depth stencil buffer exceed the size of the Xbox 360 10 MB of embedded memory (EDRAM), [predicated tiling](#) is used on this platform to compensate for the additional memory requirements. Predicated tiling is a process by which scene rendering is performed multiple times on subsections of the final render target dimensions.

When predicated tiling has been triggered, the drawing commands contained in the **Draw** function are not submitted until [Present](#) is called. (Note that **Draw** implicitly calls [Present](#) at the end of this method.) In this case, these resources are not available for modification until the GPU is finished with presenting the entire frame.

public override void Initialize ()
```

Exceptions

Exception type	Condition
InvalidOperationException	There is no IGraphicsDeviceService available in the GameServiceContainer that this DrawableGameComponent is associated with. Usually this means there is no GraphicsDeviceManager associated with the services of a Game .

Remarks

Game services are a mechanism for maintaining loose coupling between objects that need to interact with each other. Services work through a mediator—in this case, [Game.Services](#). Service providers register with [Game.Services](#), and service consumers request services from [Game.Services](#). This arrangement allows an object that requires a service to request the service without knowing the name of the service provider.

Game services are defined by an interface. A class specifies the services it provides by implementing interfaces and registering the services with [Game.Services](#). A service is registered by calling [Game.Services.AddService](#) specifying the type of service being implemented and a reference to the object providing the service. For example, to register an object that provides a service represented by the interface [IMyService](#), you would use the following code.

```
Services.AddService( typeof( IMyService ), myobject );
```

Once a service is registered, the object providing the service can be retrieved by [Game.Services.GetService](#) and specifying the desired service. For example, to retrieve [IGraphicsDeviceService](#), you would use the following code.

```
IGraphicsDeviceService graphicservice = (IGraphicsDeviceService)Services.GetService( typeof(IGraphicsDeviceService) );
```

DrawableGameComponent.LoadGraphicsContent Method

Obsolete. Called when the component needs to load graphics resources. Override this method to load any component-specific graphics resources.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void LoadGraphicsContent (
    bool loadAllContent
)
```

Parameters

loadAllContent

true if all graphics resources need to be loaded; **false** if only manual resources need to be loaded.

Remarks

Note

This method is obsolete in XNA Game Studio 2.0. Override [LoadContent](#) to load graphics resources.

DrawableGameComponent.DrawOrder Property

Order in which the component should be drawn, relative to other components that are in the same [GameComponentCollection](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public int DrawOrder { get; set; }
```

Property Value

Order in which the component should be drawn.

Remarks This value can be any integer. Components in the [GameComponentCollection](#) are drawn in ascending order based on their **DrawOrder**.

Example

In this example, the three components are added to a [GameComponentCollection](#), and the **DrawOrder** of each component is explicitly set to control the drawing order of each component regardless of the order it was added to the [GameComponentCollection](#). **MyDrawableGameComponent** is a class which derives from [DrawableGameComponent](#), and **game** is an instance of [Game](#).

```
MyDrawableGameComponent thirdGameComponent = new MyDrawableGameComponent(game);  
d3.DrawOrder = 3;  
game.Components.Add(d3);
```

```
MyDrawableGameComponent firstGameComponent = new MyDrawableGameComponent(game);  
d1.DrawOrder = 1;  
game.Components.Add(d1);
```

```
MyDrawableGameComponent secondGameComponent = new MyDrawableGameComponent(game);  
d2.DrawOrder = 2;  
game.Components.Add(d2);
```

Game Members

The following tables list the members exposed by the Game type.

Public Constructors

Name	Description
 Game	Initializes a new instance of this class, which provides basic graphics device initialization, game logic, rendering code, and a game loop.

Public Properties

Name	Description
 Components	Gets the collection of GameComponents owned by the game.
 Content	Gets or sets the current ContentManager .
 GraphicsDevice	Gets the current GraphicsDevice .
 InactiveSleepTime	Gets or sets the time to sleep when the game is inactive.
 IsActive	Indicates whether the game is currently the active application.
 IsFixedTimeStep	Gets or sets a value indicating whether to use fixed time steps.
 IsMouseVisible	Gets or sets a value indicating whether the mouse cursor should be visible.
 Services	Gets the GameServiceContainer holding all the service providers attached to the Game .
 TargetElapsedTime	Gets or sets the target time between calls to Update when IsFixedTimeStep is true.
 Window	Gets the underlying operating system window.

Public Methods

Name	Description
 Dispose	Overloaded. Immediately releases the unmanaged resources used by this object.
 Equals	(Inherited from Object .)
 Exit	Exits the game.
 GetHashCode	(Inherited from Object .)
 GetType	(Inherited from Object .)
 ReferenceEquals	(Inherited from Object .)
 ResetElapsedTime	Resets the elapsed time counter.
 Run	Call this method to initialize the game, begin running the game loop, and start processing events for the game.
 SuppressDraw	Prevents calls to Draw until the next Update .
 Tick	Updates the game's clock and calls Update and Draw .
 ToString	(Inherited from Object .)

Protected Methods

Name	Description
 BeginDraw	Starts the drawing of a frame. This method is followed by calls to Draw and EndDraw .
 BeginRun	Called after all components are initialized but before the first update in the game loop.
 Draw	Called when the game determines it is time to draw a frame.
 EndDraw	Ends the drawing of a frame. This method is preceded by calls to Draw and BeginDraw .
 EndRun	Called after the game loop has stopped running before exiting.
 Finalize	Allows a Game to attempt to free resources and perform other cleanup operations before garbage collection reclaims the Game .
 Initialize	Called after the Game and GraphicsDevice are created, but before LoadContent .
 LoadContent	Called when graphics resources need to be loaded.
 LoadGraphicsContent	Obsolete. Called when graphics resources need to be loaded. Override this method to load any game-specific graphics resources.
 MemberwiseClone	(Inherited from Object .)
 OnActivated	Raises the Activated event. Override this method to add code to handle when the game gains focus.
 OnDeactivated	Raises the Deactivated event. Override this method to add code to handle when the game loses focus.

 OnExiting	Raises an Exiting event. Override this method to add code to handle when the game is exiting.
 ShowMissingRequirementMessage	This is used to display an error message if there is no suitable graphics device or sound card.
 UnloadContent	Called when graphics resources need to be unloaded. Override this method to unload any game-specific graphics resources.
 UnloadGraphicsContent	Obsolete. Called when graphics resources need to be unloaded. Override this method to unload any game-specific graphics resources.
 Update	Called when the game has determined that game logic needs to be processed.

Public Events

	Name	Description
	Activated	Raised when the game gains focus.
	Deactivated	Raised when the game loses focus.
	Disposed	Raised when the game is being disposed.
	Exiting	Raised when the game is exiting.

Game Constructor

Initializes a new instance of this class, which provides basic graphics device initialization, game logic, rendering code, and a game loop.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public Game ()
```

Remarks

Although the [GraphicsDeviceManager](#) constructor requires an instance of [Game](#), if the application does not otherwise require an instance of [Game](#) it is often more desirable to implement the [IGraphicsDeviceService](#) interface to provide the same services that would be provided by the [GraphicsDeviceManager](#).

Similarly, when creating a new [ContentManager](#), if no instance of [Game](#) is otherwise required by the application, it is often more desirable to create a new class that implements the [IServiceProvider](#) interface rather than creating an instance of [Game](#) just to create a new instance of [GraphicsDeviceManager](#).

Example

```
/// <summary>
/// The main entry point for the application.
/// </summary>
static void Main(string[] args)
{
    using (Game1 game = new Game1())
    {
        game.Run();
    }
}

Game.Dispose Method (Boolean)

Releases all resources used by the [Game](#) class.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void Dispose (  
    bool disposing  
)
```

Parameters

disposing

true to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

This method is called by the public [Dispose](#) method and the [Finalize](#) method. [Dispose](#) invokes the protected [Dispose\(Boolean\)](#) method with the *disposing* parameter set to **true**. [Finalize](#) invokes [Dispose\(Boolean\)](#) with *disposing* set to **false**.

When the *disposing* parameter is **true**, this method releases all resources held by any managed objects that this [Game](#) references. This method invokes the [Dispose](#) method of each referenced object.

Note

Notes to Inheritors

[Dispose](#) can be called multiple times by other objects. When overriding [Dispose\(Boolean\)](#), be careful not to reference objects disposed of in an earlier call to [Dispose](#).

Game.Draw Method

Called when the game determines it is time to draw a frame. Override this method with game-specific rendering code.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void Draw (
    gameTime
```

Parameters

gameTime

Time passed since the last call to **Draw**.

Remarks

[Update](#) and [Draw](#) are called at different rates depending on whether [IsFixedTimeStep](#) is **true** or **false**. If [IsFixedTimeStep](#) is **false**, [Update](#) and [Draw](#) will be called sequentially as often as possible. If [IsFixedTimeStep](#) is **true**, [Update](#) will be called at the interval specified in [TargetElapsedTime](#), while [Draw](#) will continue to be called as often as possible. For more information on fixed-step and variable-step game loops, see [Application Model Overview](#).

⚠Caution

In the **Draw** method of an Xbox 360 game, vertex buffers, index buffers, and textures should not be written using **SetData** when they are intended to be used for rendering. This condition may lead to graphics corruption or crashes. To avoid this potential issue, use [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#) as the preferred alternative to [VertexBuffer.SetData](#) for dynamic vertex generation.

There is a good reason why you should use [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#). In cases where the size of the back buffer and depth stencil buffer exceed the size of the Xbox 360 10 MB of embedded memory (EDRAM), [predicated tiling](#) is used on this platform to compensate for the additional memory requirements. Predicated tiling is a process by which scene rendering is performed multiple times on subsections of the final render target dimensions.

When predicated tiling has been triggered, the drawing commands contained in the **Draw** function are not submitted until [Present](#) is called. (Note that **Draw** implicitly calls [Present](#) at the end of this method.) In this case, these resources are not available for modification until the GPU is finished with presenting the entire frame.

Example

In classes that derive from [Game](#), it is necessary to make these calls:

- Call base.**Draw** in **Draw** to enumerate through any graphics components that have been added to [Components](#). This method will automatically call the [Initialize](#) method for every component that has been added to the collection.

```
protected override void Draw( gameTime )
{
    base.Draw( gameTime );
}
```

Game.Initialize Method

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void Initialize ()
```

Remarks

Override this method to query for any required services, and load any non-graphics resources. Use [LoadContent](#) to load graphics resources.

Initialize is called before [Draw](#), so the length of time spent executing code in this method will be experienced by the user as a delay before he or she sees the initial game screen.

Example

In classes that derive from [Game](#), you need to call base.**Initialize** in **Initialize**, which will automatically enumerate through any game components that have been added to [Game.Components](#) and call their [Initialize](#) methods.

```
protected override void Initialize()  
{  
    base.Initialize();  
}

Remarks

This method is called by [Initialize](#). Also, it is called any time the game content needs to be reloaded, such as when the [DeviceReset](#) event occurs. You should not access the [GraphicsDevice](#) until [LoadContent](#) is called.

LoadContent is called by [Initialize](#), and before [Draw](#). During the time the code for this method is executing, the user will experience a delay before the initial game screen appears.

Raises the [Deactivated](#) event. Override this method to add code to handle when the game loses focus.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void OnDeactivated (  
    Object sender,  
    EventArgs args  
)
```

Parameters

sender

The [Game](#).

args

Arguments for the [Deactivated](#) event.

Remarks The **OnDeactivated** method allows derived classes to handle the [Deactivated](#) event without attaching a delegate. This is the preferred technique for handling the event in a derived class.

```

Parameters

sender

The [Game](#).

args

Arguments for the [Exiting](#) event.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public void Run ()
```

Exceptions

Game.ShowMissingRequirementMessage Method

This is used to display an error message if there is no suitable graphics device or sound card.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
protected virtual bool ShowMissingRequirementMessage (  
    Exception exception  
)
```

Parameters

exception

The exception to display.

Return Value

true if an error was displayed, otherwise **false**.

Remarks

Xbox 360 Specific Information

On the Xbox 360 platform, this method will not display a message box and return immediately.

Zune Specific Information

On the Zune platform, this method will not display a message box and return immediately.

Games are not expected to call this method directly. This method will be called automatically if the game throws an unhandled exception of type [NoSuitableGraphicsDeviceException](#) or [NoAudioHardwareException](#). You may override this method to add messages for additional exception types, or to provide localized versions of the error message text.

Game.SuppressDraw Method

Prevents calls to [Draw](#) until the next [Update](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```

```

Remarks

Call this method during [Update](#) to prevent any calls to [Draw](#) until after the next call to [Update](#). This method can be used on small devices to conserve battery life if the display does not change as a result of [Update](#). For example, if the screen is static with no background animations, the player input can be examined during [Update](#) to determine whether the player is performing any action. If no input is detected, this method allows the game to skip drawing until the next update.

Game.Update Method

Called when the game has determined that game logic needs to be processed. This might include the management of the game state, the processing of user input, or the updating of simulation data. Override this method with game-specific logic.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void Update (  
    gameTime  
)
```

Parameters

gameTime

Time passed since the last call to **Update**.

Remarks

★ Best Practice

When updating the game state, you can examine [SignedInGamer.GameDefaults](#) to determine a player's preferences for settings such as game difficulty and controller sensitivity.

[Update](#) and [Draw](#) are called at different rates depending on whether [IsFixedTimeStep](#) is **true** or **false**. If [IsFixedTimeStep](#) is **false**, [Update](#) and [Draw](#) will be called in a continuous loop. If [IsFixedTimeStep](#) is **true**, [Update](#) will be called at the interval specified in [TargetElapsedTime](#), while [Draw](#) will only be called if an [Update](#) is not due. If [Draw](#) is not called, [IsRunningSlowly](#) will be set to **true**.

Game.Components Property

Gets the collection of [GameComponents](#) owned by the game.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public GameComponentCollection Components { get; }
```

Property Value

The collection of game [GameComponents](#).

Remarks

Game components provide a modular way of adding functionality to a game. You create a game component by deriving the new component either from the [GameComponent](#) class, or, if the component loads and draws graphics content, from the [DrawableGameComponent](#) class. You then add game logic and rendering code to the game component by overriding [GameComponent.Update](#), [DrawableGameComponent.Draw](#) and [GameComponent.Initialize](#). A game component is registered with a game by passing the component to [Game.Components.Add](#). A registered component will have its draw, update, and initialize methods called from the [Game.Initialize](#), [Game.Update](#), and [Game.Draw](#) methods.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```

Property Value

true if the game is active; **false** otherwise.

Remarks

On Windows, a game is active if it is not minimized and has the current input focus. On Xbox 360, the game is active if the user is not interacting with the Guide or Dashboard.

★Best Practice

It is generally a good idea to pause the game when [Game.IsActive](#) is **false**.

Game.IsFixedTimeStep Property

Gets or sets a value indicating whether to use fixed time steps.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public bool IsFixedTimeStep { get; set; }
```

Property Value

true if using fixed time steps; **false** otherwise.

Remarks

The default value for [IsFixedTimeStep](#) is **true**.

A fixed-step [Game](#) tries to call its [Update](#) method on the fixed interval specified in [TargetElapsedTime](#). Setting [Game.IsFixedTimeStep](#) to **true** causes a [Game](#) to use a fixed-step game loop. A new XNA project uses a fixed-step game loop with a default [TargetElapsedTime](#) of 1/60th of a second.

In a fixed-step game loop, [Game](#) calls [Update](#) once the [TargetElapsedTime](#) has elapsed. After [Update](#) is called, if it is not time to call [Update](#) again, [Game](#) calls [Draw](#). After [Draw](#) is called, if it is not time to call [Update](#) again, [Game](#) idles until it is time to call [Update](#).

If [Update](#) takes too long to process, [Game](#) sets [IsRunningSlowly](#) to **true** and calls [Update](#) again, without calling [Draw](#) in between. When an update runs longer than the [TargetElapsedTime](#), [Game](#) responds by calling [Update](#) extra times and dropping the frames associated with those updates to catch up. This ensures that [Update](#) will have been called the expected number of times when the game loop catches up from a slowdown. You can check the value of [IsRunningSlowly](#) in your [Update](#) if you want to detect dropped frames and shorten your [Update](#) processing to compensate. You can reset the elapsed times by calling [ResetElapsedTime](#).

When your game pauses in the debugger, [Game](#) will not make extra calls to [Update](#) when the game resumes.

Game.Services Property

Gets the [GameServiceContainer](#) holding all the service providers attached to the [Game](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public GameServiceContainer Services { get; }
```

Property Value

The [GameServiceContainer](#) holding all the service providers attached to the [Game](#).

Remarks

Game services are a mechanism for maintaining loose coupling between objects that need to interact with each other. Services work through a mediator—in this case, [Game.Services](#). Service providers register with [Game.Services](#), and service consumers request services from [Game.Services](#). This arrangement allows an object that requires a service to request the service without knowing the name of the service provider.

Game services are defined by an interface. A class specifies the services it provides by implementing interfaces and registering the services with [Game.Services](#). A service is registered by calling [Game.Services.AddService](#) specifying the type of service being implemented and a reference to the object providing the service. For example, to register an object that provides a service represented by the interface `IMyService`, you would use the following code.

```
Services.AddService( typeof( IMyService ), myobject );
```

Once a service is registered, the object providing the service can be retrieved by [Game.Services.GetService](#) and specifying the desired service. For example, to retrieve [IGraphicsDeviceService](#), you would use the following code.

```
IGraphicsDeviceService graphicservice = (IGraphicsDeviceService)Services.GetService( t  
ypeof(IGraphicsDeviceService) );
```

Gets or sets the target time between calls to [Update](#) when [IsFixedTimeStep](#) is **true**.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public TimeSpan TargetElapsedTime { get; set; }
```

Property Value

The target time period for the game loop.

Exceptions

Exception type	Condition
ArgumentOutOfRangeException	The value specified for <i>TargetElapsedTime</i> is not greater than zero. Specify a nonzero positive value.

Remarks

When the game framerate is less than **TargetElapsedTime**, [IsRunningSlowly](#) will return **true**.

The default value for [TargetElapsedTime](#) is 1/60th of a second.

A fixed-step [Game](#) tries to call its [Update](#) method on the fixed interval specified in [TargetElapsedTime](#). Setting [Game.IsFixedTimeStep](#) to **true** causes a [Game](#) to use a fixed-step game loop. A new XNA project uses a fixed-step game loop with a default [TargetElapsedTime](#) of 1/60th of a second.

In a fixed-step game loop, [Game](#) calls [Update](#) once the [TargetElapsedTime](#) has elapsed. After [Draw](#) is called, if it is not time to call [Update](#) again, [Game](#) idles until it is time to call [Update](#).

Public Constructors

Name	Description
 GameComponent	Initializes a new instance of this class.

Public Properties

Name	Description
 Enabled	Indicates whether GameComponent.Update should be called when Game.Update is called.
 Game	Gets the Game associated with this GameComponent .
 UpdateOrder	Indicates the order in which the GameComponent should be updated relative to other GameComponent instances. Lower values are updated first.

Public Methods

Name	Description
 Dispose	Overloaded. Immediately releases the unmanaged resources used by this object.
 Equals	(Inherited from Object .)
 GetHashCode	(Inherited from Object .)
 GetType	(Inherited from Object .)
 Initialize	Called when the GameComponent needs to be initialized.
 ReferenceEquals	(Inherited from Object .)
 ToString	(Inherited from Object .)
 Update	Called when the GameComponent needs to be updated. Override this method with component-specific update code.

Protected Methods

Name	Description
 Finalize	Allows a GameComponent to attempt to free resources and perform other cleanup operations before garbage collection reclaims the GameComponent .
 MemberwiseClone	(Inherited from Object .)
 OnEnabledChanged	Called when the Enabled property changes. Raises the EnabledChanged event.
 OnUpdateOrderChanged	Called when the UpdateOrder property changes. Raises the UpdateOrderChanged event.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public GameComponent (  
    Game game  
)
```

Parameters

game

Game that the game component should be attached to.

Remarks

Game components provide a modular way of adding functionality to a game. You create a game component by deriving the new component either from the [GameComponent](#) class, or, if the component loads and draws graphics content, from the [DrawableGameComponent](#) class. You then add game logic and rendering code to the game component by overriding [GameComponent.Update](#), [DrawableGameComponent.Draw](#) and [GameComponent.Initialize](#). A game component is registered with a game by passing the component to [Game.Components.Add](#). A registered component will have its draw, update, and initialize methods called from the [Game.Initialize](#), [Game.Update](#), and [Game.Draw](#) methods.

GameComponent.Dispose Method ()

Immediately releases the unmanaged resources used by this object.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void Dispose (  
    bool disposing  
)
```

Parameters

disposing

true to release both managed and unmanaged resources; **false** to release only unmanaged resources.

GameComponent.Finalize Method

Allows a [GameComponent](#) to attempt to free resources and perform other cleanup operations before garbage collection reclaims the [GameComponent](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected override void Finalize ()
```

Remarks

This method overrides [System.Object.Finalize](#). Application code should not call this method; an object's [Finalize](#) method is automatically invoked during garbage collection.

GameComponent.Initialize Method

Called when the [GameComponent](#) needs to be initialized. Override this method to query for required services and load any non-graphics resources.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public virtual void Initialize ()
```

Remarks If this [GameComponent](#) has been added to the [Game.Components](#) collection, this method will be called automatically if you call **base.Initialize** in your [Game.Initialize](#) method. Note that the template code created by XNA Game Studio will already have this call to **base.Initialize** in place.

Example

In classes that derive from [Game](#), it is necessary to call **base.Initialize** in [Game.Initialize](#), which will automatically enumerate through any game components that have been added to [Game.Components](#) and call their [Initialize](#) methods.

```
protected override void Initialize()  
{  
    base.Initialize();  
}
```

GameServiceContainer Class

A collection of game services.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public class GameServiceContainer : IServiceProvider
```

Remarks

Game services are a mechanism for maintaining loose coupling between objects that need to interact with each other. Services work through a mediator—in this case, [Game.Services](#). Service providers register with [Game.Services](#), and service consumers request services from [Game.Services](#). This arrangement allows an object that requires a service to request the service without knowing the name of the service provider.

Game services are defined by an interface. A class specifies the services it provides by implementing interfaces and registering the services with [Game.Services](#). A service is registered by calling [Game.Services.AddService](#) specifying the type of service being implemented and a reference to the object providing the service. For example, to register an object that provides a service represented by the interface `IMyService`, you would use the following code.

```
Services.AddService( typeof( IMyService ), myobject );
```

Once a service is registered, the object providing the service can be retrieved by [Game.Services.GetService](#) and specifying the desired service. For example, to retrieve [IGraphicsDeviceService](#), you would use the following code.

```
IGraphicsDeviceService graphicservice = (IGraphicsDeviceService)Services.GetService( t  
typeof(IGraphicsDeviceService) );
```

Exceptions

Exception type	Condition
ArgumentNullException	The <i>type</i> parameter is null .

Remarks

Game services are a mechanism for maintaining loose coupling between objects that need to interact with each other. Services work through a mediator—in this case, [Game.Services](#). Service providers register with [Game.Services](#), and service consumers request services from [Game.Services](#). This arrangement allows an object that requires a service to request the service without knowing the name of the service provider.

Game services are defined by an interface. A class specifies the services it provides by implementing interfaces and registering the services with [Game.Services](#). A service is registered by calling [Game.Services.AddService](#) specifying the type of service being implemented and a reference to the object providing the service. For example, to register an object that provides a service represented by the interface `IMyService`, you would use the following code.

```
Services.AddService( typeof( IMyService ), myobject );
```

Once a service is registered, the object providing the service can be retrieved by [Game.Services.GetService](#) and specifying the desired service. For example, to retrieve [IGraphicsDeviceService](#), you would use the following code.

```
IGraphicsDeviceService graphicservice = (IGraphicsDeviceService)Services.GetService( t
ypeof(IGraphicsDeviceService) );
```

GameTime.ElapsedGameTime Property

The amount of elapsed game time since the last update.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public TimeSpan ElapsedGameTime { get; set; }
```

Property Value

Elapsed game time since the last update.

RemarksFixed-step clocks update by a fixed time span upon every clock step. This results in uniform clock steps that may not actually track the wall clock time. Fixed-step clocks were popular on console systems where one had tight control over code and a fixed system performance. Fixed-step clocks are also useful when trying to achieve deterministic updates for debugging, offline rendering, or other such scenarios.

```

Parameters

obj

The [Object](#) to compare with the current [GraphicsDeviceInformation](#).

Return Value

true if the objects are the same; **false** otherwise.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public class GraphicsDeviceManager : IGraphicsDeviceService, IDisposable, IGraphicsDeviceMa  
nager
```

Remarks

Custom behavior of the [GraphicsDeviceManager](#) can be achieved by deriving a class from [GraphicsDeviceManager](#). For example, to allow only widescreen devices in full-screen mode the [RankDevices](#) method could be overridden to drop non-widescreen devices (see [How To: Restrict Graphics Devices to Widescreen Aspect Ratios in Full-Screen Mode](#)).

Or, if you are creating a 2D game, you might want to create a graphics device without a depth buffer. By adding an event handler for the [PreparingDeviceSettings](#) event to the [GraphicsDeviceManager](#), you can control the [PresentationParameters](#) properties associated with the graphics device. In the example below, the event handler is named **graphics_Settings_NoDepthBuffer**.

C#

```
graphics = new GraphicsDeviceManager(this);  
graphics.PreparingDeviceSettings +=  
    new EventHandler<PreparingDeviceSettingsEventArgs>(graphics_Settings_NoDepthBuffer);
```

To ensure that no depth buffer is created, your event handler can set the [EnableAutoDepthStencil](#) property of the graphic device's [PresentationParameters](#) to **false**, as shown below.

C#

```
void graphics_Settings_NoDepthBuffer(object sender,  
    PreparingDeviceSettingsEventArgs e)  
{  
    e.GraphicsDeviceInformation.PresentationParameters.  
        EnableAutoDepthStencil = false;  
}
```

GraphicsDeviceManager Members

The following tables list the members exposed by the GraphicsDeviceManager type.

Public Constructors

Name	Description
 GraphicsDeviceManager	Creates a new GraphicsDeviceManager and registers it to handle the configuration and management of the graphics device for the specified Game .

Public Fields

Name	Description
 DefaultBackBufferHeight	Specifies the default minimum back-buffer height.
 DefaultBackBufferWidth	Specifies the default minimum back-buffer width.
 ValidAdapterFormats	Specifies the set of adapter formats supported by the GraphicsDeviceManager .
 ValidBackBufferFormats	Specifies the set of back-buffer formats supported by the GraphicsDeviceManager .
 ValidDeviceTypes	Specifies the set of valid device types supported by the GraphicsDeviceManager .

Public Properties

Name	Description
 GraphicsDevice	Gets the GraphicsDevice associated with the GraphicsDeviceManager .
 IsFullScreen	Gets or sets a value that indicates whether the device should start in full-screen mode.
 MinimumPixelShaderProfile	Gets or sets the minimum pixel shader version required by the GraphicsDeviceManager .
 MinimumVertexShaderProfile	Gets or sets the minimum vertex shader version required by the GraphicsDeviceManager .
 PreferMultiSampling	Gets or sets a value that indicates whether to enable a multisampled back buffer.
 PreferredBackBufferFormat	Gets or sets the format of the back buffer.
 PreferredBackBufferHeight	Gets or sets the preferred back-buffer height.
 PreferredBackBufferWidth	Gets or sets the preferred back-buffer width.
 PreferredDepthStencilFormat	Gets or sets the format of the depth stencil.
 SynchronizeWithVerticalTrace	Gets or sets a value that indicates whether to sync to the vertical trace (vsync) when presenting the back buffer.

Public Methods

Name	Description
 ApplyChanges	Applies any changes to device-related properties, changing the graphics device as necessary.
 Equals	(Inherited from Object .)
 GetHashCode	(Inherited from Object .)
 GetType	(Inherited from Object .)
 ReferenceEquals	(Inherited from Object .)
 ToggleFullScreen	Toggles between full screen and windowed mode.
 ToString	(Inherited from Object .)

Protected Methods

Name	Description
 CanResetDevice	Determines whether the given GraphicsDeviceInformation is compatible with the existing graphics device.
 Dispose	Releases the unmanaged resources used by the GraphicsDeviceManager and optionally releases the managed resources.
 Finalize	(Inherited from Object .)
 FindBestDevice	Finds the best device configuration that is compatible with the current device preferences.
 MemberwiseClone	(Inherited from Object .)
 OnDeviceCreated	Called when a device is created. Raises the DeviceCreated event.
 OnDeviceDisposing	Called when a device is being disposed. Raises the DeviceDisposing event.
 OnDeviceReset	Called when the device has been reset. Raises the DeviceReset event.

 OnDeviceResetting	Called when the device is about to be reset. Raises the DeviceResetting event.
 OnPreparingDeviceSettings	Called when the GraphicsDeviceManager is changing the GraphicsDevice settings (during reset or recreation of the GraphicsDevice). Raises the PreparingDeviceSettings event.
 RankDevices	Ranks the given list of devices that satisfy the given preferences.

Public Events

Name	Description
 DeviceCreated	Raised when a new graphics device is created.
 DeviceDisposing	Raised when the GraphicsDeviceManager is being disposed.
 DeviceReset	Raised when the GraphicsDeviceManager is reset.
 DeviceResetting	Raised when the GraphicsDeviceManager is about to be reset.
 Disposed	Raised when the GraphicsDeviceManager is disposed.
 PreparingDeviceSettings	Raised when the GraphicsDeviceManager is changing the GraphicsDevice settings (during reset or recreation of the GraphicsDevice).

Explicit Interface Implementations

Name	Description
 Microsoft.Xna.Framework.GraphicsDeviceManager.BeginDraw	Prepares the GraphicsDevice to draw.
 Microsoft.Xna.Framework.GraphicsDeviceManager.CreateDevice	Called to ensure that the device manager has created a valid device.
 System.IDisposable.Dispose	Releases all resources used by the GraphicsDeviceManager class.
 Microsoft.Xna.Framework.GraphicsDeviceManager.EndDraw	Called by the game at the end of drawing and presents the final rendering.

GraphicsDeviceManager Constructor

Creates a new [GraphicsDeviceManager](#) and registers it to handle the configuration and management of the graphics device for the specified [Game](#).

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
public GraphicsDeviceManager (
    Game game
)
```

Parameters

game

[Game](#) the [GraphicsDeviceManager](#) should be associated with.

Exceptions

Exception type	Condition
ArgumentNullException	The <i>game</i> parameter is null .
ArgumentException	A graphics device manager has already been added to Services and registered as the graphics device manager for the application. The graphics device manager cannot be changed once it is set.

Remarks

This constructor adds this [GraphicsDeviceManager](#) to the collection of game services that have been implicitly registered by adding them to the [Game.Services](#) property.

⚠ Caution

Although this constructor requires an instance of [Game](#), if the application does not otherwise require an instance of [Game](#) it is often better to implement a the [IGraphicsDeviceService](#) and [IGraphicsDeviceManager](#) interfaces to provide the same services that would be provided by the [GraphicsDeviceManager](#).

Custom behavior of the [GraphicsDeviceManager](#) can be achieved by deriving a class from [GraphicsDeviceManager](#). For example, to allow only widescreen devices in full-screen mode the [RankDevices](#) method could be overridden to drop non-widescreen devices (see [How To: Restrict Graphics Devices to Widescreen Aspect Ratios in Full-Screen Mode](#)).

Or, if you are creating a 2D game, you might want to create a graphics device without a depth buffer. By adding an event handler for the [PreparingDeviceSettings](#) event to the [GraphicsDeviceManager](#), you can control the [PresentationParameters](#) properties associated with the graphics device. In the example below, the event handler is named **graphics_Settings_NoDepthBuffer**.

C#

```
graphics = new GraphicsDeviceManager(this);
graphics.PreparingDeviceSettings +=
    new EventHandler<PreparingDeviceSettingsEventArgs>(
        graphics_Settings_NoDepthBuffer);
```

To ensure that no depth buffer is created, your event handler can set the [EnableAutoDepthStencil](#) property of the graphic device's [PresentationParameters](#) to **false**, as shown below.

C#

```
void graphics_Settings_NoDepthBuffer(object sender,
    PreparingDeviceSettingsEventArgs e)
{
    e.GraphicsDeviceInformation.PresentationParameters.
        EnableAutoDepthStencil = false;
}
```

ArgumentException

Invalid arguments have been requested for the creation of the graphics device.

Invalid back buffer options have been requested:

- [BackBufferCount](#) is not between 0 and 3.
- [BackBufferFormat](#) is not valid. Try [SurfaceFormat.Bgr565](#), [SurfaceFormat.Bgr555](#), [SurfaceFormat.Bgra5551](#), [SurfaceFormat.Bgr32](#), [SurfaceFormat.Color](#), [SurfaceFormat.Bgra1010102](#).
- The selected [BackBufferFormat](#) and [IsFullScreen](#) values are not valid for the selected adapter format and device type.
- The [BackBufferWidth](#) and [BackBufferHeight](#) values do not correspond to a valid display mode.
- [FullScreenRefreshRateInHz](#) does not match a valid display mode for the specified [BackBufferWidth](#) and [BackBufferHeight](#).

Invalid [PresentationParameters.PresentationInterval](#) or [SwapEffect](#) options have been requested:

- On Xbox 360, [PresentationParameters.PresentationInterval](#) has been assigned the invalid value [PresentationInterval.Four](#).
- [SwapEffect.Copy](#) has been assigned to the [PresentationParameters.SwapEffect](#) property, but [BackBufferCount](#) is not 1. When using [SwapEffect.Copy](#), [BackBufferCount](#) must be 1.
- [SwapEffect](#) is not one of the following: [SwapEffect.Copy](#), [SwapEffect.Discard](#), or [SwapEffect.Flip](#).

Invalid multisampling options have been requested:

- Multisampling has been enabled, but [SwapEffect.Discard](#) has not been specified for the [SwapEffect](#) property. [SwapEffect.Discard](#) is required when enabling multisampling.
- The selected [MultiSampleType](#) is not compatible with the current [BackBufferFormat](#) and the [IsFullScreen](#) value for the selected adapter.
- The selected [MultiSampleQuality](#) value is invalid for the selected [MultiSampleType](#).

Invalid depth stencil options have been requested:

- [AutoDepthStencilFormat](#) is not supported as a depth/stencil format when using the selected adapter [BackBufferFormat](#).
- [PresentOptions](#) has been set to [PresentOptions.DiscardDepthStencil](#), but [EnableAutoDepthStencil](#) is not **true**.
- Multiple [PresentationParameters](#) have been specified and [EnableAutoDepthStencil](#) is **true**, but [EnableAutoDepthStencil](#), [BackBufferFormat](#), [BackBufferWidth](#), and [BackBufferHeight](#) are not the same for all adapters.

[IsFullScreen](#) is **true**, but:

- [BackBufferWidth](#) and [BackBufferHeight](#) are not nonzero.
- [PresentationInterval](#) is not one of the following: [PresentationInterval.Default](#), [PresentationInterval.Immediate](#), [PresentationInterval.One](#), [PresentationInterval.Two](#), [PresentationInterval.Three](#), or [PresentationInterval.Four](#).
- [FullScreenRefreshRateInHz](#) is not nonzero.
- The selected adapter does not support the selected full screen [PresentationInterval](#).

[IsFullScreen](#) is **false**, but:

- [PresentationInterval](#) is not one of the following: [PresentationInterval.Default](#), [PresentationInterval.Immediate](#), or [PresentationInterval.One](#).
- [FullScreenRefreshRateInHz](#) is not zero.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void OnPreparingDeviceSettings (

GraphicsDeviceManager.RankDevices Method

Ranks the given list of devices that satisfy the given preferences.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework.Game (in microsoft.xna.framework.game.dll)

Syntax

C#

```
protected virtual void RankDevices (  
    List<GraphicsDeviceInformation> foundDevices

```

Parameters

foundDevices

The list of devices to rank.

Remarks **RankDevices** orders the provided list so that devices earlier in the list are preferred over devices later in the list. This method can remove devices from the list if they do not satisfy some custom criteria.

Syntax

C#

```
public void Draw (  
    gameTime  
)
```

Parameters

gameTime

Snapshot of the game's timing state.

Remarks

⚠Caution

In the **Draw** method of an Xbox 360 game, vertex buffers, index buffers, and textures should not be written using **SetData** when they are intended to be used for rendering. This condition may lead to graphics corruption or crashes. To avoid this potential issue, use [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#) as the preferred alternative to [VertexBuffer.SetData](#) for dynamic vertex generation.

There is a good reason why you should use [DrawUserPrimitives](#) or [DrawUserIndexedPrimitives](#). In cases where the size of the back buffer and depth stencil buffer exceed the size of the Xbox 360 10 MB of embedded memory (EDRAM), [predicated tiling](#) is used on this platform to compensate for the additional memory requirements. Predicated tiling is a process by which scene rendering is performed multiple times on subsections of the final render target dimensions.

When predicated tiling has been triggered, the drawing commands contained in the **Draw** function are not submitted until [Present](#) is called. (Note that **Draw** implicitly calls [Present](#) at the end of this method.) In this case, these resources are not available for modification until the GPU is finished with presenting the entire frame.

MathHelper.Barycentric Method

Returns the Cartesian coordinate for one axis of a point that is defined by a given triangle and two normalized barycentric (areal) coordinates.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static float Barycentric (
    float value1,
    float value2,
    float value3,
    float amount1,
    float amount2
)
```

Parameters

value1

The coordinate on one axis of vertex 1 of the defining triangle.

value2

The coordinate on the same axis of vertex 2 of the defining triangle.

value3

The coordinate on the same axis of vertex 3 of the defining triangle.

amount1

The normalized barycentric (areal) coordinate **b2**, equal to the weighting factor for vertex 2, the coordinate of which is specified in *value2*.

amount2

The normalized barycentric (areal) coordinate **b3**, equal to the weighting factor for vertex 3, the coordinate of which is specified in *value3*.

Return Value

Cartesian coordinate of the specified point with respect to the axis being used.

Remarks

About Barycentric Coordinates

Given a triangle with vertices **V1**, **V2**, and **V3**, any point **P** on the plane of that triangle can be specified by three weighting factors **b1**, **b2**, and **b3**, each of which indicates how much relative influence the corresponding triangle vertex contributes to the location of the point, as specified in the following formulas.

$$\begin{aligned} P_x &= (b_1 * V_{1x}) + (b_2 * V_{2x}) + (b_3 * V_{3x}); \\ P_y &= (b_1 * V_{1y}) + (b_2 * V_{2y}) + (b_3 * V_{3y}); \\ P_z &= (b_1 * V_{1z}) + (b_2 * V_{2z}) + (b_3 * V_{3z}); \end{aligned}$$

Such triple-weighting factors **b1**, **b2**, and **b3** are called *barycentric coordinates*.

Barycentric coordinates express relative weights, meaning that **(k * b1)**, **(k * b2)**, and **(k * b3)** are also coordinates of the same point as **b1**, **b2**, and **b3** for any positive value of **k**.

If a set of barycentric coordinates is normalized so that **b1 + b2 + b3 = 1**, the resulting coordinates are unique for the point in question, and are known as *areal* coordinates. When normalized in this way, only two coordinates are needed, say **b2** and **b3**, since **b1** is known to equal **(1 - b2 - b3)**.

What MathHelper Barycentric Does

On an axis **a** (**a** being the x-, y-, or z-axis), the [MathHelper.Barycentric](#) method takes three triangle vertex coordinates on that axis (**V1a**, **V2a**, and **V3a**), and two areal coordinates **b2** and **b3** of some point **P** (**b2** is the *amount1* argument, and **b3** is the *amount2* argument). The **b2** coordinate relates to vertex **V2**, and the **b3** coordinate relates to **V3**.

[Barycentric](#) then calculates the Cartesian coordinate of **Pa** as follows:

$$Pa = ((1 - b2 - b3) * V1a) + (b2 * V2a) + (b3 * V3a);$$

Thus, to calculate the x-axis Cartesian coordinate of **P**, you would pass the x-coordinates of the triangle vertices to [Barycentric](#) together with the appropriate areal coordinates of **P**.

MathHelper.CatmullRom Method

Performs a Catmull-Rom interpolation using the specified positions.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static float CatmullRom (  
    float value1,  
    float value2,  
    float value3,  
    float value4,  
    float amount  
)
```

Parameters

value1

The first position in the interpolation.

value2

The second position in the interpolation.

value3

The third position in the interpolation.

value4

The fourth position in the interpolation.

amount

Weighting factor.

Return Value

A position that is the result of the Catmull-Rom interpolation.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static float Clamp (  
    float value,  
    float min,  
    float max  
)
```

Parameters

value

The value to clamp.

min

The minimum value. If *value* is less than *min*, *min* will be returned.

max

The maximum value. If *value* is greater than *max*, *max* will be returned.

Return Value

The clamped value.

- If $value > max$, *max* will be returned.
- If $value < min$, *min* will be returned.
- If $min \leq value \leq max$, *value* will be returned.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static float Lerp (  
    float value1,  
    float value2,  
    float amount  
)
```

Parameters

value1

Source value.

value2

Source value.

amount

Value between 0 and 1 indicating the weight of *value2*.

Return Value

Interpolated value.

Remarks

This method performs the linear interpolation based on the following formula.

$$\text{value1} + (\text{value2} - \text{value1}) * \text{amount}$$

Passing *amount* a value of 0 will cause *value1* to be returned, a value of 1 will cause *value2* to be returned.

Matrix.CreateBillboard Method (Vector3, Vector3, Vector3, Nullable<Vector3>)

Creates a spherical billboard that rotates around a specified object position.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static Matrix CreateBillboard (  
    Vector3 objectPosition,  
    Vector3 cameraPosition,  
    Vector3 cameraUpVector,  
    Nullable<Vector3> cameraForwardVector  
)
```

Parameters

objectPosition

Position of the object the billboard will rotate around.

cameraPosition

Position of the camera.

cameraUpVector

The up vector of the camera.

cameraForwardVector

Optional forward vector of the camera.

Return Value

The created billboard matrix.

Remarks

This method computes the facing direction of the billboard from the object position and camera position. When the object and camera positions are too close, the matrix will not be accurate. To avoid this problem, the method uses the optional camera forward vector if the positions are too close.

Parameters

yaw

Angle of rotation, in radians, around the y-axis.

pitch

Angle of rotation, in radians, around the x-axis.

roll

Angle of rotation, in radians, around the z-axis.

result

[[OutAttribute](#)] An existing matrix filled in to represent the specified yaw, pitch, and roll.

Matrix.CreateLookAt Method (Vector3, Vector3, Vector3)

Creates a view matrix.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static Matrix CreateLookAt (  
    Vector3 cameraPosition,  
    Vector3 cameraTarget,  
    Vector3 cameraUpVector  
)
```

Parameters

cameraPosition

The position of the camera.

cameraTarget

The target towards which the camera is pointing.

cameraUpVector

The direction that is "up" from the camera's point of view.

Return Value

The created view matrix.

Remarks

View space, sometimes called camera space, is similar to world space in that it is typically used for the entire scene. However, in view space, the origin is at the viewer or camera.

Matrix.CreateOrthographic Method (Single, Single, Single, Single)

Builds an orthogonal projection matrix.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static Matrix CreateOrthographic (  
    float width,  
    float height,  
    float zNearPlane,  
    float zFarPlane  
)
```

Parameters

width

Width of the view volume.

height

Height of the view volume.

zNearPlane

Minimum z-value of the view volume.

zFarPlane

Maximum z-value of the view volume.

Return Value

The projection matrix.

Remarks

Projection space refers to the space after applying projection transformation from view space. After the projection transformation, visible content has x and y coordinates ranging from -1 to 1, and z coordinates ranging from 0 to 1.

Unlike perspective projection, in orthographic projection there is no perspective foreshortening.

The viewable area of this orthographic projection is centered on 0,0,0. The x-axis of the area ranges from $-width/2$ to $width/2$. The y-axis of the area ranges from $-height/2$ to $height/2$. The z-axis of the area ranges from *zNearPlane* to *zFarPlane*. These values are relative to the position and x, y, and z-axes of the view.

To obtain the viewable area (in world space) of a scene, create a [BoundingFrustum](#) and pass the combined view and projection matrix to the constructor.

```
public static Matrix CreateRotationY (  
    float radians  
)
```

Parameters

radians

The amount, in radians, in which to rotate around the y-axis. Note that you can use [ToRadians](#) to convert degrees to radians.

Return Value

The rotation matrix.

Matrix.CreateRotationY Method (Single, Matrix)

Populates data into a user-specified matrix that can be used to rotate a set of vertices around the y-axis.

Namespace: Microsoft.Xna.Framework

Assembly: Microsoft.Xna.Framework (in microsoft.xna.framework.dll)

Syntax

C#

```
public static void CreateRotationY (  
    float radians,  
    out Matrix result  
)
```

Parameters

radians

The amount, in radians, in which to rotate around the y-axis. Note that you can use [ToRadians](#) to convert degrees to radians.

result

[[OutAttribute](#)] The matrix in which to place the calculated data.

Matrix.CreateRotationZ Method

Creates a matrix that can be used to rotate a set of vertices around the z-axis.

Overload List

Name	Description
Matrix.CreateRotationZ (Single)	Returns a matrix that can be used to rotate a set of vertices around the z-axis.
Matrix.CreateRotationZ (Single, Matrix)	Populates data into a user-specified matrix that can be used to rotate a set of vertices around the z-axis.
